# Welcome to AVEVA Plant SCADA

AVEVA Plant SCADA is a Supervisory Control and Data Acquisition (SCADA) solution that is used to manage and monitor processes in manufacturing, primary production, utilities delivery and facilities management.

The easy-to-use configuration tools and powerful features help customers to develop and deploy solutions for small and large applications, with robust visualization and operational capabilities driving operational efficiency, helping to mitigate risk and deliver actionable insights faster.

Known for its reliability, flexibility and scalability, and used in a wide range of industries, Plant SCADA enables you to increase your return on assets by delivering highly scalable control and monitoring systems to:

- Reduce operating costs
- Improve productivity
- Improve product quality.

Plant SCADA is a leading industrial automation software platform, with over 30 years of industrial automation expertise and an extensive customer-base spanning several market segments. Plant SCADA's library of device and protocol drivers to PLC and RTU hardware available in the market as well as interoperability with AVEVA's portfolio of Engineering and Industrial Automation software make Plant SCADA an extremely versatile solution.

To learn more about Plant SCADA, see [About Plant SCADA](#).

## Safety Information

### Hazard categories and special symbols

The following symbols and special messages may appear in this manual or on the product to warn of potential hazards or to call attention to information that clarifies or simplifies a procedure.

Symbol	Description
 or 	The addition of either symbol to a "Danger" or "Warning" safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.
	This is the safety alert symbol. It is used to alert you to personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.

### DANGER

**DANGER** indicates an imminently hazardous situation, which, if not avoided, will result in death or serious injury.

**⚠ WARNING**

**WARNING** indicates a potentially hazardous situation, which, if not avoided, can result in death or serious injury.

**⚠ CAUTION**

**CAUTION** indicates a potentially hazardous situation which, if not avoided, can result in minor or moderate injury.

**NOTICE**

**NOTICE** used without a safety alert symbol, indicates a potentially hazardous situation which, if not avoided, can result in property or equipment damage.

**Please Note**

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by AVEVA for any consequences arising out of the use of this material.

**Before You Begin**

Plant SCADA is a Supervisory Control and Data Acquisition (SCADA) solution. It facilitates the creation of software to manage and monitor industrial systems and processes. Due to Plant SCADA's central role in controlling systems and processes, you must appropriately design, commission, and test your Plant SCADA project before implementing it in an operational setting. Observe the following:

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not use Plant SCADA or other SCADA software as a replacement for PLC-based control programs. SCADA software is not designed for direct, high-speed system control.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**⚠ WARNING****LOSS OF CONTROL**

- The designer of any control scheme must consider the potential failure modes of control paths and, for certain critical control functions, provide a means to achieve a safe state during and after a path failure. Examples of critical control functions are emergency stop and overtravel stop, power outage and restart.
- Separate or redundant control paths must be provided for critical control functions.
- System control paths may include communication links. Consideration must be given to the implications of unanticipated transmission delays or failures of the link.
- Observe all accident prevention regulations and local safety guidelines.<sup>1</sup>
- Each implementation of a control system created using Plant SCADA must be individually and thoroughly tested for proper operation before being placed into service.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

1. For additional information, refer to NEMA ICS 1.1 (latest edition) "Safety Guidelines for the Application, Installation, and Maintenance of Solid State Control", and to NEMA ICS 7.1 (latest edition) "Safety Standards for Construction and Guide for Selection, Installation and Operation of Adjustable-Speed Drive Systems" or their equivalent governing your particular location.

## Security Guidelines for Industrial Control Systems

The security guidelines provided here will assist you to securely deploy the Plant SCADA product as an Industrial Control Systems (ICS) application.

**Note:** This section is not meant to be comprehensive, and it does not provide any detailed instructions. It is only a collection of basic concepts and recommendations that you can use as a checklist to secure your own systems.

### See Also

[General considerations for security](#)

## General considerations for security

Before you review the information in this section, it is recommended that you go through the following checklist to ensure you plan to cover the security areas that apply to your ICS and organization.

Security Area	Reference Section
Physical and virtual access to the host	<a href="#">General guidelines for securing the host</a>
Latest Windows patches applied	<a href="#">Windows updates</a>
Protecting the host from viruses and malware	<a href="#">Scanning the Host</a>

Security Area	Reference Section
Access to content on the host	Protect the applications and content on the host
Securing your network	Secure the network
Configuring services and ports	Manage network services and ports
Securing client/server communication	Secure communication between the client and server
User and group management	Secure systems through authentication and authorization
Planning for emergencies	Plan contingency

For a list of security feature help topics refer to the table at the end of this section.

## Introduction

This appendix provides a general overview on how to securely deploy your AVEVA software product as an Industrial Control Systems (ICS) application.

**This appendix is not meant to be comprehensive, and it does not provide any detailed instructions.** It is only a collection of basic concepts and recommendations that you can use as a checklist to secure your own systems. If you need help with a specific item in this guide, see the official documentation for that item -- for example, if you need help with your anti-virus software, see the documentation for that software.

AVEVA's approach to securing site networks and ICS software is driven by the following principles:

- View security from both Management and Technical perspectives
- Ensure that security is addressed from both IT and ICS perspectives.
- Design and develop multiple network, system and software security layers.
- Ensure industry, regulatory and international standards are taken into account.
- Aim to prevent security breaches, supported by detection and mitigation.

These principles are realized by implementing the following security recommendations:

- Prevent security breaches using the following components:
  - Firewalls
  - Network-based intrusion prevention/detection
  - Host-based intrusion prevention/detection
- Segregate IT and Plant networks
- Include a clearly defined and clearly communicated change management policy. For example, firewall configuration changes.

**Note:** AVEVA strongly recommends following the guidelines prescribed by the U.S. Department of Commerce for securing ICS software. The document "Guide to Industrial Control Systems (ICS) Security" [NIST Special Publication 800-82 Revision 2] (<https://nvlpubs.nist.gov/nistpubs/SpecialPublications/NIST.SP.800-82r2.pdf>) provides detailed information about ICS, typical system topologies, security threats and vulnerabilities, and

---

recommendations for implementing security measures.

---

## Secure the host

Given the sensitive nature of industrial control, it is important to secure not only the ICS software, but also:

- the host on which it runs
- the network to which it is connected
- the hardware used for the ICS software.

---

**Note:** The "host" is the Windows computer or Windows Embedded device on which your ICS software is installed and running.

---

There are several factors to consider for securing the host including:

- Access to the host
- Keeping track of and applying the latest Windows updates
- Keeping the host computer free of viruses and malware
- Protecting the applications and content on the host

Each of these factors is covered in the sections below.

## General guidelines for securing the host

Here are a few guidelines to secure the host:

- Use an account with administrative privileges to install the ICS software, and one without administrative privileges to run the ICS software.
- Restrict configuration of ICS to a limited set of users.
- Consider running the ICS software as a Windows service, if that option is available. If the ICS software is run as a service, run it as a low privileged virtual service account.
- Once the host is fully configured and placed in its permanent location, restrict physical access and remote access to it so that only authorized personnel (for example, system administrators, application engineers, run-time operators) can use it.
- Consider disabling or removing physical ports (for example, USB, memory card) that might be used to connect external storage devices and then transfer data.

## Windows updates

Check that the Windows operating system on the host is a version that is under what Microsoft calls "mainstream support", which means Microsoft actively maintains and releases updates for it. Older versions of Windows are under Microsoft "extended support", which means they are not actively maintained and therefore might become vulnerable without notice. For more information about the different versions of Windows and the different levels of support, see [Windows lifecycle fact sheet](<https://support.microsoft.com/en-us/help/13853/windows-lifecycle-fact-sheet>).

Automate Microsoft product updates using Microsoft Windows Server Update Services (WSUS), which enables you to manage and distribute updates to computers on your network. For more information about WSUS, see [Windows Server Update Services](<https://docs.microsoft.com/en-us/windows-server/administration/windows-server-update-services/get-started/windows-server-update-services-wsus>). If the host does not or will not have a reliable connection to the WSUS server, perhaps because it is located on a private network, you can either develop a procedure to manually apply updates or consider changing the operating system to a Long-Term Servicing Channel (LTSC) version of Windows, which is updated less frequently.

In addition, AVEVA ICS software is tested for compatibility with Microsoft updates the results of which are published on the Security Central site (<https://softwaresupportsp.aveva.com/#/securitycentral>). Security advisories and bulletins are also published on this site.

## ICS software updates

Check that the ICS software on the host has all the recommended patches and hot fixes installed.

Some AVEVA applications release regular updates, which should be applied as soon as possible as they may contain security-related fixes.

---

**Note:** AVEVA's Global Customer Support (GCS) group publishes a Technology Matrix (<https://gcsresource.aveva.com/TechnologyMatrix/Home/Index>) for AVEVA software products. This matrix lists the Windows operating system versions against which a software product has been tested for compatibility. In addition, it lists compatible runtime, browser, and virtualization environments for the software. It also includes a list of other products that can be installed on the same computer and lists other products with which this software can communicate.

---

## Scanning the Host

Use both anti-virus and anti-malware software and file integrity checking software to regularly scan the host.

Windows includes Windows Defender by default, but you may choose to install and use additional software that scans for more types of malware or performs other functions. If you do that, make sure the software is provided by a reputable company. And, as with the operating system, if the host does not or will not have reliable access to the software's update service, develop a procedure to manually apply updates. If you develop a manual update procedure, it should account for all devices on a network or at a site, because a single outdated device can leave the entire network or site vulnerable.

## Protect the applications and content on the host

To protect the applications and content on the host:

- Enable Windows Firewall, and configure it to close all ports that are not used by the ICS software. For more information about port usage, see [Manage network services and ports](#).
- Disable Windows features like remote desktop and file sharing, and remove unnecessary programs like games and social media.
- Restrict access to the files, databases, registry and other resources on the host.
- Use Windows BitLocker to encrypt the hard drive of computers that are either mobile or not located in a secure facility. However, BitLocker may impact the performance of computers.
- Consider using server-class storage (SANs) infrastructure to avoid storing sensitive data on mobile devices.

- If your application stores data in SQL Server, Windows authentication can provide better application security than SQL Authentication. If you switch from Windows Authentication to SQL Authentication, a pop up dialog will appear recommending that you use Windows Authentication for this reason. If you choose to ignore this warning and proceed with SQL Authentication, select **OK**. A similar message will be logged in the OCMC (SMC) Log Viewer.

AVEVA leverages the security built into the Windows operating system to store and manage encryption keys. The encryption keys are stored in a local storage location called the encryption store. For more information about the Windows encryption store, refer to the Microsoft documentation, located at Certificate Stores (<https://docs.microsoft.com/en-us/windows-hardware/drivers/install/certificate-stores>).

## Phases of Data Protection

Data exists in three different phases, and protection must be provided for each phase:

- At rest
- In transit
- In use

### Data at rest

Data at rest is data that is not currently being used or accessed, such as data stored on a hard drive, laptop, flash drive, RAID array, network attached storage (NAS), storage area network (SAN), or archived/stored in some other way. Data protection at rest aims to secure inactive data stored on any device or network. For protecting data at rest, you can simply encrypt sensitive files prior to storing them and/or choose to encrypt the storage drive itself. BitLocker Drive Encryption, which you can invoke via the Windows Control Panel, can be used to invoke whole-drive encryption.

In the context of SCADA and ICS systems, data at rest includes stored configuration data, historical data, backups, and other static data. The duration of storage, that is, long term or short term, does not impact this classification of data at rest. Protection for data at rest is applicable for as long as the data exists in this condition; it is not a fixed condition.

Proper authorization rights need to be set in place to ensure the data is not being viewed by unauthorised users. Other steps can also help, such as storing individual data elements in separate locations, such as a corporate-approved offline backup to decrease the likelihood of attackers gaining enough information to commit fraud or other crimes. Offline backups are the best mitigation against the threat of ransomware.

### Data in transit

Data in transit, or data in motion, is data that is actively moving from one location to another.

In the context of SCADA and ICS systems, this encompasses deploying a project to a run-time node, transmitting process variables, VTQ data, and other data that is sent between nodes in a running, production system. This includes alerts and alarms.

Data protection in transit is the protection of this data while the data traveling, including the following examples:

- From node to node within a network
- From network to network

- Accessed via internet
- Transferred from a local storage device to a cloud storage device

Wherever data is moving, effective data protection measures for in-transit data are critical as data is often considered less secure while in motion. Best security practice is to ensure TLS 1.2 encryption is used for all communications using the HTTPS protocol.

## Data in use

Data in use refers to data that is being processed or accessed either locally or remotely. This generally involves placing data into memory (RAM) for access and processing by applications and users, potentially multiple users across different computers, mobile devices, remote terminals or other device. Data in use is particularly vulnerable to attack. To protect data in use, encryption, user authentication, and identity management is highly recommended.

In the context of SCADA and ICS systems, data in use can apply to databases, such as those used actively by a historian or deployed to a run-time node. This needs to be safeguarded by a secure transfer channel.

## Configure encryption in SQL server

We recommend you enable encrypted connections for SQL Server. You enable encrypted connections for an instance of the SQL Server Database Engine and use SQL Server Configuration Manager to specify a certificate. The server computer must have a certificate provisioned. To provision the certificate on the server computer, you import it into Windows. The client machine must be set up to trust the certificate's root authority.

SQL Server can use Transport Layer Security (TLS) to encrypt data that is transmitted across a network between an instance of SQL Server and a client application. The TLS encryption is performed within the protocol layer and is available to all supported SQL Server clients.

Enabling TLS encryption increases the security of data transmitted across networks between instances of SQL Server and applications. However, when all traffic between SQL Server and a client application is encrypted using TLS, the following additional processing is required:

- An extra network round trip is required at connect time.
- Packets sent from the application to the instance of SQL Server must be encrypted by the client TLS stack and decrypted by the server TLS stack.
- Packets sent from the instance of SQL Server to the application must be encrypted by the server TLS stack and decrypted by the client TLS stack.

## Certificate Requirements

For SQL Server to load a TLS certificate, the certificate must meet the following conditions:

- The certificate must be in either the local computer certificate store or the current user certificate store.
- The SQL Server Service Account must have the necessary permission to access the TLS certificate.
- The current system time must be after the **Valid from** property of the certificate and before the **Valid to** property of the certificate.

## Install on a Server

With SQL Server 2019 (15.x), certificate management is integrated into the SQL Server Configuration Manager. SQL Server Configuration Manager for SQL Server 2019 (15.x) can be used with earlier versions of SQL Server.

If using SQL Server 2012 (11.x) through SQL Server 2017 (14.x), and SQL Server Configuration Manager for SQL Server 2019 (15.x) is not available, follow these steps:

1. On the **Start** menu, select **Run**, and in the **Open** box, type **MMC** and select **OK**.
2. In the MMC console, on the **File** menu, select **Add/Remove Snap-in**.
3. In the **Add/Remove Snap-in** dialog box, select **Add**.
4. In the **Add Standalone Snap-in** dialog box, select **Certificates**, select **Add**.
5. In the **Certificates snap-in** dialog box, select **Computer account**, and then select **Finish**.
6. In the **Add Standalone Snap-in** dialog box, select **Close**.
7. In the **Add/Remove Snap-in** dialog box, select **OK**.
8. In the **Certificates snap-in**, expand **Certificates**, and then expand **Personal**.
9. Right-click **Certificates**, point to **All Tasks**, and then click **Import**.
10. Right-click the imported certificate, point to **All Tasks** and then select **Manage Private Keys**. In the **Security** dialog box, add read permission for the user account used by the SQL Server service account.
11. Complete the **Certificate Import Wizard**, to add a certificate to the computer, and close the MMC console. For more information about adding a certificate to a computer, see your Windows documentation.

## Export Server Certificate

To export the server certificate:

1. From the **Certificates** snap-in, locate the certificate in the **Certificates / Personal** folder.
2. Right-click the **Certificate**, point to **All Tasks**, and then select **Export**.
3. Complete the **Certificate Export Wizard**, storing the certificate file in a convenient location.

## Configure Server

Configure the server to force encrypted connections. The SQL Server service account must have read permissions on the certificate used to force encryption on the SQL Server. For a non-privileged service account, read permissions will need to be added to the certificate. Failure to do so can cause the SQL Server service restart to fail.

To configure the server:

1. In **SQL Server Configuration Manager**, expand **SQL Server Network Configuration**, right-click **Protocols for <server instance>**, and then select **Properties**.
2. In the **Protocols for <instance name> Properties** dialog box, on the **Certificate** tab, select the desired certificate from the drop-down for the **Certificate** box, and then select **OK**.
3. On the **Flags** tab, in the **ForceEncryption** box, select **Yes**, and then select **OK** to close the dialog box.
4. Restart the SQL Server service.

## Configure Client

Configure the client to request encrypted connections.

1. Copy either the original certificate or the exported certificate file to the client computer.
2. On the client computer, use the **Certificates** snap-in to install either the root certificate or the exported certificate file.
3. Using SQL Server Configuration Manager, right-click **SQL Server Native Client Configuration**, and then select **Properties**.
4. On the Flags page, in the **Force protocol encryption** box, select **Yes**.

---

**Note:** The sections in this topic have been derived from the Microsoft documentation. For more information, refer to the topic 'Enable encrypted connections to the Database Engine' in Microsoft Documentation.

---

## Secure the network

Usually, the host computer will have some sort of network access; it is increasingly rare for an ICS device to run as an entirely standalone device. The host may use the network to communicate with other ICS components such as controllers, sensors, databases, remote clients, and even other hosts in peer-to-peer relationships. You may also use the network to manage several ICS devices from a development or supervisory computer.

Once you determine that the host will have network access, decide how it will connect to the network. In recent years there has been a shift from wired networks (that is, "Ethernet") to wireless networks ("Wi-Fi"), even for business and industrial uses. We recommend against using Wi-Fi for your ICS network because you do not have physical control over who or what might access the network. Any computer or device within range of the Wireless Access Point (WAP) can try to access the network, and even if the network is ostensibly secure, an intruder can intercept and analyze network traffic and potentially discover a vulnerability.

Nevertheless, if you decide to use Wi-Fi for your ICS network, enable all access control features on the WAP including encryption (for example, WPA/WPA2), a strong password and a list of authorized MAC addresses. Do not try to "hide" the Wi-Fi network by disabling broadcast of the Service Set Identifier (SSID), because doing so actually generates more network traffic that can be intercepted and analysed.

## Segment the ICS network

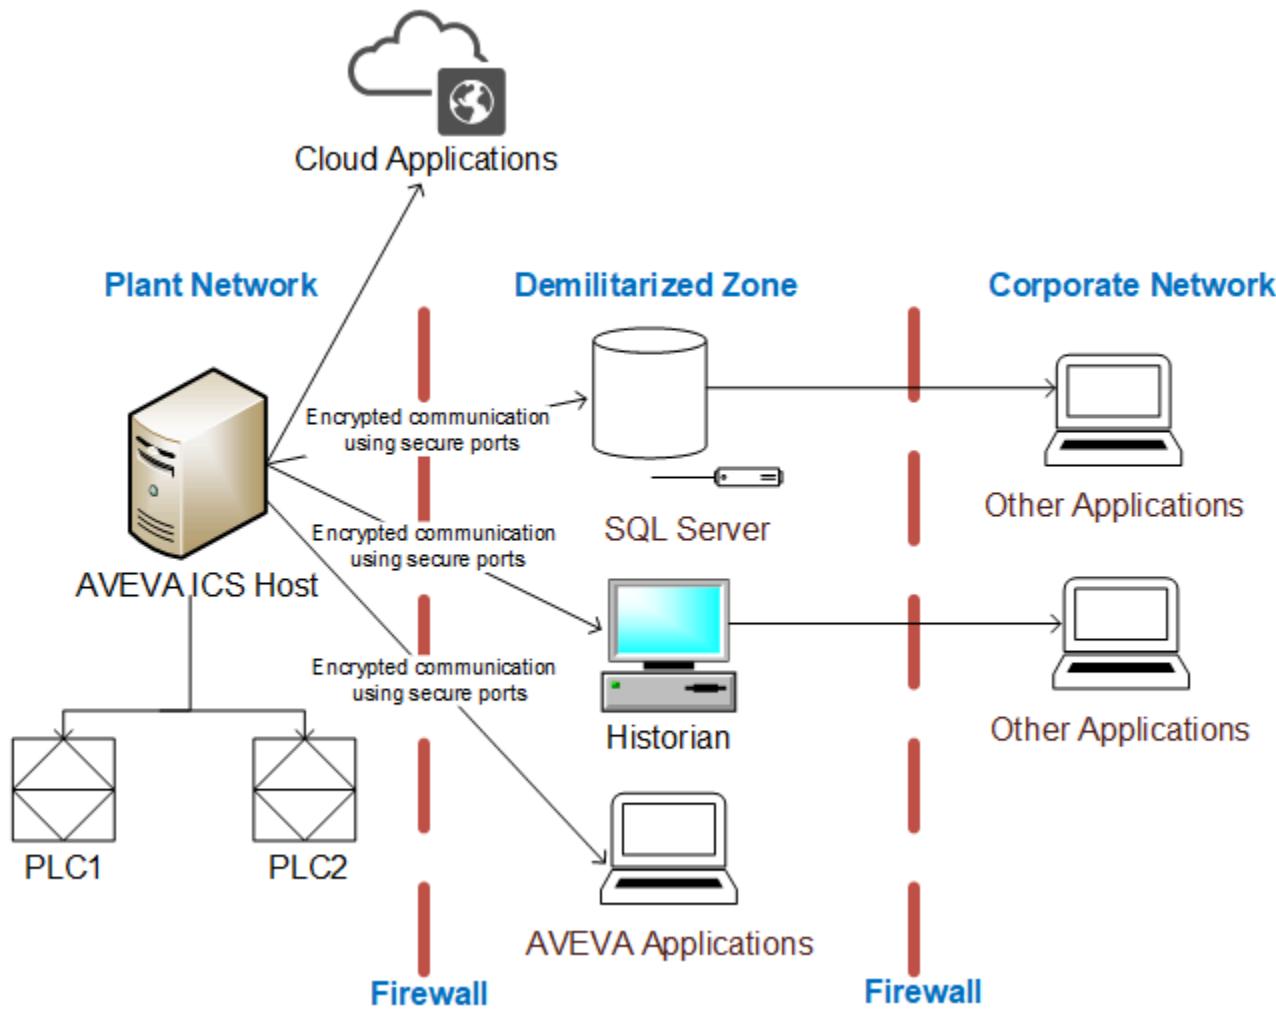

The ICS network itself can be either physically or logically segmented from your other corporate networks. A physically segmented network is by definition the most secure. The network hardware and all computers and devices connected to it form a single closed network with no physical connection to any other network, so an intruder cannot access the network unless they also have access to the physical location.

In contrast, a logically segmented network is physically connected to your other corporate networks and/or the public internet, but it uses various methods to segregate ICS network traffic from other network traffic. This may include:

- Using a unidirectional gateway
- Implementing a Demilitarized Zone (DMZ) network architecture with firewalls to prevent network traffic from passing directly between the corporate and ICS networks
- Having different authentication mechanisms and credentials for users of the corporate and ICS networks.

- The ICS should also use a network topology that has multiple layers, with the most critical communications occurring in the most secure and reliable layer.

Given below is a sample deployment topology.

In no case should your ICS network and devices be directly accessible from the public internet. If there is some part of your ICS that you want to be accessible, (for example, if you want be able to view web-enabled HMI screens from a browser or smart phone), your ICS software should include features that securely pass the necessary traffic between your ICS network and a public-facing server.

## Manage network services and ports

A network port is an endpoint of communication in an operating system. While the term is also used for hardware devices, in software it is a logical construct that identifies a specific process or a type of service. In other words, a network port is conceptually different from hardware ports like USB, memory card, and even the wired network connection.

Computers and devices can access many different network services at the same time by communicating on different network ports. Each network service or communication protocol has an associated port number. Some port numbers are specified by international standards, and therefore they are universally recognized. Other port numbers are claimed by proprietary software, and in most cases they can be changed in the software settings if

there is a conflict with other software or services.

Firewalls control network traffic by either accepting or refusing communication on these network ports. If a port is open, it accepts communication, and if a port is closed, it refuses communication. Almost every layer of a network -- from the operating system on an individual computer or device, to the router that manages traffic within a network, to the gateway that manages traffic between networks -- has its own firewall.

The documentation for your ICS software should include a list of network ports that are commonly used by the software. Given the nature of ICS, the list typically includes services like web, email, file transfer, external databases, device drivers, and the ICS software itself for server-client communications. Configure the firewalls to open only those network ports that are actually used by your ICS. Disable all unused services and close all unused ports.

## Secure communication between the client and server

Like most server-client applications, your ICS software should support secure communication between the server and client in order to prevent the messages sent between those two stations from being read by any other stations on the same network. Note that this is different from securing the network itself in order to prevent unauthorized access to the network.

This sort of communication is also sometimes known as "Encrypted Channel" because it uses the Transport Layer Security (TLS) standard to encrypt the server-client messages. The latest version of the standard is TLS 1.3 (released August 2018), but it is not yet in common use. The latest version of the standard in common use is TLS 1.2 (released August 2008). TLS supersedes the earlier Secure Sockets Layer (SSL) standard, although SSL is still used in older applications.

### Certificates

TLS and SSL use a system of certificates and keys to digitally "sign" the messages sent between the server and client. When the server establishes communication with the client (and vice versa), it presents its certificate which identifies its name, network address, organization, physical location, and so on. The client can then choose to either accept or refuse the certificate as presented. If it accepts the certificate, it agrees to accept messages encrypted with the same certificate, and it uses the associated key to decrypt those messages.

When you configure this sort of communication, you need to choose one of the following:

- Using self-signed certificate
- Using certificates signed by a Public Certificate Authority (CA)
- Using Domain-issued certificates or certificates signed by a Private Certificate Authority using systems like Microsoft Active Directory Certificate Service (AD CS)

A self-signed certificate is issued and signed by the same application that presents it. Self-signed certificates are easy to create and manage, but they are secure only if you control both the server and the client and therefore control which certificates are installed on each.

In contrast, CA-signed certificates are slightly difficult and expensive to acquire, but they are more flexible than self-signed certificates because you do not need to control both the server and the client. If you configure the server to present a CA-signed certificate, the client will accept the certificate because it recognizes the Certificate Authority.

Domain-issued certificates are internal certificates typically managed by your IT department. They are issued and validated by an Active Directory Certificate Authority. Domain-issued certificates are free and can be issued instantly.

You need to renew CA-signed and Domain-issued certificates at regular intervals.

For more information about how to enable Encrypted Channel features and manage self-signed certificates in your ICS software, see the documentation for that software. However, acquiring a CA-signed certificate and then using it to sign other certificates is typically beyond the scope of ICS software documentation.

---

**Note:** Encrypted and unencrypted communications typically use different network ports.

---

## Cloud-based systems

It is possible that your ICS software might access cloud-based solutions, or might itself be hosted on the Cloud. It is important to mitigate the risks associated with cloud-based access and hosting.

### Access cloud-based solutions

Several AVEVA applications are now being made available through the Cloud, and ICS software may need to connect to these applications. One of the main risks associated with accessing cloud-based applications is unauthorized access. Connecting ICS software to Cloud solutions must be done in a secure manner, and needs to use secure protocols such as Transport Layer Security (TLS).

It is important that data integrity is maintained at all times. Use data classification to identify data that is sensitive and data that can be made public. Secure computers, storage and networking in order to secure the data that is stored and transmitted. Work with your Cloud Service Provider (CSP) to configure users, assign access levels and monitor and control access. Ensure that the CSP's buildings are physically secure and protected from unauthorized access.

### Cloud-based ICS software

While hosting ICS software on the Cloud provides several benefits such as flexibility, scalability and availability, it is also fraught with security risks such as susceptibility to hacking resulting in damage to the organization's reputation. Therefore, it is important to implement a security strategy before you make your ICS software accessible on the Cloud. For securing ICS software on the Cloud, you need to consider the following:

- Securing access points by putting in place authentication, monitoring and support mechanisms.
- Implementing cloud-based, centralized security measures including encrypting communications using TLS.

---

**Note:** It is recommended that you review the NIST Cybersecurity Framework (<https://www.nist.gov/cyberframework>) for additional information.

---

## Secure systems through authentication and authorization

Typically, ICS software is comprised of a large number of systems, each accessed by a variety of users including engineers, operators and managers. The level of access that each type of user requires is different. So, it is necessary to manage user authentication and authorization to secure the system.

### Authentication

Authentication is the process of verifying a user's/system's identity. Authentication can be managed in the following ways:

- Within the ICS software through application accounts
- Through Windows accounts, which can be local to a single computer
- Through Authentication systems (see the next section for details)

While ICS software allows for user and role management, it can become cumbersome and complicated to manage a large number of user accounts as employees and roles change. Because of this, use of Windows accounts is generally preferred.

### **Authentication systems**

Authentication systems such as Active Directory and Lightweight Directory Access Protocol (LDAP), referred to as authentication servers, are a repository of and provide centralized management for all system accounts and individual user accounts. An authentication protocol is used for all communication between authentication servers and the user or server requesting authentication.

Even though use of authentication systems provides improved scalability, the following factors must be considered depending upon the size and complexity of your operations:

- It is important that the authentication servers are highly secured.
- The authentication server system creates a single system for managing all system accounts. Therefore, it requires to be available at all times. To ensure minimal disruption during an emergency, redundancy must be considered.
- Permit caching of user credentials only for users who have authenticated their identity recently.
- Networks that support the authentication protocol must be reliable and secure to assist in trouble-free authentication.

It may also be worthwhile implementing two-factor authentication using additional applications such as PingID.

### **Authorization**

Authorization is the process of providing the correct level of privileges to users by applying access rules to authenticated users, systems (HMI, field devices and SCADA servers) and networks (remote sites' LANs).

## Manage users and groups through windows

When you configure security, you may choose to do one of the following:

- Keep the configuration local to a single application.
- Share the configuration between multiple applications.
- Manage the configuration as part of the network domain (for example, using Active Directory). This option typically allows users to have the same user account for the network, the host, and the ICS software. Using Active Directory gives you the following advantages:
  - A centralized repository for user and group data, enabling effective implementation of security policies and procedures.
  - Provides a single point of access to all network resources after the user is identified and authenticated.

To manage users and groups:

- First define a specific role for each group, and then configure the group privileges to fit that role.
- Groups may overlap, but it is often better to have clearly separate groups and then assign individual users to

multiple groups, if necessary.

- Set or change the password for the ICS software's default user (e.g., "guest").
- Define stringent password policies to force users to create strong passwords. Enforce mandatory password updates on a regular basis.

## Manage users and groups through ICS software

Your ICS software should have a built-in security system that controls who may use the software and what privileges they have.

Users should be assigned permissions that determine what each user is authorized to do within the ICS system. Permissions can be managed either on a per-account basis or on a group basis by making use of roles. Group or role-based access control is preferred as it greatly simplifies management. Users can be moved from one role to another as the organization's needs change, and can also be members of multiple roles if required.

Each user should have their own user account with a unique user name and a strong password. The user account can then be assigned to one or more groups.

Accounts should always be assigned the least privileges necessary to perform their functions. Accounts with Windows Administrator permissions should be reduced to the minimum, and typically only used to install and configure the software. Likewise, accounts with SQL Server SysAdmin privileges should be reduced to the minimum, and typically only used to install and configure the software.

In most cases, the ICS software will allow associating Windows Groups with roles within the product. While defining and assigning roles, consider the following:

- Roles should be defined to have the least privileges necessary for their functionality.
- Roles should be limited to a single purpose in order to simplify the permissions assigned to them.
- Users can be members of multiple roles if necessary.

## Plan contingency

Incidents are inevitable. It is, therefore, important to develop a strategy to detect an incident quickly and respond to it in a timely manner in order to minimize loss and protect your system. An organization must consider contingencies arising from incidents such as fire, flood and so on, and those arising from failure of hardware or software components. Cyber attacks such as ransomware are becoming more common and must also be considered.

An organization should have contingency plans in place to cover the entire range of failures and eventualities. Employees should be trained and be familiar with the contents of the contingency plans.

As part of planning for contingencies, it is important to establish a site, physically separated from the central one, that has replication capability. Doing so will ensure the integrity of an operational system where the central site is at risk from fire, floods or other disasters. The replication capability includes having duplicated hardware, and requires software configuration and key state information to be periodically propagated from the central site to the recovery site. Each recovery scenario is unique, so it is important to consult with system integration experts regarding the design of communications equipment, hardware and the configuration of the software.

Protecting the data stored in your system is also of paramount importance. Full and incremental backups must be scheduled on a regular basis. Backups should be verified by running tests to restore from backed up data. Backups should be stored offline so that they are safe from cyber attacks such as ransomware.

Organizations should also have business continuity and disaster recovery plans that are similar to contingency plans. These plans are covered briefly in the sections to follow.

## Audit and log

As part of implementing security for ICS software, it is important to incorporate auditing and logging activities on various systems and networks.

Auditing and logging provide information on the current state of your ICS, and help to ensure that the system is functioning as expected. If an incident occurs, you can use the activity logs to trace the origin of the incident to a computer, user or network. Auditing and logging can also help with troubleshooting issues.

If you are connecting to cloud-based solutions, audit all virtual machines (VMs) to ensure data integrity.

## Plan business continuity

Business continuity planning addresses strategies to maintain or re-establish production in the event of any disruption. These disruptions may be caused by a natural disaster (flood, earthquake, etc), by an intentional or unintentional human-made event (arson, operator error, power outage, etc), or by system failure.

Depending upon the duration of the potential ICS application outage caused by a disruption, operational recovery plans for short-term outages and disaster recovery plans for long-term outages must be formulated. It is also important to employ physical security for areas of a production site that house data acquisition and control systems that might have higher-level risks. Your business continuity plan should specify system and data recovery procedures for your systems. Once the recovery procedures are documented, a schedule should be developed to test the recovery procedures. Particular attention must be paid to the verification of backups of system configuration data and product or production data. The procedures should be reviewed periodically.

If you are accessing cloud-based solutions, ensure that systems are available at all times. In case of a disaster, services should switch to a new physical location to provide continued service.

## Plan disaster recovery

A disaster recovery plan (DRP) is a set of procedures to protect and recover an IT infrastructure in case of a disaster. It contains the procedures to follow before, during and after a disaster. Disasters can be natural, environmental or human-made (intentional or unintentional).

A DRP is essential for continued availability of the ICS, and should cover the following:

- When the DRP should be activated depending upon an event, its duration and its severity.
- Detailed course of action for operating the ICS manually until external connections are secured.
- Personnel responsible for each procedure.
- Processes for securely backing up data and restoring it. This should cover:
  - Requirements for building redundancy.
  - File backup procedures.
  - Frequency of backups.
  - Storage mechanism for full and incremental backups.
  - Safe storage of installation media, license keys and configuration information.

- List of individuals responsible for performing, testing, maintaining and restoring backups.
- List of personnel with physical and virtual access to the ICS.
- Detailed configuration information about the components of the ICS.
- Schedule for testing the DRP.

## Conclusion

Security lapses present a serious threat to ICS software and infrastructure. Therefore, it is important for every organization to:

- Be proactive about preventing security lapses
- Identify potential lapses
- Detect them in a timely manner when they occur
- Address lapses to ensure minimum disruption and maximum availability

To this end:

- Computers and networks must be secured
- Users and groups must be authenticated and authorized
- Contingency plans must be in place to recover from untoward or intentional events

Refer to the document "Guide to Industrial Control Systems (ICS) Security" [NIST Special Publication 800-82 Revision 2](<https://nvlpubs.nist.gov/nistpubs/SpecialPublications/NIST.SP.800-82r2.pdf>) for additional details and recommendations.

## Security Configuration for Plant SCADA

The table below lists the security areas that you need to configure for Plant SCADA and the details of the section(s) in this guide that provide the corresponding instructions.

Security Area(s)	Topic(s) in this guide	Summary
Manage access through users and groups	<a href="#">Runtime System Security</a>	You can restrict which functions a user is allowed to perform by linking those functions to a defined set of areas and privileges.
Secure a runtime system through authentication and authorization	<a href="#">Security Roles</a>	Plant SCADA uses a set of security roles to manage access to sensitive components within the runtime system. Each role provides a different level of access to features, applications and project resources.

Security Area(s)	Topic(s) in this guide	Summary
Use Windows users accounts	<a href="#">Integrate Windows™ User Groups</a>	Plant SCADA provides the ability to integrate Windows user accounts into the security model for a runtime system. You can achieve this by linking domain Windows user accounts to a role defined within Plant SCADA.
Protect the application on the host runtime computer	<a href="#">Securing Runtime Computers</a>	There are several ways you can limit runtime access to the host operating system or software other than Plant SCADA.
Enable encrypted communications	<a href="#">Encrypted Communications</a>	Communications between Plant SCADA processes, computers and CtAPI can be encrypted. A System Management Server is required to manage the certificates that enable trusted communications.

## Information and Support

There are several options available to you when seeking information and assistance with Plant SCADA.

- **Product documentation**

If you have questions about using Plant SCADA, you should initially consult the product documentation.

You can open the documentation in a browser via the **Help** button at the bottom of Plant SCADA Studio's Activity Bar.

You can browse the **Contents** to find the topics you are interested in, or you can enter a term in the **Search**

field.

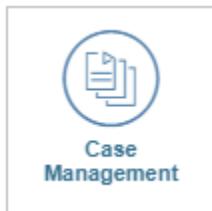

You can also access context-sensitive documentation via the **F1** key. This will open a topic in the documentation that relates to the task you are currently performing in Plant SCADA Studio.

See [AVEVA™ Help](#).

- **AVEVA Knowledge and Support Center**

If you seek more technical information than is provided in the documentation, check the [AVEVA™ Knowledge & Support Center](#).

If you cannot find the information you need, you can raise a case with Technical Support via the **Case Management** page.

- **Consulting Services**

Consulting services are also available upon request. Contact your local authorized AVEVA distributor.

## AVEVA™ Help

The documentation for Plant SCADA is presented using AVEVA Help, a browser-based tool that allows any installed AVEVA products to share a common platform for the delivery of product information.

AVEVA Help is accessible from the **AVEVA Documentation** branch of the Windows **Start** menu. When launched, it will display in your default browser.

The panel to the left includes a list of any locally installed AVEVA products that utilize the AVEVA Help platform. If installed, this will include:

- AVEVA Enterprise Licensing
- Operations Control Logger.

You can open the documentation for a product on its own browser tab by selecting the following icon:

Plant SCADA's context-sensitive help will also open content directly in AVEVA Help.

The **Search** functionality uses straightforward text-based matching, and you can save a search for repeated use.

The Plant SCADA help is also now available on AVEVA's Documentation cloud portal ([docs.aveva.com](https://docs.aveva.com)).

## AVEVA™ Knowledge & Support Center

The AVEVA Knowledge & Support Center is an online resource you can use to access technical information, updates and tools that support the company's software products. It is located at <https://softwaresupport.aveva.com/>.

**Note:** The Citect Global Support website is no longer available. If you try to visit this site, you will automatically be redirected to the AVEVA Knowledge & Support Center.

If you are new to the Knowledge & Support Center website, you will need to register for access. Use an organizational email address as generic email addresses are not supported.

If you have an existing CustomerFIRST account, it will provide access to restricted content. Be aware that it can take up to 24 hours to link your website registration to a CustomerFIRST account as it is a manual process. You can check if your registration is complete by viewing the **Manage Profile** page.

If a number appears in the **Tech Support ID** field, it indicates that your registration has been processed. The **Account Information** appears at the bottom of the page.

The home page provide access to the pages described in the table below. If you are familiar with the old Global Support Page, you will now find the existing content on the following pages.

- **Product Downloads** — Product Hub
- **Updates & Patches** — Product Hub
- **Web Help** — Product Hub
- **Forums** — Community
- **Compatibility Matrix** — Technology Matrix
- **DriverWeb** — Communication Drivers
- **License Generator** — License Activation.

Page	Description
	<b>Case Management</b> Allows you view and manage your <b>Cases</b> and <b>Service Requests</b> lodged with the support team.
	<b>Product Hub</b> Lists all products and provides the following: <ul style="list-style-type: none"><li>• Product information</li><li>• Product downloads</li><li>• Updates and patches</li><li>• Online documentation</li></ul>

	<b>Training Center</b> Links to the <b>AVEVA Training Services</b> website, which provides details about the training courses that are available for Plant SCADA and other AVEVA products.
	<b>Subscriptions</b> Use this page to set, edit or delete your subscriptions. When content for your subscription changes, you will receive an email notification. To subscribe to Tech Notes, FAQs, Tech Alerts and Notifications, navigate to the <b>Knowledge Base</b> page, open an article, and subscribe to the specific article, the document type, or the product covered by the article.
	<b>Technology Matrix</b> Links to the <b>AVEVA Technology Matrix</b> website, which provides a form that allows you to confirm if AVEVA software products align with your compatibility

Page	Description
	requirements.
	<b>Communication Drivers</b> This page lists all OI, DA and other connectivity applications, including product documentation and videos. In the case of Plant SCADA, this is where you find all information related to drivers and the old Driver Web. Click the <b>Related Tech Notes, FAQs</b> button to view the Tech Notes and FAQs related to the selected products.
	<b>License Activation</b> Select <b>Citect</b> to activate licenses for Plant SCADA. See <a href="#">Licensing</a> for further instructions.
	<b>Security Central</b> Provides Microsoft™ Security Update Reports, Product Cyber Security Updates, and Policies & Guidelines. Use the <b>Select Product Line</b> menu to display information related to Plant SCADA.
	<b>Digital Exchange</b> Links to the AVEVA Digital Exchange, which allows you to browse available solutions for specific industries.
	<b>SAM Software</b> Links to the Software Asset Manager (SAM) download site, which provides access to the files and instructions necessary to run Software Asset Manager (SAM) at your plant. SAM is a software application from AVEVA that helps you manage Plant SCADA software installations and licenses.

Most pages will allow you to filter a list according to **Product** and/or content type. For example, to see the available **Tech Notes** for **Plant SCADA**, you would use the following filter.

**Filters**

Document # or Legacy #

Title...

**Document Type**

Select All  
 Tech Notes  
 Tech Alerts  
 FAQS  
 Notifications

**Products**

Select All  
 Ampla  
 Avantis  
 Citect  
     Citect Historian  
     Citect SCADA  
 OASyS

You can also use the **Manage Profile** page to set **Preferences** based on the products you use. Every time you view a page with a filter, your preferences will be preselected.

# What's New in Plant SCADA

Plant SCADA 2023 R2 incorporates the following new or modified features:

- Support for Plant SCADA on AVEVA Integration Studio
- Double Point Status Alarms
- Kernel Access Improvements
- New Installation Framework
- AVEVA™ Help
- Setup Wizard supports HMI Computer Role
- Unique IDs for Equipment
- Equipment Update Improvements
- Project DBF AddIn supports 64-bit Excel.

---

**Note:**

- With the release of Plant SCADA 2023 R2, the **CSV\_Include** project is no longer supported as a system project. If you have any projects based on the CSV\_Include templates, you will need to create a separate backup of the CSV\_Include project and restore manually it in version 2023 R2 (or later). You can then include it as a user project.
  - Process Analyst no longer supports CitectHistorian integration.
- 

For updates to Citect.ini parameters, see [Citect.ini Parameters in Plant SCADA 2023 R2](#).

For updated to Cicode functions, see [Cicode Functions in Plant SCADA 2023 R2](#).

For details on how to upgrade an existing project to 2023 R2, refer to [Upgrade Plant SCADA](#).

## Support for Plant SCADA on AVEVA Integration Studio

AVEVA Integration Studio is an infrastructure-as-a-service virtual development environment that is delivered on AVEVA's cloud services platform CONNECT.

Integration Studio lets you run and manage software applications without the complexity of building and maintaining the physical infrastructure typically required when developing and launching software. You can create templates for virtual machines and deploy multiple instances on demand.

AVEVA Integration Studio now allows you to include Plant SCADA nodes in a project template. These nodes can be used to create multiple instances of virtual machines with a fully licensed version of Plant SCADA installed.

For more information, see [Plant SCADA and AVEVA Integration Studio](#).

## Double Point Status Alarms

Plant SCADA 2023 R2 now supports double point status alarms.

A double point status alarm responds to eight states in a field device that are represented in Plant SCADA as a single integer tag.

For each of the eight states you can specify the following:

- **State Name <n>** — a name that identifies the condition that the state represents.
- **State Type <n>** — the action that occurs when the device transitions to a defined state. The options are:
  - "Alarm" - an alarm is added to the Active Alarms page and an event is logged to the SOE page. The State Name will appear in the State field.
  - "Event" - indicates an OFF state has occurred. An event is logged on the SOE page, even if an alarm state transition did not occur. The State Name will appear in the State field.
  - "None" - indicates an OFF state has occurred. The State Name will appear in the State field on both the SOE and Active Alarm pages when an alarm transition occurs.

---

**Note:** If an alarm is currently in an "Event" or "None" state, a further transition to a "None" state will not be reported.

---

This means when the value of the integer tag is 0, the alarm will go into "State Name 0". When the value of the tag is 1, it will go into "State Name 1", and so on. When this occurs, the associated State Type action will be triggered.

Just like time stamped analog and time stamped digital alarms, double point status alarms are timestamp based and designed to work with the Driver Runtime Interface (DRI). They need to use tags where values are pushed to the alarm server by a driver.

See [Add a Double Point Status Alarm](#).

## Kernel Access Improvements

Access to the Kernel has been changed to provide improved security while monitoring a runtime system. These changes also allow you to display the Kernel from Runtime Manager while running Plant SCADA as a service.

You can still launch the Kernel on a display client in the following ways:

- From the **Control** menu (see [Display the Kernel from the Control Menu](#))
- Via the Cicode function DspKernel (see [Define a Runtime Command](#))
- From the Runtime Manager (see [Use the Kernel with a Selected Process](#)).

To display the Kernel window for a display client, the user that is currently logged in now needs to be assigned to a **Roles** that has the **Kernel Access** property set to "Full Access" or "Read Only". A Read Only user can access the Kernel, but cannot perform some privileged commands like running Cicode.

---

**Note:** The special Kernel user that enabled Kernel access in previous versions no longer has default access to the Kernel window.

---

To display the Kernel window for a server process (including when running Plant SCADA as a service), you will need to log in using the dialog that is displayed when the Kernel window is launched.

You will need to enter a user that is assigned to a Role that has the **Kernel Access** property set to "Full Access" or "Read Only".

---

**Note:** Before commissioning a system, it is recommended that you review the **Kernel Access** setting for each Role. This will avoid accidental or unauthorized use of the Kernel.

---

## See Also

[Display the Kernel Window](#)

## New Installation Framework

Plant SCADA 2023 R2 includes a new installation framework that simplifies the selection and installation of required components.

Plant SCADA's core components appear as a single entry within the **Programs and Features** list in Windows Control Panel, making it easier to uninstall. The new framework also supports **Modify** functionality, which means you can easily add and remove components (see [Uninstall or Change Components](#)).

The installation of Plant SCADA can also be executed via a command line, enabling support for an unattended silent installation. The required components are specified via a configurable response file that represents the forms normally seen when interacting with the user interface of the Plant SCADA installer.

Four preconfigured response files are provided. They install a typical set of required components, or they can be used as reference for your own customized response file.

- **All.txt** – installs all components
- **DevelopmentWorkstation.txt** – installs components for a development workstation
- **RuntimeClient.txt** – installs components for a runtime client
- **Server.txt** – installs components for a runtime server.

## See Also

[Unattended Silent Installation](#)

## AVEVA™ Help

The documentation for Plant SCADA is now presented using AVEVA Help, a browser-based tool that allows any installed AVEVA products to share a common platform for the delivery of product information.

AVEVA Help is accessible from the **AVEVA Documentation** branch of the Windows **Start** menu. When launched, it will display in your default browser.

The panel to the left includes a list of any locally installed AVEVA products that utilize the AVEVA Help platform. You can open the documentation for a product on its own browser tab by selecting the following icon:

Plant SCADA's context-sensitive help will also open content directly in AVEVA Help.

The **Search** functionality uses straightforward text-based matching, and you can save a search for repeated use.

The Plant SCADA help is also now available on AVEVA's Documentation cloud portal at <https://docs.aveva.com/bundle/plant-scada/>.

## Setup Wizard supports HMI Computer Role

The Setup Wizard and Profile Wizard now allow you to assign the role **HMI (Standalone, no networking)** to a computer within a Plant SCADA system. This change aligns the available computer roles in a Plant SCADA system with the license types supported by AVEVA Enterprise Licensing.

If your Enterprise License Server hosts a combination of client, server and HMI licenses, you can now specify the HMI role for any computers that require a dedicated HMI license. This means the computer will not pick up a server license that was not intended for it.

It also means you can host both server and HMI licenses on the same Enterprise License Server. Previously, you had to setup two different systems to host these licenses

The **HMI (Standalone, no networking)** role can be configured on the [Computer Role Setup](#) page of the Setup Wizard and Profile Wizard.

### See Also

[Allocating AVEVA™ Enterprise Licenses](#)

## Unique IDs for Equipment

A unique ID is now applied to any equipment and equipment types in a Plant SCADA project. This is done to provide consistent identification for integration with future software releases.

The unique IDs are Globally Unique Identifiers that are generated by Plant SCADA whenever equipment is added to a project. The IDs are not available to access at runtime.

The Migration Tool also includes an option to **Create unique IDs for Variables and Equipment**.

For more information, see [Unique IDs for Variable Tags and Equipment](#).

## Equipment Update Improvements

The performance of an Equipment Update has been improved. In most cases, the time taken to generate tags and equipment will be significantly reduced compared to earlier versions.

## Project DBF AddIn supports 64-bit Excel

The Plant SCADA Project DBF AddIn now supports 64-bit versions of Microsoft Excel.

### See Also

[Using Microsoft Excel to Edit DBF Tables](#)

# Citect.ini Parameters in Plant SCADA 2023 R2

This topic lists the parameters that have changed in Plant SCADA 2023 R2.

## Removed Parameters

The following parameters have been removed from this release.

### Debug Parameters

[Debug]Kernel	You can no longer launch the Kernel at startup.
---------------	---

### CSV\_Include Parameters

[Alarm]ActiveHeading	The CSV_Include project is no longer supported by Plant SCADA as a system project.
[Alarm]DisabledHeading	
[Alarm]SummaryHeading	
[Alarm]HardwareHeading	
[MultiMonitors]LastPageStackSize	
[MultiMonitors]ScreenWidth	
[Page]NewPageInBase	
[Page]DelayRepaint	
[Navigation]AlarmPage	
[Navigation]DisabledPage	
[Navigation]FilePage	
[Navigation]HardwarePage	
[Navigation]HelpPage	
[Navigation]HomePage	
[Navigation]MenuBackColour	
[Navigation]MenuForeColour	
[Navigation]MenuXPos	
[Navigation]NetworkPage	
[Navigation]MenuYPos	

[Navigation]ProcessAnalystPage
[Navigation]SummaryPage
[Navigation]TrendPage
[Navigation]ToolsPage
[Printer]Port
[Privilege]EngTools
[TrendX]Duration
[TrendX]KeySeq
[TrendX]TagListEnable

## What's New - Previous Releases

This section lists the features that were added in previous releases of Plant SCADA, and provides links to the relevant sections in the online help.

- [Introduced in Plant SCADA 2023](#)
- [Introduced in Plant SCADA 2020 R2](#)
- [Introduced in Citect SCADA 2018 R2](#)
- [Introduced in Citect SCADA 2018](#)
- [Introduced in Citect SCADA 2016](#)
- [Introduced in Citect SCADA 2015 SP1](#)
- [Introduced in Citect SCADA 2015](#)
- [Introduced in Citect SCADA 7.40 SP1](#)
- [Introduced in Citect SCADA 7.40](#)
- [Introduced in Citect SCADA 7.30](#)
- [Introduced in Citect SCADA 7.20](#)
- [Introduced in Citect SCADA 7.10](#)
- [Introduced in Citect SCADA 7.0](#)

## See Also

[What's New in Plant SCADA](#)

## What's New in Plant SCADA 2023

Plant SCADA 2023 incorporates the following new or modified features:

- [AVEVA™ Enterprise Licensing](#)
- [Configuration Parameters Database for Equipment Types](#)
- [Add Web Content to a Graphics Page](#)
- [Tag Writes Enabled for Industrial Graphics Applications](#)
- [Tag Writes Enabled for OPC UA Client Applications](#)
- [Alarm Filtering Performance Improvements](#)
- [Unique IDs for Variables](#)

- Unique IDs for Projects
- Debug Cicode without Compiling.

The colors, buttons and other elements used for the Plant SCADA Studio interface have been changed to provide more efficient workflows and a common look-and-feel across AVEVA's products.

**Note:**

The following features are no longer supported with this release of Plant SCADA.

- Schneider Electric's **Floating License Manager** is no longer supported by Plant SCADA. Existing users of the Floating License Manager will need to reconfigure their system to use AVEVA Enterprise Licensing.
- Plant SCADA's legacy Active X Web Client is no longer supported.

For updates to Citect.ini parameters, see [Citect.ini Parameters in Plant SCADA 2023](#).

For updates to Cicode functions, see [Cicode Functions in Plant SCADA 2023](#).

## AVEVA™ Enterprise Licensing

In Plant SCADA 2023, AVEVA Enterprise Licensing is now fully integrated for use with Plant SCADA.

AVEVA Enterprise Licensing is a common platform solution that allows you to manage AVEVA Enterprise Software product licenses.

The system is comprised of a browser-based License Manager and a License Server that allow you to share and deliver licenses to installed AVEVA applications. This distributed architecture enables centralized management of activated licenses and flexible topologies that support systems of any size.

AVEVA Enterprise Licensing is required if you intend to use AVEVA Industrial Graphics.

**Note:** With this release, Schneider Electric's Floating License Manager is no longer supported by Plant SCADA. Existing users of the Floating License Manager will need to reconfigure their system to use AVEVA Enterprise Licensing.

## See Also

[AVEVA™ Enterprise Licensing](#)

## Configuration Parameters Database for Equipment Types

In Plant SCADA 2023, "configuration parameters" replace "custom parameters" for Equipment Types.

[Configuration Parameters](#) provide the same functionality as custom parameters. They can be used to represent specific information about a physical piece of equipment, such as a set point or delay setting. However, they are stored in a dedicated configuration parameters database. This means you will no longer be restricted by a 256 character limitation, providing greater flexibility if you need to add multiple parameters.

Only Equipment Types created in Plant SCADA 2023 (or later) will make use of the new database. You can identify one of these new Equipment Types via the following version "2.0" label in the source XML:

```
<template version="2.0" desc="Equipment template">
```

**Note:** This change requires any existing equipment types to be migrated to a new format. If Plant SCADA detects any version 1.0 equipment types, a dialog will appear asking if you want to migrate them. If this occurs, see [Migrate Custom Parameters to the Configuration Parameters Database](#).

## See Also

[Add Configuration Parameters to an Equipment Type](#)

## Add Web Content to a Graphics Page

Plant SCADA now allows you to natively incorporate modern web-based content in your runtime system. This is achieved by adding a **Web Content** object to a page in Graphics Builder (see [Add a Web Content Object](#)).

Each instance of a Web Content object has a **URL** property that allows you to specify the content that is displayed when the host graphics page is launched.

---

**Note:** If one of your projects uses the Microsoft Web Browser ActiveX object on a graphics page, it is recommended that you replace it with the new Web Content object.

---

## See Also

[Web Content](#)

## Tag Writes Enabled for Industrial Graphics Applications

You can now write to Plant SCADA tags and equipment.items directly from Industrial Graphics applications. This involves the following changes to Plant SCADA:

- The "Industrial Graphics R/W Users" security role is now enabled on any computer hosting an Industrial Graphics Server. It is used to manage access for client application users that require read/write access to a Plant SCADA runtime system.
- Variable tags now include a **Write Roles** property that is used to enable writes for users from specific Plant SCADA roles. The current user of an Industrial Graphics application needs to be associated with the role specified in this property to write to a variable tag.

For more information, see [Enable Tag Writes for Industrial Graphics Applications](#).

## Tag Writes Enabled for OPC UA Client Applications

You can now write to Plant SCADA tags directly from an OPC UA client application connected to a Plant SCADA OPC UA Server.

To do this, you need to set the **Write Roles** property for each variable tag that will have writes enabled. The Property Grid allows you to select one of the roles configured in your Plant SCADA project, or you can manually enter a comma-separated list to include multiple roles. See [Add a Variable Tag](#).

To write to a variable tag, the user that is currently logged in to the OPC UA client application needs to be part of a Windows™ domain group that is associated with the role specified in the **Write Roles** property.

---

**Note:** Tag writes will only work if encryption is enabled for the OPC UA Server.

---

For more information, see [Confirm the Settings for an OPC UA Server](#).

## Alarm Filtering Performance Improvements

The performance of filtering operations on the **Sequence of Events** and **Alarm Summary** pages have been improved.

Queries that return a small number of alarm records from a large alarm database will see the greatest performance improvement. For example, when you filter alarms that have occurred on a single piece of equipment.

In addition, a new parameter has been added that allows you to switch off alarm filter optimization. For a description of the circumstances where this may be beneficial, see [\[Alarm\]DisableFilterOptimization](#).

## Unique IDs for Variables

A unique ID is applied to each of the variable tags in a Plant SCADA project to provide consistent identification for integration with future software releases. The unique IDs are Globally Unique Identifiers that are generated by Plant SCADA whenever tags are added to a project.

The Migration Tool has a new option to automatically add IDs to any existing project.

For more information, see [Unique IDs for Variable Tags and Equipment](#).

## Unique IDs for Projects

With the release of Plant SCADA 2023, unique IDs are now applied to each Plant SCADA project. This provides consistent identification across the lifetime of a project.

Each unique ID is a Globally Unique Identifier (GUID) generated by Plant SCADA using the following format:

XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX

If you [Copy a Project](#) or [Restore a Project](#) a project, you will need to consider how its Unique ID will be impacted.

## See Also

[Plant SCADA Projects](#)

[Edit a Project's Properties](#)

## Debug Cicode without Compiling

To start a debugging session without the project being recompiled, you can use **Start Debugging Without Compile** to quickly start debugging your Cicode.

The **Start Debugging Without Compile** option can be selected from Cicode Editor's **Debug** menu.

---

**Note:** You can only use this option if you have already compiled a project at least once.

---

### UNINTENDED EQUIPMENT OPERATION

Do not use the following command to start Plant SCADA if you have uncompiled project changes that are

necessary for the safe operation of your plant and process.

- Start Debugging Without Compile

This option is only intended to assist debugging an already compiled project.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

## See Also

[Debugging Cicode](#)

## Citect.ini Parameters in Plant SCADA 2023

This topic lists the parameters that have changed in Plant SCADA 2023.

### New Parameters

The following parameters are new in this release. For an entire list of the system parameters, refer to the Parameters documentation.

#### Alarm Parameters

[Alarm]DisableFilterOptimization	Allows you to turn off filter optimization for alarm queries.
[Alarm]StandbyCommandDelay	Sets a delay (in milliseconds) that a standby alarm server will apply when executing alarm commands received from the main alarm server.

#### AnmCursor Parameters

[AnmCursor]RubberBandColor	Sets the color of the trend selection rubber band.
----------------------------	--

#### CTAPI Parameters

[CtAPI]MaxConnections	Specifies the maximum number of connections supported by a CTAPI client.
-----------------------	--

#### Debug Parameters

[Debug]ChromiumDevToolsPort	Enables debugging for a Web Content object located on a Plant SCADA graphics page.
-----------------------------	--

#### General Parameters

[General]AELManagerUrl	This parameter stores the current URL for the AVEVA™ Enterprise License Manager.
[General]EnforceTagGlobalUniqueness	Instructs the compiler to generate a warning message for each tag name that is not globally unique.

**OpcDaServer Parameters**

[OpcDaServer]RoundToFormat	Specifies if tag values published to an OPC DA Server are rounded.
----------------------------	--

**Security Parameters**

[Security]DeleteWebContentProfile	Use this parameter to automatically delete the application data associated with users of a Web Content control.
-----------------------------------	---

**Removed Parameters**

The following parameters have been removed from this release.

**Address Forwarding Parameters**

[AddressForwarding]LicenseStore	Floating License Manager is no longer supported by Plant SCADA.
---------------------------------	---

**CtEdit Parameters**

[CtEdit]WebDeploy	The Plant SCADA IIS Web Client is no longer supported.
-------------------	--

**DNS Parameters**

[DNS]Primary	The Plant SCADA Internet Display Client is no longer supported.
[DNS]Standby	The Plant SCADA Internet Display Client is no longer supported.

**Internet Parameters**

[Internet]Client	The Plant SCADA Internet Display Client is no longer supported.
[Internet]Display	The Plant SCADA Internet Display Client is no longer supported.
[Internet]FTPTimeout	The Plant SCADA Internet Display Client is no longer supported.
[Internet]FTPWatchTime	The Plant SCADA Internet Display Client is no longer supported.
[Internet]IPAddress	The Plant SCADA Internet Display Client is no longer supported.
[Internet]LogFile	The Plant SCADA Internet Display Client is no longer supported.

[Internet]Manager	The Plant SCADA Internet Display Client is no longer supported.
[Internet]Password	The Plant SCADA Internet Display Client is no longer supported.
[Internet]Port	The Plant SCADA Internet Display Client is no longer supported.
[Internet]Redundancy	The Plant SCADA Internet Display Client is no longer supported.
[Internet]RunFTP	The Plant SCADA Internet Display Client is no longer supported.
[Internet]SearchCurrentPath	The Plant SCADA Internet Display Client is no longer supported.
[Internet]Server	The Plant SCADA Internet Display Client is no longer supported.
[Internet]ShowFileFTPDlg	The Plant SCADA Internet Display Client is no longer supported.
[Internet]ShowSetupDlg	The Plant SCADA Internet Display Client is no longer supported.
[Internet]UpdateTime	The Plant SCADA Internet Display Client is no longer supported.
[Internet]ZipFiles	The Plant SCADA Internet Display Client is no longer supported.

**Web Server Parameters**

[WebServer]DeployRoot	The Plant SCADA IIS Web Client is no longer supported.
[WebServer]WebClientCab	The Plant SCADA IIS Web Client is no longer supported.

**See Also**

[What's New in Plant SCADA 2023](#)

**Cicode Functions in Plant SCADA 2023**

Some Cicode functions have been introduced or modified. The following sections detail these changes:

## New Functions

### Color Functions

MakeColour	Creates a color from red, green and blue component parts. For backwards compatibility, you can refer to this function using the alias "MakeCitectColour".
------------	---

### Display Functions

DspRubSetColor	Sets the color of the rubber band tool that is used to select a section within a trend object.
DspWebContentGetURL	Gets the current URL for a Web Content control on a graphics page.
DspWebContentSetURL	Sets the URL for a Web Content control on a graphics page.

### Security Functions

UserCreateByRole	Creates a record for a new Plant SCADA user. The user can be assigned to a specified role. Not available when logged in as Windows user.
------------------	--

## Deprecated Functions

### Security Functions

UserCreate	Creates a record for a new Plant SCADA user. This function is now deprecated and will be removed in the next release. Use the function instead.
------------	---

## Removed Functions

### FTP Functions

FTPClose	The Plant SCADA Internet Display Client is no longer supported.
FTPFileCopy	The Plant SCADA Internet Display Client is no longer supported.
FTPFileFind	The Plant SCADA Internet Display Client is no longer supported.
FTPFileFindClose	The Plant SCADA Internet Display Client is no longer supported.
FTPOpen	The Plant SCADA Internet Display Client is no longer

	supported.
--	------------

[Citect.ini Parameters in Plant SCADA 2023](#)

## What's New in Plant SCADA 2020 R2

Plant SCADA 2020 R2 incorporates the following new or modified features:

- [Rebranding to Plant SCADA](#)
- [Integration of AVEVA™ Industrial Graphics](#)
- [Integrated OPC UA Server Functionality](#)
- [IPv6 Support](#)
- [Graphics Usage](#)
- [Graphics Editing Enhancements](#)
- [Driver Classifications](#).

For new Citect.ini Parameters, see [Citect.ini Parameters in Plant SCADA 2020 R2](#).

---

**Note:**

The following features are no longer supported with this release of Plant SCADA.

- **EcoStruxure Web Services (EWS)** are no longer supported. You will not be able to create or use an EWS server or client.
  - The **Vijeo Web Gate Control** has been deprecated and is no longer part of the Plant SCADA installation. The control will still work with Plant SCADA. However, to continue to use it you will need to manually reinstall it from another source as it will have been uninstalled when the previous version of Citect SCADA was uninstalled.
  - The **Pelco ActiveX Control** has been deprecated and is no longer part of the Plant SCADA installation. If you have upgraded your computer from a previous version with this control installed, it will continue to function. However, it is recommended that you communicate with Pelco cameras using a different method.
- 

## Rebranding to Plant SCADA

The 2020 R2 release signifies the transition away from the Citect SCADA brand to AVEVA™ Plant SCADA. The new name reflects the positioning of Plant SCADA within the broader family of AVEVA products.

The rebranding incorporates several changes, including updates to splash screens and graphics, icons, installer and installation directories, start menu paths, and more.

To determine the new directory locations, see [View a Project's Folders](#).

## Integration of AVEVA™ Industrial Graphics

AVEVA Industrial Graphics is the common graphics technology used across AVEVA's SCADA, HMI and cloud solutions. You can create HTML5 screens and dashboards in Plant SCADA and access them in desktop browsers and mobile devices.

Industrial Graphics are accessible in Plant SCADA Studio for integrated browsing and filtering. From here, they can be launched within the new Industrial Graphics Editor for all editing activities. AVEVA Industrial Graphics are accessed by clients in an HTML browser via an Industrial Graphics Server. It authenticates clients details and provides access to the graphical and functional content.

"IndustrialGraphics\_Include" is a system project designed for the Industrial Graphics platform. This project is included in the "ExampleSA" project for demonstration of Industrial Graphics. It contains a default set of Industrial Graphics which includes charting and dashboard symbols, as well as ISA symbols.

For more information, see [AVEVA Industrial Graphics](#).

## Integrated OPC UA Server Functionality

You can now make your I/O data accessible to third-party systems with the new OPC UA Server. This enables IT and OT convergence through secure connectivity.

For more information, see [Install an OPC UA Server](#).

## Graphics Usage

Supporting both Plant SCADA native graphics and AVEVA Industrial Graphics, the new Graphics Usage feature allows you to identify the graphical references that exist in your system. For example, you can confirm where a Genie or symbol is used, or if a project contains unused graphics.

To take advantage of this feature, see the new **Used By** section of the **Libraries** view in the **Visualization** activity (see [Browse Libraries in Plant SCADA Studio](#) and/or [Browse Industrial Graphics Libraries in Plant SCADA Studio](#)).

## Graphics Editing Enhancements

Graphics Builder now persists its window positions and the size of the "Go To Object" dialog.

### See also

[Object Groups](#)

## IPv6 Support

Plant SCADA now supports Internet Protocol version 6 (IPv6) and will accept 128 bit IP addresses (including any acceptable abbreviations). For example:

- 2001:0db8:0000:0000:8a2e:0123:1234
- or

- 2001:db8::8a2e:123:1234 (abbreviated).

You can now operate a Plant SCADA system on an IPv6 network. IPv6 protocol can be used for communication between servers and clients, and for any drivers that support IPv6.

IPv6 support can be enabled via the [Network Model](#) page of the Setup Wizard.

## See Also

[Add Network Addresses](#)

[Server Redirection Using Address Forwarding](#)

## Driver Classifications

As part of an ongoing effort to set clear expectations and provide better support to our customers, we have introduced a classification system for our driver portfolio to communicate the level of ongoing maintenance and version updates that customers can reasonably expect. These classifications and status of each driver can be found online at <https://gcsresource.aveva.com/PlantSCADA/Drivers/>.

In line with these classifications, we have limited the number of drivers included by default on the Plant SCADA installation media to a reduced set of 'core' drivers that have undergone recent updates, however all other drivers continue to be available for download from the **Communication Drivers** page at the [AVEVA Knowledge and Support Center](#).

It is recommended that you visit on a regular basis and subscribe to the forum so that you are alerted to any updates that occur.

For more information, see [Install Communication Drivers](#).

## Citect.ini Parameters in Plant SCADA 2020 R2

This topic lists the parameters that have changed in Plant SCADA 2020 R2.

## New Parameters

The following parameters are new in this release. For an entire list of the system parameters, refer to the [Parameters documentation](#).

### Client Parameters

[Client]TagReadRoundToFormat	Determines if the variable tag values returned by the TagRead and TagReadEx will be rounded to the format of the variable tag.
[Client]AdditionalClientsArePartOfTrustedNetwork	Tells an /X Client process to attempt to authenticate using the stored server password, which results in the client node becoming part of a "trusted network".

### LAN Parameters

[LAN]AddressScope	Specifies the address scope types for IPv6 addresses.
[LAN]AddressType	Enables support for IPv4 or IPv6 network types, or both.

### General Parameters

[General]EnforceTagGlobalUniqueness	Instructs the compiler to generate a warning message for each tag name that is not globally unique.
-------------------------------------	---

### Scheduling Parameters

[Scheduling]AlwaysExecuteEntryAction	This parameter determines how entry actions are executed by Scheduler.
--------------------------------------	--

### Removed Parameters

[Server]EWSAllowAnonymousAccess	Removed as the EcoStruxure Web Services (EWS) are no longer supported by Plant SCADA.
---------------------------------	---

### See Also

[What's New in Plant SCADA](#)

## What's New in Citect SCADA 2018 R2

Citect SCADA 2018 R2 incorporates the following new or modified features:

- [Graphics Browsing](#)
- [Size and Position Objects](#)
- [Encrypted Connections](#) between Citect SCADA server, clients and other processes
- [Publish Plant SCADA Data to the Cloud](#)
- [Situational Awareness Improvements.](#)

For changes to:

- Cicode functions, see [Cicode Functions in Citect SCADA 2018 R2](#).
- Citect.ini Parameters, see [Citect.ini Parameters in Citect SCADA 2018 R2](#).

**Note:** The Plant SCADA drivers that are installed with version 2018 R2 have been recreated to allow Aveva Group Plc branding.

## Graphics Browsing

Enhancements have been made to the **Visualization** activity that allow you to browse the pages and library items

in the active project and its included projects.

Browsing provides you with a thumbnails view or list view of pages and library items, allowing you to easily see their attributes. You can perform the following operations in these views:

- Browse, search and filter pages (see [Browse Pages in Plant SCADA Studio](#)).
- Browse, search and filter library items by project and/or library (see [Browse Libraries in Plant SCADA Studio](#)).
- Perform bulk operations directly from Plant SCADA Studio including delete, update pages and pack libraries.
- Open existing pages or library items in Graphics Builder directly from Plant SCADA Studio.
- Create new pages or library items in Graphics Builder directly from Plant SCADA Studio.

## Size and Position Objects

Editing graphics has been simplified, as you can manually enter the size and position of a selected object.

It is also possible to move or nudge an object using the keyboard.

See [Adjust Position and Size Dialog](#).

## Encrypted Connections

Citect SCADA 2018 R2 allows for [Encrypted Communications](#) between Citect SCADA servers, clients and other processes. Security certificates are centrally configured for all nodes (when on a domain), including secure deployment of configuration to remote clients.

This provides enhanced protection against external security threats by providing secure connectivity for remote CtAPI clients.

## Publish Plant SCADA Data to the Cloud

A new interface is now available to AVEVA Insight, which allows you to publish your Plant SCADA data to the cloud easily and securely. You can:

- Access your data from browsers and mobile devices.
- Create and share customized content for your process/plan.
- Automatically detect anomalous patterns in your historical data and display these via the AVEVA Insight "newsfeed".

For more information, refer to the **AVEVA Insight** documentation.

## Situational Awareness Improvements

The following enhancements have been made to the workspace for Situational Awareness projects.

1. The Navigation Zone can be configured to support icons for four alarm priorities.
2. The equipment tree view on alarm pages can also support icons for four alarm priorities.

See [Configure Display Properties for a Fourth Alarm Priority](#).

You can also add a fourth alarm priority filter button to your alarm pages (see [Add a Fourth Alarm Priority Filter to Alarm Pages](#)).

Additional topics have been added to the documentation to provide an overview of key functionality and concepts. These topics include:

- [Alarms](#)
- [Libraries](#)
- [Interlocks](#)
- [Page Levels](#).

The workspace will also support a new blue theme (see [Apply a Color Theme to a Workspace](#)).

## Citect.ini Parameters in Citect SCADA 2018 R2

This topic lists the parameters that have changed in Citect SCADA 2018 R2.

### New Parameters

The following parameters are new or have been altered in this release. For an entire list of the system parameters, refer to the Parameters documentation.

#### Accumulator Parameters

[Accumulator]Debug	Enables trace logging messages for accumulators.
--------------------	--

#### DDE Parameters

[DDE]Enable	Allows Citect SCADA Runtime to function as a DDE Server.
-------------	--

#### Page Parameters

[Page]ValueAbnormalPattern	Displays a diagonal pattern across a graphics object when the corresponding device goes offline, that is, it loses communication.
----------------------------	---

#### Scheduler Parameters

[Scheduling]BACnetSchedulePollPeriod	Sets the subscription poll period (rate) for the BACnet tags.
--------------------------------------	---

#### Report Parameters

[Report]Debug	Enables trace logging messages for the report server process.
---------------	---

#### Workspace Parameters

[Workspace]NumberOfTopPriorities	Determines how many alarm priorities are included in
----------------------------------	--

	the alarm counts presented in the Tree View on alarm and trend pages, and the tabs and buttons in the Navigation Zone.
--	--

## Modified Parameters

### Page Parameters

[Page]KeyEcho	Zero (0) has been added as an allowable value. It can be used to disable the supported functionality.
[Page]Prompt	Zero (0) has been added as an allowable value. It can be used to disable the supported functionality.

## Removed Parameters

[CtAPI]AllowLegacyConnections	Allowed connections from client applications compiled against version 7.00 (and earlier).
-------------------------------	---

## See Also

[Cicode Functions in Citect SCADA 2018 R2](#)

## Cicode Functions in Citect SCADA 2018 R2

Some Cicode functions have been introduced or modified. The following sections detail these changes:

## New Functions

### Alarm Functions

StrReplaceAlarmFilterEditHasField	Checks whether an alarm field name or any field in a set of field names is used in the filter specified in an alarm filter edit session.
-----------------------------------	--

### String Functions

StrReplace	Replaces a substring in a string with a replacement substring.
------------	--

### Scheduler Functions

SchdSpecialItemAddRange	Adds a range of special days in a specified special day group.
SchdSpecialItemDeleteRange	Deletes a range of special days in a specified special

	day group.
SchdSpecialItemModifyRange	Modifies a range of special days in a specified special day group.

## Modified Functions

### Alarm Functions

AlarmSetInfo	The function was enhanced to allow alarms to be sorted by type.
--------------	---

### Trend Functions

TrnGetTable	New display mode options have been introduced to allow users to synchronize samples to the specified time instead of the nearest display period.
-------------	--

## Deprecated Functions

No functions have been deprecated for Citect SCADA 2018 R2.

## Removed Functions

No functions have been removed for Citect SCADA 2018 R2.

## See Also

[Citect.ini Parameters in Citect SCADA 2018 R2](#)

## What's New in Citect SCADA 2018

Citect SCADA 2018 incorporates the following new or modified features:

- Situational Awareness Starter Project
- Additional Example Project
- Alarm Management
- Graphics Improvements
- Screen Profiles
- Equipment References
- Composite Genies
- Refresh Super Genie Associations
- Grid Column Resizing in Plant SCADA Studio
- Display Name for Equipment

- Menu Configuration Enhancements
- Array Functions
- Indirect Tag Value Lookups in Foreground Code.

For changes to:

- Cicode functions, see [Cicode Functions in Citect SCADA 2018](#).
- Citect.ini Parameters, see [Citect.ini Parameters in Citect SCADA 2018](#).

## Situational Awareness Starter Project

The Situational Awareness Starter Project can be used to create a Plant SCADA project that is designed to support abnormal situation management for operators. This provides accurate information to an operator in a way that can be perceived and acted upon quickly, without overwhelming their cognitive abilities. A consistent look and feel is applied to all graphical content, and standardized colors settings are used to emphasize important process data and alarms.

Situational Awareness projects differ to other pure template-based projects as they use "Workspace" technology to manage the content of a Master Page that appears on each configured client screen. Each pane in a Master Page displays a page that can be updated independently at runtime based on navigational or contextual changes. The Workspace is responsible for managing contextual updates to those panes by using the association between the hierarchical location of a detected change, and the type of content each pane is configured to display.

A set of library objects are also available via an included library project (named "SA\_Library"). The included objects support the Workspace autofill functionality at runtime and maintain a consistent look and feel across a project's display pages.

You can also use the workspace without equipment to build a project that does not utilize the new context features. This is achieved using a Pane Genie on a customized master page.

For more information, see [Situational Awareness Projects](#).

---

**Note:** This release of Plant SCADA also includes a [Additional Example Project](#) to demonstrate a Situational Awareness Project.

---

## See Also

[What's New in Citect SCADA 2018](#)

## Additional Example Project

Citect SCADA now includes an additional example project, ExampleSA.

ExampleSA is a project created using the [Situational Awareness Starter Project](#). It features the default layout used, including elements such as a header bar, content area, and a dashboard that displays contextual information and navigational tools.

It also demonstrates the autofill functionality of the workspace, which enables contextual updates managed via a project's equipment hierarchy. This is driven by an association between the hierarchical location of the current context, and the type of content each pane is configured to display.

The project pages are built using objects that are available in an included library project (named "SA\_Library").

These objects (and associated faceplates) support the autofill functionality of the workspace and maintain a consistent look and feel across a project's display pages.

For more information, see [Situational Awareness Projects](#).

## See Also

[What's New in Citect SCADA 2018](#)

## Alarm Management

Citect SCADA 2018 includes the following enhancements to the way operators can manage alarms at runtime.

### Alarm Cause and Response

Citect SCADA 2018 allows you to associate cause and response information with an alarm tag. This means you can describe the circumstances that are likely to cause the alarm, and the appropriate course of action required to address the alarm. This information can then be presented to an operator at runtime. See [Provide Cause and Response Information to Operators](#).

To specify cause and response information for an alarm tag, you need to use the new **Alarming > Cause and Response** view in the Setup activity. See [Add Cause and Response Information to Alarms](#).

### Alarm Shelving

When you shelf an alarm, it is disabled for a specified period of time, or until a specified time is reached. This allows an operator to temporarily disable alarms that are causing an unnecessary distraction.

Shelving is available via the Workspace's new Alarm tab in the Information zone.

If your project uses the SxW or Tab Style templates (accessible via a starter project), you can shelf alarms during runtime from the Active Alarms and Alarm Summary page.

You can also shelf alarms by setting the *EndTime* argument for the following Cicode functions:

- [AlarmDisable](#)
- [AlarmDisableRec](#)
- [AlarmDisableTag](#)
- [AlmBrowseDisable](#)
- [AlmSummaryDisable](#)
- [AlmTagsDisable](#).

For more information, see [Shelve Alarms](#).

### Alarm Indicators

Citect SCADA 2018 allows you to use alarm indicators. Consisting of an alarm border and flag that appear around the extent of an object group or Genie, an alarm indicator provides a prominent visual indication of alarm occurrences at runtime.

See [Use Alarm Indicators](#).

To configure an alarm indicator for an object group or Genie, there are two tasks you need to consider:

1. You need to define display properties for the alarm priorities that an indicator will represent. See [Configure Display Properties for an Alarm Priority](#).
2. For each object group or Genie, you need to define the Alarm Indicator properties in Graphics Builder. See [Alarm Indicator](#).

## Alarm Priority Display Properties

You can configure optional display properties for an alarm priority that allow you to:

- Specify a name for a priority value to provide a meaningful representation of its purpose.
- Define background and foreground colors that support a visual representation of priority on a graphics page.
- Define a Large and Small genie to visually represent the priority on the Alarm Indicator and Alarm Lists.

These additional properties are configured in the **Setup** activity (see [Configure Display Properties for an Alarm Priority](#)).

For more information, see [Prioritize Alarms](#).

## See Also

[What's New in Citect SCADA 2018](#)

## Graphics Improvements

Citect SCADA 2018 includes the following enhancements to Graphics and the Graphics builder.

## Name a Graphics Object

In Citect SCADA 2018 you can now name graphics objects ( for example, a Polyline, Rectangle, Text and Genie). Use this name to reference a graphics object via expressions and Cicode at runtime.

Configure the animation name when defining the general access properties of a graphics object.

See the following topics for more information.

- [General Access to Objects](#)
- [Animation Points](#)
- [Naming Graphic Objects](#)
- [PropertiesAttributeNameGetEx](#)
- [PropertiesAttributeNamePutEx](#)

- [PropertiesAttributeNamePutEx](#)
- [Referencing an Object Using a Name at Runtime](#)
- [DspAnSetName.](#)

## Animated Polygon Vertices

Plant SCADA now allows you to associate a tag or Cicode expression with the vertices in a polygon. This means the shape of a polygon can be manipulated at runtime in response to values generated by a production system.

This is achieved by applying offset values to each vertex that define a path along which the vertex can move. As the return value for an expression changes, a vertex will move along the path defined for it, altering the shape of the polygon.

For more information see [Animate a Polygon at Runtime](#).

## Pinned Windows

Windows can now be "pinned" at specified locations within a main window or within other pinned windows. A new Cicode function WinNewPinAt() has been added that when configured opens a new display window at a specified location, relative to the current active window, with a selected page displayed. The window can later be removed with the WinFree() function.

For more information see [WinNewPinAt](#).

## Activate/Deactivate

You can now configure events to run when a window is activated or deactivated. This is useful when using pinned windows on a page. For example, the activate event can be used to run an event if the user clicks on the pinned window.

## Dynamically Display Symbols

In Plant SCADA 2018 you can use the [DspSym](#) Cicode function with a Genie to dynamically display content that is only generated at runtime.

You can also use bitmap and non-bitmap images as part of a symbol set in Graphics Builder.

See [Dynamically Instantiate a Genie at Runtime](#) for more information.

## Runtime Cursor

The runtime input focus cursors' color can now be set to transparent. Also, a new function DspSetCurColor() has been added to allow simpler dynamic setting of the cursor color.

## See Also

[What's New in Citect SCADA 2018](#)

## Screen Profiles

A [screen profile](#) specifies the physical characteristics of one or more workstation screens and how these screens are arranged with respect to each other. Each screen icon that appears in a screen profile represents a physical screen.

You can create, manage and configure screen profiles with the Screen Profile Editor, which is displayed below the Screen Profile table in the **Setup** activity. You can create as many screen profiles as you want.

A screen profile can also be set up for your project through the [Screen Setup](#).

## See Also

[What's New in Citect SCADA 2018](#)

## Equipment References

Citect SCADA 2018 allows you to link a piece of equipment to items, or tags belonging to another piece of equipment in your Citect SCADA project. This means you can establish a relationship with equipment or equipment.items outside the equipment hierarchy. With equipment reference browse functions you can then track, group and display all information for the equipment and referenced equipment in one interface at runtime.

Add equipment references within the **System Model > Equipment References** view. Refer to [Equipment References](#) for more information.

## See also

[What's New in Citect SCADA 2018](#)

## Composite Genies

Citect SCADA provides several Composite Genies for use in graphics pages. A Composite Genie is a collection of individual Genies assembled to form a single object based on parameters/options chosen by the Engineer. The individual objects and their parameters/options are defined in an XML template file along with layouts for the collection, that is, the Composite Genie. You can insert multiple instances of the composite object on to a graphics page, and specify different parameter settings including values, alignment and display options for each instance to tailor the Composite Genie to suit your requirements.

For example, you want to build a mirrorable compressor object that is capable of optionally displaying a label, a mode indicator and a meter alongside the symbol. Prior to Citect SCADA 2018, you could either create separate genies for each of the permutations, or you could build a single genie that used visibility to show/hide elements at runtime. With Composite Genies, you can simply select the XML template for a compressor, which presents a set of presentation options for you to configure label, orientation, etc. All you need to do is set values for these options and insert the object on to a page. You can change parameters/options at any time. For more information, see [Composite Genies](#).

## See Also

[What's New in Citect SCADA 2018](#)

## Refresh Super Genie Associations

A new Cicode function called AssWinReplace allows you to update the associations for a Super Genie without the need to reload the entire page. The function removes the associations on a specified Super Genie window, and applies any pending associations.

For more information, see [AssWinReplace](#).

## See Also

[What's New in Citect SCADA 2018](#)

## Grid Column Resizing in Plant SCADA Studio

You can now re-size the columns in the Plant SCADA Studio Grid Editor according to their content.

To do this, select **Size Columns to Content** from the menu on the left side of the Grid Editor header. Alternatively, you can double-click the divider of a specific column to auto resize it.

For more information, see [Customize Grid Editor Columns](#).

## See Also

[What's New in Citect SCADA 2018](#)

## Display Name for Equipment

Equipment definitions now support a **Display Name** property. This allows you to specify a meaningful name that can identify a piece of equipment at runtime.

The Display Name can also be used to reference equipment in a Genie.

For more information, see [Define Equipment in Plant SCADA Studio](#).

## See Also

[What's New in Citect SCADA 2018](#)

## Menu Configuration Enhancements

Plant SCADA's menu system has been enhanced. You can now associate equipment with a menu item, allowing you to align the equipment model with page navigation. In the case of a Situational Awareness project, this

drives the functionality that enables a runtime system to respond to the current context of a display client (see [Prepare the Navigation Menu](#)).

Further enhancements include:

1. Support for two more menu levels
2. Support for up to eight **Custom** properties for each menu item
3. All properties can be queried at runtime.

For more information, see [Menu Configuration](#).

## See Also

[What's New in Citect SCADA 2018](#)

## Array Functions

Citect SCADA now includes a set of functions that allow you to create arrays that use up to three dimensions (x,y,z). This can offer performance benefits when handling large amounts of data, for example, when generating an alarms list.

For more information, see [Array Functions](#).

## See Also

[What's New in Citect SCADA 2018](#)

## Indirect Tag Value Lookups in Foreground Code

A new function [TagGetValue](#) has been added that allows values of tags to be automatically looked up in foreground cicode expressions. This function automatically sets up and maintains the subscriptions for the referenced tag / equipment.item.

## See also

[What's New in Citect SCADA 2018](#)

## Citect.ini Parameters in Citect SCADA 2018

This topic lists the parameters that have changed in Citect SCADA 2018.

## New Parameters

The following parameters are new or have been altered in this release. For an entire list of the system parameters, refer to the Parameters documentation.

### CtEdit Parameters

[CtEdit]IncrementalEquipmentUpdateAutoClose	Determines if the Update Equipment confirmation dialog appears when an incremental equipment update has completed.
---	--

**Debug Parameters**

[Debug]DebugLogHistoryFiles	Determines how many "debug.<process name>.log" files are kept when rolled over.
[Debug]DebugLogFileSize	Sets the maximum size of the "debug.<process name>.log" file.

**MultiMonitors Parameters**

[MultiMonitors]Context<n>	Allows you to share a single context with one or more screens.
[MultiMonitors]ScreenProfile	Sets the arrangement of monitors on a client workstation.
[MultiMonitors]StartupPage<Name>	Sets the pages that appear when using a particular screen profile.
[MultiMonitors]Workspaces	Indicates the number of workspace pages to be shown at startup.

**SA\_Library.Meter Parameters**

[SA_Library.Meter]UseDefaultPLCLimits	Allows you to use PLC alarm limits for faceplates.
[SA_Library.Meter]PLCLimitNames	Names for PLC alarm limits. This is a comma-separated list of values.
[SA_Library.Meter]PLCLimitLabels	Display labels that correspond to each PLC alarm limit defined. This is a comma-separated list of values.
[SA_Library.Meter]DefaultPLCLimits	A number that determines the order in which to use the defined PLC alarm limits. 0 corresponds to the lowest PLC alarm limit defined, while the largest number corresponds to the highest limit defined.

**Workspace Parameters**

[Workspace]AlarmSortOrder	Defines a customized sort order for the default alarms pages in a Situational Awareness project.
[Workspace] EquipmentNavigationModelFilter	Filters the equipment model loaded by the workspace.
[Workspace]InfoZoneAlarms.IncludeReferences	Determines if alarms from referenced equipment are included in the Alarms page on the Information Zone.
[Workspace]InfoZoneTrends	Determines the pens that will be displayed in the

	Information Zone of the workspace based on the equipment items configured.
[Workspace]InfoZoneTrends.Type	Determines the pens that will be displayed in the Information Zone of the workspace based on the equipment types configured in the Equipment Editor.

## Modified Parameters

[Format]FormatName	Defines a display format for tabular data and identifies it with a specified name. This allows you to name a customized display format that you can then apply to an alarms list.
[Code]Thread	Defines the number of Cicode threads (tasks) that can run concurrently. The default value has changed from 64 to 128.

## Cicode Functions in Citect SCADA 2018

Some Cicode functions have been introduced or modified. The following sections detail these changes:

### New Functions

#### Alarm Filter Functions

AlarmFilterEditAppendEquipment	Appends the provided expression that can include equipment names or category to the current filter session content without validation.
--------------------------------	--

#### Alarm Functions

AlarmCommentRecID	Allows an operator to add a comment to a selected alarm summary or SOE entry during runtime.
AlarmHighestPriority	Returns the alarm priority and/or state of the current highest priority alarm for the given equipment in conjunction with the selected filter criteria.
AlarmListCreate	Creates an alarms list at a specified AN.
AlarmListDisplay	Displays an alarms list at a specified AN.
AlarmListDestroy	Destroys an alarms list at a specified AN.
AlarmListFill	Fills an alarms list at a specified AN to be used by another routine (e.g. the interlocks processing routine).

AlarmTagFromEquipment	Returns the first alarm tag associated with a piece of equipment.
-----------------------	---

**Array Functions**

ArrayCopy	Makes a copy of an array.
ArrayCreate	Creates an array.
ArrayCreateByAn	Creates an array at a specified AN.
ArrayDestroy	Destroys an array.
ArrayDestroyByAn	Destroys an array associated with the specified AN.
ArrayExists	Determines if an array with a specified handle exists.
ArrayExistsByAn	Determines if an array is associated with a specified AN.
ArrayFillFromAlarmDataByAn	This function is used to fill an array with information from internal alarm record caches.
ArrayGetArrayByAn	Retrieves an array associated with a specified AN.
ArrayGetInfo	Retrieves the size of the x-, y-, or z-dimension for an array.
ArrayGetInt	Retrieves an integer value from an array.
ArrayGetIntByAn	Retrieves an integer value from an array associated with a specified AN.
ArrayGetMapName	Retrieves the name of the map associated with an array.
ArrayGetMapNameByAn	Retrieves the name of the map associated with an array at a specified AN.
ArrayGetString	Retrieves a string from an array.
ArrayGetStringByAn	Retrieves a string from an array associated with a specified AN.
ArrayIsDirty	Determines if an array is 'dirty' (information in the array has changed).
ArraySetInt	Sets an integer value within an array.
ArraySetIntByAn	Sets an integer value in an array associated with a specified AN.

ArraySetIsDirty	Allows you to indicate that an array is dirty (meaning the information in the array has changed).
ArraySetString	Sets a string value in an array.
ArraySetStringByAn	Sets a string value in an array associated with a specified AN.
ArraySwap	Swaps the contents of two arrays.
DspArrayByAn	Displays an alarms list. The array that contains the alarm data is associated with the specified AN.

**Display Functions**

DspAnSetName	Using a valid AN set the name of an animation object.
DspClearClip	Clears the clipping rectangle surrounding the object or group of objects.
DspGetAnFromName	Name used to retrieve the AN of an object on the page.
DspGetAnFromNameRelative	Retrieves the animation number (AN) of an object on the page relative to a given Animation Number(AN).
DspGetAnRawExtent	Gets the extent of the object from the graphics page at the specified AN.
DspGetNameFromAN	Using a valid An the animation name of the object is returned.
DspGetMetadataFromName	Name used to retrieve the metadata of an object on the page.
DspGetMetadataFromNameRelative	Retrieves the metadata of an object on the page relative to a given Animation Number (AN).
DspSetCurColor	Sets the color of the focus rectangle.
DspSetMetadataFromName	Name used to set the metadata of an object on the page.
DspSetPopupMenuFont	Sets the font for popup menu text at runtime.

**Equipment Database Functions**

EquipGetParameter	Reads a runtime parameter of an equipment database record from the EQPARAM.RDB database file.
EquipRefBrowseClose	Terminates an active data browse session and cleans up resources associated with the session.

EquipRefBrowseFirst	Places the reference browse cursor at the first record.
EquipRefBrowseGetField	Retrieves the value of the specified field from the record the data browse cursor is currently referencing.
EquipRefBrowseNext	Moves the data browse cursor forward one record.
EquipRefBrowseNumRecords	Returns the number of records that match the filter criteria.
EquipRefBrowseOpen	Initiates a new browse session and returns a handle to the new session that can be used in subsequent equipment reference browse function calls.
EquipRefBrowsePrev	Moves the data browse cursor back one record.

**Map Functions**

MapClear	Clears all entries in a map and returns the error status.
MapClose	Deletes a previously created map.
MapExists	Check if the map exists using a returned error code.
MapKeyCount	Retrieves the number of keys in a map.
MapKeyDelete	Delete a key and its value from a map.
MapKeyExists	Check if a key exists in a map.
MapKeyFirst	Retrieves the first key in a maps so that all the keys in a map can be discovered.
MapKeyNext	Retrieves the next key after the supplied key in a map so that all the keys in a map can be discovered.
MapOpen	Creates a new map or to open an existing map.
MapValueGet	Retrieves the value from a key in a map.
MapValueSet	Sets a value of a map key.
MapValueSetQuality	Sets the quality of a property in a map.

**Menu Functions**

MenugetNodeByPath	Returns a menu handle corresponding to a menu item expressed as a string path in the format <level>.<level>.<level>.<level>.
MenuNodeGetCurr	Allows you to get the handle of the menu node when this associated command is called.

MenuNodeGetDepth	Returns the depth of a specified menu node within a menu hierarchy.
MenuNodeGetExpanded	Returns the expansion state value of the specified menu node.
MenuNodeGetTargetPage	Returns the target page for a specified menu node.
MenuNodeSetExpanded	Sets the expansion state value of the specified menu node.

**Page Functions**

PageFileInfoEx	Returns the width, height, content type, parent or title of an unopened page.
----------------	---

**Screen Profile Functions**

ResetScreenProfile	Returns all top level windows back to their original screen starting position as defined by the screen profile in a multi-monitor setup.
--------------------	--

**String Functions**

StrEndsWith	Verifies whether the given string ends with a specific string.
StrListContainsItem	Checks whether the string passed is an item contained in a delimited list of strings.
StrReplace	Replaces a substring in a string with replacement substring.
StrSplit	Splits a string into sub-strings based on the specified delimiter. Sub-strings are stored in a new array and a handle to this array is returned.
StrTruncFontToolkit	Returns a truncated string with ellipsis, and sets an AN with a tooltip containing the complete string if a truncation occurs.

**Super Genie Functions**

AssEquipParameters	Associates a set of equipment parameters defined in <b>System Model   Equipment   Runtime Parameters</b> with a page.
AssWinReplace	Removes the associations on a specified Super Genie window and applies any pending associations.

**Tag Functions**

TagGetValue	Reads the value, quality and timestamp of a tag based
-------------	---

	on the tag subscription.
--	--------------------------

**Windows Functions**

WinGetClicked	Gets the number of the Plant SCADA window that has most recently been clicked on using the left mouse button.
WinGetName	Gets the name previously associated with a particular window number using WinSetName.
WinNewPinAt	Opens a new display window at a specified location, relative to the current active window, with a selected page displayed.
WinFreeEx	Removes the active display window and allows you to pass a Windows handle to the function for closing the window.
WinGetFirstChild	Gets the window number of the first child of a parent window.
WinGetNextChild	Gets the window number of the next child in a child link.
WinGetParent	Retrieves the window number of the specified window's parent or root window.
WndMonitorInfoEx	Returns information about a particular monitor using the screen name of the screen profile.

**Modified Functions****Alarm Functions**

AlarmDisable	<i>EndTime</i> and <i>Comment</i> arguments have been added to support alarm shelving.
AlarmDisableRec	<i>EndTime</i> and <i>Comment</i> arguments have been added to support alarm shelving.
AlarmDisableTag	<i>EndTime</i> and <i>Comment</i> arguments have been added to support alarm shelving.
AlarmEnable	<i>bAcknowledge</i> argument has been added to force acknowledgment of an alarm after it is enabled.
AlarmEnableRec	<i>bAcknowledge</i> argument has been added to force acknowledgment of an alarm after it is enabled.
AlarmEnableTag	<i>bAcknowledge</i> argument has been added to force

	acknowledgment of an alarm after it is enabled.
AlarmGetDsp	Alarm response properties are now accessible via the <i>Field</i> argument.
AlarmGetFieldRec	Alarm response properties are now accessible via the <i>Field</i> argument.
AlmBrowseDisable	<i>EndTime</i> and <i>Comment</i> arguments have been added to support alarm shelving.
AlmBrowseEnable	<i>bAcknowledge</i> argument has been added to force acknowledgment of an alarm after it is enabled.
AlmBrowseGetField	Alarm response properties are now accessible via the <i>Field</i> argument.
AlmSummaryDisable	<i>EndTime</i> and <i>Comment</i> arguments have been added to support alarm shelving.
AlmSummaryEnable	<i>bAcknowledge</i> argument has been added to force acknowledgment of an alarm after it is enabled.
AlmTagDisable	<i>EndTime</i> and <i>Comment</i> arguments have been added to support alarm shelving.
AlmTagEnable	<i>bAcknowledge</i> argument has been added to force acknowledgment of an alarm after it is enabled.

**Display Functions**

DspAnInfo	Mode 3 added as an option for the <i>nType</i> argument.
DspText	<i>bTooltip</i> argument added.
DspStr	<i>bTooltip</i> argument added.

**Form Functions**

FormButton	"Disabled" has been added as an option for the <i>Mode</i> argument.
FormPrompt	<i>Width</i> and <i>Height</i> arguments have been added to create an area that the prompt string will wrap within.

**Reinstated Functions**

No functions have been re-instated in Citect SCADA 2018.

## Deprecated Functions

No functions have been deprecated for Citect SCADA 2018.

## Removed Functions

No functions have been removed for Citect SCADA 2018.

## What's New in Citect SCADA 2016

Citect SCADA 2016 incorporates the following new or modified features.

Introduced in Citect SCADA 2016:

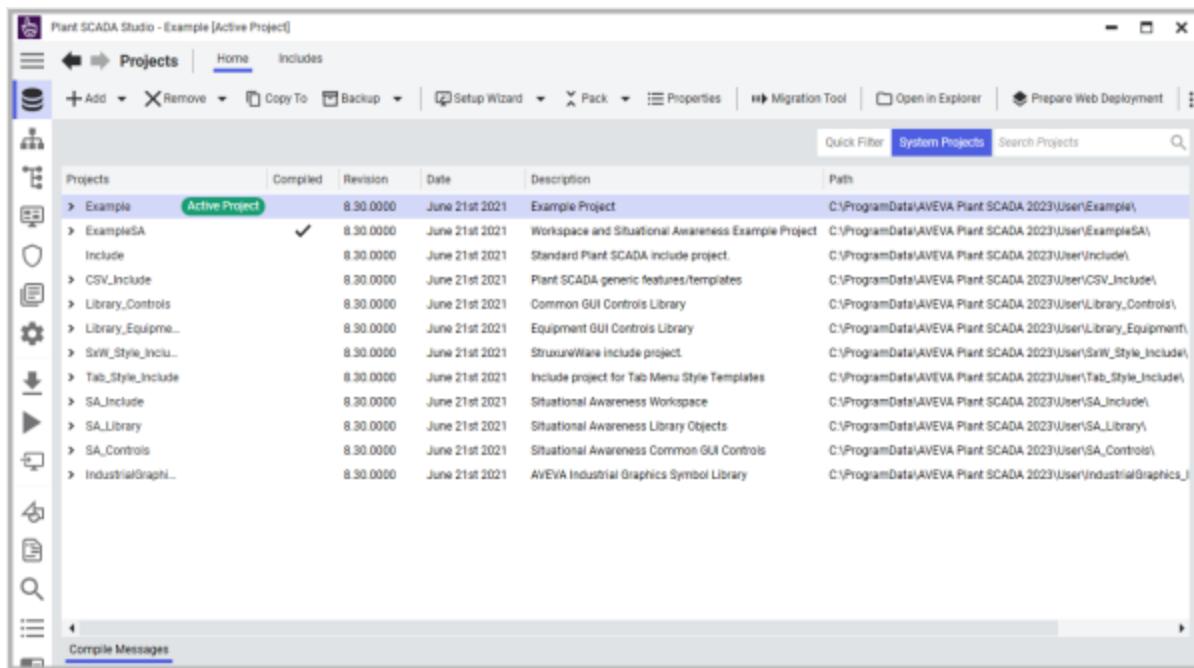

- [Plant SCADA Studio](#)
- [Topology](#)
- [Deployment](#)
- [Calculated Variables](#)
- [Schedule Integration](#)

For changes to:

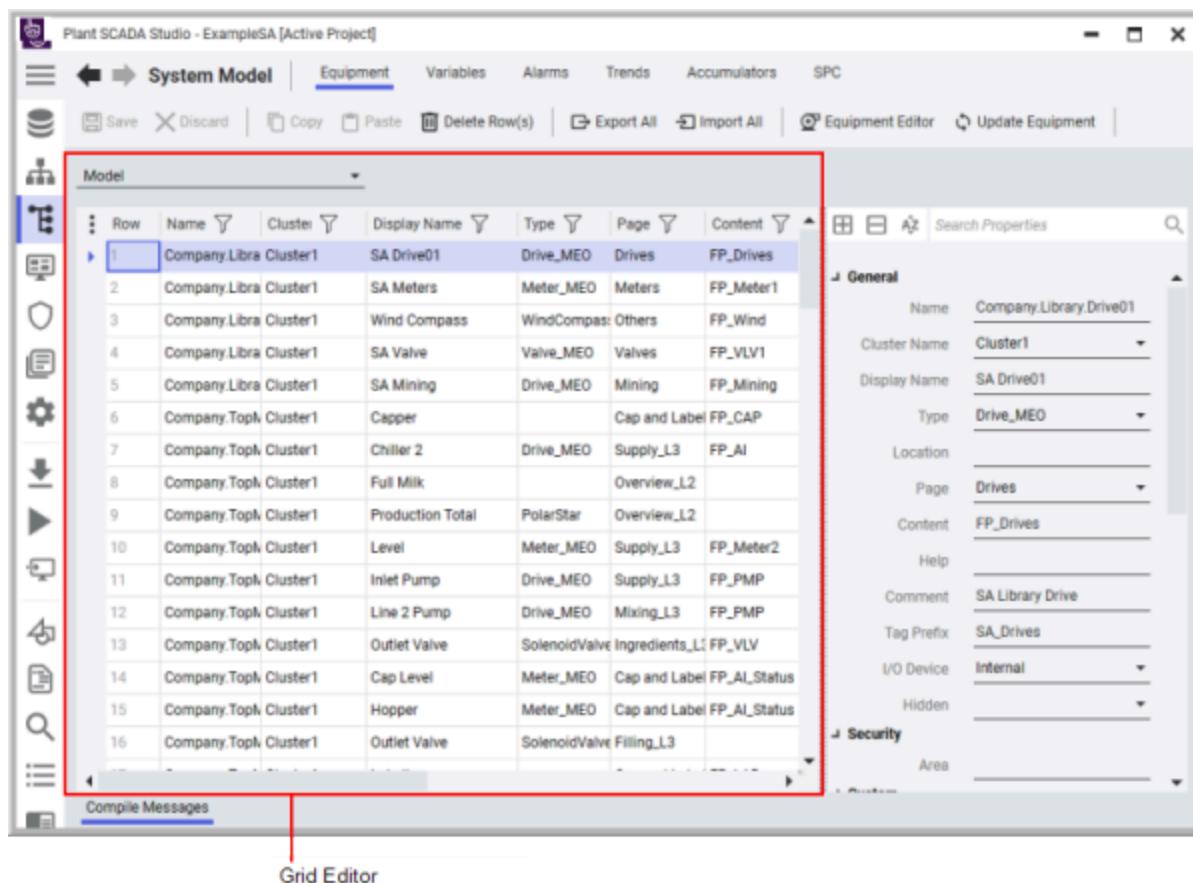

- Citect.ini parameters, see [Citect.ini Parameters in Citect SCADA 2016](#).
- Cicode functions, see [Cicode Functions in Citect SCADA 2016](#).

## Plant SCADA Studio

Plant SCADA 2016 comes with a brand new user interface that is intuitive and easy to use. The new interface replaces the Citect Explorer and the Project Editor and allows you access to projects, topology, system model information such as equipment, variable tags and alarms, and other configuration areas.

The highlight of [Plant SCADA Studio](#) is the Grid Editor, which allows tabular editing of alarms, variable tags, equipment across your entire project hierarchy. The [The Grid Editor](#) makes editing values very easy as a change made to a single record can be propagated throughout the system. The Grid Editor allows for bulk editing of multiple records, which makes it easy to maintain projects. Properties of a selected record are displayed next to the Grid Editor in a [Property Grid](#) where you can update values. Grid Editor views also allow multi-column sorting and filtering.

## See Also

[Plant SCADA Studio](#)

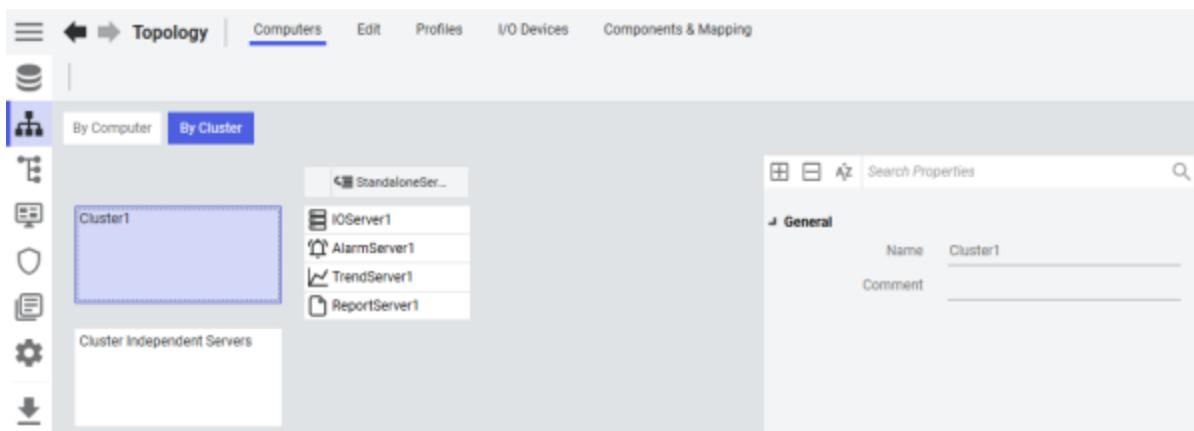

[Plant SCADA Activities](#)

[The Grid Editor](#)

[Property Grid](#)

## Topology

Plant SCADA 2016 allows you to quickly visualize the computers, network addresses, clusters and services being used in your system through a new interface that displays all related information in a single view. This view is available from the [Topology](#) activity of Plant SCADA Studio.

## See Also

[Computers](#)

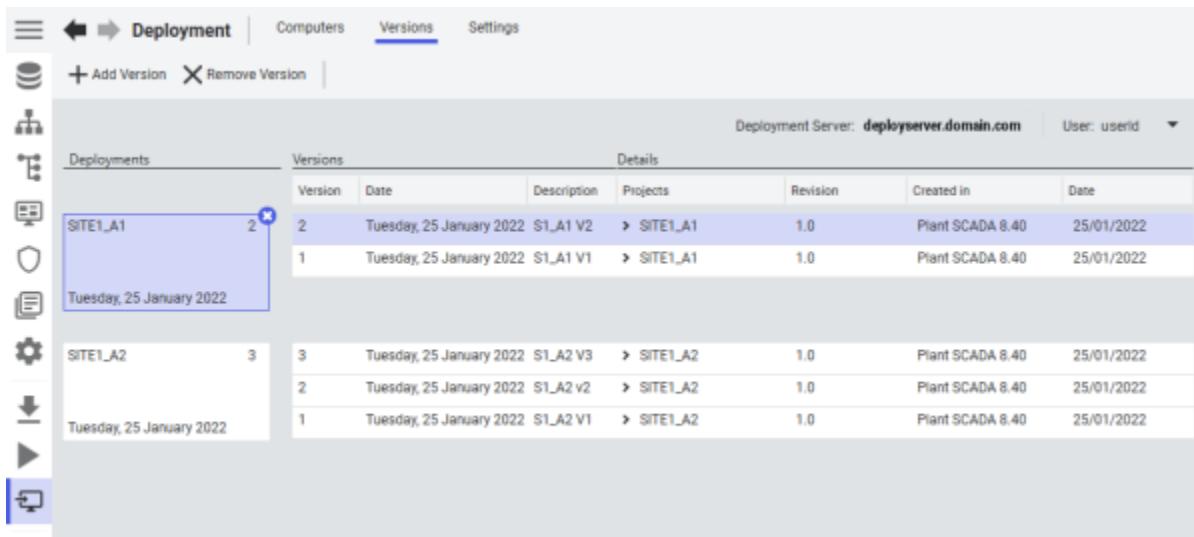

[Clusters](#)

[Server Processes](#)

## Deployment

Plant SCADA 2016 allows you to roll out small and large project changes to computers in your SCADA system located at a single site or across multiple sites quickly and efficiently through the Deployment feature. This feature allows for centralized management of project versions to be deployed to servers and clients including Citect Anywhere clients. Changes can be deployed automatically or through a customizable notification to the operator. Deployed changes can be rolled back if required.

When new project versions are deployed, only the project changes are sent to the computers instead of the entire project. The amount of bandwidth available when deploying changes on the network can also be throttled.

**Note:** It is recommended that you use Deployment instead of the Run/Copy functionality. The Run/Copy functionality is also available for use if required.

## See Also

- [Deployment](#)
- [Prepare Your System for Deployment](#)
- [Using the Deployment Activity](#)

## Calculated Variables

Calculated Variables in Plant SCADA 2016 allow users to generate tags at runtime from a Cicode expression and to call internal Cicode functions. A tag value is calculated for I/O devices that have their protocol set to "CICODE" and a tag associated with the I/O device that has a valid Cicode expression as its address.

Calculated variables significantly reduce the coding required in Cicode functions to manipulate tag values, thus improving code maintainability.

## See Also

- [Calculated Variables](#)
- [Add a Calculated Variable](#)

## Schedule Integration

Scheduler now supports the integration of schedules that are configured on a BACNet device. Locally configured schedule items on a BACNet device can be imported into Plant SCADA. You can also view and modify schedule-object and calendar-object properties on a BACNet device at runtime.

Schedule integration is enabled via the following process:

- A BACnet I/O device is configured in Plant SCADA Studio and connected to Plant SCADA via the BACNET driver.
- Variable tags and equipment definitions that represent the device's schedule and calendar objects are configured on the I/O server through tag import.
- The reports server subscribes to the tags on the I/O server and generates schedule entries in Scheduler.
- Any changes to the schedule entries are written back to the BACnet device via the I/O server.

## See Also

- [Integrate BACnet Schedules into Scheduler](#)

## Citect.ini Parameters in Citect SCADA 2016

This topic lists the parameters that have changed in Citect SCADA 2016.

## New Parameters

The following parameters are new or have been altered in this release. For an entire list of the system parameters, refer to the Parameters documentation.

### Deployment Parameters

[CtEdit]Deploy	The location where a project will be stored when a deployment package is received from the deployment server.
[Deployment]AskRestartArgs	Passes arguments to the Cicode function called by [Deployment]AskRestartFunc.
[Deployment]AskRestartFunc	Calls a Cicode function instead of displaying a restart notification dialog when a prompted deployment occurs.
[Deployment]Enabled	Determines if Runtime Manager runs a project that has been deployed from the deployment server, or the Active Project.

## Modified Parameters

[Win]Configure	Determines whether Plant SCADA Studio and Graphics Builder options are displayed on the control many of the runtime system.
----------------	---

## Removed Parameters

[Lan]SecureLogin	[LAN]SecureLogin is no longer supported.
------------------	--

## Obsolete Parameters

### OID Parameters

[OID]Reset	Resets all OIDs (Object IDs) at compile. This parameter has been removed.
[CtEdit]MaxFields	The maximum number of fields that can display on a Citect Project Editor form.
[CtEdit]ShowToolbar	Shows / hides the toolbar in the Citect Project Editor.

## Cicode Functions in Citect SCADA 2016

Some Cicode functions have been introduced. The following sections detail the changes made to these functions:

### New Functions

#### Alarm Functions

AlarmCountEquipment	Counts the available alarms for specified equipment in conjunction with the selected filter criteria.
---------------------	---

#### Modified Functions

No functions have been modified for Citect SCADA 2016.

#### Reinstated Functions

No functions have been re-instated in Citect SCADA 2016.

#### Deprecated Functions

No functions have been deprecated for Citect SCADA 2016.

#### Removed Functions

No functions have been removed for Citect SCADA 2016.

## What's New in Citect SCADA 2015 SP1

Citect SCADA 2015 SP1 incorporates the following new or modified features.

### Scheduler integration for Bacnet

New properties have been added to the Scheduler ActiveX control to allow you to control:

- The selected cluster
- The selected equipment
- The selected tab
- The selected special day category
- To remove the configuration view.

## Tag Import improvements for Bacnet

Variable tags for Bacnet schedules can now be imported directly from Bacnet compatible devices into CitectSCADA using the Tag Import feature. Equipment can automatically be created Bacnet schedules and Bacnet calendar objects which allows integration into the Scheduler.

## Generate Project Summary

The project summary is an xml based file that contains information about the current project and usercreated include projects. The project summary contains statistics on:

- Variable Tags
- Alarms
- Trends
- I/O Devices
- Internal Cicode functions used

A project summary can be generated by selecting “Generate Project Summary” from the tools menu in Project Editor.

All information in the project summary is anonymous.

## Cicode Profiler

The performance of user created Cicode functions can now be measured using the Cicode profiler. This feature will create a report showing the amount of time each Cicode function has taken to execute. This is useful for debugging large projects with complex Cicode.

## Exclusive Redundancy

I/O Devices now support exclusive redundancy. This can be enabled by setting the “Exclusive” setting to true for an I/O Device and all of its matching redundant devices.

When Exclusive redundancy is enabled, only one redundant device will send requests to the field device at any one time. All I/O Devices will still create a channel to the field device.

## See Also

[Cicode Functions in Citect SCADA 2015](#)

## Cicode Functions in Citect SCADA 2015 SP1

Some Cicode functions have been introduced. The following sections detail the changes made to these functions:

## New Functions

### Page Functions

PageExists	Determines if a page exists or not
------------	------------------------------------

### Tag Functions

TagWriteArrayInt	Writes an array of integer values to a tag.
TagWriteArrayReal	Writes an array of real values to a tag.

## Modified Functions

No functions have been modified for 2015 SP1.

## Reinstated Functions

No functions have been reinstated for 2015 SP1.

## Deprecated Functions

No functions have been deprecated for 2015 SP1.

## Removed Functions

No functions have been removed for 2015 SP1.

## What's New in Citect SCADA 2015

Citect SCADA 2015 incorporates the following new or modified features.

- Alarm Server Upgrade
- Backup and Restore Included Projects
- Incremental Equipment Update
- Link a Genie to an Equipment Type
- Partial Associations can be used with Dynamic Associations
- Running Plant SCADA as a Windows Service
- Extended Memory Mode
- OPC Factory Server Version Update
- Time Scheduler support for Swedish and Norwegian.

For changes to:

- Cicode functions in 2015 and service pack/patches updates, see [Cicode Functions in Citect SCADA 2015](#).

- Citect.ini Parameters 2015 and service pack/patches updates, see [Citect.ini Parameters in Citect SCADA 2015](#).

## Citect.ini Parameters in Citect SCADA 2015

This topic lists the parameters that have changed in Citect SCADA 2015.

### New Parameters

The following parameters are new or have been altered in this release.

#### Alarm Parameters

[Alarm]AlarmListRequestTimeout	Specifies the length of time (in seconds) that an alarm display will wait to receive data from all clusters.
[Alarm]DBLogDBServer	Use to turn on logging for the ClearSCADA Database Server.
[Alarm]DBLogHistoric	When set to 119 this parameter provides logging of historic ClearSCADA data.
[Alarm]DBLogServerCore	Used to find redundancy and synchronization issues.
[Alarm]DeltaTimeUpdate	Determines if DeltaTime (duration) field is set on non-OFF alarms by calculating volatile duration between current time and the time when the alarm was activated.
[Alarm]DisableSOE	Used to turn off the processing for the event journal.
[Alarm]DisableSummary	Allows a user to turn off processing for the summary events in the alarm server.
[Alarm]IsolationDetectInterval	Sets the interval between ICMP packets to detect network isolation on alarm servers.
[Alarm]IsolationDetectIP1	Determines status of the disconnected alarm server when network communication has been interrupted.
[Alarm]IsolationDetectIP2	Determines status of the disconnected alarm server when network communication has been interrupted.
[Alarm]IsolationDetectRetryCount	Sets the ICMP retry count to detect network isolation on alarm servers.
[Alarm]MaxQueryExecuteTime	Creates a log entry if an internal SQL query takes longer than a specified amount of time.
[Alarm]MemoryWarningLimit	Value in Mb, of the threshold of the alarm server memory.

[Alarm]SummaryAutoRefreshMode	Represents the default value for AlarmSetInfo type 15.
[Alarm]SummaryTimeoutTolerance	The length of time from timeout after which an alarm summary entry is committed to Summary Device regardless the fact that Off Time is not set.

**Alarm Process Parameters**

[Alarm<ClusterName><ServerName>]IsolationDetectInterval	Sets the interval between ICMP packets to detect network isolation on alarm servers.
[Alarm<ClusterName><ServerName>]IsolationDetectIP1	Determines status of the disconnected alarm server when network communication has been interrupted.
[Alarm<ClusterName><ServerName>]IsolationDetectIP2	Determines status of the disconnected alarm server when network communication has been interrupted.
[Alarm<ClusterName><ServerName>]IsolationDetectRetryCount	Sets the ICMP retry count to detect network isolation on alarm servers.

**CtEdit Parameters**

[CtEdit]IncrementalEquipmentUpdate	Determines whether an incremental equipment update will occur.
------------------------------------	--

**DBClient Parameters**

[DBClient]Enabled	Enables ODBC logging.
[DBClient]FileBase	Specifies a location for the ODBC log files.
[DBClient]MaxFiles	Specifies the maximum number of ODBC log files that are retained.
[DBClient]MaxSize	Specifies the maximum size for an ODBC log file (in kilobytes).
[DBClient]OldFiles	Specifies the maximum number of log file sets that can be retained.

**LAN Parameters**

[LAN]HeartbeatPeriod	Controls how frequently a tran channel sends a heartbeat packet to the other peer.
[LAN]HeartbeatTimeout	Controls how much idle time on network is accepted prior to dropping the tran connection.

**Modified Parameters**

[Alarm]DisplayDisable	In Plant SCADA 2015, when you set this parameter to
-----------------------	---

	1 (disabled alarms are suppressed), disabled alarm will now be listed on the Alarm Summary page.
[Debug]CategoryFilter	New alarm filters are now supported.
[LAN]EarliestLegacyVersion	The allowable values were updated and the default value is now "7500".

## Reinstated Parameters

[Alarm]StartTimeout	Sets the timeout period for loading each packet from the primary Alarms Server. This parameter has been reinstated for v2015 only.
---------------------	--

## Obsolete Parameters

### Alarm Parameters

[Alarm]ArgyleTagValueTimeout	Defines the length of time that the alarm server will wait for argyle tag values to become available (without error) before starting to scan for argyle alarms.
[Alarm]DefaultSOETimeRange	Applies a time range filter to all SOE queries.
[Alarm]SOERowLimit	Defined the maximum number of SOE rows per cluster that can be displayed on an SOE page.
[Alarm]SummaryLength	The maximum number of alarm summary entries that can be held in memory.
[Alarm]SumStateFix	Determined whether an alarm summary entry maintained its state information when the alarm changed to an OFF state.

### LAN Parameters

[LAN]KeepAliveInterval	Sets the length of time between two keep alive transmissions by the client.
[LAN]KeepAliveTime	Sets the length of time between two keep alive transmissions in idle conditions.

## Cicode Functions in Citect SCADA 2015

Some Cicode functions have been introduced. The following sections detail the changes made to these functions:

## New Functions

### .Net Functions

DllClassDispose	Use this function to clean up resources used by the .Net object and any other .Net objects created via the use of the object.
DllClassCreate	Use this function to instantiate a new .Net object by specifying the path, class and arguments required for the matching constructor of the class.
DllClassGetProperty	Use this function to get a property of the .Net object.
DllClassIsValid	Use this function to validate class. Uses the handle of the class returned from DllClassCreate.
DllClassCallMethod	Use this function to call a method of a .Net object, passing in the method name and any arguments required for the matching prototype of the method.
DllClassSetProperty	Use this function to set a property of the .Net object. The property may be of any type or an object itself.

## Modified Functions

No functions have been modified for Citect SCADA 2015.

## Reinstated Functions

### Alarm Functions

AlarmDelete	Deletes alarm summary entries that are currently displayed.
AlarmSplit	Splits an alarm summary entry which has no Off time.
AlarmSumAppend	Appends a new blank record to the alarm summary.
AlarmSumCommit	Commits the alarm summary record to the alarm summary device.
AlarmSumDelete	Deletes alarm summary entries.
AlarmSumFind	Finds an alarm summary index for an alarm record and alarm on time.
AlarmSumFirst	Gets the oldest alarm summary entry.
AlarmSumGet	Gets field information from an alarm summary entry.

AlarmSumLast	Gets the latest alarm summary entry.
AlarmSumNext	Gets the next alarm summary entry.
AlarmSumPrev	Gets the previous alarm summary entry.
AlarmSumSet	Sets field information in an alarm summary entry.
AlarmSumSplit	Duplicates an alarm summary entry.
AlarmSumType	Retrieves a value that indicates a specified alarm's type.

## Deprecated Functions

No functions have been deprecated for Citect SCADA 2015.

## Removed Functions

No functions have been removed for Citect SCADA 2015.

## What's New in Citect SCADA 7.40 SP1

Citect SCADA 7.40 SP1 incorporates the following new or modified features.

Introduced in 7.40 SP1:

- Alarm Performance Improvement
- Enhancements to the Equipment Editor
- Library\_equipment include project
- EcoStruxure Web Services Client

---

**Note:** With the release of Plant SCADA version 2020 R2, EcoStruxure Web Services (EWS) are no longer supported.

---

For changes to:

- Cicode functions in 7.40 SP1 and service pack/patches updates, see [Cicode Functions in 7.40 SP1](#)
- Citect.ini Parameters 7.40 SP1 and service pack/patches updates, see [Citect.ini Parameters in 7.40 SP1](#)

## Citect.ini Parameters in 7.40 SP1

This topic lists the parameters that have been added in version 7.40 SP1 of Citect SCADA.

## New Parameters

The following parameters are new in version 7.20. For an entire list of the system parameters, refer to the

Parameters documentation.

### Alarm Parameters

[Alarm]WebClientUpdatePollPeriod	Sets the polling period in milliseconds for web client to get data updates.
[Alarm]ClientUpdatePollPeriod	Sets the polling period in milliseconds for the display client to get data updates.

### Modified Parameters

No parameters were modified in 7.40 SP1

### Obsolete Parameters

No parameters were made obsolete in 7.40 SP1

### Cicode Functions in 7.40 SP1

Some Cicode functions have been introduced. The following sections detail the changes made to these functions:

### New Functions

#### Security Functions

GetLanguage	Gets the language currently used on the display client.
-------------	---

### Modified Functions

#### Alarm Functions

AlarmGetInfo	Gets data on the alarm list displayed at a specified AN. A new type of 13 was added to return the ready state of the data on an alarm display view.
--------------	---

### Reinstated Functions

No functions have been reinstated for 7.40 SP1.

### Deprecated Functions

No functions have been deprecated for 7.40 SP1.

## Removed Functions

No functions have been removed for 7.40 SP1.

## What's New in Citect SCADA 7.40

Citect SCADA 7.40 incorporates the following new or modified features.

- Referencing a variable tag using Equipment.Item
- New Cicode functions to maintain a list of unique Pages "opened"
- New Equipment Editor
- New SxW Templates
- OPC Factory Server (OFS) Security Updates

For changes to:

- Cicode functions in 7.40 and service pack/patches updates, see [Cicode Functions in 7.40](#)
- Citect.ini Parameters 7.40 and service pack/patches updates, see [Citect.ini Parameters in 7.40](#)

## Citect.ini Parameters in 7.40

This topic lists the parameters that have been added or changed in version 7.40 of Citect SCADA.

### New Parameters

The following parameters are new in version 7.20. For an entire list of the system parameters, refer to the Parameters documentation.

#### CTEdit Parameters

[CTEDIT]DisplayEquipmentItem	Used to control the population of the variable tag list, or equipment item list in graphics builder.
------------------------------	--

#### General Parameters

[General]TagDBReloadOnChange	Determines whether the Variable Tags database is checked for changes and reloaded when a new page is displayed.
------------------------------	---

#### Page Parameters

[Page]MaxList	The maximum number of pages that can be placed on the page list stack.
---------------	--

#### Server Parameters

[Server]AllowAnonymousAccess	Determines whether the EWS Server will allow the
------------------------------	--

	EWS Client anonymous data access.
--	-----------------------------------

## Modified Parameters

### Code Parameters

[Code]Stack	The size of the Cicode stack. The default has been changed from 127 to 256.
-------------	---

### General Parameters

[General]TagDB	Determines whether the Variable Tags database is loaded at runtime. The Variable Tags database needs to be loaded to allow tags to be referenced with the Equipment.Item syntax.
----------------	--

## Cicode Functions in 7.40

Some Cicode functions have been introduced, and modified. The following sections detail the changes made to these functions:

## New Functions

### Page Functions

PageListCount	Gets number of pages in the page list of the current window.
PageListCurrent	Gets index of the current page in the page list of the current window.
PageListInfo	Gets information of a page at the specific index in the page list of current window.
PageListDisplay	Displays a page at the specific index in the page list of the current window, and moves the current index to the page. When a page is recalled, the original parameters (such as cluster context, super genie associations, PageTask arguments if applicable) used to display the page will be restored.
PageListDelete	Deletes a page at the specific index from the page list of the current window.

### XML Functions

XMLClose	Deletes an XML document in memory
XMLCreate	Creates a new XML document in memory
XMLGetAttribute	Retrieves the attribute value of the node from an XML document in memory
XMLGetAttributeCount	Retrieves the number of attributes (properties of a node. Each attribute has a name and a value) within an XML document in memory
XMLGetAttributeName	Retrieves the name of an attribute (property of a node. Each attribute has a name and a value) within an XML document in memory
XMLGetAttributeValue	Retrieves the value of an attribute (property of a node. Each attribute has a name and a value) within an XML document in memory
XMLGetChild	Retrieves the child node for the specified parent node in XML document in memory
XMLGetChildCount	Retrieves the total number of child nodes for the specified parent node in an XML document in memory
XMLGetParent	Retrieves the parent node within the contents of an XML document in memory
XMLGetRoot	Retrieves the root node of an XML document in memory
XMLNodeAddChild	Creates an element node with the specified Name and Namespace and appends the node to the end of the list of child nodes of specified parent node in the XML document.
XMLNodeFind	Selects a single node from the contents of an XML document in memory
XMLNodeGetName	Retrieves the name of the specified node
XMLNodeGetValue	Retrieves the value of a node from the contents of an XML document in memory
XMLNodeRemove	Removes specified XML node from its parent and XML document
XMLNodeSetValue	Sets the value of the specified node.
XMLOpen	Loads an XML file from disk

XMLSave	Saves an XML file to disk
XMLSetAttribute	Sets the value of specified attribute of the node in the XML document. If the attribute does not exist, it will be created.

## Modified Functions

### Super Genie Functions

Ass	Associates a variable tag with a Super Genie. Now supports Equipment.Item.
-----	--

### Tag Functions

TagGetProperty	Gets a property for a variable tag from the datasource. Now supports Equipment.Item.
TagGetScale	Gets the value of a tag at a specified scale from the datasource. Now supports Equipment.Item.
TagInfo	Gets information about a variable tag. Now supports Equipment.Item.
TagInfoEx	Gets information about a variable tag. Now supports Equipment.Item.
TagRead	Reads a variable from the I/O device. Now supports Equipment.Item.
TagReadEx	Reads the value, quality or timestamp of a particular tag from the I/O device. Now supports Equipment.Item.
TagResolve	Used to increment a reference count on a tag to keep it resolved, making it readily available to a client. Now supports Equipment.Item.
TagScaleStr	Gets the value of a tag at a specified scale. Now supports Equipment.Item.
TagSetOverrideBad	Sets a quality Override element for a specified tag to Bad Non Specific. Now supports Equipment.Item.
TagSetOverrideGood	Sets a quality Override element for a specified tag to Good Non Specific. Now supports Equipment.Item.
TagSetOverrideUncertain	Sets a quality Override element for a specified tag to Uncertain Non Specific. Now supports Equipment.Item.

TagSetOverrideQuality	Sets a quality Override element for a specified tag. Now supports Equipment.Item.
TagSubscribe	Subscribes a tag for periodic monitoring and event handling. Now supports Equipment.Item.
TagWrite	Writes to an I/O Device variable. Now supports Equipment.Item.

## Reinstated Functions

No functions have been reinstated for 7.40.

## Deprecated Functions

No functions have been deprecated for 7.40.

## Removed Functions

No functions have been removed for 7.40.

## CtAPI Functions in 7.40

The following section details the changes made to CtAPI functions in Plant SCADA 7.40.

## New Functions

No new functions have been added for 7.40.

## Modified Functions

ctListAdd	Adds a tag to the list. Now accepts "Equipment.item".
ctListAddEx	Adds a tag to the list with a specified poll period. Now accepts "Equipment.item".
ctTagGetProperty	Gets the given property of the tag. Now accepts "Equipment.item".
ctTagRead	Reads the current value from the given I/O Device variable tag. Now accepts "Equipment.item".
ctTagReadEx	Performs the same as ctTagRead, but with an additional new argument. Now accepts "Equipment.item".

ctTagWrite	Writes the given value to the I/O Device variable tag. Now accepts "Equipment.item".
ctTagwriteEx	Performs the same as ctTagWrite, but with an additional new argument. Now accepts "Equipment.item".

## Obsolete Functions

No functions were made obsolete in 7.40.

## What's New in Citect SCADA 7.30

Citect SCADA 7.30 incorporates the following new or modified features.

- ActiveX Data Objects (ADO.NET)
- Alarm Enhancements
- GUI Enhancements
- Equipment Hierarchy
- Importing Equipment
- New Licensing Method
- OPC DA Server
- Software Update
- Supportability
- Tag Browsing
- Scheduler

For changes to:

- Cicode functions in 7.30 and service pack/patches updates, see [Cicode Functions in 7.30](#)
- Citect.ini Parameters 7.30 and service pack/patches updates, see [Citect.ini Parameters in 7.30](#)

## Citect.ini Parameters in 7.30

This topic lists the parameters that have been added or changed in version 7.30 of Citect SCADA.

### New Parameters

The following parameters are new in version 7.20 . For an entire list of the system parameters, refer to the Parameters documentation.

#### Alarm Parameters

[Alarm]DefaultSOETimeRange	Specifies the default time range, in days, for SOE views
----------------------------	--

	that have no other time-based filter.
[Alarm]DefSOEFormat	Specifies an SOE display format to use if the SOE Display Format field is blank (in Alarm Categories).
[AlarmFilterRuleList.Active]Rule<n>	Defines the name of rules to appear on the Simple Rule dropdown list of the active alarm filter form.
[AlarmFilterRuleList.Disabled]Rule<n>	Defines the name of rules to appear on the Simple Rule dropdown list of disabled alarm filter form.
[AlarmFilterRuleList.SOE]Rule<n>	Defines the name of rules to appear on the Simple Rule dropdown list of alarm summary filter form.
[AlarmFilterRuleList.Summary]Rule<n>	Defines the name of rules to appear on the Simple Rule dropdown list of alarm summary filter form.
[AlarmFilterRules]<RuleName>	Defines the filter expression represented by the rule name.
AlarmFilterRuleList].Rule<n>	Defines the name of the common rules to appear on the Simple Rule dropdown list of all alarm filter form.

**AlarmFilterRules Parameters**

[AlarmFilterRuleList.Active]Rule<n>	Defines the name of rules to appear on the Simple Rule dropdown list of the active alarm filter form.
[AlarmFilterRuleList.Disabled]Rule<n>	Defines the name of rules to appear on the Simple Rule dropdown list of disabled alarm filter form.
[AlarmFilterRuleList.SOE]Rule<n>	Defines the name of rules to appear on the Simple Rule dropdown list of alarm summary filter form.
[AlarmFilterRuleList.Summary]Rule<n>	Defines the name of rules to appear on the Simple Rule dropdown list of alarm summary filter form.
[AlarmFilterRules]<RuleName>	Defines the filter expression represented by the rule name.
AlarmFilterRuleList].Rule<n>	Defines the name of the common rules to appear on the Simple Rule dropdown list of all alarm filter form.

**Alarm Process Parameters**

Alarm.<ClusterName>.<ServerName> ArchiveAfter	The archive after time (Event Journal) is the amount of time between each archive of Event Journal data.
Alarm.<ClusterName>.<ServerName> CacheSize	Defines the amount of memory (in megabytes) dedicated to the storage of event data.
Alarm.<ClusterName>.<ServerName>	Defines the amount of time, in milliseconds, in which

ClientConnectTimeout	the client can attempt to make a connection.
Alarm.<ClusterName>.<ServerName> ClientDisconnectTimeout	Defines the amount of time, in milliseconds, in which the client can attempt to terminate a connection to the server.
Alarm.<ClusterName>.<ServerName>ClientRequestTimeout	Defines the amount of time, in milliseconds, in which the client can request data from a server.
Alarm.<ClusterName>.<ServerName> FutureMessages	Event Journal records that have a time stamp with a date and time in the future can be stored historically.
Alarm.<ClusterName>.<ServerName> HeartbeatTimeout	Defines how long a server will wait before terminating a link that has been used for receiving heartbeat poll requests from its pair server, but is currently idle.
Alarm.<ClusterName>.<ServerName> KeepOnlineFor	The Event Journal Life is the amount of time for which the Alarm Server stores event messages on-line.
Alarm.<ClusterName>.<ServerName> MonitorConnectTimeout	Defines the amount of time, in seconds, that the server will wait for a monitor connection to occur.
Alarm.<ClusterName>.<ServerName> MonitorRequestTimeout	Defines the amount of time, in seconds, that the server will wait for a response from the other server in the pair.
Alarm.<ClusterName>.<ServerName>QueryCPUUsage	Defines the percentage of processor use you want to allocate to query searches.
Alarm.<ClusterName>.<ServerName> QueryRowLimit	Defines the maximum number of rows that can be returned in the result set for a single query.
Alarm.<ClusterName>.<ServerName>QueryTimeout	Defines the amount of time (in seconds) that is permitted for query searches.
Alarm.<ClusterName>.<ServerName> StreamSize	Defines the amount of data that is included in each event data file.
Alarm.<ClusterName>.<ServerName> SyncAllHistoricData	On multi-server systems, the Primary server and Standby server synchronize their data so that the Standby server contains an accurate, up to date backup of the Primary server's data.
Alarm.<ClusterName>.<ServerName>TransferConnectTimeout	Defines the amount of time, in seconds, that the Primary server will wait for a connection to occur.
Alarm.<ClusterName>.<ServerName> TransferInterleave	Controls how often the data synchronization is triggered by the Primary to the Standby Server.
Alarm.<ClusterName>.<ServerName>TransferInterval	Defines the number of seconds between each attempt to update the data on the Standby server.

**BrowseTableView Parameters**

[BrowseTableView]<BrowseType>.<ViewName>.ColWidths	Sets the column widths in pixels of the current data browse table.
[BrowseTableView]<BrowseType>.<ViewName>.Fields	Sets the field names of the columns in the current data browse table under the View Name configured on the page.

**ClientParameters**

[Client]PointCountRequired	Specifies what license point count a client requires.
----------------------------	---

**General Parameters**

[General]ClusterReplication	Controls whether tag will be replicated in a multi-cluster system.
[General]LicenseReservationTimeout	Specifies the number of seconds to reserve a license for a given IP address in cases where a remote client connection is lost.

**Page Parameters**

[Page]SOEPage	The name of the graphics page to display when you call up an sequence of events (SOE) page via the Cicode function PageSOE().
---------------	---

**SQL Parameters**

[SQL]MaxConnections	Defines the maximum number of DB connection objects.
---------------------	--

**Scheduler Parameters**

[Scheduling]PersistPath	Directs where the configuration data for the scheduler is stored.
[Scheduling]StartDelay	Sets the delay from when the Scheduler's server components are initialized to the point when Scheduler begins processing active schedule entries.

**Modified Parameters****Alarm Parameters**

[Alarm]SavePrimary	This parameter is now used only to import alarm history from previous versions of Plant SCADA.
[Alarm]SaveSecondary	This parameter is now used only to import alarm history from previous versions of Plant SCADA.

[Alarm]SummaryLength	The maximum number of alarm summary entries that can be held in memory. The maximum number for this parameter has been modified from 4096000 to 100000.
----------------------	---

**Language Parameters**

Language]LocalLanguage	Used to set the default language during start-up.
------------------------	---

**SQL Parameters**

[SQL]QueryTimeout	Sets the timeout period for SQL queries globally.
-------------------	---

**Tab Style Template Parameters**

[Format]FormatName	Define the display format by name.
--------------------	------------------------------------

**Obsolete Parameters**

[Alarm]Ack	Determined whether Plant SCADA acknowledges current alarms on startup.
[Alarm]AckHold	Determined whether alarms that have become inactive (and have been acknowledged) remain in the OFF ACKNOWLEDGED alarm list.
[Alarm]CacheLength	The maximum number of alarms that can be held in the cache of a client
[Alarm]FilterViewByPrivilege	If privilege is not checked, a user with no privilege (0) can browse and view trends and alarms that require privilege 1. This behavior is the same as [Alarm]FilterViewByPrivilege = 0 in 7.20.  The set of records returned from browse is now filtered by area.
[Alarm]SavePeriod	Set the path to the primary save file.
[Alarm]SaveStyle	Determines whether alarms records are identified by their record number or alarm tag.
[Alarm]StartTimeout	Sets the timeout period for loading data from the primary Alarms Server.

**Cicode Functions in 7.30**

Some Cicode functions have been introduced, modified, deprecated or removed. The following sections detail the changes made to these functions:

## New Functions

### Alarm Functions

AlarmAckTag	Acknowledge a specified alarm.
AlarmCount	Counts the available alarms for the selected filter criteria.
AlarmCountList	Counts the available alarms for the selected alarm list (selected by its animation).
AlmBrowseAck	Acknowledges the alarm tag at the current cursor position in an active data browse session.
AlmBrowseClose	Closes an alarm tags browse session.
AlmBrowseDisable	Disables the alarm tag at the current cursor position in an active data browse session.
AlmBrowseEnable	Enables the alarm tag at the current cursor position in an active data browse session.
AlmBrowseFirst	Gets the oldest alarm tags entry.
AlmBrowseGetField	Gets the field indicated by the cursor position in the browse session.
AlmBrowseNext	Gets the next alarm tags entry in the browse session.
AlmBrowseNumRecords	Returns the number of records in the current browse session.
AlmBrowseOpen	Opens an alarm tags browse session.
AlmBrowsePrev	Gets the previous alarm tags entry in the browse session.
AlarmFilterClose	Removes named filter from memory.
AlarmFilterEditAppend	Appends the provided expression to the current filter session content without any validation.
AlarmFilterEditClose	Removes the session from the memory.
AlarmFilterEditCommit	Validates the filter built in this session and, if valid, applies the filter to the list associated with the session.
AlarmFilterEditFirst	Retrieves the first part of the filter.
AlarmFilterEditLast	Retrieves the last part of the filter.

AlarmFilterEditNext	Retrieves the next part of the filter.
AlarmFilterEditOpen	Creates a session for the historical list associated with the provided animation number (AN).
AlarmFilterForm	Displays a form for specifying filtering criteria for either an alarm list or a named filter.
AlarmFilterOpen	Creates a named filter.
AlmFilterEditPrev	Retrieves the previous part of the filter.
AlmFilterEditSet	Replaces the current filter session content by the provided expression without any validation.
AlarmGetFilterName	Retrieves the name of the linked filter for the supplied AN.
AlarmResetQuery	Clears the filter of the specified filter source. Used to reset the filter set up by the Cicode function AlarmFilterForm().
LibAlarmFilterForm	Displays a generic alarm filter pop-up for specifying filtering criteria for either an alarm list or a named filter.

**Equipment Functions**

EquipSetProperty	Sets the property of an item of equipment.
EquipStateBrowseClose	Terminates a browsing session and cleans up the resources used by the session.
EquipStateBrowseFirst	Places the data browse cursor at the first record.
EquipStateBrowseGetField	Returns the value of the particular field in a record to which the data browse cursor is currently referencing.
EquipStateBrowseNext	Places the data browse cursor at the next available record.
EquipStateBrowseNumRecords	Returns the number of records that match the current filter criteria.
EquipStateBrowseOpen	Initiates a new session for browsing the equipment states configured.
EquipStateBrowsePrev	Places the data browse cursor at the previous record.

**Page Functions**

PageSOE	Displays a category of sequence of events (SOE)
---------	---

	entries on the SOE page.
--	--------------------------

**Scheduler Functions**

SchdClose	Terminates a browsing session and cleans up the resources used by the session.
SchdConfigClose	Terminates a browsing session and cleans up the resources used by the session.
SchdConfigFirst	Places the data browse cursor at the first record.
SchdConfigGetField	Returns the value of the particular field in a record to which the data browse cursor is currently referencing.
SchdConfigNext	Places the data browse cursor at the next available record.
SchdConfigNumRecords	Returns the number of records that match the current filter criteria.
SchdConfigOpen	Initiates a new session for browsing the schedules configured.
SchdConfigPrev	Places the data browse cursor at the previous record.
SchdFirst	Places the data browse cursor at the first record.
SchdGetField	Returns the value of the particular field in a record to which the data browse cursor is currently referencing.
SchdNext	Places the data browse cursor at the next available record.
SchdNumRecords	Returns the number of records that match the current filter criteria.
SchdOpen	Initiates a new session for browsing the runtime schedules.
SchdPrev	Places the data browse cursor at the previous record.
SchdSpecialAdd	Adds a new special day group to the scheduler engine.
SchdSpecialClose	Terminates a browsing session and cleans up the resources used in the session.
SchdSpecialDelete	Deletes an existing special day group.
SchdSpecialFirst	Places the data browse cursor at the first record.
SchdSpecialGetField	Returns the value of the particular field in a record to

	which the data browse cursor is currently referencing.
SchdSpecialItemAdd	Adds a new special day to the scheduler engine.
SchdSpecialItemClose	Terminates a browsing session and cleans up the resources used in the session.
SchdSpecialItemDelete	Deletes an existing schedule.
SchdSpecialItemFirst	Places the data browse cursor at the first record.
SchdSpecialItemGetField	Returns the value of the particular field in a record to which the data browse cursor is currently referencing.
SchdSpecialItemModify	Modifies an existing special day.
SchdSpecialItemNext	Places the data browse cursor at the next available record.
SchdSpecialItemNumRecords	Returns the number of records that match the current filter criteria.
SchdSpecialItemOpen	Initiates a new session for browsing the special days.
SchdSpecialItemPrev	Places the data browse cursor at the previous record.
SchdSpecialModify	Modifies an existing special day group.
SchdSpecialNext	Places the data browse cursor at the next available record.
SchdSpecialNumRecords	Returns the number of records that match the current filter criteria.
SchdSpecialOpen	Initiates a new session for browsing the special day groups.
SchdSpecialPrev	Places the data browse cursor at the previous record.
ScheduleItemAdd	Adds a new schedule to the scheduler engine.
ScheduleItemDelete	Deletes an existing schedule.
ScheduleItemModify	Modifies an existing schedule.
ScheduleItemSetRepeat	Adds recurrence information for an existing schedule to the scheduler engine.

**Sequence of Event Functions**

SOEArchive	Archives event journal.
SOEDismount	Use to dismount archive volume.

SOEventAdd	Inserts a new event into the event journal.
SOEMount	Use to mount archive volume.

**SQL Functions**

SQLCall	Executes an SQL query on a database
SQLClose	Closes a SQL connection between the DB connection object specified by the function's parameter and a database
SQLCreate	Creates an internal DB connection object and returns a handle to the object for use by the other DB functions
SQLDispose	Disposes the DB connection object
SQLGetRecordset	Executes an SQL query on a database
SQLGetScalar	Executes an SQL query on a database
SQLIsNullField	Checks presence of null value in field from a recordset
SQLNumFields	Gets the number of fields or columns that were returned by the last SQL statement
SQLOpen	Opens an SQL connection between the DB connection object
SQLParamsClearAll	Turns on a debug trace
SQLParamsSetAsInt	Adds or replaces a parameterized query's parameter as integer and its value in the specified connection
SQLParamsSetAsReal	Adds or replaces a parameterized query's parameter as real and its value in the specified connection
SQLParamsSetAsString	Adds or replaces a parameterized query's parameter as string and its value in the specified connection
SQLPrev	Gets the previous database record from an SQL query.
SQLQueryCreate	The function creates a new query and returns its handle
SQLQueryDispose	The function disposes the query which handle is given as the argument.
SQLRowCount	Gets the number of rows in the recordset.

**Timestamp Functions**

StrToTimestamp	Converts timestamp in a STRING format into a TIMESTAMP format
----------------	---

**Tag Functions**

TagBrowseClose	Close an existing browsing session
TagBrowseFirst	Move to the first record
TagBrowseGetField	Get the specified field of a record.
TagBrowseNext	Move to the next record
TagBrowseNumRecords	Get the number of records for a given browsing session.
TagBrowseOpen	Opens a new browsing session.
TagBrowsePrev	Move to the previous record

**Modified Functions****Alarm Functions**

AlarmAck	Acknowledges an active alarm.
AlarmCatGetFormat	Returns the display format string of the specified alarm category. Type has been extended to include SOE format.
AlarmDisable	Disables an alarm.
AlarmDsp	Displays alarms.
AlarmDspNext	Displays the next page of alarms. Works with new SOE display type.
AlarmDspPrev	Displays the previous page of alarms. Works with new SOE display type.
AlarmEnable	Enables a disabled alarm.
AlarmFirstTagRec AlarmFirstCatRec AlarmFirstPriRec AlarmFirstQueryRec AlarmNextTagRec AlarmNextCatRec AlarmNextPriRec AlarmNextQueryRec AlarmAckRec	Alarm 'Rec' functions listed are now executed in the client process, with the function MsgRPC no longer required when called remotely to the Alarm Server.

AlarmEnableRec	
AlarmDisableRec	
AlarmGetDelayRec	
AlarmSetDelayRec	
AlarmGetThresholdRec	
AlarmSetThresholdRec	
AlarmGetFieldRec	
AlarmGetDsp	Retrieves field data from the alarm record that is displayed at the specified AN. Works with new SOE display type.
AlarmGetInfo	Retrieves data on the alarm list displayed at a specified AN. New type 12 added.
AlarmSetInfo	Controls different aspects of the alarm list displayed at a specified AN. Supports automatic refresh of the new SOE display type.
AlmSummaryGetField	Gets the field indicated by the cursor position in the browse session. Now supports Equipment field.
AlmSummaryOpen	Opens an alarm summary browse session. Now supports Equipment field. Will not return data for 'NODE' field name.
AlmTagsGetField	Gets the field indicated by the cursor position in the browse session. Now supports Equipment field.
AlmTagsOpen	Opens an alarm tags browse session. Now supports Equipment field. Will not return data for 'NODE' field name.

**Accumulator Functions**

AccumBrowseGetField	Gets the field indicated by the cursor position in the browse session. Now supports Equipment field.
AccumBrowseOpen	Opens an accumulator browse session. Now supports Equipment field.

**Equipment Functions**

EquipBrowseGetField	Gets the field indicated by the cursor position in the browse session. Now supports Parent and Composite fields.
EquipBrowseOpen	Opens an equipment database browse session. Now supports Parent and Composite fields.
EquipGetProperty	Reads a property of an equipment database record

	from the EQUIP.DBF file. Now supports Parent and Composite fields.
--	--

**Format Functions**

FmtOpen	Opens a format template. mode has been extended to include SOE format.
---------	--

**Security Functions**

Login	Logs a user into the Plant SCADA system, using Plant SCADA security and gives users access to the areas and privileges assigned to them in the Users database. New sLanguage parameter added.
UserLogin	Logs a user into the Plant SCADA system, using either Windows security or Plant SCADA security and gives users access to the areas and privileges assigned to them in the Users database. New sLanguage parameter added.

**Server Functions**

ServeGetProperty	Returns information about a specified server and can be called from any client.
ServerReload	Reloads the server specified by cluster and server name.

**Super Genie Functions**

AssGetProperty	Gets association information about the current Super Genie from the datasource.
AssInfo	Gets association information about the current Super Genie.
AssInfoEx	Gets association information about the current Super Genie.

**SQL Functions**

SQLGetField	Gets field or column data from a database record.
SQLInfo	Gets information about a database connection. No longer supports type 3 and 4.
SQLNoFields	Gets the number of fields or columns that were returned by the last SQL statement.

**Tag Functions**

TagGetProperty	Gets a property for a variable tag from the datasource. Now supports Equipment field.
TagInfo	Gets information about a variable tag. Now supports Equipment field.
TagInfoEx	Gets information about a variable tag. Now supports Equipment field.

**Trend Functions**

TrnBrowseGetField	Gets the field indicated by the cursor position in the browse session. Now supports Equipment field.
TrnBrowseOpen	Opens a trend browse session. Now supports Equipment field.

**Reinstated Functions**

No functions have been reinstated for 7.30.

**Deprecated Functions**

AlmTagsEnable	Enables the alarm tag at the current cursor position in an active data browse session.
AlmTagsDisable	Disables the alarm tag at the current cursor position in an active data browse session.
AlmTagsNext	Gets the next alarm tags entry in the browse session.
AlmTagsAck	Acknowledges the alarm tag at the current cursor position in an active data browse session.
AlmTagsClear	Clears the alarm tag at the current cursor position in an active data browse session.
AlmTagsClose	Closes an alarm tags browse session.
AlmTagsFirst	Gets the oldest alarm tags entry.
AlmTagsGetField	Gets the field indicated by the cursor position in the browse session.
AlmTagsNumRecords	Returns the number of records in the current browse session.

AlmTagsOpen	Creates a session for the historical list associated with the provided animation number (aN).
AlmTagsPrev	Gets the previous alarm tags entry in the browse session.

## Removed Functions

AlmBrowseClear	Clears the alarm tag at the current cursor position in an active data browse session. Now obsolete.
AlarmClear	Clears acknowledged, inactive alarms from the active alarm list.
AlarmClearRec	Clear an alarm by its record number. Now obsolete.
AlarmDelete	Deletes alarm summary entries that are currently displayed. Now obsolete.
AlarmSetQuery	Specifies a query to be used in selecting alarms for display. Now Obsolete. Use the new Alarm Filter Edit functions.
AlarmSumAppend	Appends a new blank record to the alarm summary. Now obsolete.
AlarmSumCommit	Commits the alarm summary record to the alarm summary device. Now obsolete.
AlmSummaryCommit	Commits the alarm summary record to the alarm summary device. Now obsolete.
AlarmSplit	Duplicates an alarm summary entry where the cursor is positioned. Now obsolete.
AlarmSumDelete	Deletes alarm summary entries. Now obsolete.
AlarmSumFind	Finds an alarm summary index for an alarm record and alarm on time. Now obsolete.
AlarmSumFindExact	Finds the alarm summary index for an alarm specified by the alarm record identifier and alarm activation time.
AlarmSumFirst	Gets the oldest alarm summary entry. Now

	obsolete.
AlarmSumGet	Gets field information from an alarm summary entry. Now obsolete.
AlarmSumLast	Gets the latest alarm summary entry. Now obsolete.
AlarmSumNext	Gets the next alarm summary entry. Now obsolete.
AlarmSumPrev	Gets the previous alarm summary entry. Now obsolete.
AlarmSumSet	Sets field information in an alarm summary entry. Now obsolete.
AlmSummarySetFieldValue	Sets the value of the field indicated by the cursor position in the browse session. Now obsolete.
AlarmSumSplit	Duplicates an alarm summary entry. Now obsolete.
AlarmSumType	Retrieves a value that indicates a specified alarm's type. Now obsolete.
QueryFunction	The user-defined query function set in AlarmsetQuery. Now obsolete.

**Miscellaneous Functions**

SetLanguage	Sets the language database from which the local translations of native strings in the project will be drawn, and specifies the character set to be used. Now obsolete. Use the Login(), UserLogin() and LoginForm() to set the preferred language.
-------------	--

**CtAPI Functions in 7.30**

The following section details the changes made to CtAPI functions in Plant SCADA 7.30.

**New Functions**

ctFindNumRecords	Get the number of records for a given browsing session
------------------	--

## Modified Functions

CtFindFirst	Searches for the first object in the specified table, device, trend, tag, or alarm data which satisfies the filter string. Now accepts "Equipment" as an argument.
CtFindFirstEX	Performs the same as ctFindFirst, but with an additional new argument. Now accepts "Equipment" as an argument.
CtGetProperty	Retrieves an object property or meta data for an object. Now accepts "Equipment" as an argument.

## Obsolete Functions

None

## What's New in Citect SCADA 7.20

Citect SCADA 7.20 incorporates the following new features.

Introduced in 7.20:

- Control SCADA Client Connections
- Dynamically Optimized Writes
- Environment Variable Changes
- Graphics Enhancements
- Improved Installation Process
- Improved Citect SCADA Security
- Microprocessor Support in Demo Mode
- New Example Project
- New Web-based Help
- OPC Factory Server (OFS) Driver
- Performance Improvements
- Persisted I/O Memory Mode
- Post Compile Commands
- Improved Client Side Online Changes
- Server Side Online Changes
- Microsoft® Windows 7 Support
- Supportability Enhancements

- Tab Menu Templates
- Tag Extensions

For changes to:

- Citect.ini parameters, see [Citect.ini Parameters in 7.20](#).
- Cicode functions, see [Cicode Functions in 7.20](#).

## Citect.ini Parameters in 7.20

This topic lists the parameters that have been added or changed in version 7.20 of Citect SCADA.

It includes the following:

### New Parameters

The following parameters are new in version 7.20 . For an entire list of the system parameters, refer to the Parameters documentation.

#### Alarm Parameters

[Alarm.ClusterName.ServerName]DisableConnection	Specifies if a client will not connect to a server.
[Alarm.ClusterName.ServerName]Priority	Specifies the client priority for the server connection.
[Alarm]ReloadBackOffTime	Back-off time configured to control the pace of the reload on an alarm server.

#### Client Parameters

[Client]AutoLoginClearPassword	When set to 1 the cache is cleared of any client login credentials.
[Client]DisableDisplay	Sets whether to allow the client process to run in the background without a visible window.
[Client]EvictTimeout	Sets the amount of time a tag reference is cached before it is evicted.
[Client]PartOfTrustedNetwork	Tells a Client process to attempt to authenticate using the stored server password. It is automatically set by the Setup Wizard.
[Client]StalenessPeriod	Number of seconds to use for tag staleness period.
[Client]StalenessPeriodTolerance	Staleness period tolerance

#### CtAPI Parameters

[CtAPI]RoundToFormat	Indicates to the user if values rounded to format.
----------------------	--

#### CtDraw.RSC Parameters

[CtDraw.RSC]AllowEditSuperGeniePage	When set enables the user to choose whether or not to open and edit a Super Genie page.
-------------------------------------	---

**CtEdit Parameters**

[CtEdit]CompileSuccessfulCommand	Indicates to the compiler an optional command, script or batch file to execute after a successful compile.
[CtEdit]CompileUnsuccessfulCommand	Indicates to the compiler an optional command, script or batch file to execute after an unsuccessful compile.
[CtEdit]Starter	Specifies the directory where the starter projects are located.

**Debug Parameters**

[Debug]ArchiveFiles	Archives log files once the size specified by [Debug]MaximumFileSize is reached.
[Debug]CategoryFilter	Allows you to filter logging messages by component category.
[Debug]CategoryFilterMode	Enables logging of categories declared by the [Debug]CategoryFilter value.
[Debug]EnableLogging	Enables or disables the logging mechanism.
[Debug]MaximumFileSize	Sets the maximum size for a log file.
[Debug]Priority	Allows you to filter logging messages according to their priority.
[Debug]SeverityFilter	Allows you to filter logging messages according to their severity.
[Debug]SeverityFilterMode	Enables logging of severities declared by the [Debug]SeverityFilter value.

**General Parameters**

[General]MiniumlUpdateRate	Specifies the time period (sec) at which a DataSource will send tag update value notifications to the subscription clients.
[General]StalenessPeriod	Specifies the time period (sec) after which a tag value is considered to be "stale" if it was not updated during this period.

**IOServer Parameters**

[IOServer]EnableEventQueue	Enables the event queue.
[IOServer]MaxEventsDrop	Sets the number of events that are dropped when too

	many are queued.
[IOServer]MaxEventsQueued	Sets the total number of events that can be queued.
[IOServer]MaxTimeInQueueMs	Sets the total time for which an event can be queued.

**LAN Parameters**

[LAN]AllowRemoteReload	Enables remote reloading of servers from a client.
[LAN]ClientRetryTime	Sets the length of time between connection attempts by a client.
[LAN]EarliestLegacyVersion	Specify the minimum legacy version from which the current version will accept connections.
[LAN]HighWaterMark	The number of messages waiting to be sent on a particular network connection at which the high water mark event will occur.
[LAN]KeepAliveInterval	Sets the length of time between two keep alive transmissions by the client.
[LAN]KeepAliveTime	Sets the length of time between two keep alive transmissions in idle conditions.
[LAN]ListenerRetryTime	Sets the length of time a server waits between attempts to listen for a client connection.
[LAN]LowWaterMark	After the high water mark has been reached on a particular network connection, the low water mark represents the number of messages waiting to be sent at which we will resume normal operations.
[LAN]NoSocketDelay	Switches off the delay on a socket caused by the use of the Nagle algorithm.
[LAN]ReadOnlyLegacyConnections	When set to 1 version 7.10 clients can only communicate in read-only mode. This parameter overrides 'EarliestLegacyVersion' .

**Multi-Monitor Parameters (CSV Include project)**

[MultiMonitor]DisableAutoStart	Disables the new multi-monitor functionality.
--------------------------------	---

**Page Parameters**

[Page]AddDefaultMenu	Determines whether to add the default menu items to the tabbed menu bar.
[Page]BadDitheringColor	Sets the dithering color for graphics elements which are dithered if the value quality is "bad".

[Page]BadDitheringDensity	Sets the dithering density for graphics elements which are dithered if the value quality is "bad".
[Page]BadText	Text Objects can be displayed as #COM type errors, or as the text overlaid with a dithered pattern if the 'display value' expression has "bad" quality.
[Page]BadTextBackgroundColor	Sets the background color for numeric / text graphics objects to indicate "bad" quality.
[Page]EnableQualityToolTip	Set by default it controls the quality tooltip
[Page]ErrorDitheringColor	Sets the dithering color for graphics elements which are dithered if an internal error occurs.
[Page]ErrorDitheringDensity	Sets the dithering density for graphics elements which are dithered if an internal error occurs.
[Page]ErrorTextBackgroundColor	Sets the background color for numeric / text graphics objects to indicate an internal error.
[Page]IgnoreValueQuality	Defines the value quality handling by graphics pages.
[Page]OverrideDitheringColor	Sets the dithering color for graphics elements which are dithered if their values are override ("forced").
[Page]OverrideDitheringDensity	Sets the dithering density for graphics elements which are dithered if an internal error occurs.
[Page]OverrideTextBackgroundColor	Sets the background color for numeric / text graphics objects to indicate that the value presented on the objects is override ("forced").
[Page]ShowBadText	Text Objects can be displayed as #BAD text, or as the text overlaid with a dithered pattern if the "display value" expression has "bad" quality.
[Page]ShowErrorText	Text Objects can be displayed as #COM type errors, or as the text overlaid with a dithered pattern if the 'display value' expression has "uncertain" quality.
[Page]ShowUncertainText	Text Objects can be displayed as #UNC text, or as the text overlaid with a dithered pattern if the "display value" expression has "uncertain" quality.
[Page]Splash	Specify the name of the Splash Screen page.
[Page]SplashTimeout	Time in milliseconds for the Splash Screen to display.
[Page]SplashWinName	Specify the label of the Splash Window for use with the Cicode function WinNumber().

[Page]StartupDelay	Milliseconds between when Splash Screen and Start Screen are displayed.
[Page]StartupHeight	Height of the Start Page on main display monitor.
[Page]StartupMode	Mode of Start Page on main display monitor.
[Page]StartupWidth	Width of the Start Page on main display monitor.
[Page]StartupWinName	Specify the label of the Start Window for use with the Cicode function WinNumber().
[Page]StartupX	X coordinate of Start Page on main display monitor.
[Page]StartupY	Y coordinate of Start Page on main display monitor.
[Page]UncertainDitheringColor	Sets the dithering color for graphics elements which are dithered if the value quality is "uncertain".
[Page]UncertainDitheringDensity	Sets the dithering density for graphics elements which are dithered if the value quality is "uncertain".
[Page]UncertainText	Text Objects can be displayed as #COM type errors, or as the text overlaid with a dithered pattern if the 'display value' expression has "uncertain" quality.
[Page]UncertainTextBackgroundColor	Sets the background color for numeric / text graphics objects to indicate "uncertain" quality.
[Page]WaitForValidData	Specifies whether the animation system will attempt to wait for valid data from subscriptions necessary to draw a graphics page before it is animated.

**Report Parameters**

[Alarm.ClusterName.ServerName]DisableConnection	Specifies if a client will not connect to a server.
[Alarm.ClusterName.ServerName]Priority	Specifies the client priority for the server connection.

**Runtime Manager Parameters**

[RuntimeManager]AllowReload	Enables or disables the reload option in the Runtime Manager menu.
-----------------------------	--

**Security Parameters**

[Security]DisableDEP	Set to turn off DEP protection for the Plant SCADA runtime.
----------------------	---

**Server Parameters**

[Server]AutoLoginMode	Determines the auto login method the server will use when establishing connections to other servers.
-----------------------	--

**Trend Parameters**

[Trend]AcquisitionTimeout	Sets a timeout to stop a trend server infinitely acquiring a valid data sample from an I/O device.
[Trend.ClusterName.ServerName]DisableConnection	Specifies if a client should not connect to a server.
[Trend.ClusterName.ServerName]Priority	Specifies the client priority for the server connection.
[Trend]ReloadBackOffTime	Back-off time configured to control the pace of the reload on an Trend server.

**Modified Parameters****CtEdit Parameters**

[CtEdit]Copy	Supports runtime changes, it enables you to switch the SCADA node to use a new runtime configuration by pointing to a new location.
--------------	---

**Re-instanted Parameters****IOServer Parameters**

[IOServer]BlockWrites	Determines whether Plant SCADA will try to block optimize writes to I/O devices.
-----------------------	--

**Obsolete Parameters****AnmCursor Parameters**

[AnmCursor]Colour	Replaced with [AnmCursor]Color. Sets the color of the cursor.
-------------------	---

**General Parameters**

[General]TagAssMode	Validates the tag name in the Association Function. Refer to [General]TagDB instead.
---------------------	--

**LAN Parameters**

[LAN]AllowLegacyConnections	Set to allow previous versions of client to connect to the server.  Replaced with [LAN]EarliestLegacyVersion and the new trusted network authentication between SCADA servers. The Setup Wizard now allows a server password to be set on each server on your network.
[LAN]ServerLoginEnabled	Set to disable default server login.

	Replaced with [LAN]EarliestLegacyVersion and the new trusted network authentication between SCADA servers. The Setup Wizard now allows a server password to be set on each server on your network.
--	--

**Page Parameters**

[Page]BackgroundColour	Replaced with [Page]BackgroundColor. Specifies the color used to fill in the background when a page is smaller than the minimum width of a window.
[Page]ComBreak	Determines whether an error status is displayed on the screen if a communication error occurs.  Replaced with new page quality settings such as [Page]IgnoreValueQuality, [Page]BadText,[Page]BadDitheringDenisty.
[Page]ComBreakText	Determines the display of text objects if a communication error occurs that affects the text.  Replaced with new page quality settings such as [Page]IgnoreValueQuality, [Page]BadText,[Page]BadDitheringDenisty.
[Page]DynamicComBreakColour	Replaced with [Page]DynamicComBreakColor. Sets the color of the ComBreak dithering.
[Page]DynamicComBreakDensity	Sets the density of the ComBreak.  Replaced with new page quality settings such as [Page]IgnoreValueQuality, [Page]BadText,[Page]BadDitheringDenisty.

**Time Parameters**

[Time]Deadband	The deadband time checked by the Time Server before it adjusts the time on the client(s).
[Time]Disable	Enables/disables the processing of time messages from the Time Server.
[Time]Name	Enables the time synchronization functionality.
[Time]PollTime	The period that the Time Server uses to synchronize other Plant SCADA computers on the network.
[Time]RTsync	Determines whether the Time Server will synchronize with the hardware clock.
[Time]Server	Determines whether this computer is a Time Server.

**Trend Parameters**

[Trend]CursorColour	Replaced with [Trend]CursorColor. Allows the cursor color to be specified.
---------------------	--

## Cicode Functions in 7.20

Some Cicode functions have been introduced, modified, deprecated or removed. The following sections detail the changes made to these functions:

### New Functions

#### Alarm Functions

AlarmCatGetFormat	Returns the display format string of the specified alarm category.
AlarmDspClusterAdd	Adds a cluster to a client's alarm list.
AlarmDspClusterInUse	Determines if a cluster is included in a client's alarm list.
AlarmDspClusterRemove	Removes a cluster from a client's alarm list.

#### Display Functions

DspAnGetMetadata	Retrieves the field value of the specified metadata entry.
DspAnGetMetadataAt	Retrieves metadata information at the specified index.
DspAnSetMetadata	Non-blocking function, that sets the value of the specified metadata entry.
DspAnSetMetadataAt	Sets the value of a metadata entry.
DspPopupConfigMenu	Displays the contents of a menu node as a pop-up (context) menu, and run the command associated with the selected menu item.

#### Format Functions

FmtGetFieldCount	Retrieves the number of fields in a format object.
FmtGetFieldName	Retrieves the name of a particular field in a format object.
FmtGetFieldWidth	Retrieves the width of a particular field in a format object.

#### Menu Functions

MenuGetChild	Returns the handle to the child node with the specified name.
MenuGetFirstChild	Returns the handle to the first child of a menu node.
MenuGetGenericNode	Returns the root node of the default menu tree.
MenuGetNextChild	Returns the next node that shares the same parent.
MenuGetPageNode	Returns the Base menu node of a specific page
MenuGetParent	Returns the parent node of the menu item.
MenuGetPrevChild	Returns the previous node that shares the same parent.
MenuGetWindowNode	Returns the handle of the root menu node for a given window.
MenuNodeAddChild	Dynamically adds a new item to the menu at runtime.
MenuNodeGetProperty	Return the item value of the specified menu node.
MenuNodeHasCommand	Checks whether the menu node has a valid Cicode command associated with it.
MenuNodeIsDisabled	Checks whether the menu node is disabled by evaluating its DisabledWhen Cicode expression.
MenuNodeIsHidden	Checks whether the menu node is hidden by evaluating its HiddenWhen Cicode expression.
MenuNodeRemove	Remove the menu node from the menu tree.
MenuNodeRunCommand	Run the associated command for a menu node.
MenuNodeSetDisabledWhen	Set the DisabledWhen expression for a newly added node.
MenuNodeSetHiddenWhen	Set the HiddenWhen expression for a newly added node.
MenuNodeSetProperty	Set the item value of the specified menu node.
MenuReload	Reload base Menu Configuration from the compiled database.

**Miscellaneous Functions**

GetLogging	Gets the current value for one or more logging parameters.
SetLogging	Adjusts logging parameters while online.
ProductInfo	Returns information about the Plant SCADA product.
ProjectInfo	Returns information about a particular project, which is identified by a project enumerated number.

**Page Functions**

PageBack	Displays the previously displayed page in the Window.
PageForward	PageForward() restores the previously displayed page in the window following a PageBack command.
PageHistoryDspMenu	Displays a pop-up menu which lists the page history of current window.
PageHistoryEmpty	Returns whether page history of the current window is empty.
PageHome	Displays the predefined home page in the window.
PagePeekCurrent	Return the index in the page stack for the current page.
PageProcessAnalyst	Displays a Process Analyst page (in the same window) preloaded with the pre-defined Process Analyst View (PAV) file.
PageProcessAnalystPens	Displays a Process Analyst page (in the same window) preloaded with the pre-defined Process Analyst View (PAV) file and specified trend or variable tags.
PageRecall	Displays the page at a specified depth in the stack of previously displayed pages.
PageTask	Used for running preliminary Cicode before displaying a page in a window.
PageTransformCoords	Converts Page coordinates to absolute screen coordinates.

**Process Analyst Functions**

ProcessAnalystLoadFile	Loads the specified PAV file to a Process Analyst object, which is identified by parameter ObjName.
ProcessAnalystPopup	Displays a Process Analyst page (in the same window) preloaded with the pre-defined Process Analyst View

	(PAV) file and specified trend or variable tags.
ProcessAnalystSelect	Allows a set of pens to be selected before displaying the PA page.
ProcessAnalystSetPen	Allows a new pen to be added to a PA display.
ProcessAnalystWin	Displays a Process Analyst page (in a new window) preloaded with the pre-defined Process Analyst View (PAV) file.

**Quality Functions**

QualityCreate	Creates a quality value based on the quality fields provided.
QualityGetPart	Extracts a requested part of the Quality value from the QUALITY variable.
QualityIsBad	Returns a value indicating whether the quality is bad.
QualityIsGood	Returns a value indicating whether the quality is good.
QualityIsUncertain	Returns a value indicating whether the quality is uncertain.
QualitySetPart	Sets a Quality part's value to the QUALITY variable.
QualityToStr	Returns a textual representation of the Plant SCADA quality.
QualityIsOverride	Returns a value indicating whether the tag is in Override Mode.
QualityIsControlInhibit	Returns a value indicating whether the tag is in Control inhibit mode.
VariableQuality	Extracts the quality from a given variable.

**Server Functions**

ServerBrowseClose	This function terminates an active data browse session and cleans up resources associated with the session.
ServerBrowseFirst	This function places the data browse cursor at the first record.
ServerBrowseGetField	This function retrieves the value of the specified field from the record the data browse cursor is currently referencing.
ServerBrowseNext	This function moves the data browse cursor forward

	one record.
ServerBrowseNumRecords	This function returns the number of records that match the filter criteria.
ServerBrowseOpen	This function initiates a new browse session and returns a handle to the new session that can be used in subsequent data browse function calls.
ServerBrowsePrev	This function moves the data browse cursor back one record.
ServerGetProperty	This function returns information about a specified server and can be called from any client.
ServerReload	This function reloads the server specified by cluster and server name.
ServerIsOnline	This function checks if the given server can be contacted by the client for giving the online/offline status of the server.

**String Functions**

StrCalcWidth	Retrieves the pixel width of a string using a particular font.
StrTruncFont	Returns the truncated string using a particular font (specified by name) or the specified number of characters.
StrTruncFontHnd	Returns the truncated string using a particular font (specified by font number) or the specified number of characters.

**Super Genie Functions**

AssMetadata	Performs Super Genie associations using the "Name" and "Value" fields.
AssMetadataPage	Uses the metadata information from the current animation point for the page associations for a new Super Genie page, and displays the new Super Genie in the current page.
AssMetadataPopup	Uses the metadata information from the current animation point for the associations for a new Super Genie page, and displays the new Super Genie in a new pop up window.
AssMetadataWin	Uses the metadata information from the current

	animation point for the associations for a new Super Genie page, and displays the new Super Genie in a new window.
--	--

**Tag Functions**

SubscriptionGetInfo	Reads the specified text information about a subscribed tag.
SubscriptionGetQuality	Reads quality of a subscribed tag.
SubscriptionGetTag	Reads a value, quality and timestamps of a subscribed tag.
SubscriptionGetTimestamp	Reads the specified timestamp of a subscribed tag.
SubscriptionGetValue	Reads a value of a subscribed tag.
TagSetOverrideBad	Sets a quality Override element for a specified tag to Bad Non Specific.
TagSetOverrideGood	Sets a quality Override element for a specified tag to Good Non Specific.
TagSetOverrideUncertain	Sets a quality Override element for a specified tag to Uncertain Non Specific.
TagSetOverrideQuality	Sets a quality of Override element for a specified tag.

**Task Functions**

TaskCall	Calls a Cicode function by specifying the function name and providing an arguments string.
----------	--

**Timestamp Functions**

TimestampToStr	Converts a TIMESTAMP variable into a string.
TimestampDifference	Returns a difference between two TIMESTAMP variables as a number of milliseconds.
TimestampCreate	Returns a timestamp variable created from the parts.
TimestampFormat	Format a TIMESTAMP variable into a string.
TimestampGetPart	Returns one part (year, month, day, etc) of the timestamp variable.
TimestampToInt	Converts a TIMETSTAMP variable into a time INTEGER which is represented as a number of seconds since 01/01/1970.
TimeIntTo Timestamp	Converts a time INTEGER which is represented as a

	number of seconds since 01/01/1970 to a TIMETSTAMP
TimestampCurrent	Returns the current system date and time as a TIMESTAMP variable.
TimestampAdd	Adds time (in milliseconds) to a TIMESTAMP variable.
TimestampSub	Subtracts time (in milliseconds) from a TIMESTAMP variable.
VariableTimestamp	Extract the TIMESTAMP from a given variable.

**Window Functions**

MultiMonitorStart	Displays a Plant SCADA window on each of the configured monitors when a display client starts up.
WinSetName	Associates a name with a particular window by its window number.
WndMonitorInfo	Returns information about a particular monitor.

**Modified Functions****Accumulator Functions**

AccumBrowseOpen	Opens an accumulator browse session.
-----------------	--------------------------------------

**Alarm Functions**

AlarmDsp	Displays alarms.
AlarmDspLast	Displays the latest, unacknowledged alarms.
AlmSummaryOpen	Opens an alarm summary browse session.
AlmTagsOpen	Opens an alarm tags browse session.

**Display Functions**

DspStr	Displays a string at an AN.
DspText	Displays text at an AN.

**Format Functions**

FmtOpen	Creates a format template.
---------	----------------------------

**Miscellaneous Functions**

Shutdown	Ends Plant SCADA operation.
----------	-----------------------------

**Page Functions**

PageGetInt	Gets a local page-based integer.
PageGetStr	Gets a local page-based string.
PageInfo	Gets information about the current page.
PagePeekLast	Gets any page on the PageLast stack.
PageSetInt	Stores a local page-based integer.
PagesetStr	Stores a local page-based string.

**Security Functions**

Login	Logs an operator into the Plant SCADA system. Not available when logged in as Windows user.
-------	---

**Super Genie Functions**

The following functions were updated to accept string identifiers for substitution parameters.

Ass	Associates a variable tag with a Super Genie.
AssGetProperty	Retrieves association information about the current Super Genie from the datasource.
AssGetScale	Gets scale information about the associations of the current Super Genie from the datasource (that is scale information about a variable tag that has been substituted into the Super Genie)
AssInfo	Gets association information about the current Super Genie (that is information about a variable tag that has been substituted into the Super Genie).
AssInfoEx	Retrieves association information about the current Super Genie (that is information about a variable tag that has been substituted into the Super Genie).
AssScaleStr	Gets scale information about the associations of the current Super Genie (that is scale information about a variable tag that has been substituted into the Super Genie).

**Tag Functions**

SubscriptionGetAttribute	Reads an attribute value of a tag subscription.
TagRead	Reads the value of a particular tag element.
TagWrite	Writes a tag element value for the tag elements which have read/write access.

TagSubscribe	Subscribes to a particular tag element.
--------------	---

### Window Functions

WinNumber	Gets the window number of the active Plant SCADA window.
WndInfo	Gets the Windows system metrics information.

### Reinstated Functions

Following functions have been reinstated for 7.20.

#### Time and Date Functions

TimeSet	Sets the new system time. Requires UAC to be disabled in order for the time to be set.
---------	--

## CtAPI Functions in 7.20

The following section details the changes made to CtAPI functions in Plant SCADA 7.20.

### New Functions

ctListItem	Gets the tag element item data.
ctTagReadEx	Performs the same as ctTagRead, but with an additional new argument

### Modified Functions

ctTagRead	Reads the current value from the given I/O device variable tag element value.
ctTagWrite	Writes the given value to the I/O device variable tag elements which have read/write access.
ctTagWriteEx	Asynchronously writes the given value to the I/O device variable tag element value for the tag elements which have read/write access.
ctListAdd	Adds a tag element value to the list.
ctListAddEx	Adds a tag element value to the list.

## Obsolete Functions

None

## What's New in Citect SCADA 7.10

Citect SCADA 7.10 incorporates the following new features.

Introduced in 7.10:

- Windows® Integrated Security
- Citect SCADA Security Enhancements
- Multi-Signature Support
- Edit DBF Files in Microsoft® Excel
- Enhanced Driver Installation
- New Font Selection for Graphics Button
- Microsoft® Windows Vista™ Support
- New Location for Configuration and Project Files
- New Alarm Field Enhancements
- New Time Synchronization Service
- New Equipment Database Functions and Forms

For changes to:

- Citect.ini parameters, see [Citect.ini Parameters in 7.10](#).
- Cicode functions, see [Cicode Functions in 7.10](#).

## Citect.ini Parameters in 7.10

This topic lists the parameters that have been added or changed in version 7.10 of Citect SCADA.

### New Parameters

The following parameters are new in version 7.10. For an entire list of the system parameters, refer to the Parameters documentation.

#### Alarm Parameters:

[Alarm]ArgyleTagValueTimeout	Defines the length of time that the alarm server will wait for argyle tag values to become available (without error) before starting to scan for argyle alarms.
------------------------------	---

#### Code Parameters:

[Code]HaltOnInvalidTagData	When enabled will cause the Cicode to halt when any tag read returns invalid data.
----------------------------	--

**Client Parameters:**

[Client]AutoLoginPage	Set to enable auto login. Users can select one of seven modes.
-----------------------	--

**CtApi Parameters:**

[CtAPI]AllowLegacyConnections	When enabled current version of CTAPI server can accept connections from previous versions of CTAPI client.
[CtAPI]AllowLegacyServices	When enabled the Citect Web Service and the Citect OLEDB Provider can connect to the CTAPI server.

**DDE Parameters:**

[DDE]AllowCicode	Allows Cicode to be run on the Citect server via the DDE Execute command.
[DDE]AllowWrites	Allows tag writes to the Citect server via the DDE Poke command.

**Kernel Parameters:**

[Kernel]ErrorBuffers	The total number of error buffers available for logging to the syslog.dat file.
----------------------	---

**LAN Parameters:**

[LAN]AllowLegacyConnections	Set to allow previous versions of client to connect to the server.
[LAN]AnonymousLoginName	The name of the default identifier to allow 'view-only' data access for a client process to the SCADA server(s).
[LAN]SecureLogin	When set to 0 security measures are disabled and the system acts as it did in versions prior to 7.10.
[LAN]ServerLoginEnabled	Set to disable default server login.
[LAN]ServerLoginName	The name of the default identifier to allow data access for a server process to another SCADA server process(es).

**ODBC Parameters:**

[ODBC]Server	Set to enable ODBC connections.
--------------	---------------------------------

**Page Parameters:**

[Page]AllowHScroll	Defines the default behavior for horizontal scrolling.
[Page]AllowHScrollBar	Defines the default behavior when displaying horizontal scroll bars.
[Page]AllowVScroll	Defines the default behavior for vertical scrolling.
[Page]AllowVScrollBar	Defines the default behavior when displaying vertical scroll bars.

## Obsolete Parameters

### Win Parameters:

[Win]CtrlEsc	Determines whether the Windows key command [Ctrl]+[Esc] can be used in the runtime system (to display the start menu).
--------------	--

### COM Parameters:

[Com]StartTimeout	Determines the period to wait for I/O Devices to come online before displaying any data.
-------------------	--

## Cicode Functions in 7.10

Some Cicode functions have been introduced, modified, deprecated or removed. The following sections detail the changes made to these functions:

## New Functions

### Security Functions

FormSecurePassword	Adds both a password prompt and edit field to the current form.
MultiSignatureForm	Displays a form that allows up to 4 users to have their credentials verified in order to approve an operation.
MultiSignatureTagWrite	Displays a form that allows up to 4 users to have their credentials verified in order to approve a write of a specific value to a specific tag.
UserLogin	Logs an operator into the Citect SCADA system using a secure password string.
UserVerify	Uses the authentication functionality in the user login system

VerifyPrivilegeForm	Displays a form that allows a single user to enter their credentials.
VerifyPrivilegeTagWrite	Displays a form that allows any single user to enter their credentials in order to approve a write of a specific value to a specific tag.

**Miscellaneous Functions**

KernelQueueLength	Obtains the number of rows in a queue.
KernelTableInfo	Provides a consistent method of accessing items within Kernel Table.
KernelTableItemCount	Obtains the number of rows in a Kernel Table
ProcessRestart	Restarts the current process in which Cicode is running.
ServerRestart	Restart any alarm, report, trend or I/O server from any Cicode node in system, without affecting other server processes running on same machine.

**Tag Functions**

TagRDBReload	Works in conjunction with the TagInfo function. Reloads the variable tag database so when TagInfo is called it picks up online changes to the tag database.
--------------	---

**Windows Functions**

WinStyle	Switches on and off scrolling and scroll bar features for existing windows.
----------	---

**Modified Functions**

None

**Obsolete Functions****Window Functions**

WndGetProfile	Gets the value of a WIN.INI parameter. If called it will return 0. No longer available due to Vista support.
WndPutProfile	Updates a parameter in WIN.INI. If called it will return 0. No longer available due to Vista support.

**Time and Date Functions**

TimeSet	Sets the new system time. No longer available due to
---------	--

	Vista support.
--	----------------

## What's New in Citect SCADA 7.0

Citect SCADA 7.0 incorporates the following new features.

Introduced in 7.0:

- The Migration Tool
- Clustering
- Local Variables
- Publish Alarm Property
- Memory Mode
- Client-side Online Changes
- Dual Network Support
- Project-Based Network Configuration

For changes to:

- Citect.ini parameters, see [Citect.ini Parameters in version 7.0](#).
- Cicode functions, see [Cicode Functions in 7.0](#).

### Citect.ini Parameters in version 7.0

The following sections detail the changes made to Citect.ini parameters in Citect SCADA version 7.0:

- New Parameters
- Obsolete Parameters

#### New Parameters

The following parameters are new in version 7.0. For a complete list of the system parameters, refer to the Parameters help.

##### Alarm Parameters:

[Alarm.ClusterName.ServerName]Clusters	Sets which clusters this Alarm Server process connects to at startup
[Alarm.ClusterName.ServerName]CPU	Sets the CPU that the Alarm Server process is assigned to
[Alarm.ClusterName.ServerName]Events	The list of events that this Alarm Server process enables
[Alarm.ClusterName.ServerName]ShutdownCode	Determines the Cicode function to run when Alarm

	Server process shuts down
[Alarm.ClusterName.ServerName]StartupCode	Determines the Cicode function to run when Alarm Server process starts up

**Note:** The default alarm property write behavior was to write the new value to DBF/RDB. This has changed in version 7.0 onwards. Refer to the parameter [Alarm]UseConfigLimits.

#### Backup Parameters:

[Backup]SaveiniFiles	Determines whether the "Save ini files" check box is checked by default during Backup.
----------------------	--

#### Client Parameters:

[Client]Clusters	Selects which clusters the client is connected to at startup.
[Client]ComputerRole	Specifies the role of the computer
[Client]Events	Sets the events to be enabled on the client.
[Client]ForceClient	Starts only the client process, and connects to a configured Citect servers using a network connection.
[Client]FullLicense	Specifies that a Control Client will use a full server license
[Client]ShutdownCode	Determines the Cicode function to run when DisplayClient component shuts down.
[Client]StartupCode	Determines the Cicode function to run when DisplayClient component starts up.
[Client]WaitForConnectAtStartup	Specifies that connection to a server will wait until it can establish a connection to the server processes before starting up.

#### CtCicode Parameters:

[CtCicode]FastFormat	Controls whether fast formatting is used in the Cicode Editor
----------------------	---

#### CtEdit Parameters:

[CtEdit]Config	The directory where the Citect SCADA configuration files such as citect.ini are located.
[CtEdit]Logs	The directory where the Citect SCADA log files are located.

#### Dial Parameters:

[Dial]MissedScheduleTolerance	Specifies how many consecutive scheduled dial
-------------------------------	---

	attempts can be missed before the cache becomes stale
--	---

**Driver Parameters:**

[<DriverName>]OverriderOSProtection	Determines whether to override the protection mechanism built-in to the I/O Server for drivers that may not be compatible with Windows Vista.
-------------------------------------	---

**General Parameters:**

[General]Multiplexor	Determines whether Citect SCADA runs as a multi-process or single-process application.
----------------------	--

**IOServer Parameters:**

[IOServer.ClusterName.ServerName]Clusters	Sets the clusters that the I/O Server process will connect to at startup
[IOServer.ClusterName.ServerName]CPU	Sets the CPU that the I/O Server process is assigned to
[IOServer.ClusterName.ServerName]Events	The list of events that this I/O Server process enables
[IOServer.ClusterName.ServerName]ShutdownCode	Determines the Cicode function to run when I/O Server process shuts down
[IOServer.ClusterName.ServerName]StartupCode	Determines the Cicode function to run when I/O Server process starts up

**Report Parameters:**

[Report.ClusterName.ServerName]Clusters	Sets the clusters this Reports Server process will connect to at startup
[Report.ClusterName.ServerName]CPU	Sets the CPU that this Reports Server process is assigned to
[Report.ClusterName.ServerName]Events	The list of events that this Reports Server process enables
[Report.ClusterName.ServerName]ShutdownCode	Determines the Cicode function to run when this Reports Server process shuts down
[Report.ClusterName.ServerName]StartupCode	Determines the Cicode function to run when this Reports Server process starts up

**Trend Parameters:**

[Trend.ClusterName.ServerName]Clusters	Sets the clusters this Trends Server process will connect to at startup
[Trend.ClusterName.ServerName]CPU	Sets the CPU that the Trends Server process is assigned to

[Trend.ClusterName.ServerName]Events	The list of events that this Trends Server process enables
[Trend.ClusterName.ServerName]ShutdownCode	Determines the Cicode function to run when Trends Server process shuts down
[Trend.ClusterName.ServerName]StartupCode	Determines the Cicode function to run when Trends Server process starts up

## Obsolete Parameters

The following parameters are no longer supported in version 7.0:

### Alarm Parameters:

[Alarm]CPU	Sets the CPU that the Alarm Server component is assigned to. Replaced with a cluster specific CPU parameter in the following format:[ServerType.ClusterName.ServerName]CPU.
[Alarm]Name	The name of the default Alarm Server. To retrieve the server name in your Cicode, refer to the ServiceGetList Cicode function.
[Alarm]Primary	Determines if this Alarm Server is the Primary Alarm Server. Information is now configured within the project via the server form.
[Alarm]Process	Sets the Citect SCADA process the Alarm Server component is assigned to. No longer required as each process is separate when running multi-process.
[Alarm]Server	Determines whether this computer is an Alarm Server. To retrieve the server enabled status in your Cicode, refer to the ProcessIsServer Cicode function.

### Client Parameters:

[Client]Display	Sets the Citect SCADA computer as a Control Client. To retrieve the client status in your Cicode, refer to the ProcessIsClient Cicode function or the parameter [Client]ComputerRole. The computer role parameter can be set to the following: 0 = Server & Control client, 1 = Control client, 2 =View only client.
[Client]Manager	Sets the Citect SCADA computer as a View-only Client.

	To retrieve the client status in your Cicode, refer to the ProcessIsClient Cicode function or the parameter [Client]ComputerRole. The computer role parameter can be set to the following: 0 = Server & Control client, 1 = Control client, 2 =View only client.
[Client]Primary	The name of the primary Citect SCADA server
[Client]Process	Sets the Citect SCADA process the Control Client component is assigned to.  No longer required as each process is separate when running multi-process.
[Client]Standby	The name of the standby Citect SCADA server
[Client]Shutdown	Determines the Cicode function to run when DisplayClient component shuts down.  Replaced with [Client]ShutdownCode.
[Client]Startup	Determines the Cicode function to run when DisplayClient component starts up.  Replaced with [Client]StartupCode.

**Code Parameters:**

[Code]AlarmShutdown	Determines the Cicode function to run when Alarm Server component shuts down.  Replaced with a cluster specific code startup and shutdown parameters in the following format:[ServerType.ClusterName.ServerName]StartupCode and [ServerType.ClusterName.ServerName]ShutdownCode .
[Code]AlarmStartup	Determines the Cicode function to run when Alarm Server component starts up.  Replaced with a cluster specific code startup and shutdown parameters in the following format:[ServerType.ClusterName.ServerName]StartupCode and [ServerType.ClusterName.ServerName]ShutdownCode .
[Code]AutoReRead	Controls whether the ReRead() function is automatically called
[Code]IOServerShutdown	Determines the Cicode function to run when I/O Server component shuts down.  Replaced with a cluster specific code startup and

	shutdown parameters in the following format:[ServerType.ClusterName.ServerName]StartupCode and [ServerType.ClusterName.ServerName]ShutdownCode .
[Code]IOServerStartup	Determines the Cicode function to run when I/O Server component starts up. Replaced with a cluster specific code startup and shutdown parameters in the following format:[ServerType.ClusterName.ServerName]StartupCode and [ServerType.ClusterName.ServerName]ShutdownCode .
[Code]Process	Sets the process a code component is assigned to
[Code]ReportShutdown	Determines the Cicode function to run when Reports Server component shuts down. Replaced with a cluster specific code startup and shutdown parameters in the following format:[ServerType.ClusterName.ServerName]StartupCode and [ServerType.ClusterName.ServerName]ShutdownCode .
[Code]ReportStartup	Determines the Cicode function to run when Reports Server component starts up. Replaced with a cluster specific code startup and shutdown parameters in the following format:[ServerType.ClusterName.ServerName]StartupCode and [ServerType.ClusterName.ServerName]ShutdownCode .
[Code]Shutdown	Determines the Cicode function to run when Control Client component shuts down
[Code]Startup	Determines the Cicode function to run when Control Client component starts up
[Code]TrendShutdown	Determines the Cicode function to run when Trends Server component shuts down. Replaced with a cluster specific code startup and shutdown parameters in the following format:[ServerType.ClusterName.ServerName]StartupCode and [ServerType.ClusterName.ServerName]ShutdownCode .

	.
[Code]TrendStartup	<p>Determines the Cicode function to run when Trends Server component starts up.</p> <p>Replaced with a cluster specific code startup and shutdown parameters in the following format:[ServerType.ClusterName.ServerName]StartupCode and [ServerType.ClusterName.ServerName]ShutdownCode</p> <p>.</p>

**DNS Parameters:**

[DNS]<Server name>	<p>Determines the IP address (or fully qualified host name) of the primary I/O Server.</p> <p>Functionality replaced by the server network address configuration form and the server redirection parameters with the following format:[AddressForwarding].=</p>
--------------------	---

**Event Parameters:**

[Event]Alarm	<p>The classes of events to be enabled by the Alarm Server.</p> <p>Replaced with a cluster specific event parameter in the following format:[ServerType.ClusterName.ServerName]Events.</p>
[Event]IOMonitor	<p>The classes of events to be enabled by the I/O Server.</p> <p>Replaced with a cluster specific event parameter in the following format:[ServerType.ClusterName.ServerName]Events.</p>
[Event]Name	<p>The classes of events assigned to the Name entry to be enabled.</p> <p>Has been replaced with the parameter [Client]Events.</p>
[Event]Report	<p>The classes of events to be enabled by the Reports Server.</p> <p>Replaced with a cluster specific event parameter in the following format:[ServerType.ClusterName.ServerName]Events.</p>
[Event]Trend	<p>The classes of events to be enabled by the Trends Server.</p> <p>Replaced with a cluster specific event parameter in the following format:[ServerType.ClusterName.ServerName]Events.</p>

**General Parameters:**

[General]BadOptimise	Determines whether certain strings are replaced with labels on compile
[General]CitectRunningCheck	Checks if a project is currently running on the local machine when a compile is triggered

**IOServer Parameters:**

[IOServer]BlockWrites	Determines whether Citect SCADA will try to block optimize writes to I/O Devices. The IOserver will not block writes
[IOServer]CPU	Sets the CPU that the I/O Server component is assigned to. Replaced with a cluster specific CPU parameter in the following format:[ServerType.ClusterName.ServerName]CPU.
[IOServer]Name	The name of the default I/O Server. To retrieve the server name in your Cicode, refer to the ServiceGetList Cicode function.
[IOServer]Process	Sets the Citect SCADA process the I/O Server component is assigned to. No longer required as each process is separate when running multi-process.
[IOServer]SaveBackup	This parameter has been superseded by SaveNetwork
[IOServer]Server	Determines whether this computer is an I/O Server . To retrieve the server enabled status in your Cicode, refer to the ProcessIsServer Cicode function.

**LAN Parameters:**

[LAN]Bridge	Determines the bridge level
[LAN]CancelOnClose	For users with Novell NetBIOS emulator issues
[LAN]Disable	Enables/disables Citect SCADA from the LAN
[LAN]GroupName	Determines whether Citect SCADA uses the group name 'CITECT STATION50' or the computer name specified by the [Lan]Node parameter.
[LAN]KillPiggyBackAck	Controls whether Citect SCADA will try to optimize network protocols which support piggyback ACK
[LAN]LanA	Defines the protocol stack that Citect SCADA uses for

	NetBIOS communication
[LAN]NetBIOS	Enables/disables NetBIOS
[LAN]NetTrace	Determines whether the NetBIOS window is enabled on startup
[LAN]NetTraceBuff	Sets the number of trace buffers.
[LAN]NetTraceErr	Enables the error mode of the NetBIOS window
[LAN]NetTraceLog	Enables the logging mode of the NetBIOS window
[LAN]Poll	Puts Citect SCADA LAN communications into polled mode
[LAN]RemoteTimeOut	The timeout period for remote I/O Device write requests from a Control Client to the I/O Server
[LAN]Retry	The number of times to retry establishing communications after a timeout - before an alert message is generated
[LAN]SendTimeOut	The timeout to send a network packet across the network
[LAN]SesRecBuf	The number of receive NetBIOS Control Blocks (NCBs) that Citect SCADA uses for every session
[LAN]SesSendBuf	The number of send NetBIOS control blocks that Citect SCADA uses for every session
[LAN]TimeOut	The timeout to send a network packet across the network

**Proxi Parameters:**

[Proxi]<I/O Server name>	Defines a list of proxy server associations
--------------------------	---

**Report Parameters:**

[Report]CPU	Sets the CPU that the Report Server component is assigned to.  Replaced with a cluster specific CPU parameter in the following format:[ServerType.ClusterName.ServerName]CPU.
[Report]Name	The name of the default Report Server.  To retrieve the server name in your Cicode, refer to the ServiceGetList Cicode function.

[Report]Primary	Determines if this Reports Server is the Primary Reports Server.  Information is now configured within the project via the server form.
[Report]Process	Sets the Citect SCADA process the Reports Server component is assigned to.  No longer required as each process is separate when running multi-process.
[Report]Server	Determines whether this computer is a Reports Server .  To retrieve the server enabled status in your Cicode, refer to the ProcessIsServer Cicode function.

**Server Parameters:**

[Server]Name	The name of the Citect SCADA server .  To retrieve the server enabled status in your Cicode, now refer to the ProcessIsServer Cicode function.
--------------	--

**Trend Parameters:**

[Trend]BlockByIODevice	Verifies that I/O problems causing gaps for a trend tag do not cause gaps for every trend tag.  Trend blocking is no longer required due to the new subscription architecture.
[Trend]CPU	Sets the CPU that the Trends Server component is assigned to.  Replaced with a cluster specific CPU parameter in the following format:[ServerType.ClusterName.ServerName]CPU.
[Trend]Name	The name of the default Trend Server.  To retrieve the server name in your Cicode, refer to the ServiceGetList Cicode function.
[Trend]Primary	Determines if this Trend Server is the Primary Trend Server.  Information is now configured within the project via the server form.
[Trend]Process	Sets the Citect SCADA process the Trends Server component is assigned to.  No longer required as each process is separate when running multi-process.

[Trend]Redundancy	Enables/disables trend redundancy action.  Trend blocking is no longer required due to the new subscription architecture.
[Trend]Server	Determines whether this computer is a Trends Server.  To retrieve the server enabled status in your Cicode, refer to the ProcessIsServer Cicode function.
[Trend]StaggerRequestSubgroups	Reduces network traffic by spacing out trend sample requests.  Trend blocking is no longer required due to the new subscription architecture.

## Cicode Functions in 7.0

Some Cicode functions have been introduced, modified, deprecated or removed. The following sections detail the changes made to these functions:

### New Functions

#### Miscellaneous Functions

AccControl	Controls accumulators for example motor run hours.
AccumBrowseClose	Closes an accumulator browse session.
AccumBrowseFirst	Gets the oldest accumulator entry.
AccumBrowseGetField	Gets the field indicated by the cursor position in the browse session.
AccumBrowseNext	Gets the next accumulator entry in the browse session.
AccumBrowseNumRecords	Returns the number of records in the current browse session.
AccumBrowseOpen	Opens an accumulator browse session.
AccumBrowsePrev	Gets the previous accumulator entry in the browse session.
ProcessIsClient	Determines if the currently executing process contains a Client component
ProcessIsServer	Determines if the currently executing process contains a particular server component.

ServiceGetList	Gets information about services running in the component calling this function.
----------------	---

**Alarm Functions:**

AlmDspLast	Displays the latest unacknowledged alarms.
AlmSummaryAck	Acknowledges the alarm at the current cursor position in an active data browse session.
AlmSummaryClear	Clears the alarm at the current cursor position in an active data browse session.
AlmSummaryClose	Closes an alarm summary browse session.
AlmSummaryCommit	Commits the alarm summary record to the alarm summary device.
AlmSummaryDelete	Deletes alarm summary entries from the browse session.
AlmSummaryDeleteAll	Deletes alarm summary entries from the browse session.
AlmSummaryDisable	Disables the alarm at the current cursor position in an active data browse session.
AlmSummaryEnable	Enables the alarm at the current cursor position in an active data browse session.
AlmSummaryFirst	Gets the oldest alarm summary entry.
AlmSummaryGetField	Gets the field indicated by the cursor position in the browse session.
AlmSummaryLast	Places the data browse cursor at the latest summary record from the last cluster of the available browsing cluster list.
AlmSummaryNext	Gets the next alarm summary entry in the browse session.
AlmSummaryOpen	Opens an alarm summary browse session.
AlmSummaryPrev	Gets the previous alarm summary entry in the browse session.
AlmSummarySetFieldValue	Sets the value of the field indicated by the cursor position in the browse session.
AlmTagsAck	Acknowledges the alarm tag at the current cursor position in an active data browse session.

AlmTagsClear	Clears the alarm tag at the current cursor position in an active data browse session.
AlmTagsDisable	Disables the alarm tag at the current cursor position in an active data browse session.
AlmTagsEnable	Enables the alarm tag at the current cursor position in an active data browse session.
AlmTagsFirst	Gets the oldest alarm tags entry.
AlmTagsGetField	Gets the field indicated by the cursor position in the browse session.
AlmTagsNext	Gets the next alarm tags entry in the browse session.
AlmTagsNumRecords	Returns the number of records in the current browse session.
AlmTagsOpen	Opens an alarm tags browse session.
AlmTagsPrev	Gets the previous alarm tags entry in the browse session.

**Super Genie Functions**

AssGetProperty	Gets association information about the current Super Genie from the datasource
AssGetScale	Gets scale information about the associations of the current Super Genie from the datasource
AssInfoEx	Replaces the AssInfo function and supports online changes.

**Cluster Functions**

ClusterActivate	Allows the user to activate an inactive cluster.
ClusterDeactivate	Allows the user to deactivate an active cluster.
ClusterFirst	Allows the user to retrieve the first configured cluster in the project.
ClusterIsActive	Allows the user to determine if a cluster is active.
ClusterNext	Allows the user to retrieve the next configured cluster in the project.
ClusterServerTypes	Allows the user to determine which servers are defined for a given cluster.

ClusterStatus	Allows the user to determine the connection status from the client to a server on a cluster.
ClusterSwapActive	Allows the user to deactivate an active cluster at the same time as activating an inactive cluster.

**I/O Device Functions**

SubscriptionAddCallback	Adds a callback function to a tag subscription.
SubscriptionGetAttribute	Reads an attribute value of a tag subscription.
SubscriptionRemoveCallback	Removes a callback function from a tag subscription
TagGetProperty	Gets a property for a variable tag from the datasource.
TagGetScale	Gets the value of a tag at a specified scale from the datasource
TagSubscribe	Subscribes a tag for periodic monitoring and event handling.
TagUnsubscribe	Unsubscribes a tag for periodic monitoring and event handling.

**Tag Functions**

TagInfoEx	Supports online changes.
TagWriteEventQue	Opens the tag write event queue.

**Task Functions**

TaskCluster	Gets the name of the cluster context in which the current task is executing
-------------	---

**Trend Functions**

TrnBrowseClose	Closes a trend browse session.
TrnBrowseFirst	Gets the oldest trend entry.
TrnBrowseGetField	Gets the field indicated by the cursor position in the browse session.
TrnBrowseNext	Gets the next trend entry in the browse session.
TrnBrowseNumRecords	Returns the number of records in the current browse session.
TrnBrowseOpen	Opens a trend browse session.
TrnBrowsePrev	Gets the previous trend entry in the browse session.

TrnGetCluster	Gets the name of the cluster the trend graph is associated with.
TrnGetPenComment	Gets the comment of a trend pen.

**Report Functions**

RepGetCluster	Retrieves the name of the cluster the report is running on.
---------------	---

**Modified Functions****Alarm Functions**

AlarmAck	Acknowledges alarms.
AlarmAckRec	Acknowledges alarms by record number
AlarmActive	Determines if any alarms are active in the user's area.
AlarmClear	Clears acknowledged, inactive alarms from the active alarm list.
AlarmClearRec	Clear an alarm by its record number
AlarmDelete	Deletes alarm summary entries.
AlarmDisable	Disables alarms.
AlarmDisableRec	Disables alarms by record number
AlarmDsp	Displays alarms.
AlarmDspLast	Displays the latest unacknowledged alarms.
AlarmEnable	Enables alarms.
AlarmEnableRec	Enables alarms by record number
AlarmFirstTagRec	Searches for the first occurrence of an alarm tag, name, and description
AlarmGetDelayRec	Gets the delay setting for an alarm via the alarm record number
AlarmGetFieldRec	Gets alarm field data from the alarm record number
AlarmGetThresholdRec	Gets the thresholds of analog alarms by the alarm record number
AlarmNextTagRec	Searches for the next occurrence of an alarm tag,

	name, and description.
AlarmNotifyVarChange	Activates a time-stamped digital or time-stamped analog alarm
AlarmSumAppend	Appends a new blank record to the alarm summary.
AlarmSumCommit	Commits the alarm summary record to the alarm summary device.
AlarmSumDelete	Deletes alarm summary entries.
AlarmSumFind	Finds an alarm summary index for an alarm record and alarm on time.
AlarmSumFirst	Gets the oldest alarm summary entry.
AlarmSumGet	Gets field information from an alarm summary entry.
AlarmSumLast	Gets the latest alarm summary entry.
AlarmSumNext	Gets the next alarm summary entry.
AlarmSumPrev	Gets the previous alarm summary entry.
AlarmSumSet	Sets field information in an alarm summary entry.
AlarmSumSplit	Duplicates an alarm summary entry.
AlarmSumType	Retrieves a value that indicates a specified alarm's type.

**I/O Device Functions**

DriverInfo	Provides information about the driver for a particular I/O Device.
IODeviceControl	Provides control of individual I/O Devices. The I/O device client operations used by the function (via the mode parameter) are no longer available.
IODeviceInfo	Gets information on an I/O Device.

**Miscellaneous Functions**

AccControl	Controls accumulators for example motor run hours.
ServerInfo	Gets client and server information.
ServerInfoEx	Gets client and server information from a specified process in a multiprocessor environment.
Shutdown	Ends Plant SCADA's operation.

**Report Functions**

RepGetControl	Gets report control information.
Report	Runs a report.
RepSetControl	Sets report control information.

**SPC Functions**

SPCALarms	Returns the status of the specified SPC alarm.
SPCProcessXRSGet	Gets the process mean, range and standard deviation overrides.
SPCProcessXRSSet	Sets the process mean, range and standard deviation overrides.
SPCSpecLimitGet	Gets the specification limits (USL and LSL) for the specified tag.
SPCSpecLimitSet	Sets the specification limits (USL and LSL) for the specified tag.
SPCSubgroupSizeGet	Gets the size of a subgroup for the specified SPC tag.
SPCSubgroupSizeSet	Sets the subgroup size for the specified SPC tag.

**Super Genie Functions**

Ass	Associates a variable tag with a Super Genie.
AssPage	Associates up to eight variable tags with a Super Genie and displays the Super Genie in the current window.
AssPopUp	Associates up to eight variable tags with a Super Genie and displays the Super Genie in a popup window.
AssTag	Associates a variable tag with the current Super Genie. The association will be created for the current Super Genie only, and will only come into effect after you re-display the Super Genie.
AssVarTags	Associates up to eight variable tags with a Super Genie. This association is only made for the next Super Genie you display (either in the current window or in a new window). You can use this function repeatedly to associate more than 8 variable tags to a Super Genie.
AssWin	Associates up to eight variable tags with a Super Genie, and displays the Super Genie in a new window.

**Tag Functions**

TagGetProperty	This function reads a property of a variable tag from the datasource
TagGetScale	Gets the value of a tag at a specified scale from the datasource
TagRamp	This function will increment a Tag by the amount defined by iPercentInc
TagRead	Reads a variable from the I/O Device
TagScaleStr	Gets the value of a tag at a specified scale
TagWrite	Writes to an I/O Device variable by specifying the variable tag.

**Task Functions**

MsgOpen	Opens a message session with a Plant SCADA server or client.
---------	--

**Trend Functions**

TrendDspCursorTag	Displays the tag name of the current pen.
TrnAddHistory	Restores an old history file to the trend system.
TrnDelHistory	Deletes an old history file from the trend system.
TrnEventSetTable	Sets trend data from a table, for a specified trend tag.
TrnEventSetTableMS	Sets event trend data and time data (including milliseconds) for a specified trend tag.
TrnFlush	Flushes the trend to disk.
TrnGetDefScale	Gets the default engineering zero and full scales of a trend tag.
TrnGetPen	Gets the trend tag of a pen.
TrnGetTable	Stores trend data in an array.
TrnInfo	Gets the configured values of a trend tag.
TrnNew	Creates a new trend at run time.
TrnSelect	Sets up a page for a trend.

**Window Functions**

WinCopy	Copies the active window to the Windows clipboard.
WinFile	Writes the active window to a file.
WinNewAt	Opens a new display window at a specified location, with a selected page displayed.
WinPrint	Prints the active window.

## Obsolete Functions

### Cluster Functions

ClusterGetName	Returns the names of the primary and standby cluster servers. Has been replaced with the cluster specific events parameter formatted as [ServerType.ClusterName.ServerName]Events
ClusterSetName	Connects to a specific cluster server. Has been replaced with the cluster specific events parameter formated as [ServerType.ClusterName.ServerName]Events

### Display Functions

DspCol	Displays a color at an AN.
--------	----------------------------

### Task Functions

ReRead	<p>Causes Plant SCADA to re-read the I/O Device data associated with the current Cicode task.</p> <p>Tags are now subscribed at the start of a function and updated tag values are sent to the subscribing function.</p> <p>Tag subscriptions are made at the update rate of:</p> <ul style="list-style-type: none"> <li>• the graphics page if called from a page</li> <li>• the default subscription rate as determined by [Code]TimeData in the Parameters online help if called from Cicode (default 250 ms)</li> <li>• the update rate requested of a task created using TaskNewEx</li> <li>• the update rate requested of a subscription created using TagSubscribe</li> </ul> <p>Verify that the subscription update rate matches the requirements of your function.</p> <p>After removing ReRead from looping code you may</p>
--------	--

	<p>need to extend the period of the Sleep function. This is to replace the pause ReRead created while it read the tag values.</p> <p><b>Note:</b> The parameter[Code]TimeData is used to set the Cicode refresh rate. when using the TaskNew Cicode function, use mode 4 to replace ReRead at the start of the function.</p>
--	--

## CtAPI Functions in 7.0

The following section details the changes made to CtAPI functions in Plant SCADA 7.0.

### Obsolete Functions

Previously available "Point" related functions are now no longer available, and if used will detect and return an error indicating that they are not supported. In order to obtain the same result as was previously invoked by those function, replace them with the Tag based equivalent using the appropriate Tag arguments and conditions. The "point" functions that are no longer available are listed below along with their replacement functions:

Function	Replacement
ctPointGetProperty	ctTagGetProperty
ctPointNew	ctListNew or ctTagWrite and ctTagRead
ctPointRead	ctTagRead or ctListRead with ctListData
ctPointWrite	ctTagWrite or ctListWrite

If you are using the point functions on single tags, use the ctTagRead, ctTagWrite functions instead. If you are building up multiple tags into one point, use ctListNew and add tags to the list through ctListAdd. Then use ctListWrite, ctListRead and ctListData to write and read from the tags.

The following functions are not relevant to tag based operations. They are obsolete and there is no replacement function.

- ctPointBitShift
- ctPointClose
- ctPointCopy
- ctPointSize
- ctPointToStr
- ctStrToPoint
- ctTagToPoint

## Kernel Commands in Version 7.0

The following Kernel commands are obsolete in Plant SCADA from Version 7.0:

- Kernel Alarm
- Kernel Trend
- Kernel Report
- Kernel IOServer
- Kernel Client
- Probe
- NetBIOS
- PageNetstat

# About Plant SCADA

AVEVA Plant SCADA is a Supervisory Control and Data Acquisition (SCADA) solution that is used to manage and monitor processes in manufacturing, primary production, utilities delivery and facilities management.

Plant SCADA can be configured as a standalone or a distributed client-server system, including native redundancy and load sharing capabilities. Plant SCADA's client-server architecture allows system components to be distributed across a number of computers on a LAN, creating a system that offers geographical flexibility and performance benefits over standalone systems.

For detailed information on Plant SCADA, see:

- [Working with Plant SCADA](#)
- [Typical System Scenarios](#)
- [Licensing](#)
- [Upgrade Plant SCADA](#)
- [What's New in Plant SCADA](#)
- [What's New - Previous Releases](#)

## Working with Plant SCADA

This section of the help provides an overview of Plant SCADA by introducing the fundamental activities you need to consider when building and operating a system. They include the following:

- [Configure Plant SCADA Projects](#)
- [Define a Topology](#)
- [Build a System Model](#)
- [Create Graphics Pages](#)
- [Secure Your System](#)
- [Compile and Run a Project](#)
- [Deploy a Project.](#)

These steps outline a typical work flow that is reflected in Plant SCADA Studio and runtime tools.

## See Also

[Plant SCADA Studio](#)

## Configure Plant SCADA Projects

Everything you create and configure for a Plant SCADA system is stored in projects. This can include graphic pages, variable tags, alarms, communications settings, equipment definitions, programming content, and so on.

Plant SCADA allows you to work with projects in a way that logically reflects the architecture of the SCADA system. If the system you are building represents a large production facility, you could manage the required content using multiple projects that operate in tandem. Each project could represent a geographical area within the plant, or a particular production flow.

- **Included Projects**

To enable the runtime integration of multiple projects, Plant SCADA allows you to "include" a project within another project. This means you can share content across a number of projects while maintaining each as a separate entity.

For example, you could create separate projects to represent each of the production lines within a factory. You could then include these projects in a main project that represents the whole factory. By doing this, you are able to develop and test the included projects independently.

- **System Projects**

Plant SCADA also comes with a number of system projects that you can include in the projects you create. These projects contain pre-configured content (such as page templates and control objects) that you can add to your own content.

This framework is fully realized with Plant SCADA's "starter projects". A starter project allows you to create a new project that includes the basic components required to start building your own system. A set of Plant SCADA's system projects are automatically included in any new projects you create (based on a selected template style), which means a complete set of page templates and library controls are ready for you to use.

To prepare a project for use in a runtime environment, you need to compile it and distribute the required files to the computers that will be engaged in the runtime system. This initially requires the creation of a system topology (see [Define a Topology](#)).

For more information, see [Plant SCADA Projects](#).

## Define a Topology

Plant SCADA supports a client-server network architecture. This provides the flexibility to adapt a Plant SCADA system to any production scenario, with support for scalability, server clustering, and system redundancy. When you define a topology, you are identifying the **computers** and **I/O devices** that are built into this architecture, and the role each will perform at runtime.

## Computers

In a Plant SCADA system, a computer can act as a server, or a client, or both. Servers are used to manage communication with plant equipment and collate production data, while clients provide the interface to assess and interact with the system. A topology allows you to view how your servers and clients are arranged.

There are several different types of server processes used in a Plant SCADA system. These include:

- Alarms server process
- I/O server process
- Trends server process
- Reports servers process.

How you arrange these sever process types across the computers included in your system topology will be determined by the following:

- **Operational requirements** — a standalone system may contain a single computer that hosts every component of a system, whereas a distributed system may have a separate computer dedicated to each server type.
- **Redundancy** — the servers associated with a system can be duplicated and defined as primary and standby units, allowing the system to keep running if one of the servers becomes inoperative.
- **Clusters** — Clustering allows you to group independent sets of Plant SCADA's server components within a single project, allowing multiple systems to be monitored and controlled simultaneously. The clusters offer the benefit of keeping a logical structure to the project during configuration.

Plant SCADA's configuration environment allows to you view a system topology as a computer-based view or a cluster-based view.

## I/O Devices

I/O devices can include any control or monitoring equipment with a communication port or data exchange interface, such as programmable logic controllers, loop controllers, bar code readers, scientific analyzers, remote terminal units, or distributed control systems.

To incorporate an I/O device into a system topology, you will need to install the relevant driver. A driver allows an I/O device to communicate with a Plant SCADA I/O server.

You also need to configure the various components required to enable runtime communication with the device. This can include boards, ports and modems. You will need to consider the following:

- **Transport medium** — the physical communications medium and the low-level logic necessary to drive it.
- **Protocol** — typically a device will support an industry-standard communications protocols, such as Modbus, OPC, DNP 3.0 or BACnet. This will, however, depend on the device.

Much of the functionality supported by the protocols and transports you select can be modified using the driver options and parameters. Each driver has its own specific section in the online help that will guide you through configuration options.

To help you get started, Plant SCADA includes a Device Communications Wizard that can assist with the configuration of the communications settings for a particular device.

## Build a System Model

You can use a System Model to organize a Plant SCADA project in a way that reflects the physical production system. This will simplify the configuration of a project, and deliver inherent logic when the project is executed at

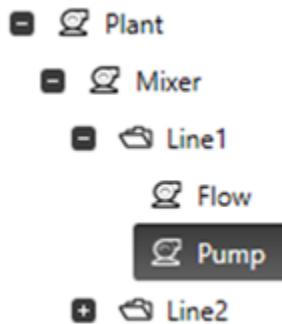

runtime.

You can build a System Model into a project through equipment definitions and tags.

## Equipment

Equipment facilitates the creation of an object-oriented System Model in a Plant SCADA project. This allows you to logically reference production system hardware based on its location in an equipment hierarchy.

Equipment definitions use dot notation to indicate levels within this hierarchy. For example, the equipment name "Plant.Mixer.Line1.Pump" refers to the current selection in the following equipment hierarchy:

Each piece of equipment become a parent to the tags that are associated with it. At runtime, the hierarchy can be used to search and display information in a way that is logically aligned with your System Model.

## Tags

In a Plant SCADA project, you use tags to label the inputs and outputs on your production system hardware. They can include **variables**, **trends**, **alarms**, **accumulators**, and so on.

A structured tag naming strategy that logically reflects geographical areas or processes within a plant is an example of a way you can use tags to implement a simple System Model. This type of approach means the purpose of each tag is inherently clear through its name.

To configure tags and equipment in a Plant SCADA project, you use the **System Model** activity in Plant SCADA Studio.

- [Variable Tags](#)
- [Trends](#)
- [Accumulators](#)

## Create Graphics Pages

Graphics pages present the content that appears on a Plant SCADA display client at runtime. They create the visual interface an operator uses to monitor and control a production system.

With graphics pages, you can:

- Use animated objects to display the operating status and performance of a plant
- Provide operators with centralized or local control of production equipment using graphical tools and keyboard commands
- Implement historical trending of tag data in a graphical format
- Develop a multi-layered security system that controls user access according to functional or geographical areas.

Graphics pages are created and edited using **Graphics Builder** or the **AVEVA™ Industrial Graphics Editor**. You can also browse and manage pages and library items in the **Visualization** activity.

To help you create graphics pages, Plant SCADA supports page templates. Templates can incorporate standard navigation and support tools that are common across a set of functional page layouts. This delivers a consistent look and feel to a runtime system.

To create a project based on one of the template sets included with Plant SCADA, you can use a [Create a Project Using a Starter Project](#). Any project that is created from a starter project will also include a set of library objects that you can add to your graphics pages, such as **Genies** and **Super Genies** (controls that can be passed information at runtime).

## See Also

- [Visualization](#)
- [Graphics Builder](#)
- [AVEVA Industrial Graphics](#)

## Secure Your System

A Plant SCADA system is protected by implementing a user-based security model. When planning a project, you need to consider who will be using the system and the areas they will need to access.

There are two ways you can manage user accounts:

- **Integrated Windows security** (recommended) — Windows user accounts are used to access Plant SCADA computers. The security measures specified for the local network domain will apply.
- **Plant SCADA security** — user accounts are created within the Plant SCADA project. They can be organized into groups.

In both cases, access to the Plant SCADA system is managed by assigning user accounts to "roles" defined within a project. Roles specify for a particular type of user:

- The areas they will be able to access
- The privileges they will have.

Roles and Plant SCADA user accounts are configured using the **Security** activity.

You can also [Securing Runtime Computers](#), or run Plant SCADA as a [Windows service](#).

## See Also

[Security](#)

[Roles](#)

## Compile and Run a Project

Whenever you modify a Plant SCADA project, you need to compile it to incorporate the changes you have made. Compiling a Plant SCADA project assembles the included content (such as configuration databases, graphics and Cicode files) and prepares it for runtime. If required, error notifications will display in the Compile Messages area of Plant SCADA Studio.

Runtime activates a project and engages it with the production system. Staff can visually monitor the system, initiate production processes and respond to alarm conditions. Historical and trend data can also be collated and distributed to assess operational performance metrics such as production volume, efficiency, and maintenance requirements.

A set of runtime tools are available to support this:

- **Runtime Manager** — an application used to manage and control the CPU configuration of the project, and the running state of each component. See [Runtime Manager](#)
- **Process Analyst** — an Active X control that allows you to compare and analyze historical and real-time trend and alarm data during runtime. See [Process Analyst](#).
- **Scheduler** — a calendar-based tool that allows you specify how a piece of equipment will operate at a particular time. See [Scheduler](#).

## See Also

[Compile](#)

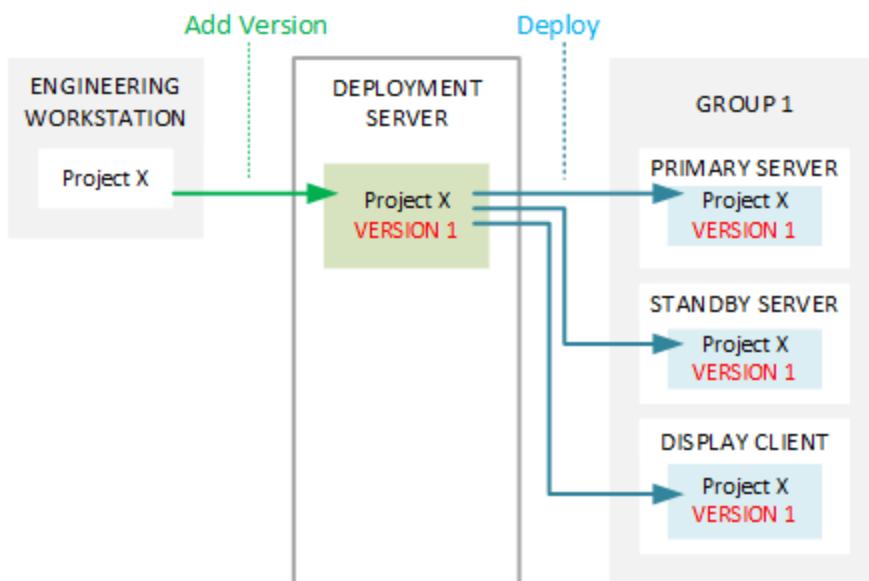

[Runtime](#)

## Deploy a Project

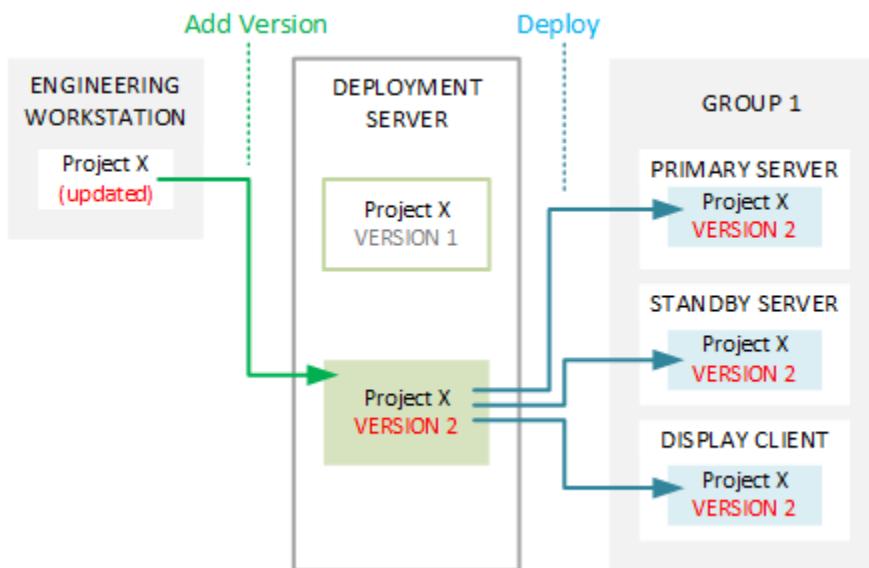

To engage in a runtime system, each computer in a Plant SCADA topology requires a copy of a project's runtime files. To help you distribute these files, Plant SCADA supports a deployment server.

The deployment server stores runtime files as "versions" and distributes them to deployment clients across an encrypted connection. Each version is created by adding a project to the deployment server.

In the diagram below, Project X has been configured on an engineering workstation. A version of the project is added to the deployment server as "Version 1". The project's runtime files can then be deployed to the computers included in a group named "Group 1".

If any changes are made to Project X, a new version of the project is simply added to the deployment server, allowing version 2 to be deployed.

To enable deployment, you firstly need to set up the deployment server and establish a connection to each deployment client using a tool called the Configurator.

You can then use the **Deployment** activity in Plant SCADA Studio to manage and distribute project versions.

[Deployment](#)

## Typical System Scenarios

The scenarios described in this section of the help demonstrate how Plant SCADA can be used to support typical

processes found in primary production, utilities delivery, and manufacturing.

In reality, a project will incorporate a combination of the scenarios described here, with a high degree of customization and scalability. However, these examples have been simplified to demonstrate how Plant SCADA can be configured and deployed to meet the specific requirements of a production system.

System Type	Description
Standalone	Every component of a system runs on a single computer. See <a href="#">Standalone System</a> .
Distributed I/O	Plant SCADA is used to monitor and manage distributed devices that are each connected to remote I/O servers. See <a href="#">Distributed I/O System</a> .
Redundant Server	One or more of the servers associated with a system are duplicated and defined as primary and standby units, allowing the system to keep running in the event one of the servers becomes inoperative. See <a href="#">Redundant Server System</a> .
Client-server	The servers and clients associated with a system are independently distributed across a number of computers on a network, offering greater accessibility and performance benefits. See <a href="#">Client-Server System</a> .
Redundant and Distributed Control	Remote or geographically separate sections of a production system have fully operational sub-systems in place that are monitored and controlled locally. If such a sub-system becomes partially or wholly inoperative in a manner preventing local control, this arrangement allows remote Control Clients to take control of the affected sub-system. See <a href="#">Redundant and Distributed Control System</a> .
Cluster Controlled	A production system is organized into discrete areas being monitored by operators within each area. However, there is also a level of control that supervises every area of the system. See <a href="#">Clustered Control System</a> .
Load Sharing System	The system splits the load of an otherwise stressed system across multiple machines, better utilizing the available infrastructure. See <a href="#">Load Sharing System</a> .

## See Also

[Clusters](#)

[Redundancy](#)

## Standalone System

A standalone installation of Plant SCADA runs every server and client component of a system on a single computer. These include:

- I/O server
- Alarm server
- Trends server
- Reports server
- Control client.

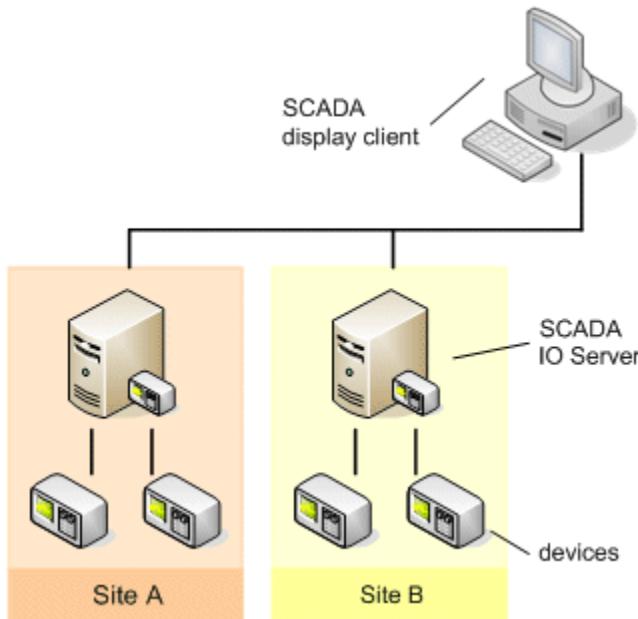

This allows Plant SCADA to be run as a small, self-contained system.

**Note:** You can run the server and client components of a standalone system as a single-process or multi-process system. It is recommended that a single- process setup only be used as a short term solution for your control system, or to run demonstrations and test projects. Adding redundancy to your system will make it more reliable and more efficient.

## Distributed I/O System

This scenario demonstrates a method of connecting Plant SCADA to a number of devices that are distributed across several sites over a wide geographical area.

Instead of attempting to connect devices directly via a remote connection, an I/O server is placed at each site, enabling communication to be managed within the system.

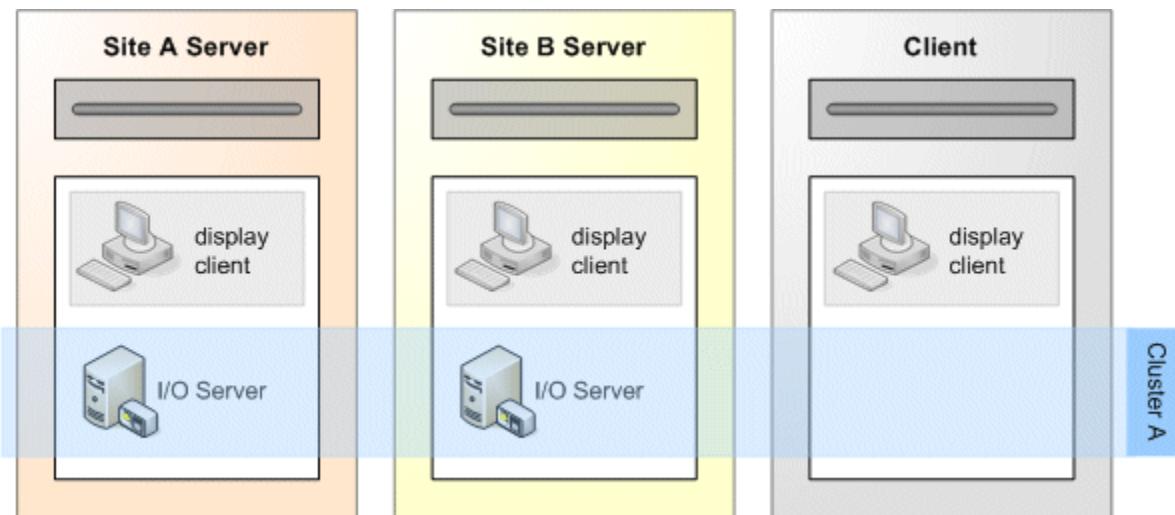

This model is also useful in plants that contain devices with a serial port or limited communications capabilities. By placing I/O servers on the factory floor to interface with these devices, you can optimize communications on slow or low-bandwidth networks and improve overall performance.

Despite the geographical distribution of I/O servers across many sites, this type of system can be configured as a

single cluster system, as a cluster is able to support many I/O servers.

The diagram below demonstrates how to approach the deployment of this type of system across the server machines using a single cluster.

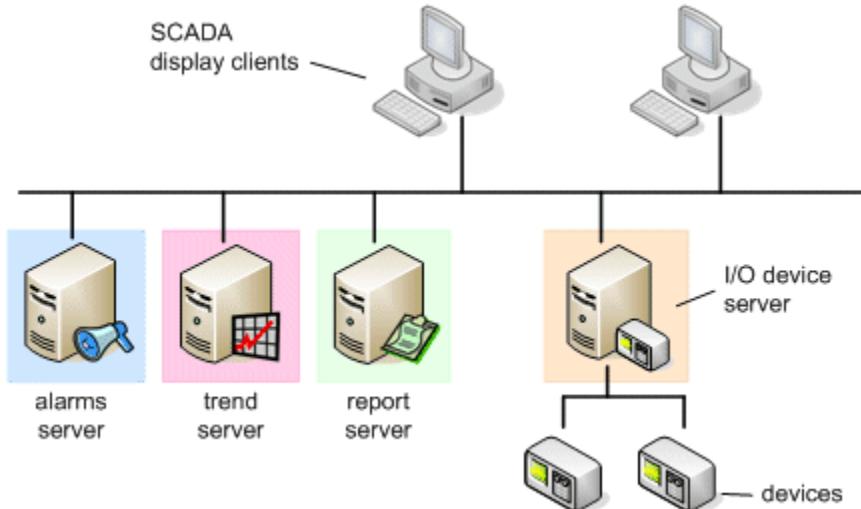

A second cluster will only become necessary if your project requirements call for more than one redundant pair of alarms, trends or reports servers.

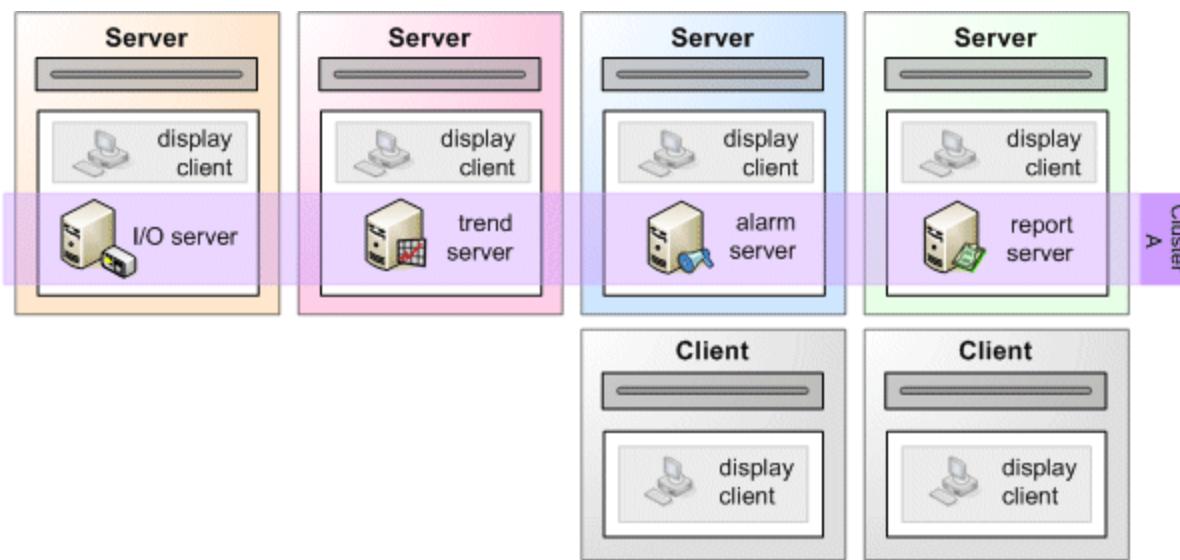

## Client-Server System

Plant SCADA's client-server architecture allows the components of a system to be distributed across a number of computers on a LAN, creating a system that offers geographical flexibility and performance benefits.

Each component is simply identified within the project by an address, allowing the location and hardware requirements for each to be considered independently.

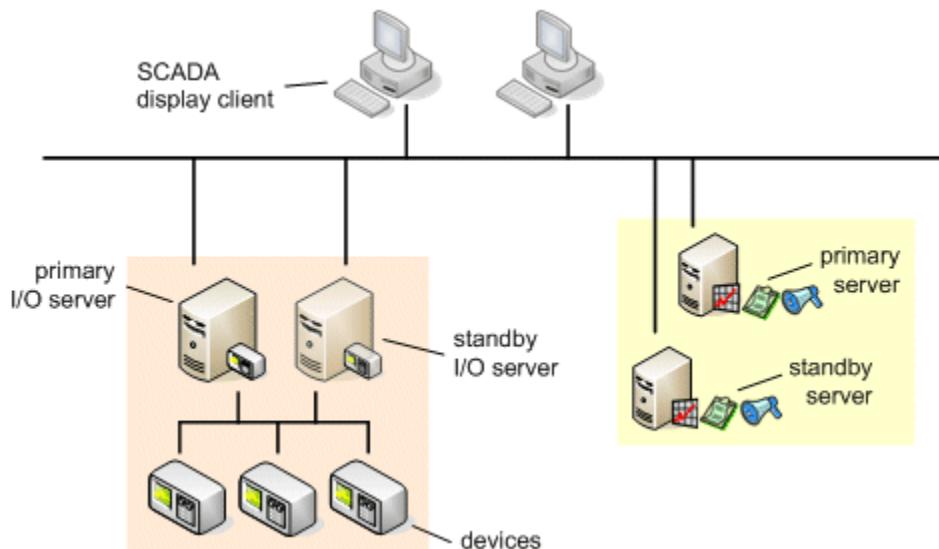

The diagram below demonstrates how this example can still be configured within a single cluster.

Each server also acts as a display client across the system architecture.

## Redundant Server System

The ability to define primary and standby servers within a project allows hardware redundancy to be built into your system infrastructure. This helps prevent situations where an error on one server results in the overall system becoming inoperative. Systems of this type are especially beneficial when service continuity and/or secure data collection are important.

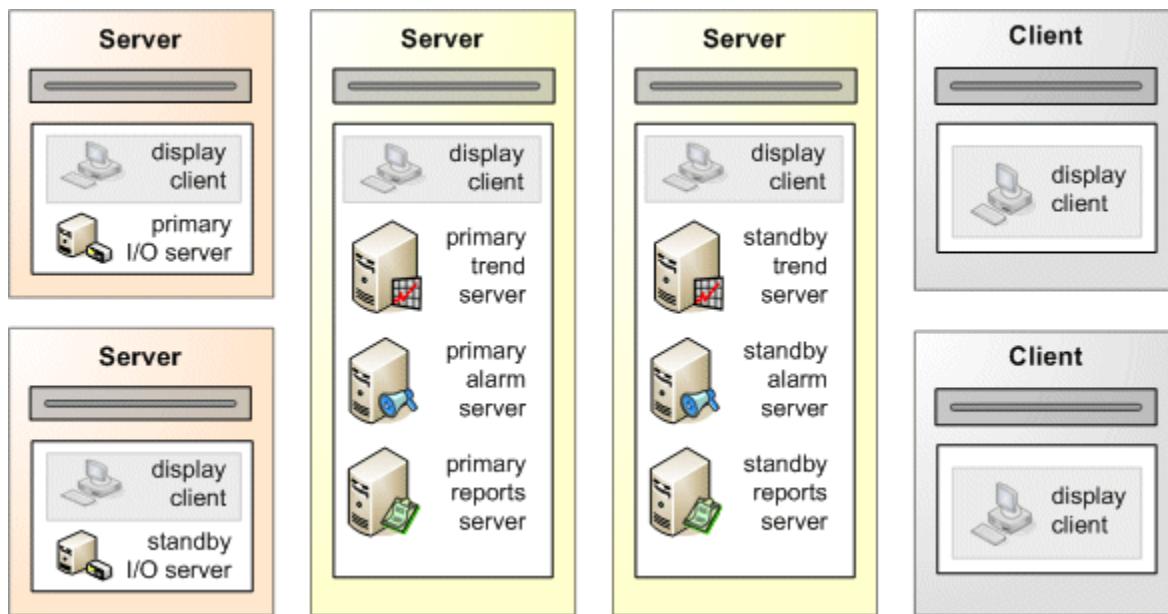

In the case of I/O server redundancy, a standby server is maintained in parallel to the primary server. If a hardware error is detected, the standby server can assume control of device communication with minimal interruption to the system. You can also use redundant I/O servers to split the processing load.

Alarm, report and trends servers can also be implemented as redundant servers. This improves the likelihood that clients will continue to have access to data from a standby server in the case a primary server becomes inoperative. Plant SCADA maintains identical data on both servers.

In the diagram below, the primary and standby I/O servers are deployed independently, while the alarms, trends

and reports servers are run as separate processes on common primary and standby computers. In this case, the entire system can be configured as a single cluster.

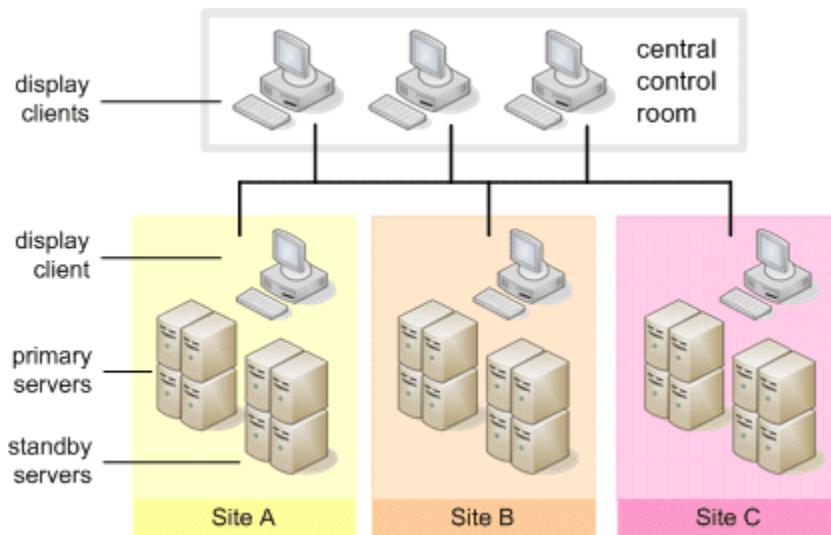

## See Also

[Redundancy](#)

## Clustered Control System

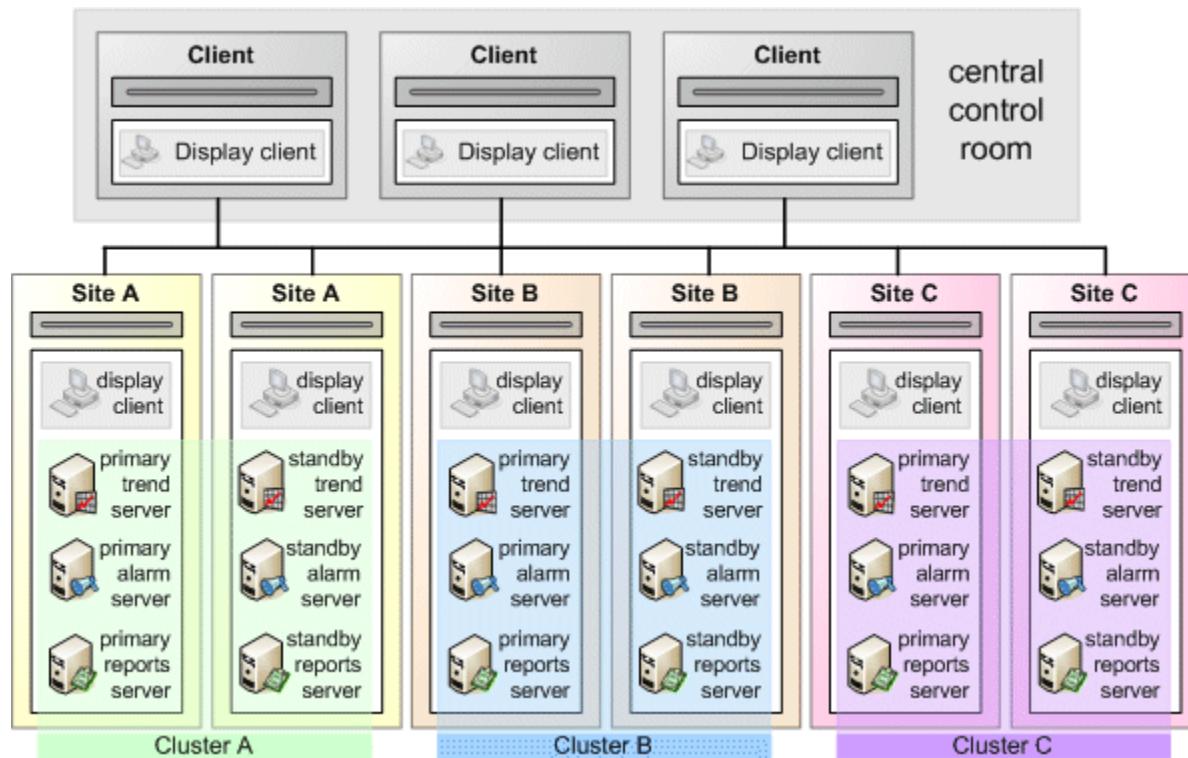

In this scenario, the system is organized into discrete sites being controlled by local operators, and supported by local redundant servers. At the same time, there is a level of management that requires sites across the system to be monitored simultaneously from a central control room.

Each site is represented in the project with a separate cluster, grouping its primary and standby servers. Clients at each site are only interested in the local cluster, whereas clients at the central control room are able to view every cluster.

The deployment of a control room scenario is straightforward, as each site can be addressed independently within its own cluster. The control room itself only needs control clients.

The deployment of servers could be mapped out as follows:

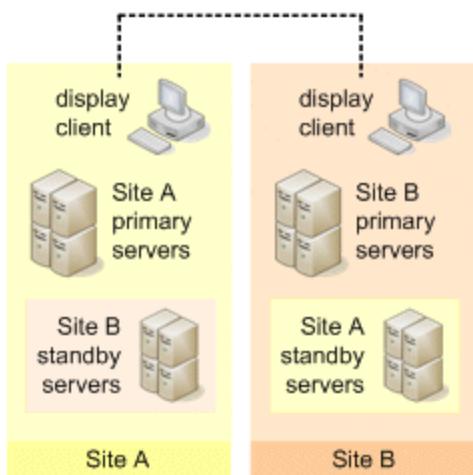

Plant SCADA's support for dynamic clustering means each site can be monitored and controlled from the central control room if necessary. For example, if an operator at a particular site only works during regular business hours, then the monitoring can be switched to the central control room after hours.

## Redundant and Distributed Control System

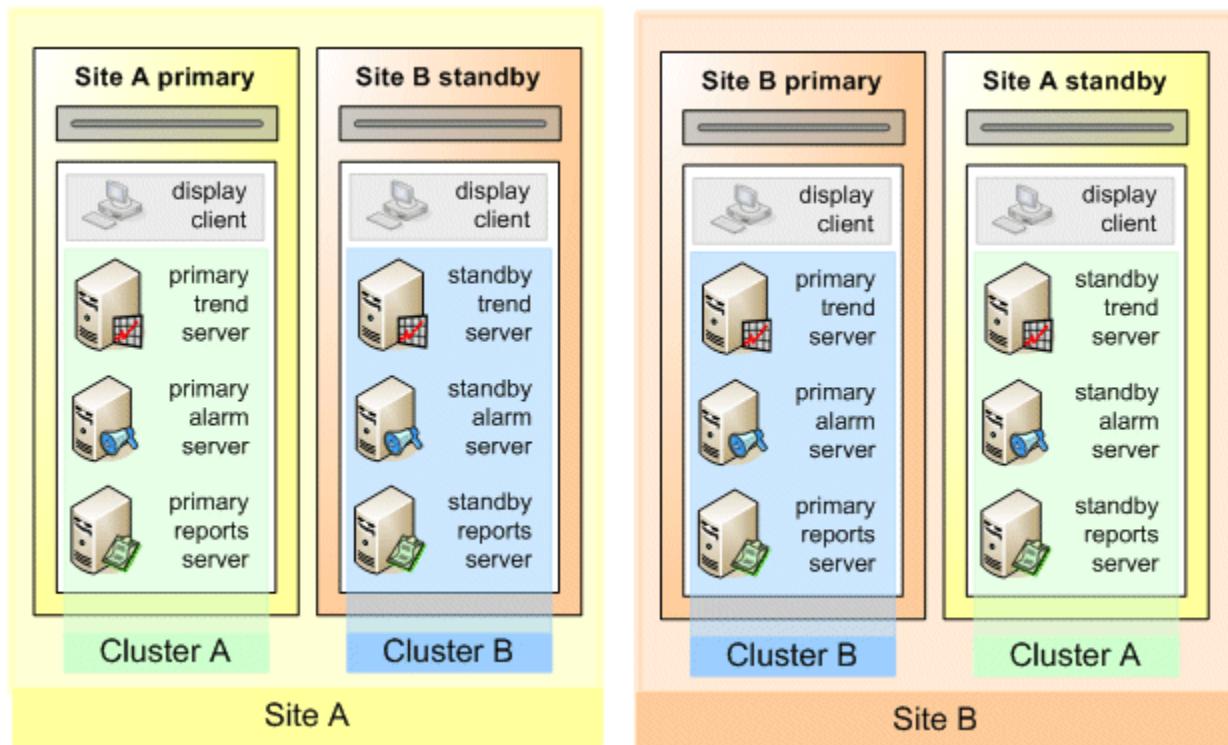

In this scenario, a project represents a number of locally operated sites each containing its own set of servers and clients. For example, a number of pumping stations across a water distribution system, or multiple production lines in a manufacturing facility. However, there is a requirement for monitoring to continue in the event the system at one of the sites becomes inoperative.

This is achieved by distributing the primary and standby servers across the different sites, or by placing the standby servers in a central location.

Clustering is used to define the role of the different servers at each site, which can be viewed in a common project running on every client. This means Site A can be monitored from Site B, and vice versa, if a system becomes inoperative at one of the sites.

The example above would require the creation of two clusters, so that the project can include two sets of primary and standby servers. The clusters represent the redundant pairs of servers, and would be deployed across the two sites as follows:

The clusters offer the benefit of keeping a logical structure to the project during configuration, despite the unusual distribution of redundant server pairs.

## Load Sharing System

Load sharing of system components across different computers and CPUs means the work load of a potentially stressed system can be split across multiple machines, better utilizing the available infrastructure.

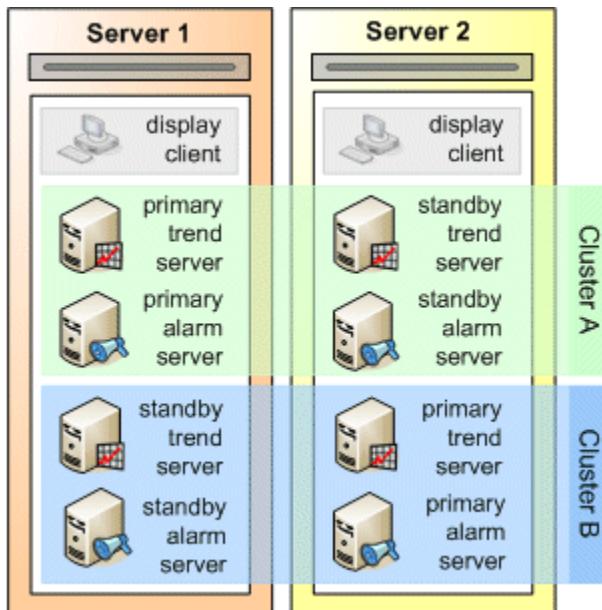

For example, managing alarms can draw heavily on a CPU's performance, while trending data can use a lot of disk space. By assigning your trends and alarm servers to different processes on a shared computer, an alarm

server can be used as a standby trends server, making practical use of idle disk space.

This approach can be used to improve network performance, data access times, and general system stability.

If you introduce clustering, you have the flexibility to run multiple servers of the same type on a single computer. As long as a client has access to every cluster configured in a project, it doesn't matter if a set of servers is distributed across a number of clusters.

In the diagram below, two servers have been configured to act as standby units for each other, supporting two sets of redundant trends and alarm servers.

Both machines have an even balance of trends and alarm servers, making effective use of the CPU and disk space. By distributing the servers across two clusters, the servers are also able to act as redundant units to each other. This has reduced the necessary number of computers from a maximum of eight down to just two.

## Licensing

To determine the licensing requirements for a Plant SCADA system, you firstly need to consider the roles assigned to your runtime computers. Roles are used to define how a computer will function within a runtime system. There are four options:

- Server
- Control client
- View-only client
- Standalone HMI (a system on a single computer with no networking).

A role is specified for a computer using the [Computer Role](#) page of the Setup Wizard, or via the Citect.ini parameter [\[Client\]ComputerRole](#).

The computer roles align with the different license types that are supported by Plant SCADA. When licenses are allocated at runtime, it is the role that determines the type of license a computer will attempt to retrieve. This process also takes into account the following:

- A server license also provides authorization for a single control client license.
- A computer running as a server only needs one license, even if it is running multiple server processes.

**Note:** Every runtime computer includes a client process that manages license acquisitions. If you shut down the client process, licensing will stop working for all other local processes.

---

This means you need to consider the following before you implement the licensing for a Plant SCADA system.

- The number of computers that are assigned to each role in your runtime system.
- The number of licenses you have for each computer type.
- Where the licenses will be stored.
- How the licenses will be retrieved by each computer.

This will largely be determined by the licensing technology you use; **AVEVA Enterprise Licensing** (software based) or **Sentinel Licensing** (USB keys).

**Note:** You cannot run both licensing systems on the same Plant SCADA computer.

---

- **AVEVA™ Enterprise Licensing**

The AVEVA Enterprise Licensing system is a common platform solution that allows you to manage AVEVA Enterprise Software product licenses.

The system is comprised of a browser-based License Manager and a License Server that allow you to share and deliver licenses for your installed AVEVA applications. This distributed architecture provides the following benefits:

- Centralized license management.
- Increase license security through the use of activated licenses.
- Flexible topologies for any size system.

You can use Plant SCADA Studio to launch Enterprise License Manager from any installed location within your Plant SCADA system. See [Launch Enterprise License Manager from Plant SCADA Studio](#).

**Note:** The AVEVA Enterprise Licensing system is required for Industrial Graphics applications.

---

For more information, see [AVEVA™ Enterprise Licensing](#).

- **Sentinel Licensing (using USB keys)**

Sentinel Licensing is a legacy licensing solution for Plant SCADA. It uses physical USB keys that plug in to each computer in your Plant SCADA system. The USB key contains details of your user license, such as its type and I/O point count.

When a USB key is detected on a computer, all of the available licenses are loaded into runtime. Any additional licenses that are not used by the local computer are then made available to other computers. This is enabled via a floating license mechanism that allows server computers to allocate licenses to clients.

You are occasionally required to update your Sentinel keys, for example, when you upgrade to a new version of Plant SCADA. To do this, you need to retrieve an authorization code from AVEVA's online License Generator. See [Update a Sentinel Key with CiUSAPE](#).

In both cases, Plant SCADA uses a [Dynamic Point Count](#) to determine if your system is operating within the limitations of your license agreement. This process tallies the number of I/O device addresses being used by the runtime system.

A point limit is allocated to each type of license included in your license agreement.

If required, you can specify how many points will be required by a particular computer (see [Specify the Required Point Count for a Computer](#)).

---

**Note:** With the release Plant SCADA 2023, Schneider Electric's Floating License Manager is no longer supported. Existing users of the Floating License Manager will need to reconfigure their system to use AVEVA Enterprise Licensing.

---

[Demo Mode](#)

## AVEVA™ Enterprise Licensing

The AVEVA Enterprise Licensing system is a common platform that allows you to manage AVEVA Enterprise Software product licenses.

The system was introduced to allow centralized license management, remove the need for dongles, and increase license security by use of activated licenses. It supports flexible topologies for any size system.

The following describes the components of the AVEVA Enterprise Licensing system.

### **License Manager**

The License Manager allows you to access and maintain licenses for certain AVEVA Enterprise Software products in your different environments using its scalable, flexible design features:

- Browser-based for scalability and ease of use; can be remotely accessed by any of the supported web browsers.
- Light-weight, standalone software you can install on the same node as the License Server computer, or on any other node based on your deployment needs.
- Manage one or multiple License Servers to organize the licensing requirements for your environment.
- Access details about your licenses, such as usage information, from the License Manager interface.

You can use Plant SCADA Studio to launch Enterprise License Manager from any installed location within your Plant SCADA system. See [Launch Enterprise License Manager from Plant SCADA Studio](#).

### **License Server**

License Server provides the functionality to acquire, store, maintain, and serve licenses to your installed AVEVA Enterprise software.

- Licenses are hosted and maintained on the License Server.
- Securely serve any type of software applications being licensed, including Windows browsers, tablets, and mobile devices.
- Provide current license usage information.

---

**Note:** Plant SCADA 2023 R2 allows you to run your AVEVA Enterprise License Server in **Secure Mode**. This facilitates encrypted communication for any Plant SCADA computers that connect with your license server to acquire licenses. For more information, see *Running in Secure Mode* in the topic [Use Configurator to Set Up an Enterprise License Server](#).

---

### [Activation Server](#)

Activation Server is a cloud-based Internet-accessible server to which the License Manager connects for license activation. The License Manager connects to the AVEVA Activation Server in the Cloud only temporarily during the activation process.

### Installed Products

Once the AVEVA Enterprise Software product is installed it relies on the licensing system to enable its functionality. Following installation, you use Configurator to specify from which License Server you want the product to get its license.

- If a License Server is installed on the same computer as the product, it will be selected in Configurator by default.
- If the product is installed on a different computer than the License Server, you can use Configurator to point the product to the required License Server computer.

You need to configure the connection to the License Server for any computers that need to acquire licenses. See [Use Configurator to Set Up an Enterprise License Server](#).

All AVEVA products installed on the same computer need to point to the same License Server.

If you are implementing a distributed topology, we recommend creating a network diagram as an initial step. This will allow you to visually model your system before you decide where to install the License Manager and License Server components. For more information, see [AVEVA™ Enterprise Licensing Topologies](#).

---

**Note:** When working with virtual environments, you need to deactivate all licenses in a License Server before cloning a virtual machine. If this is not done, the cloned License Server will go into Grace Period mode of 15 days, after which it will cease serving licenses.

---

[Enterprise License Server Installation Requirements](#)

[Enterprise License Server Installation Procedure](#)

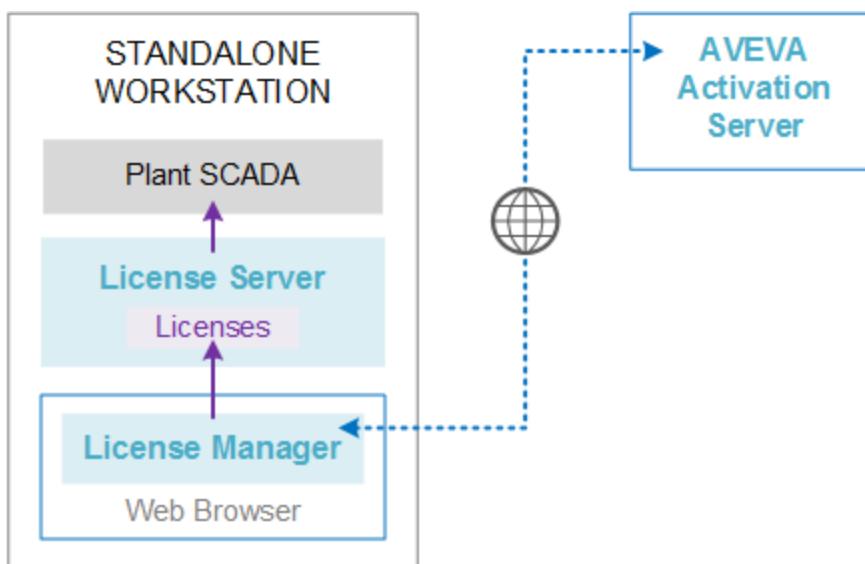

## AVEVA™ Enterprise Licensing Topologies

Use the models described in this topic to design the topology for your [AVEVA™ Enterprise Licensing](#) platform. This will help you decide where you need to install the License Manager and License Server components.

There are three topology types to consider.

### [Single Node Topology](#)

A single node topology involves a computer with Plant SCADA, License Manager, and License Server installed. In this configuration, the communication between the server components, License Server, and License Manager is local. Internet access is required to connect to the Activation Server.

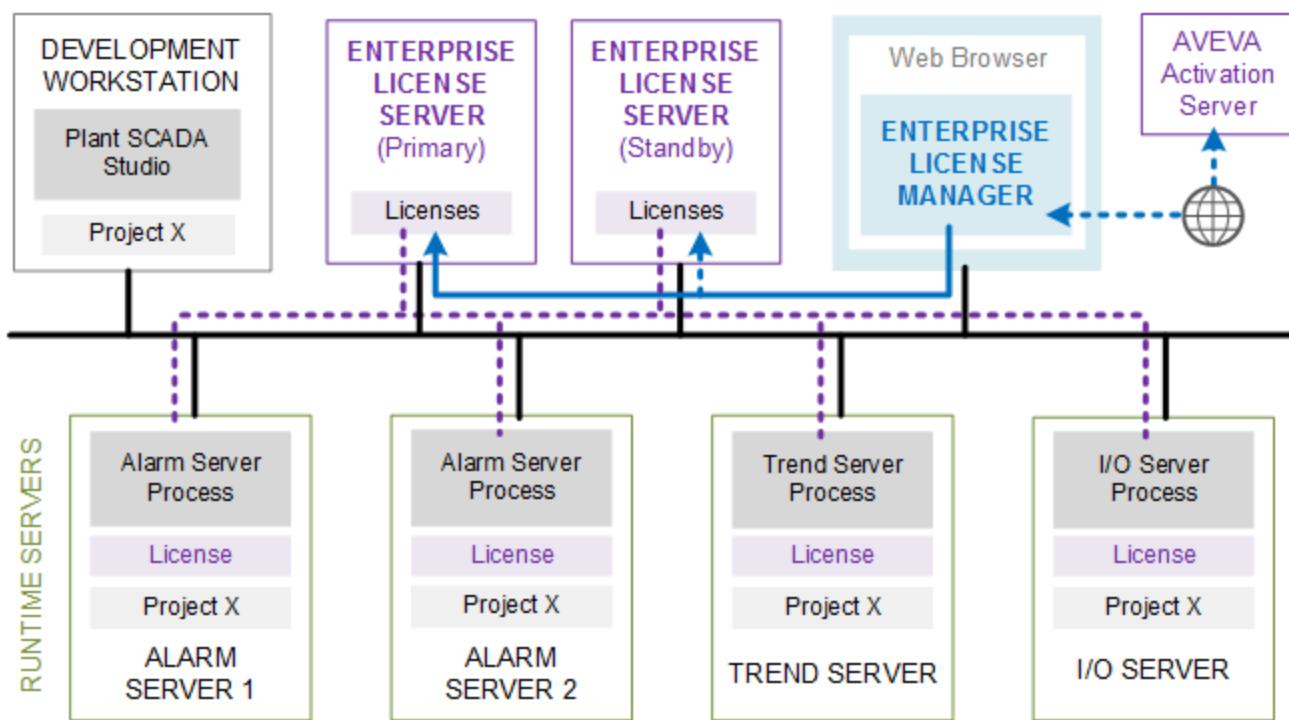

Typically a single node topology would be used to test a project on a development workstation. It can also be used for training or evaluation purposes.

### Distributed Topology

The licensing components can be installed on separate computers as long as there is reliable network connectivity between them. This type of topology is suitable for systems where you need to manage licenses for multiple installations of Plant SCADA across a distributed runtime system.

In the following example:

- The **Enterprise License Manager** components are installed on a computer with Internet access to the Activation Server. The interface runs locally in a web browser.
- The **Enterprise License Server** components are installed on two separate computers that are acting as a redundant pair.
- The Plant SCADA runtime computers each require network access to the License Servers.

This type of topology allows you to manage multiple License Servers for a runtime system from a single License Manager browser interface.

License Server redundancy is highly recommended when centralizing your licenses. It is available at no additional cost. A paired set of License Servers keeps licenses, reservations and the status of licenses synchronized to help maintain stability for the runtime system.

If you use clustering to manage a system that is physically distributed across multiple sites, it is recommended that you have a pair of redundant license servers at each location.

For information and procedures about implementing redundancy, see the topic *Working With License Server Redundancy* in the AVEVA Enterprise Licensing documentation in [AVEVA™ Help](#).

#### **Disconnected Topology**

This topology is required if an internet connection is not available. For example, a firewall or other constraints may exist between the License Manager components and the Activation Server.

In this scenario, you need to set up a separate computer with Internet access to the License Activation Web Page and Activation Server and then complete the activation process in "offline" mode. For more information, see the topic *Activating Licenses in Offline Mode* in the AVEVA Enterprise Licensing documentation in [AVEVA™ Help](#).

---

**Note:** If you are planning to run a system that includes a combination of client, server, and HMI licenses, you need to confirm that your Plant SCADA computers have the appropriate role configured. This will allow an Enterprise License Server to correctly allocate different license types. Computer roles are configured using the [Computer Role Setup](#) page of the Setup Wizard.

For an example of how to acquire, activate and distribute your licenses, see [AVEVA™ Enterprise Licensing Workflow](#) in the Plant SCADA documentation.

For more detailed information see the AVEVA Enterprise Licensing documentation in [AVEVA™ Help](#).

## AVEVA™ Enterprise Licensing Workflow

The following example of the AVEVA Enterprise Licensing workflow assumes that both License Manager and License Server are installed on the same computer, and that the computer can connect to the Internet.

### 1. Purchase one or more AVEVA Enterprise Software products

Along with your installation media or downloads, you will receive one or more entitlement files containing license details.

### 2. Start License Manager

It opens in a browser window and accesses the installed License Manager components.

### 3. Select the License Server

Use the License Manager to select an available server to host the licenses you want to activate. You can also add a new license server.

---

**Note:** You need to configure the connection to the License Server on any computer that needs to acquire licenses. See .

---

### 4. Import the entitlement file

Once you import the entitlement file, the License Manager displays the available licenses.

The entitlement file contains information for specific product licenses that are imported into the License Manager to activate purchased licenses. It is sent to you in an email upon purchase of your product licenses. It is in a zipped .xml file format.

### 5. Activate licenses

License Manager connects to the AVEVA Enterprise Activation Server over the Internet to activate the selected licenses on the License Server. The Activation Server activates licenses on the License Server.

### 6. Manage your licenses

Licenses are now available for their respective product to use. You can now:

- Activate new licenses
- Deactivate current licenses
- Reserve and unreserve licenses
- Checkout licenses.

In some cases, you may need to reserve a license for a specific computer using the device reservation feature. For example, it is recommended that you checkout a license for any critical runtime computers. For more information, see [Allocating AVEVA™ Enterprise Licenses](#).

---

**Note:** Plant SCADA only supports device reservations. You cannot reserve licenses for specific users.

---

### 7. Install and configure Plant SCADA

When running, Plant SCADA will acquire licenses from the License Server selected in Configurator (see Use Configurator to Set Up an Enterprise License Server). They will release them when no longer needed.

---

**Note:** For more detailed information see the AVEVA Enterprise Licensing documentation in [AVEVA™ Help](#).

---

## Allocating AVEVA™ Enterprise Licenses

After you have activated licenses on an AVEVA Enterprise License Server for your Plant SCADA servers, clients

and standalone HMI systems, you need to allocate them to the appropriate computers in your SCADA system.

When Plant SCADA runtime starts, it will request a license from the AVEVA Enterprise License Server that it is connected to. The type of license will be determined by the role configured for the computer in Plant SCADA's Computer Setup Wizard.

For example, Plant SCADA servers will request a server license, control clients will request a control client license and view-only clients will request a view-only client license. Plant SCADA Access Anywhere clients or remote desktop clients will also automatically retrieve a license directly from the AVEVA Enterprise License Server.

However, there are circumstances where you may need to reserve a license for a specific computer using the device reservation feature.

- **Critical runtime computers**

For any computers in your SCADA system that support critical runtime functionality (for example, an I/O server or an alarm server), it is recommended you reserve the required license and download it directly on to the computer using the **Checkout** feature.

---

**Note:** If you are using device reservations with a computer that hosts an Industrial Graphics Server, a Plant SCADA Access Anywhere client or an RDS client, you also need to use the **Checkout** feature. Be aware, however, that you should shut down runtime before you remove a checkout for a computer.

---

- **Specific license types**

If your servers, control clients and view only clients have the same point count, you will not need to allocate specific licenses to each computer.

However, if you have purchased licenses with different point counts, or any licenses similar to the following, you will need to allocate them to the relevant computers using Enterprise Licensing's device reservation feature.

- Plant SCADA Control Client 250 Pack
- Plant SCADA View-Only Client 250 Pack
- Plant SCADA Driver, PowerConnect
- Plant SCADA Driver, KNX
- Plant SCADA Driver, BACnet
- Plant SCADA Driver, S7TCP
- Plant SCADA Driver, PSDirect MPI
- Plant SCADA Driver, PSDirect ETH
- Plant SCADA Driver, IEC60870.

This will avoid a license with a specific point count or support for a specific driver being automatically retrieved by a computer that does not require it.

For more information, see *Reserving Licenses* in the AVEVA Enterprise Licensing documentation in [AVEVA™ Help](#).

If you need to access a license that has been allocated to a computer that is currently inaccessible, you can use a "drop device" operation in AVEVA License Manager to release licenses. For more information, see *Dropping Devices* in the AVEVA Enterprise Licensing documentation.

## Launch Enterprise License Manager from Plant SCADA Studio

AVEVA™ Enterprise License Manager is a browser-based application that manages the AVEVA Enterprise License

Server. It allows you to view and organize the licenses for a Plant SCADA system.

You can use Plant SCADA Studio to launch Enterprise License Manager from any installed location within your Plant SCADA system.

#### To launch Enterprise License Manager from Plant SCADA Studio:

1. Go to the **Licensing** activity.
2. On the AVEVA Enterprise Manager tile, select **Launch**.

If it is the first time you have launched the License Manager from Plant SCADA Studio, the **Configure Enterprise License Manager URL** dialog will appear. By default, the following address will be used:

`http://localhost/AELicenseManager`

This URL will launch the local installation of License Manager. If you want to use a remote installation, enter the following:

`http://<ComputerName>/AELicenseManager`

Where:

`<ComputerName>` is the name of the computer that hosts the installation you would like to use.

---

**Note:** If you have configured License Manager to use a port number other than the default (port 80), you need to include the port number in the License Manager URL:

`http://<ComputerName>:<PortNumber>/AELicenseManager`

---

3. Select **Update**.

License Manager will launch from the specified location.

The next time you select the **Launch** button, License Manager will automatically open in a browser from this specified location.

If you want to change this location to a different computer, select the **Configure** button and enter a new URL in the **Configure Enterprise License Manager URL** dialog.

---

**Note:** For more information about working with Enterprise License Manager, see the chapter *Using AVEVA Enterprise Licensing* in the *AVEVA Enterprise Licensing* documentation in *AVEVA™ Help*.

---

## Update a Sentinel Key with CiUSAFE

If your Plant SCADA system uses Sentinel Licensing, there may be times when you need to update your USB keys (for example, when you upgrade to a new version of Plant SCADA). To do this, you use the CiUSAFE dialog box.

#### To update a Sentinel USB key with CiUSAFE:

1. Plug the key you would like to update in a local USB port.
2. Open Plant SCADA Studio.
3. On the **Activity Bar**, select **Licensing** from the menu.  
Or:  
Click the Licensing icon.

4. On the **Sentinel Key Update** panel, click **Launch**.

The CiUSAPE dialog box will appear. (See below for a description of the CiUSAPE dialog box fields.)

5. Retrieve the **Serial Number** for the key from CiUSAPE.
6. Visit the **License Activation** page on the [AVEVA Knowledge and Support Center](#), and enter the serial number in the USB Key Serial Number field.
7. Click **Submit**.  
If the key is validated, an authorization code will be generated.
8. In CiUSAPE, enter the generated code in the **Authorization Code** field.
9. Click **Update**.

CiUSAPE will display a **Return Code** to confirm if the update was successful. See the table below for an explanation of the return code values.

### [CiUSAPE Dialog Box Fields](#)

#### *Serial Number*

The serial number of the attached hardware key. If it does not appear automatically in CiUSAPE, you can read the number from the label on the hardware key. You need to enter the serial number into AVEVA's online License Generator to update the key.

#### *KeyID*

Each time you launch CiUSAPE, a Key ID will display in the KEYID field. You might need to provide the Key ID plus the serial number when updating the hardware key. This depends on the status of the key in the Plant SCADA license database, and you are prompted if the Key ID is required. Click Save KeyID to save the Key ID and serial number to a text file, which you can refer to when visiting the AVEVA web site.

#### *Authorization Code*

To update the hardware key, enter the 106-character authorization code. You are asked for this code once you have entered the Key ID and serial number, and your license and Customer Service agreement have been verified. Click Update to update your hardware key.

#### *Return Code*

The Return Code indicates the result of the key update:

0	The key was updated successfully.
1.3	Either the KeyID or the Authorization code you entered is invalid.
2	Either the KeyID or the Authorization code you entered has been corrupted.
4,16	Either the KeyID or the Authorization code you entered is invalid.
9	No hardware key could be found.

#### [Licensing](#)

## Dynamic Point Count

Plant SCADA counts I/O device addresses dynamically at runtime.

The client process keeps track of the dynamic point count. When in multi-process mode, the client component will accumulate its own point count, which will include all the variable tags that are used by the process. This includes variable tags associated with the following:

- Events
- OPC DA Server
- Pages and Super Genies
- Cicode functions (TagRead, TagWrite, TagSubscribe, TagGetProperty and TagResolve)
- Any tag referenced by Cicode
- Reads or writes using DDE, ODBC, CTAPI or external OPC DA clients.

When in multi-process mode, the machine point count will be the point count of the client component, or the point count added up from each server component, depending on whichever is bigger. If the server license point count is 500 or greater, the client component point count is disregarded.

---

**Note:** If you are running a control client using a full license ([Client]FullLicense=1) and the point count of the license is 500 or more, then the point count is unlimited on that client and is disregarded.

---

A particular variable tag is only counted towards your point count the first time it is requested. Even if you have configured a certain tag on a particular page in your project, the variable tag will not be counted towards your point count unless you navigate to that page and request the data.

You should also be aware of the following:

- A dynamic point count is tag based, not address based. For example, two tags that use the same PLC address will be counted twice.
- If two trend tags use the same variable tag, it will be counted once. If two server components use the same tag(s) (say alarm and trend), the tags will not be counted twice when the point count gets totaled in the client process.
- Reading properties of a tag with [TagGetProperty\(\)](#) or [TagSubscribe\(\)](#) will cause that tag to be included in the point count, even if the value is not read.
- Persisted I/O (memory devices), local variables and disk I/O variable tags will not count towards the dynamic point count, unless they are written to by an external source (via OPC, DDE, ODBC, or CTAPI). For example, if you use an OPC client to write to a local variable, each local variable will be counted once the first time it is used.

---

**Note:**

- You can use the [CitectInfo\(\)](#) Cicode function or the General page in the Plant SCADA Kernel to determine the point count status of a client process.
  - You can specify the point count required by a client computer by using the [\[Client\]PointCountRequired](#) INI parameter.
- 

## See Also

[Demo Mode](#)

## Specify the Required Point Count for a Computer

The available point count for a Plant SCADA computer is determined by the type of license to which it is entitled. This is based on the role assigned to the computer by the [\[Client\]ComputerRole](#) parameter (which is typically set via the [Computer Role](#) page of the Setup Wizard).

Normally, the computer will get the first available matching point count. However, you can specify the point count required by a client computer by using the [\[Client\]PointCountRequired](#) INI parameter.

When any remote clients disconnect, the corresponding licenses that have been served to them can be reclaimed.

---

**Note:** A INI parameter is also available to control IP address aging. It is used to indicate how long to reserve a license for a given IP address in cases when a remote client connection is lost. This does not apply to full server licenses. The parameter is [\[General\]LicenseReservationTimeout](#).

---

## See Also

[Dynamic Point Count](#)

## Demo Mode

You can run Plant SCADA without the hardware key in demonstration (demo) mode. Demo mode lets you use every Plant SCADA feature normally, but with runtime and I/O restrictions.

In demo mode, you can run multiple processes on a single computer (with the networking model selected as "stand alone"), or in single process mode.

The following demonstration modes are available:

- 15 minutes with a maximum of 50,000 real I/O or calculated variables.
- 10 hours with a maximum of one dynamic real I/O or one calculated variable. This is useful for demonstrations using memory and disk I/Os.

Plant SCADA starts in this mode if no other licensing is available. If the system detects that you are using more than one real I/O point at runtime, it will swap to the 15 minutes demo mode.

---

**Note:** Writing to any tag through DDE, CTAPI, or ODBC will cause that tag to contribute to the dynamic point count even if it is a memory or disk I/O point. So if you write to more than one point through these interfaces, it will swap to the 15 minute demo mode.

---

## OPC UA Server and Industrial Graphics

The Industrial Graphics Server and OPC UA Server can both support demo mode, as long as they run on same computer as your Plant SCADA servers. In both cases, the setup is slightly different as the system needs to run in network mode. Remote Plant SCADA processes cannot connect to a server running in demo mode.

### To set up demo mode for an OPC UA Server and/or an Industrial Graphics Server:

1. Use the Setup Wizard to set the **Network Model** to "Networked" (see [Network Model](#)).
2. Configure your system to use encrypted communications (see [Enable Encryption](#)).

This means you will need to have a System Management Server configured and the Runtime Manager

running as a service.

3. Confirm that all server processes use an enabled network address that points to the local computer (see [Add Network Addresses](#)).

# Install Plant SCADA

This guide provides instructions for installing AVEVA™ Plant SCADA.

The Plant SCADA installer initially requires you to specify the "role" a computer will play within your control system. You can select from the three following options:

- **Development Workstation** — the computer will be used to build and test Plant SCADA projects.
- **Server** — the computer will be responsible for running a Plant SCADA system. It will perform tasks such as processing I/O device communications and managing alarms and trends.
- **Runtime-only Client** — the computer will be a display client for monitoring and controlling a system.

When you specify a role for a computer, a set of default components are automatically selected for installation. If required, you can customize the list of default selections. For example, if you select "Server", you can specify which type of server(s) you want to install.

If you are not familiar with Plant SCADA, see [Installation Information](#) for guidance on the installation process and some specific requirements.

If you need help to determine the role for a computer, see [What Should I Install?](#)

---

**Note:** If you want your system to use secured features such as encryption or deployment, you should not install Plant SCADA on the computer that acts as the domain controller within your Windows® domain.

---

When installation is complete, a dialog will appear asking if you would like to launch Configurator. This is a tool that is used to prepare a computer for its role within a Plant SCADA system. For example, it can be used to manage the certificates required to enable encrypted communications, or to map the local Windows® user groups to Plant SCADA's security roles. For more details, see [Configurator](#).

---

**Note:** The installation experience is not complete until after you exit Configurator. A restart request is likely to appear at this point. To avoid permission issues, you should close Configurator and confirm if a reboot is required before you run Plant SCADA.

---

## Upgrading

If you already have Plant SCADA installed, the Upgrading section of this guide provides information to help you update to the latest version. It describes:

- Instructions for both online and offline upgrade methods
- Supported upgrade paths
- The Plant SCADA Migration Tool.

See [Upgrade Plant SCADA](#).

**Note:** Due to significant component organizational changes in this release, you need to fully uninstall any existing versions of Plant SCADA and its associated components before you install Plant SCADA 2023 R2. You do not need to uninstall Platform Common Services.

## Installation Information

If you are not familiar with Plant SCADA, the following topics include information you need to know about the installation process and some specific requirements.

### Licensing Tools

Plant SCADA supports two different software licensing models:

- **Sentinel Licensing**

Sentinel Licensing uses physical USB keys that plug in to each computer in your Plant SCADA system.

To use Sentinel Licensing, you need to install the **Sentinel USB Driver**. It can be selected for installation via the **Extensions** branch of the products/components page of the Plant SCADA installer.

- **AVEVA™ Enterprise Licensing**

The [AVEVA™ Enterprise Licensing](#) system is a common platform solution that allows you to manage AVEVA Enterprise Software product licenses.

The system is comprised of a browser-based License Manager and a License Server that allow you to share and deliver licenses for your installed AVEVA applications. This distributed architecture enables centralized management of activated licenses and flexible topologies to support systems of any size.

The AVEVA Enterprise Licensing system is required for Industrial Graphics applications.

In both cases, Plant SCADA uses a Dynamic Point Count to determine if your system is operating within the limitations of your license agreement. This process tallies the number of I/O device addresses being used by the runtime system.

You can run Plant SCADA without a key in demonstration (demo) mode. Demo mode lets you use every feature normally, but with runtime and I/O restrictions (15 minutes with a maximum of 50,000 real I/O, or 10 hours with a maximum of one dynamic real I/O).

**Note:** In Plant SCADA 2023 and 2023 R2, Schneider Electric's Floating License Manager is no longer supported. Existing users of the Floating License Manager will need to reconfigure their system to use AVEVA Enterprise Licensing.

### Windows User Groups and Security Roles

You can only perform certain operations within Plant SCADA's engineering and runtime environments with relevant permissions. A page in **Configurator** allows you to grant these permissions to local and domain user groups.

Plant SCADA creates a set of security roles and local Windows user groups on a computer during installation. By default the local Windows user groups are associated with these security roles as members. Each role provides a different level of access to features, applications and project resources.

If you are installing Plant SCADA on a clean computer (one that has not hosted an earlier version), the following security roles and local Windows user groups will be created and mapped as follows:

Security Role	Windows User Group	Description
Configuration Users	SCADA.ConfigUsers	<p>Members of this role can run configuration tools (such as Plant SCADA Studio or Computer Setup Wizard) and start the runtime display client and server processes.</p> <p><b>Note:</b> It is recommended that members of this role only start runtime for development purposes and not in a production system environment.</p>
Runtime Users	SCADA.RuntimeUsers	Members of this role can run the runtime display client and make local CtAPI connections.
Server Users	SCADA.ServerUsers	<p>Members of this role can run Plant SCADA as a server process.</p> <p>If you are not running Plant SCADA as a service, add a member to this role who needs to run a Plant SCADA server (including a display client with [CtAPI]Remote enabled).</p>

If you choose to install Deployment Server components on a clean computer, additional security roles and local Windows user groups will be created and mapped as follows:

Security Role	Windows User Group	Description
Deployment Administrators	SCADA.DeploymentAdmins	Members of this role can add or remove client computers to/from deployment server. They can also perform upload and deploy operations.
Deployment Uploaders	SCADA.DeploymentUploaders	Members of this role can upload a new project version to the deployment server.
Deployment Users	SCADA.DeploymentUsers	Members of this role can deploy a new project to a connected deployment client computer.

If you choose to install an Industrial Graphics Server on a computer, additional security roles and local Windows user groups will be created and mapped as follows:

Security Role	Windows User Group	Description
Industrial Graphics Users	AIGUsers	<p>Members of this role can connect and authenticate with the Industrial Graphics Server with read-only access.</p> <p><b>Note:</b> You should avoid adding individual users to this security role. To allow authorization in a distributed system, only add domain groups to an Industrial Graphics security role.</p>
Industrial Graphics R/W Users	AIGUsersRW	<p>Members of this role can connect and authenticate with the Industrial Graphics Server. They will also be able to write to variable tags in a Plant SCADA system, provided the tags have been configured to support writes via the Write Roles property.</p> <p>See <a href="#">Enable Tag Writes for Industrial Graphics Applications</a>.</p> <p><b>Note:</b> You should avoid adding individual users to this security role. To allow authorization in a distributed system, only add domain groups to an Industrial Graphics security role. Members of this role can upload a new project version to the deployment server.</p>

If you are upgrading Plant SCADA from an earlier version, equivalent user groups will already exist on the computer. If the installer detects these existing groups, they will be retained. Only the security roles will be created and mapped to the existing local Windows user groups.

Security Role	Windows User Group Name	
	Clean installation	Upgrade from earlier version
Configuration Users	SCADA.ConfigUsers	Citect.Engineers
Runtime Users	SCADA.RuntimeUsers	Citect.LocalUsers
Server Users	SCADA.ServerUsers	Citect.ServerUsers
Deployment Administrators	SCADA.DeploymentAdmins	Asb.Deployment.AdminRole
Deployment Uploaders	SCADA.DeploymentUploaders	Asb.Deployment.UploadRole

Deployment Users	SCADA.DeploymentUsers	Asb.Deployment.DeployRole
------------------	-----------------------	---------------------------

**Note:** In an upgrade scenario, the Asb.Deployment.ReadRole user group is obsolete and not associated with any security role.

If required, you can use [Configurator](#) to change the associated members with these security roles (see [Modifying the Members of a Security Role](#)).

### Windows Firewalls

Following installation, your Windows Firewall settings will need to be adjusted so that Plant SCADA and its components are included in the list of authorized programs.

Plant SCADA can automatically adjust these settings for you. If Windows Firewall is operational on a computer, the installer will display a **Firewall** page. To allow Plant SCADA to adjust these setting for you, select **Yes, please modify Windows Firewall settings**.

This will add the following applications to the list of authorized programs.

Name	Program	Local Port
Citect SCADA Runtime (x64)	C:\Program Files (x86)\AVEVA Plant SCADA\Bin\Bin (x64)\Citect.exe	All ports
Plant SCADA Runtime	C:\Program Files (x86)\AVEVA Plant SCADA\Bin\Citect32.exe	All ports
Configurator	C:\Program Files (x86)\Common Files\Archestra\configurator.exe	All ports
Configurator 443	All programs	443
Configurator 80	All programs	80
LicenseServerPort	All programs	55555
LicenseServerAgentPort	All programs	59200

If during installation you select **No, I will modify Windows Firewall settings later**, you will need to manually configure an **Inbound Rule** for these components in Windows Firewall Advanced Settings (if they do not already exist).

See the topic [Firewall Settings and Plant SCADA](#) in the Runtime section of the Plant SCADA documentation.

**Note:** Plant SCADA networking and redundancy needs the option "Plant SCADA Runtime" to communicate through a Windows Firewall.

### Communication Drivers

Plant SCADA communicates with I/O devices such as PLCs, loop controllers, bar code readers, scientific analyzers, remote terminal units (RTUs), and distributed control systems (DCS). This communication takes place with each device through the implementation of a communications driver.

The installation process allows you to select from a set of individual drivers that are specific to your system and its I/O devices. There are also certain drivers that are necessary for Plant SCADA to function correctly. These will be installed automatically.

**Note:** With the release of Plant SCADA 2020 R2, a classification system for the driver portfolio was introduced to indicate the level of ongoing maintenance that customers can reasonably expect for each driver. In line with

---

these classifications, the number of drivers included by default with the Plant SCADA installation media has been reduced to a set of 'core' drivers that have undergone recent updates. All other drivers continue to be available for download from the **Communication Drivers** page at the **AVEVA Knowledge and Support Center** located at <https://softwaresupport.aveva.com/>.

---

### OPC Factory Server

The Plant SCADA installer allows you to install a copy of Schneider Electric's OPC Factory Server.

Based on the OPC protocol, OPC Factory Server enables Windows-based OPC client applications to communicate with a range of Schneider Electric's PLCs.

For more information, see [Install OPC Factory Server](#).

### Anti-virus Software Setup

If a computer uses an anti-virus software product, you need to be aware of the following implications for a Plant SCADA installation.

#### **WARNING**

##### **SYSTEM PERFORMANCE DEGRADATION**

The "on access" scan in anti-virus products can lock files used by Plant SCADA, usually having the effect of slowing Plant SCADA down whilst it waits for the scan of that file to finish.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

#### **CAUTION**

##### **INOPERABLE SYSTEM OR LOSS OF DATA**

In some extreme cases, anti-virus software may (incorrectly) detect certain patterns within data files as being viruses. Depending on the anti-virus configuration, this may result in files being relocated or deleted, resulting in data being lost or the system being inoperable.

**Failure to follow these instructions can result in injury or equipment damage.**

It is recommended that the following directories are excluded from scanning by any anti-virus products:

- Program Files installation directory (including files and sub directories)
- Data and Logs directories
- Any alarm server archive paths.

The above exclusions are recommended for "on access" or "real time" scans that run continuously and scan each file that is read from or written to.

### Maintaining System Currency

After you have completed the installation and configuration of Plant SCADA and deployed it as your production system, it is recommended that you keep your software up to date.

AVEVA will periodically publish software updates for Plant SCADA and advisories relating to safety, security and functionality. These are available from the Product Hub page of the AVEVA Knowledge & Support Center website at <https://softwaresupport.aveva.com>. We especially recommend that you nominate a person in your organization to refer, and subscribe, to the RSS feeds for Safety and Security, as well as the latest articles on the web site.

### Virtualization Host Support

You can run components of your Plant SCADA system in a virtual environment. The following virtualization environments are supported:

- Microsoft Hyper-V: based on the version of Windows.
- VMware Workstation: basic virtualization without High Availability and Disaster Recovery.
- VMware vSphere.

## What Should I Install?

The Plant SCADA installer directs you through a set of pages that will help you determine which components you require on a computer. Before you begin this process, you need to consider the questions below.

**Note:** If you are building a large system, it is important to carefully consider the overall topology of the system. For example, a distributed architecture, server redundancy, load sharing and clustered control scenarios can help to address your process requirements and benefit the overall performance of a system.

### Will you use the computer to configure a Plant SCADA project?

To configure a Plant SCADA project, you need to use a development workstation. An installation of a development workstation includes two fundamental sets of components:

- **Configuration Environment** — includes Plant SCADA Studio and other tools used to create and configure a project.
- **Runtime** — includes components used to run a project.

See [Install a Development Workstation](#).

### Do you want to use AVEVA™ Industrial Graphics?

AVEVA Industrial Graphics is a thin client solution for the delivery of HTML5 graphics to desktop browsers and mobile devices. It provides a common graphics technology that can be used across AVEVA's SCADA and HMI solutions.

Clients access AVEVA Industrial Graphics via an Industrial Graphics Server, a dedicated computer that authenticates client details and provides access to the graphical and functional content.

If you want to use Industrial Graphics, you will need to set up an Industrial Graphics Server. You will also need to configure a Deployment Server in your network to deploy content to the Industrial Graphics Server.

An AVEVA Enterprise License Server also needs to be part of your network to provide licenses for client access.

See [Install an Industrial Graphics Server](#).

### Do you need to use AVEVA™ Enterprise Licensing?

AVEVA Enterprise Licensing is a centralized license management solution that removes the need for dongles and increases license security through the use of activated licenses.

If you are setting up a new Enterprise Licensing system, you should review the following topics to determine your installation requirements.

- [AVEVA™ Enterprise Licensing](#) describes the required components in a system.
- [AVEVA™ Enterprise Licensing Topologies](#) describes the recommended system topologies.

If you are implementing a distributed system, we recommend creating a network diagram to determine where

you need to install the **License Manager** and **License Server** components.

#### **Do you want Plant SCADA to act as a server for OPC UA client applications?**

Setting up an OPC UA Server allows Plant SCADA's runtime system to function as a server to OPC UA client applications. For more information, see [Install an OPCUA Server](#).

#### **Does your system require encrypted communications?**

Communications between Plant SCADA processes, computers and CtAPI can be encrypted. This is required if:

- You need to use trusted communications for your runtime system computers.
- You want to connect an OPC UA server to your system.
- You want to connect an Industrial Graphics Server to your system.

To enable encryption, a **System Management Server** is required to manage the certificates used to support trusted communications. A System Management Server is set up using a tool called (see [Set Up a System Management Server](#)).

---

**Note:** To use encrypted communication, your Plant SCADA servers need to be running as a service.

If you already have a System Management Server set up, you will need access to the certificate that will connect your new installation to the System Management Server. This can be also be configured using Configurator. See [Connect a Computer to a System Management Server](#).

#### **Do you need to run Plant SCADA as a service?**

Plant SCADA can be run as a Windows™ service, allowing for unattended operation of a system's servers.

To create an encrypted connection, your Plant SCADA servers need to be running as a service. This is required when:

- You are running with encryption enabled. This includes running in mixed mode.
- You want to connect an OPC UA server to your system.
- You want to connect an Industrial Graphics Server to your system.

If you are using Plant SCADA's **Deployment** feature, you also need to run as a service under the following circumstances:

- When a deployment client is configured on a computer, and you want to push project updates using "Force" mode.
- If you are using encrypted communications, and the current user on a deployment client does not have required privileges.

To configure Runtime Manager to run as a service, see [Configure a Runtime Computer for Encryption](#).

#### **Do you want to use Plant SCADA's Deployment feature?**

Plant SCADA's Deployment functionality allows you to send runtime files to specific computers in a Plant SCADA system. This simplifies the process of distributing project changes across multiple computers.

If you want to use this feature, a **Deployment Server** is required. This is where you store versions of a project for distribution. Specific components need to be installed for a Deployment Server (and any Deployment Clients that connect to it).

See [Install a Deployment Server](#).

---

**Note:** A Deployment Server uses encrypted communications, so you will need to connect the host computer

---

(and any connected clients) to an existing System Management Server.

#### Do you just need to install a runtime client?

If you are setting up a computer that will only operate as a runtime client, you have the option to install just the Plant SCADA runtime components.

See [Install a Runtime-only Client](#).

---

**Note:** If you want to install a standalone Plant SCADA system for training or evaluation purposes, [Install a Development Workstation](#).

---

## Configurator

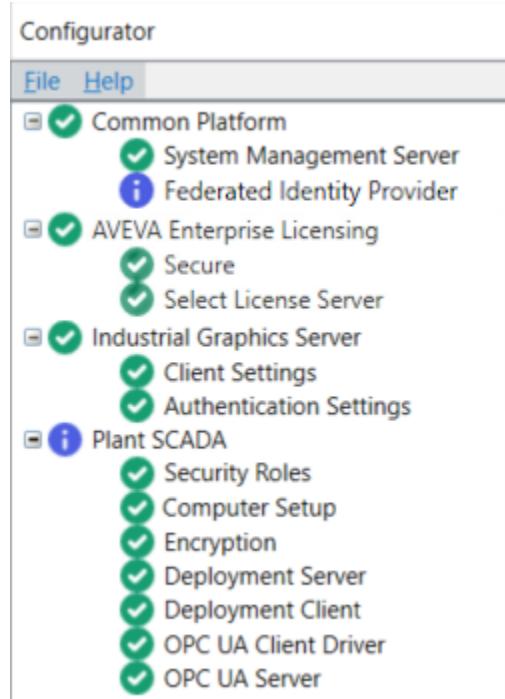

Configurator is a tool you can use to prepare a computer for its role within a Plant SCADA system.

When a Plant SCADA installation is complete, a dialog will appear asking if you would like to launch Configurator. In most cases, you will require Configurator to complete the setup of a computer.

To access Configurator at other times:

- Go to the Windows® **Start** menu and locate **AVEVA | Configurator**.  
Or:
- Go to the **Projects** activity in Plant SCADA Studio and select **Configurator** from the **Setup Wizard** drop-down menu.

Configurator presents a set of pages that can be accessed via a directory to the left of the interface.

For AVEVA **Common Platform** components, the following page is included:

- **System Management Server** — used to configure a System Management Server.  
See [Configure a System Management Server](#).

---

**Note:** The **Federated Identity Provider** will appear under the Common Platform components. This is not used by Plant SCADA. If required, you can set the **Identity Provider** field to "None". This will present a green tick for the page in the Configurator tree.

---

For **AVEVA Enterprise Licensing**, the following pages are included:

- **Secure** — indicates if the Enterprise License Server is running in Secure Mode.
- **Select License Server** — configures or connects to an Enterprise License Server.  
See [Use Configurator to Set Up an Enterprise License Server](#).

For an **AVEVA Industrial Graphics Server**, the following pages are included:

- **Client Settings**
- **Authentication Settings**  
See [Use Configurator to Set Up an Industrial Graphics Server](#) for more information.

For **Plant SCADA**, the following pages are included:

- **Security Roles** — used to map Plant SCADA Roles to Windows® user groups, Domain Groups and Individual users.  
See [Security Roles](#).
- **Computer Setup** — used to configure environment settings for a runtime computer, including a server password and some deployment settings.  
See [Use Configurator to Set Up a Runtime Server](#).
- **Encryption** — used to encrypt communications between Plant SCADA processes, computers and CTAPI applications.  
See [Enable Encryption](#).
- **Deployment Server** — used to set up a Deployment Server for the distribution of Plant SCADA project versions.  
See [Configure a Deployment Server](#).
- **Deployment Client** — used to set up a Deployment Client.  
See [Configure a Deployment Client](#).
- **OPC UA Client Driver** — used to manage secure communications with OPC UA devices connected to Plant SCADA via an external OPC UA server. This relates to an installed driver, not Plant SCADA's OPC UA Server.  
See [OPC UA Client Driver](#).
- **OPC UA Server** — allows Plant SCADA's runtime system to function as a server to third-party OPC UA client application.  
See [Use Configurator to Set Up an OPC UA Server](#).

The icons next to each page indicate the current status of the associated settings, according to the following legend.

Each page includes the **Configuration Messages** panel to advise you of the outcome of any adjustments you make. You can also [View the Configurator Messages List](#).

## View the Configurator Messages List

The Configurator Messages List allows you to view and export all of Configurator's current messages.

### To view the Configurator Messages List:

- On a Configurator page, click the **All Messages** button.

The Messages List dialog box displays all current messages in a tabular format. Click on a column heading to sort the table according to the column. Click again to toggle between ascending or descending order.

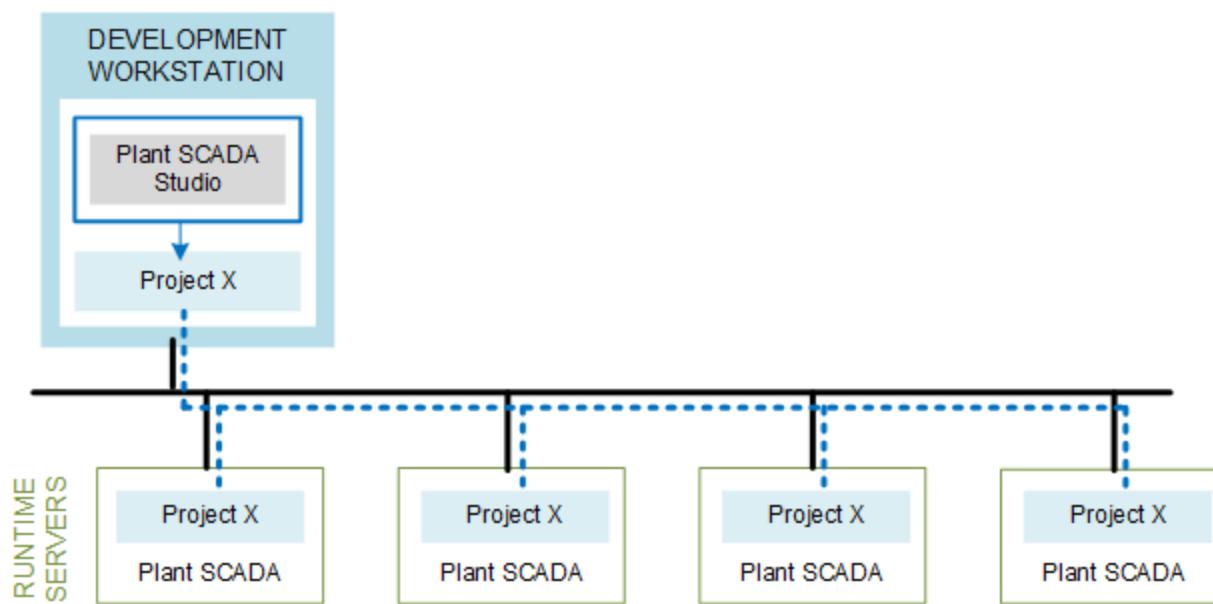

### To export the Configurator Messages List:

1. Click the **Export to file** button.
2. Use the Save As dialog to save the file.

## Install a Development Workstation

A development workstation uses configuration tools such as **Plant SCADA Studio** and **Graphics Builder** to create a Plant SCADA project.

A project includes runtime content and configuration information. You need to distribute a copy of the project to each computer in a Plant SCADA runtime system.

When you chose to install a development workstation, the following components are selected by default:

- AVEVA Plant SCADA
  - Configuration Environment
  - Runtime
  - Deployment Server
- AVEVA Plant SCADA Communications Drivers
  - A set of commonly used drivers
- AVEVA Industrial Graphics
  - Industrial Graphics Web Server
- Extensions
  - Software Update by Schneider Electric

The following licensing options are also selected by default.

- AVEVA Enterprise Licensing
  - AVEVA Enterprise License Manager
  - AVEVA Enterprise License Server.

See the section *Licensing Tools* in the topic [Installation Information](#) to determine your licensing requirements.

If required, you can use the **Customize the components that will be installed** page to modify the list of selected components.

## See Also

- [Development Workstation Installation Requirements](#)
- [Development Workstation Installation Procedure](#)
- [Use Configurator to Set Up a Development Workstation](#)

## Development Workstation Installation Requirements

This topic describes the hardware and software requirements for a Plant SCADA development workstation.

**Note:** Before you install Plant SCADA, it is recommended that you install the latest updates from Microsoft® for your operating system and system software.

### Hardware Requirements

The hardware requirements for a development workstation are as follows, based on the size of the system you are configuring.

	Compact System <1,500 pts	Small System <15,000 pts	Medium System <50,000 pts	Large System <500,000 pts	Huge System >500,000 pts
CPU PassMark®	2000	2000	4250	4250	8000
Cores	2	2	4	4	4
RAM	8 GB				
HDD	10 GB	20 GB	50 GB	50 GB	100 GB
Graphics	DirectX 11 or later with WDDM 1.0 Driver. 128 MB of dedicated VRAM.	DirectX 11 or later with WDDM 1.0 Driver. 128 MB of dedicated VRAM.	DirectX 11 or later with WDDM 1.0 Driver. 128 MB of dedicated VRAM.	DirectX 11 or later with WDDM 1.0 Driver. 128 MB of dedicated VRAM.	DirectX 11 or later with WDDM 1.0 Driver. 128 MB of dedicated VRAM.
Screen Resolution	1920 x 1080				
Network	100 Mb				

The suggested disk space requirements for the HDD is an estimate only and includes:

- A full Plant SCADA installation including optional components and documentation
- Project assets for the specified system size.

If the deployment feature is being used, the HDD needs to have the required space for the number of configured project versions + 2. You should remove unused project versions periodically to reduce HDD usage.

An SSD is recommended for engineering machines for better performance. If a non-SSD is used, select a minimum RPM of 7200.

## Operating System Requirements

The following operating systems are supported (64-bit only):

- Windows 11 21H2 (or later)
- Windows 10 21H2 (or later)
- Windows 10 LTSC 1607 (or later)
- Windows Server 2016
- Windows Server 2019
- Windows Server 2022

Microsoft .NET Framework 4.8 is required. It will be installed by Plant SCADA if not detected.

When .NET installation is complete, you may be prompted to restart your computer. If this occurs, you should initiate a restart before you continue.

## Development Workstation Installation Procedure

This table below describes the pages included in the Plant SCADA installer and the settings required to install a development workstation.

Use the **Back** and **Next** buttons to navigate through the pages.

Installer Page	Notes
Installation Documentation	If required, view the available documents.
License Agreement	Accept the terms of the License Agreement.
What is the role of this computer?	Select <b>Development Workstation</b> .
The selected products/components will be installed/upgraded.	By default, the following components are selected when you install a Development Workstation. <ul style="list-style-type: none"><li>• Platform Common Services</li><li>• AVEVA Plant SCADA<ul style="list-style-type: none"><li>• Configuration Environment</li><li>• Runtime</li><li>• Deployment Server</li></ul></li><li>• AVEVA Plant SCADA Communications Drivers<ul style="list-style-type: none"><li>A set of commonly used drivers.</li></ul></li></ul>

Installer Page	Notes
	<ul style="list-style-type: none"><li>• AVEVA Industrial Graphics<ul style="list-style-type: none"><li>• Industrial Graphics Web Server</li></ul></li><li>• AVEVA Enterprise Licensing<ul style="list-style-type: none"><li>• AVEVA Enterprise License Manager</li><li>• AVEVA Enterprise License Server.</li></ul></li><li>• Extensions<ul style="list-style-type: none"><li>• Software Update by Schneider Electric</li></ul></li></ul> <p>You can use this page to customize the list of selected components. For example, you can select any additional communication drivers, OPC UA components, or the Project DBF Add-In for Excel.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"><li>• The AVEVA Enterprise Licensing system only requires one License Server. If you are going to connect to an existing License Server, you do not need to select this option.</li><li>• Plant SCADA 2023 R2 installs version 4.0 of AVEVA Enterprise Licensing. If your system includes computers that are not upgraded to AEL 4.0, you will need to install <b>AVEVA Enterprise Licensing Server Legacy Support</b> on your Enterprise License Server. This enables backwards compatibility for clients nodes that are running an earlier version of AEL.</li></ul>
Access Restriction	<p>This page provides information about the local Windows groups the installer will create to manage security (see the section <i>Windows User Groups and Security Roles</i> in the topic <a href="#">Installation Information</a>).</p> <p><b>Note:</b> This page will only appear if you are installing Plant SCADA on a clean computer (one that has not hosted an earlier version). If you are upgrading from an earlier version, equivalent user groups will already exist on the computer.</p> <p>If you want your current Windows user account to be included in the groups that are being created, select <b>Add the current Windows user to these groups</b>.</p> <p>A dialog will let you know that the group membership changes will not occur until after a restart.</p>
Firewall	If the installer detects that the computer has Windows Firewall enabled, you will be asked if you would like the installer to modify your settings.

Installer Page	Notes
	<p>If you select <b>Yes</b>, Plant SCADA Runtime will be added to the list of authorized programs.</p> <p>See the section <i>Windows Firewalls</i> in the topic <a href="#">Installation Information</a>).</p>
Customize the installation location	<p>This page identifies the destination folders for:</p> <ul style="list-style-type: none"><li>• The selected Plant SCADA program files.</li><li>• The Plant SCADA User and Data folders.</li></ul> <p>You can modify the folder locations by clicking the <b>Change</b> buttons and selecting alternative locations.</p> <p>You can also <b>Reset</b> the default locations.</p> <p><b>Note:</b> The installation folder and the 'User and Data' folder cannot be the same, or a sub-directory of one another. You should also avoid selecting your Windows user folder.</p>
Ready to Install the Program	<p>This page lists the components that will be installed based on your selections.</p> <p>If required, use the <b>Back</b> button to make any modifications.</p> <p>Click <b>Install</b> to start the installation process.</p>

When installation is complete, a dialog will appear asking if you would like to launch [Configurator](#). This may take a few minutes if you have installed some external components (for example, AVEVA Enterprise Licensing components).

---

**Note:** The installation experience is not complete until after you exit Configurator. A restart request is likely to appear at this point. To avoid permission issues, you should close Configurator and confirm if a reboot is required before you run Plant SCADA.

---

## See Also

[Use Configurator to Set Up a Development Workstation](#)

## Use Configurator to Set Up a Development Workstation

When your Plant SCADA installation is complete, a dialog appears to inform you that some components require configuration before use. Click **Configure** to launch [Configurator](#).

The following descriptions of the Configurator's pages will help you determine which settings you need to consider.

## Computer Setup

The Computer Setup page allows you to specify three key settings for a Plant SCADA computer.

- **Server Authentication** — specifies the password the Plant SCADA server processes use to communicate with each other. If the computer will run a server process, you will need to configure the server password.
- **Project Run Path** — instructs Runtime Manager to run the project currently selected in Plant SCADA Studio, or a deployed project from the Deployment Server.
- **Runtime Manager Configuration** — allows you to run Runtime Manager as a service, which may be required for a Deployment Client.

## Security Roles

To manage the usage of Plant SCADA and restrict access to its sensitive components, only users with relevant permissions can perform certain security-related operations.

Each security role has specific permissions to access different features, software applications and project resources. Using the **Security Roles** page in the Configurator, you can assign the security roles to a user account or a group account. For more information, see [Security Roles](#).

## Encryption

If your Plant SCADA system uses encrypted communications, you will have to enable encryption for each new installation of Plant SCADA. This is achieved using Configurator's **Encryption** page (see [Enable Encryption](#)).

As a prerequisite, the computer needs to be registered with a System Management Server. This is achieved using Configurator's **System Management Server** page (see below).

## System Management Server

This page allows you to set up the computer as a System Management Server (see [Configure a System Management Server](#)).

If your Plant SCADA system already has a System Management Server, you can use this page to establish a trusted connection to it (see [Connect a Computer to a System Management Server](#)).

## Additional Components

Some pages will appear in the Configurator if you chose to install additional components. Use the links below for more information on how to configure these pages.

- **Deployment Server** — see [Configure a Deployment Server](#).
- **Deployment Client** — see [Configure a Deployment Client](#).
- **OPC UA Server** — see [Use Configurator to Set Up an OPC UA Server](#).
- **OPC UA Client Driver** — see [OPC UA Client Driver](#).
- **Industrial Graphics Server** — see [Use Configurator to Set Up an Industrial Graphics Server](#).

---

**Note:** The installation experience is not complete until after you exit Configurator. A restart request is likely

---

to appear at this point. To avoid permission issues, you should close Configurator and confirm if a reboot is required before you run Plant SCADA.

---

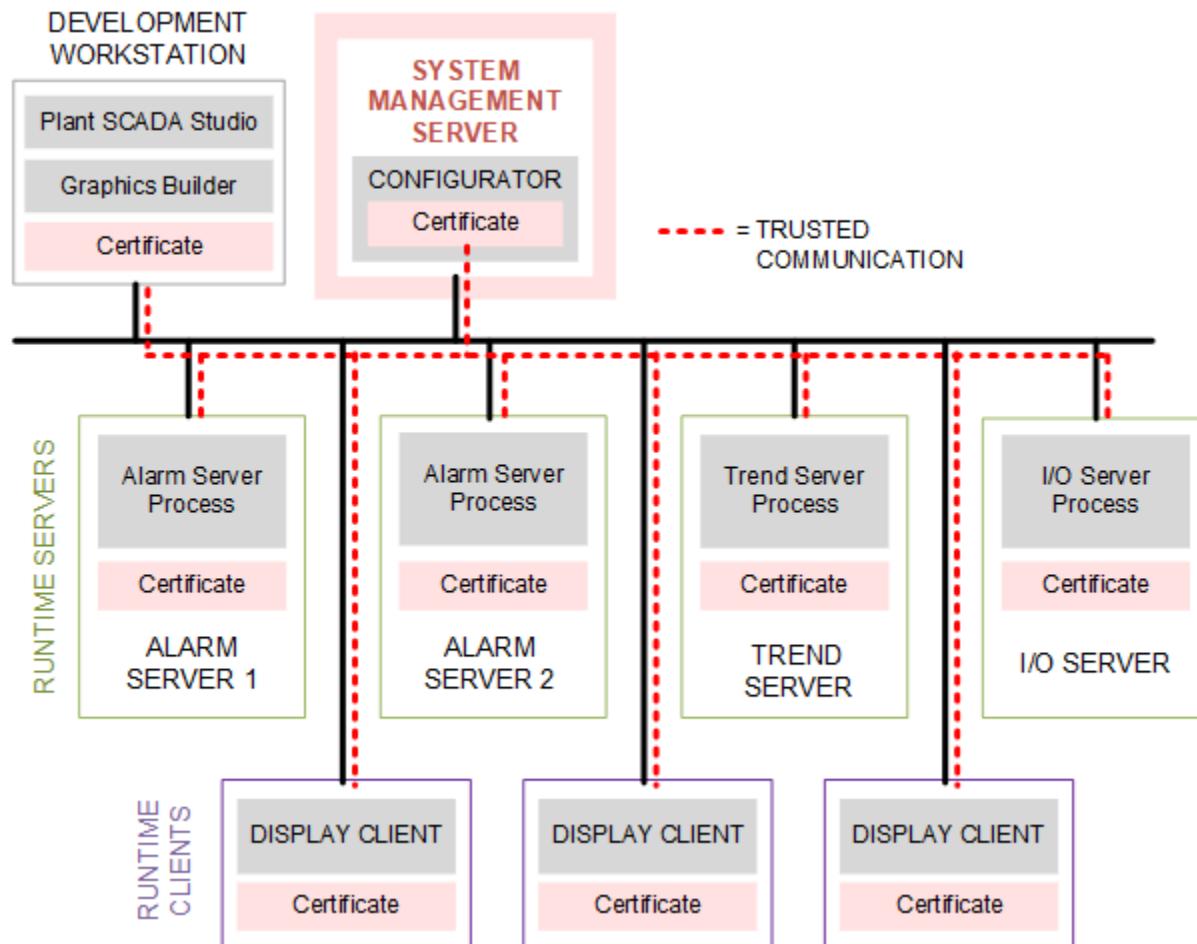

## See Also

- [Development Workstation Installation Requirements](#)
- [Development Workstation Installation Procedure](#)

## Set Up a System Management Server

A System Management Server ensures Plant SCADA components only work on trusted computers. It also enables support for end-to-end encryption (which is highly recommended).

Only one of the computers in a Plant SCADA system can be set up as a System Management Server.

A System Management Server does not need to be on a dedicated computer. In a typical Plant SCADA system that is also using deployment, it is recommended that the System Management Server is on the same computer as the Deployment Server.

The components required to enable encryption are included with every installation of Plant SCADA. You need to use [Configurator](#) to specify which computer in your system will act as the System Management Server.

The certificates required to enable trusted communications can then be created on this computer using

Configurator. Alternatively, you can also use your own third party certificates if required.

All other computers in your system then use this certificate to acquire validation from the System Management Server.

## See Also

[Configure a System Management Server](#)

## Configure a System Management Server

Plant SCADA needs post-installation configuration in order to use encrypted communications via a **System Management Server**. Encryption is a requirement for components such as a Deployment Server, an Industrial Graphics Server or an OPC UA Server.

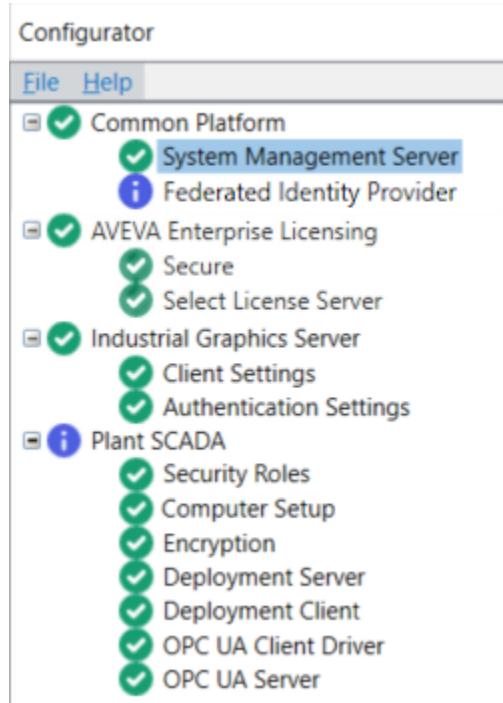

Only one of the computers in the network can be configured as a System Management Server. This is achieved using [Configurator](#).

You can then use Configurator to establish a trust relationship between one or more computers running Plant SCADA and its services. This is achieved by configuring a certificate on the System Management Server that can then be distributed to other computers to enable encrypted communications.

Certificates may be generated automatically on the System Management Server, or provided by a system administrator or IT department (see [Use Externally Provided Certificates for Encryption](#) in the Plant SCADA documentation).

### To configure the System Management Server:

1. Start the [Configurator](#).
2. In the left pane, select **Common Platform | System Management Server**.

The following page is displayed:

Machines running AVEVA software must be configured to trust each other so that encrypted communications can be utilized. This is done by connecting them to a System Management Server.

- Connect to an existing System Management Server.

- This machine is the System Management Server.

There should only be one System Management Server in your topology for all AVEVA products. All other machines should be configured to connect to this System Management Server.

When configuring other machines, you should validate that the security code shown in the Configurator matches:

[Details...](#)

- No System Management Server configured. (NOT RECOMMENDED)

This option also allows you to remove any existing certificates that were managed by the System Management Server.

You can connect to an existing System Management Server or configure a new System Management Server by selecting one of the first two options, respectively. When you click Configure, a certificate and the web ports to use for communication are configured. To modify these configurations, click Advanced.

Advanced

3. Select **This machine is the System Management Server**. Review the notes on the screen before you start the configuration.

**Note:** The machine on which you want to install the System Management Server needs to be configured to have a static IP address.

- #### 4. Click **Configure**.

**Note:** If you need to change the port used by a System Management Server see the topic *Advanced Configuration for a System Management Server* in the Plant SCADA documentation.

5. On successful configuration, the message "Device configuration completed" is displayed. The security code is displayed in the **Configurator** as shown below. To view more information about the certificate, click **Details**.

## Configuration Messages

Certificates are configured.

Connecting to the System Management Server 'https://[REDACTED].com:443'.

#### **Registering the device.**

The device is registered.

Device configuration completed.

If the configuration is unsuccessful, check the [Log Viewer](#).

You can access the Log Viewer by selecting **AVEVA | Operations Control Management Console** in the Windows **Start** menu.

Alternatively, view the error messages in the System Management Console.

6. Click **Close** to exit the **Configurator**.

---

**Note:** After you have configured a System Management Server, it is recommended that you either sign out or reboot the computer to ensure all settings are applied correctly.

---

## See Also

[Connect a Computer to a System Management Server](#)

## Connect a Computer to a System Management Server

Computers running Plant SCADA need to connect to the **System Management Server** to use encrypted communication enabled by a certificate.

If you do not have a System Management Server configured, refer to the section [Configure a System Management Server](#) for instructions. AVEVA applications need to be configured to trust each other to use encrypted communications.

To connect a computer to the System Management Server, you use the System Management Server page in **Configurator**. You can launch **Configurator** at the completion of the installation procedure, or from the Windows™ Start menu.

To establish a connection, the current user on the remote computer needs to be a member of either the "aaAdministrators" or the "Administrators" group on the machine where the System Management Server is installed. This is necessary to establish a trust relationship, it is not a runtime requirement.

---

**Note:** For a Deployment Server, you need to authorize the connection to a System Management Server from Configurator's Deployment Server page. See [Configure a Deployment Server](#).

---

### To connect a computer to the System Management Server:

1. In the panel on the left side of the **Configurator** select **Common Platform, System Management Server**.
2. Select the option **Connect to an existing System Management Server**.
3. In the field below, select the name of the System Management Server you want to use from the drop-down list.

The Configurator uses SSDP (Simple Service Discovery Protocol) to detect a System Management Server on a remote computer. If SSDP has been blocked on your network, nothing will appear in the drop-down list.

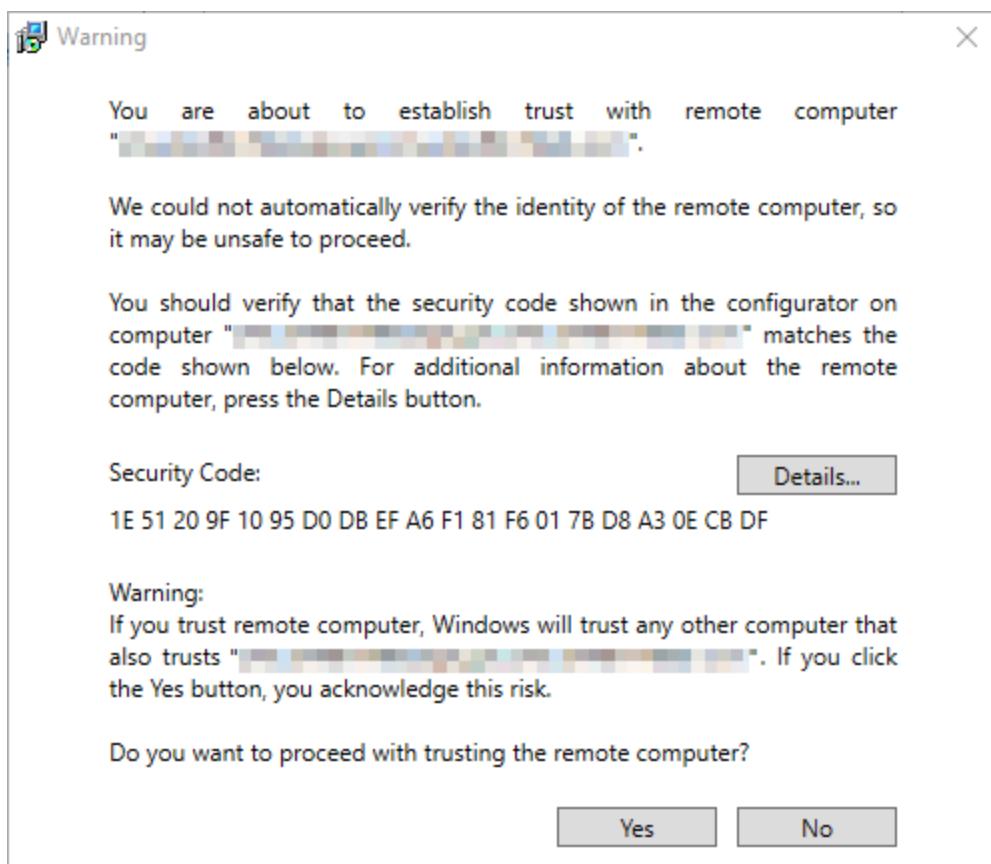

If the required computer name does not appear in the list, you can manually enter a hostname or Fully Qualified Domain Name (FQDN) for the computer on which the System Management Server is installed. Connecting via an FQDN will require a connection to a domain server.

---

**Note:** The Configurator interface refers to "redundant SSO servers". This feature is not supported by Plant SCADA, you cannot configure a computer as a redundant SSO server.

---

4. Click **Configure**. The root certificate is downloaded, and the following message is displayed.

5. Review the message carefully before you click Yes. If you select No, the configuration process will be canceled.

A dialog box may appear prompting you to log on to the System Management Server. This will occur if the current user is not a member of either the "aaAdministrators" or the "Administrators" group on the machine where the System Management Server is installed. If this happens, enter the credentials for a member of one of these groups and click OK.

The Configuration Messages area displays the steps in the configuration process and the progress.

If the configuration is unsuccessful, view details of the error messages in the System Management Console. See the topic [Troubleshooting Certificate Error Messages](#).

Alternatively, check the [Log Viewer](#).

You can access the Log Viewer by selecting **AVEVA | Operations Control Management Console** in the Windows **Start** menu.

6. Click **Close** to exit the **Configurator**.

**Note:** After you have connected a computer to a System Management Server, it is recommended that you either sign out or reboot the computer to ensure all settings are applied correctly.

Once you have connected to a System Management Server, you can modify the configuration settings by selecting **Advanced**. Refer to the topic [Advanced Configuration for a System Management Server](#) in the Plant SCADA documentation for more information.

**Note:** If you need to connect a client computer that is not on the same domain as the System Management Server (for example, it is part of a Workgroup), you need to configure the **Primary DNS Suffix** on the client to identify the domain on which the System Management Server resides. Refer to the Windows documentation for

---

instructions on how to specify a Primary DNS Suffix for a computer.

---

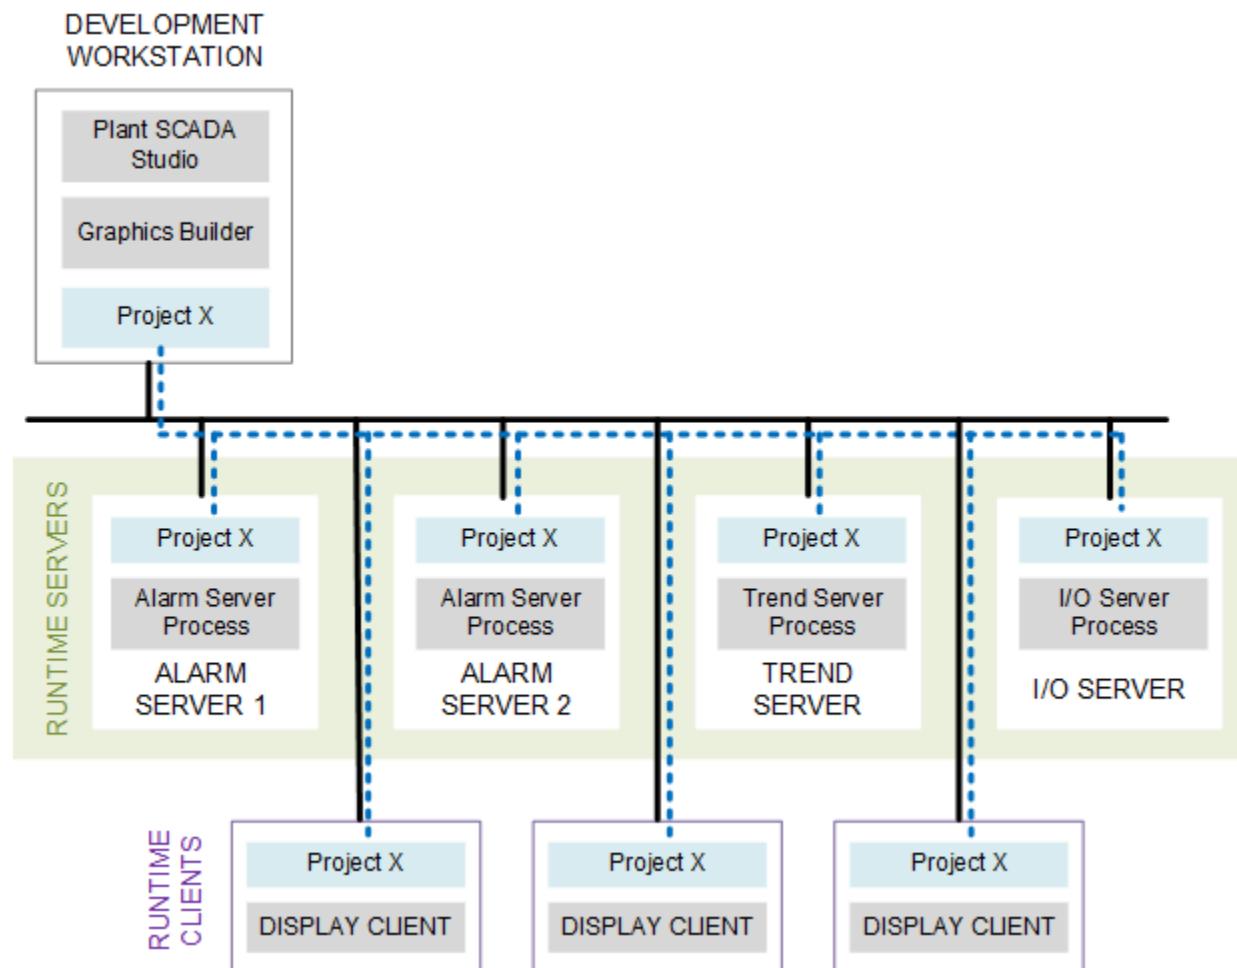

## Install a Runtime Server

A Runtime Server is any computer that hosts a server process in support of the runtime system. For example, a Runtime Server can perform one or more of the following functions:

- Alarms server - evaluates the conditions that define an alarm
- Trends server - manages the accumulation and logging of trend information
- Reports server - generates configured reports
- I/O device server - manages communication with field devices.

The server processes that are hosted by a runtime server are not configured during the installation process. These are defined in a project using the **Topology** activity in Plant SCADA Studio.

These processes can be installed on a single computer, or separated onto multiple computers across a distributed system. See the topic *Typical System Scenarios* in the Plant SCADA documentation for examples of how you can distribute server processes.

## See Also

- [Runtime Server Installation Requirements](#)
- [Runtime Server Installation Procedure](#)
- [Use Configurator to Set Up a Runtime Server](#)

## Runtime Server Installation Requirements

This topic describes the hardware and software requirements for a computer that will act as a Runtime Server.

Before you install Plant SCADA, it is recommended that you install the latest updates from Microsoft® for your operating system and system software.

## Hardware Requirements

The hardware requirements for a Runtime Server are as follows, based on the size of your system.

	<b>Compact System</b> <b>&lt;1,500 pts per server</b>	<b>Small System</b> <b>&lt;15,000 pts per server</b>	<b>Medium System</b> <b>&lt;50,000 pts per server</b>	<b>Large System</b> <b>&lt;200,000 pts per server</b>
CPU PassMark®	2000	2000	4250	8000
Cores	2	2	4	8
RAM	8 GB	8 GB	8 GB	16 GB
HDD	10 GB	20 GB	50 GB	100 GB
Graphics	DirectX 11 or later with WDDM 1.0 Driver. 128 MB of dedicated VRAM.	DirectX 11 or later with WDDM 1.0 Driver. 128 MB of dedicated VRAM.	DirectX 11 or later with WDDM 1.0 Driver. 128 MB of dedicated VRAM.	DirectX 11 or later with WDDM 1.0 Driver. 128 MB of dedicated VRAM.
Screen Resolution	1920 x 1080	1920 x 1080	1920 x 1080	1920 x 1080
Network	100 Mb	100 Mb	100 Mb	100 Mb

**Note:** The recommendations above are for a single cluster and server only running I/O, alarms, trends and reports. System resources for CPU and memory should be increased when using clustering, or if there is high rate of change of data (I/O or alarms).

The suggested disk space requirements for the HDD is an estimate only and includes:

- Runtime components.

- Compiled project.
- 20% of the I/O trending with a change on average every 10 seconds, 24 x 7 for 3 months.
- Alarm changes equal to the number of I/O changing per day.

If the deployment feature is being used, the HDD needs to have the required space for the number of configured project versions + 2. You should remove unused project versions periodically to reduce HDD usage.

An SSD is recommended for engineering machines for better performance. If a non-SSD is used, select a minimum RPM of 7200.

## Operating System Requirements

The following operating systems are supported (64-bit only):

- Windows 11 21H2 (or later)
- Windows 10 21H2 (or later)
- Windows 10 LTSC 1607 (or later)
- Windows Server 2016
- Windows Server 2019
- Windows Server 2022

Microsoft .NET Framework 4.8 is required. It will be installed by Plant SCADA if not detected.

When .NET installation is complete, you may be prompted to restart your computer. If this occurs, you should initiate a restart before you continue.

## Runtime Server Installation Procedure

This section lists the pages displayed by the Plant SCADA installer and the settings required for a Runtime Server. Use the **Back** and **Next** buttons to navigate through the included pages.

Installer Page	Notes
Installation Documentation	If required, view the available documents.
License Agreement	Accept the terms of the License Agreement.
What is the role of this computer?	Select <b>Server</b> .
Select the server(s) you want to install	Select <b>Runtime Server</b> . If required, you can also select other server types.

Installer Page	Notes
The selected products/components will be installed/upgraded.	<p>By default, the following components are selected when you install a Runtime Server.</p> <ul style="list-style-type: none"><li>• Platform Common Services</li><li>• AVEVA Plant SCADA<ul style="list-style-type: none"><li>• Runtime</li></ul></li><li>• AVEVA Plant SCADA Communications Drivers<ul style="list-style-type: none"><li>A set of commonly used drivers</li></ul></li><li>• Extensions<ul style="list-style-type: none"><li>• Software Update by Schneider Electric</li></ul></li></ul> <p>You can use this page to customize the list of components selected for installation.</p>
Access Restriction	<p>This page provides information about the local Windows groups the installer will create to manage security (see the section <i>Windows User Groups and Security Roles</i> in the topic <a href="#">Installation Information</a>).</p> <p><b>Note:</b> This page will only appear if you are installing Plant SCADA on a clean computer (one that has not hosted an earlier version). If you are upgrading from an earlier version, equivalent user groups will already exist on the computer.</p> <p>If you want your current Windows user account to be included in the groups that are being created, select <b>Add the current Windows user to these groups</b>.</p> <p>A dialog will let you know that the group membership changes will not occur until after a restart.</p>
Firewall	<p>If the installer detects that the computer has Windows Firewall enabled, you will be asked if you would like the installer to modify your settings.</p> <p>If you select <b>Yes</b>, Plant SCADA Runtime will be added to the list of authorized programs.</p> <p>See the section <i>Windows Firewalls</i> in the topic <a href="#">Installation Information</a>).</p>
Customize the installation location	<p>This page identifies the destination folders for:</p> <ul style="list-style-type: none"><li>• The selected Plant SCADA program files.</li><li>• The Plant SCADA User and Data folders.</li></ul> <p>You can modify the folder locations by clicking the <b>Change</b> buttons and selecting alternative locations.</p>

Installer Page	Notes
	You can also <b>Reset</b> the default locations. <b>Note:</b> The installation folder and the 'User and Data' folder cannot be the same, or a sub-directory of one another. You should also avoid selecting your Windows user folder.
Ready to Install the Program	This page lists the components that will be installed based on your selections. If required, use the <b>Back</b> button to make any modifications. Click <b>Install</b> to start the installation process.

When installation is complete, a dialog will appear asking if you would like to launch [Configurator](#). This may take a few minutes if you have installed some external components (for example, AVEVA Enterprise Licensing components).

**Note:** The installation experience is not complete until after you exit Configurator. A restart request is likely to appear at this point. To avoid permission issues, you should close Configurator and confirm if a reboot is required before you run Plant SCADA.

## See Also

[Runtime Server Installation Requirements](#)

[Use Configurator to Set Up a Runtime Server](#)

## Use Configurator to Set Up a Runtime Server

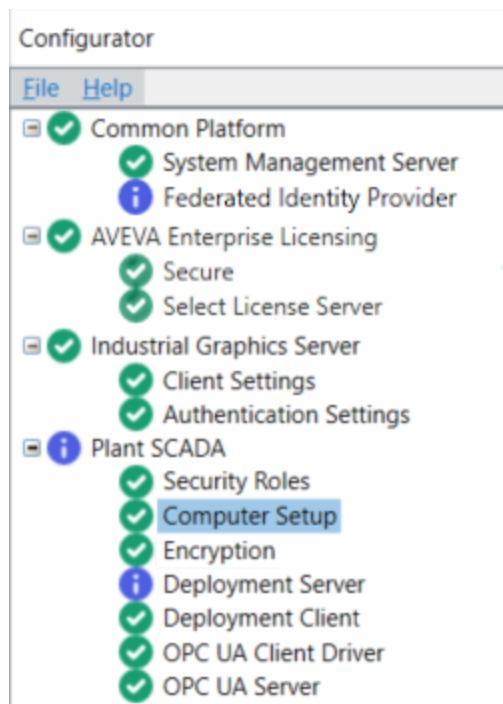

When your Plant SCADA installation is complete, a dialog will appear asking if you would like to launch [Configurator](#). You can use the **Configurator's Computer Setup** page to adjust the following runtime environment settings for a runtime server.

## Server Authentication

A server process requires the configuration of a password. This allows servers to authenticate and create trust with each other. If a computer will run a server process, you will need to create a new password, or use the password that is already used by other server computers in your Plant SCADA system.

[To configure server authentication for a runtime computer:](#)

1. In the panel on the left side of the **Configurator**, select **Plant SCADA | Computer Setup**.

2. The **Computer Setup** page appears. Navigate to the Server Authentication section. **Server Authentication** section.

#### Server Authentication

*Running a server process requires the configuration of a server password. Setting this password allows servers to authenticate and create trust with each other.*

Password	<input checked="" type="checkbox"/> Configure Server Password
<input type="password"/> <span style="font-family: monospace;">*****</span>	
Confirm Password	<input type="password"/> <span style="font-family: monospace;">*****</span>

3. Select the **Configure Server Password** check box.
4. Enter the required password and confirm it in the fields provided.

If the **Password** and **Confirm Password** fields already contain an entry, it means a server password has already been configured on the local computer. If required, you can enter a new password.

The password you use needs to match the password configured for the other server processes included in your Plant SCADA system. This password can be set on each computer using Configurator or the Setup Wizard.

5. To apply your settings, click the **Configure** button.

**Note:** If you change the server password while the runtime system is active, it will not disrupt any established connections as the password is only retrieved when authentication needs to occur. However, it is recommended that you apply the new password as soon as possible. To do this, you need to restart the runtime system.

## Project Run Path

If the computer will receive project updates from a Deployment Server, you need to indicate that you want to run the deployed project.

If you are not using deployment, you can use the default setting **Run the project selected in Plant SCADA Studio**.

### To set the Project Run Path:

1. In the panel on the left side of the **Configurator**, select **Plant SCADA | Computer Setup**.

The **Computer Setup** page appears.

2. Navigate to the **Project Run Path** section.

#### Project Run Path

*Runtime can run the project selected in Plant SCADA Studio, or the project that has been deployed by the Deployment Server*

- Run the project selected in Plant SCADA Studio.**  
 **Run the project deployed from the Deployment Server.**

3. Select one of the following options to determine which project will be launched by Runtime Manager:

- **Run the project currently selected in Plant SCADA Studio** — This is selected by default and will run the project from Plant SCADA Studio.
- **Run the project deployed from the Deployment Server** — Select this option to set up a computer for deployment. This option allows you to run the deployed projects from the deployment server.

4. To apply your settings, click the **Configure** button.

---

**Note:** If Plant SCADA Runtime is running as a service and the **Project Run Path** option in the Configurator is changed to **Run the project deployed from the Deployment Server**, you need to restart the Runtime Manager service for deployment to function correctly.

---

## Runtime Manager Configuration

This setting instructs Runtime Manager to run as a service. This allow a project to be deployed and run on a computer without having to change other settings.

You need to select **Run Runtime Manager as a service** under the following circumstances:

- When a deployment client is configured on a computer and you want to push project updates using "Force" mode.
- If you are using encrypted communications, and the current user on a deployment client may not have required privileges.

---

**Note:** The current user on a deployment client needs to be a member of **Configuration Users** security role to run the deployment client (see [Security Roles](#)).

---

These settings can be made using the **Configurator's Plant SCADA | Computer Setup** page. You can launch Configurator at the completion of the installation procedure, or go to the Windows® **Start** menu and locate AVEVA | **Configurator**.

### To run Runtime Manager as a service:

1. In the panel on the left side of the **Configurator**, select Plant SCADA | **Computer Setup**. The **Computer Setup** page appears. Navigate to the **Runtime Manager Configuration** section of the dialog.

#### Runtime Manager Configuration

*The Runtime Manager can be configured to run as a service or as a standard process. When run as a service, Runtime Manager allows projects to be deployed to the machine without having to change any other settings.*

Run Runtime Manager as a service

2. Select **Run Runtime Manager as a Service**.

---

**Note:** If you are using Deployment to run a project and do not select the **Run Runtime Manager as a Service** option, you will need to manually start the Plant SCADA Runtime Manager before deploying the project.

---

3. To apply your settings, click the **Configure** button.

---

**Note:** If you have configured a Plant SCADA OPC DA server on a computer that is running Plant SCADA as a Windows service, you will need to make the additional configuration changes. See the topic [Running an OPC DA Server as a Service](#) in the *Runtime* section of the Plant SCADA documentation.

---

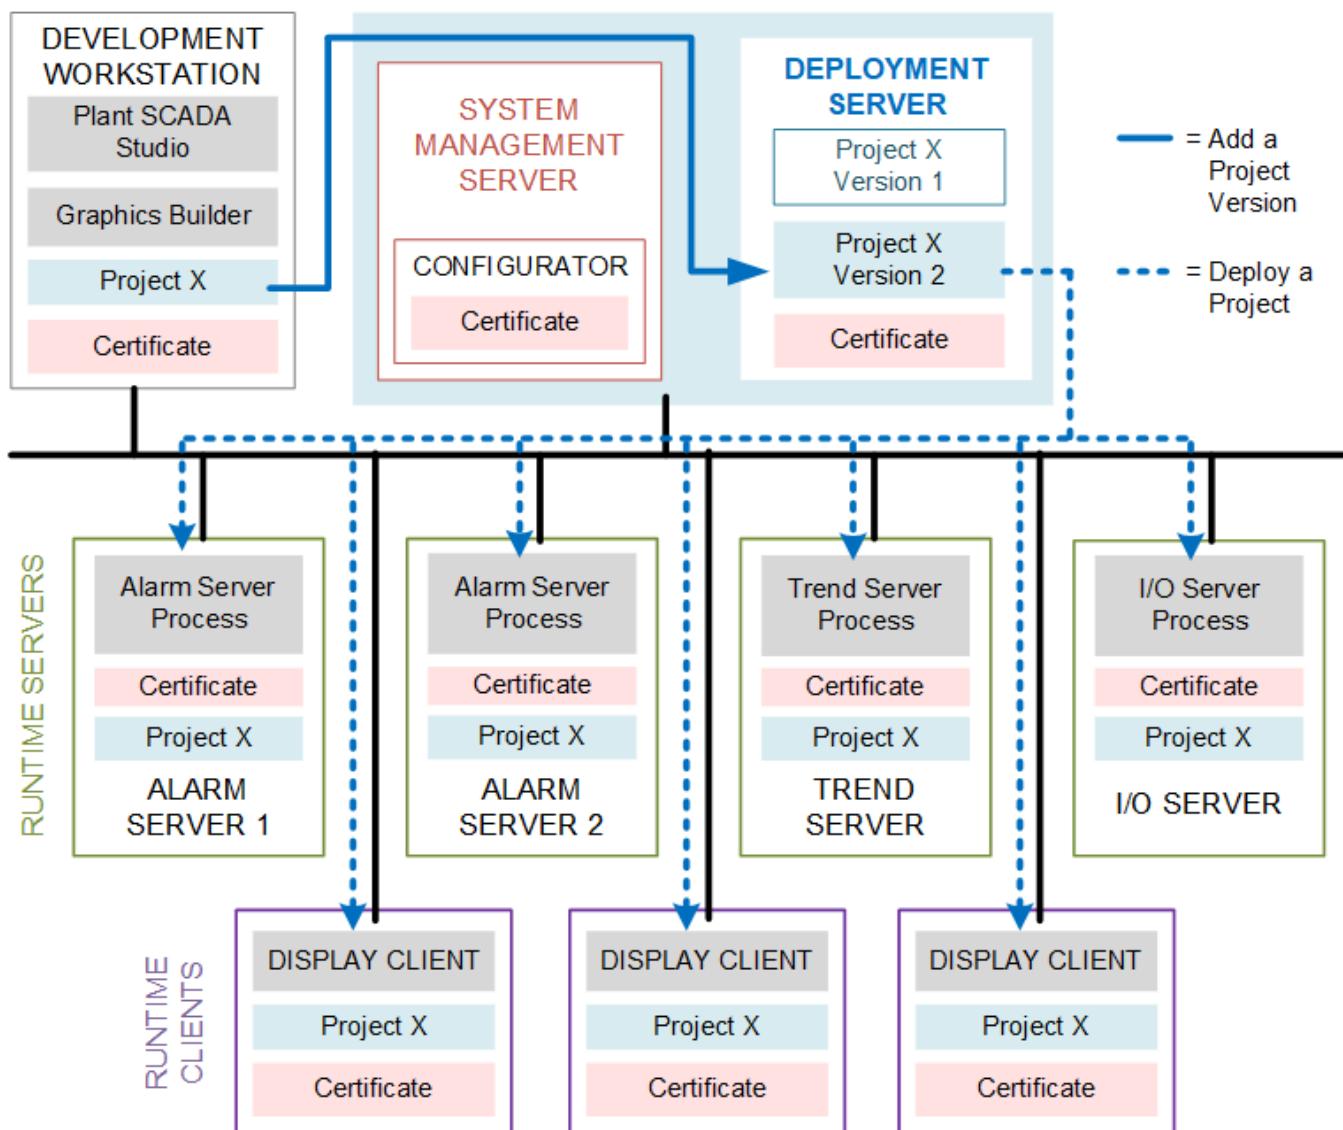

## See Also

[Runtime Server Installation Requirements](#)

[Runtime Server Installation Procedure](#)

## Install a Deployment Server

A Deployment Server allows you to distribute projects (and any subsequent updates) to the computers in your Plant SCADA system. It stores multiple "versions" of a project's runtime files, allowing you to deploy a specific version to any computer that has been configured as a deployment client.

A Deployment Server uses encrypted communications, which means it requires access to a System Management Server. Ideally the Deployment Server should be installed on the same computer as the System Management Server. See [Set Up a System Management Server](#).

#### Note:

- If you install the Deployment Server on a different computer to the System Management Server, you cannot use the default local user groups assigned to the Deployment Security Roles as they will not work in a distributed environment. You need to create domain user groups that align with the existing local groups, and add these to the Deployment Security Roles. The domain groups can then be used instead of the following default local user groups.

Deployment Administrators role: 'SCADA.DeploymentAdmins' or 'Asb.Deployment.AdminRole'.

Deployment Uploaders role: 'SCADA.DeploymentUploaders' or 'Asb.Deployment.UploadRole'.

Deployment Users role: 'SCADA.DeploymentUsers' or 'Asb.Deployment.DeployRole'.

See [Modifying the Members of a Security Role](#).

- When installing a Deployment Server as part of a workgroup, it must be installed on the same computer as the System Management Server. If you need the Deployment Server on a separate computer to the System Management Server, you will need to move your IT infrastructure to a domain.

When using Industrial Graphics, a Deployment Server is required to deliver project versions to the Industrial Graphics Server.

**Note:** The deployment architecture installed with Plant SCADA 2023 (and later) is no longer compatible with deployment servers running an earlier version. This means:

- You cannot use Plant SCADA Studio to add projects to a deployment server that is running a different version of Plant SCADA.
- You cannot deploy a project from a deployment server to a deployment client if they are running different versions of Plant SCADA.

If you have a distributed system that includes some computers on an earlier version of Plant SCADA, you should retain your existing deployment server to distribute projects to these computers until the roll out of the new version is complete. You will also need to configure a new deployment server to deploy new projects to your upgraded computers.

[Configure a Deployment Client](#)

## Deployment Server Installation Requirements

This section describes the hardware and software requirements for a computer that will host a Deployment Server.

Before you install Plant SCADA, it is recommended that you install the latest updates from Microsoft® for your operating system and system software.

## Hardware Requirements

The hardware requirements for a Deployment Server are as follows:

Cores	4
Memory	8 GB
HDD	Size of project backed up, multiplied by the number of versions expected to be stored.  An SSD is recommended for better performance. If a non-SSD is used, select a minimum RPM of 7200.
CPU PassMark®	4250
Network	1 GB

## Operating System Requirements

The following operating systems are supported (64-bit only):

- Windows 11 21H2 (or later)
- Windows 10 21H2 (or later)
- Windows 10 LTSC 1607 (or later)
- Windows Server 2016
- Windows Server 2019
- Windows Server 2022

Microsoft .NET Framework 4.8 is required. It will be installed by Plant SCADA if not detected.

When .NET installation is complete, you may be prompted to restart your computer. If this occurs, you should initiate a restart before you continue.

When installation is complete, a dialog will appear asking if you would like to launch [Configurator](#). This may take a few minutes if you have installed some external components (for example, AVEVA Enterprise Licensing components).

---

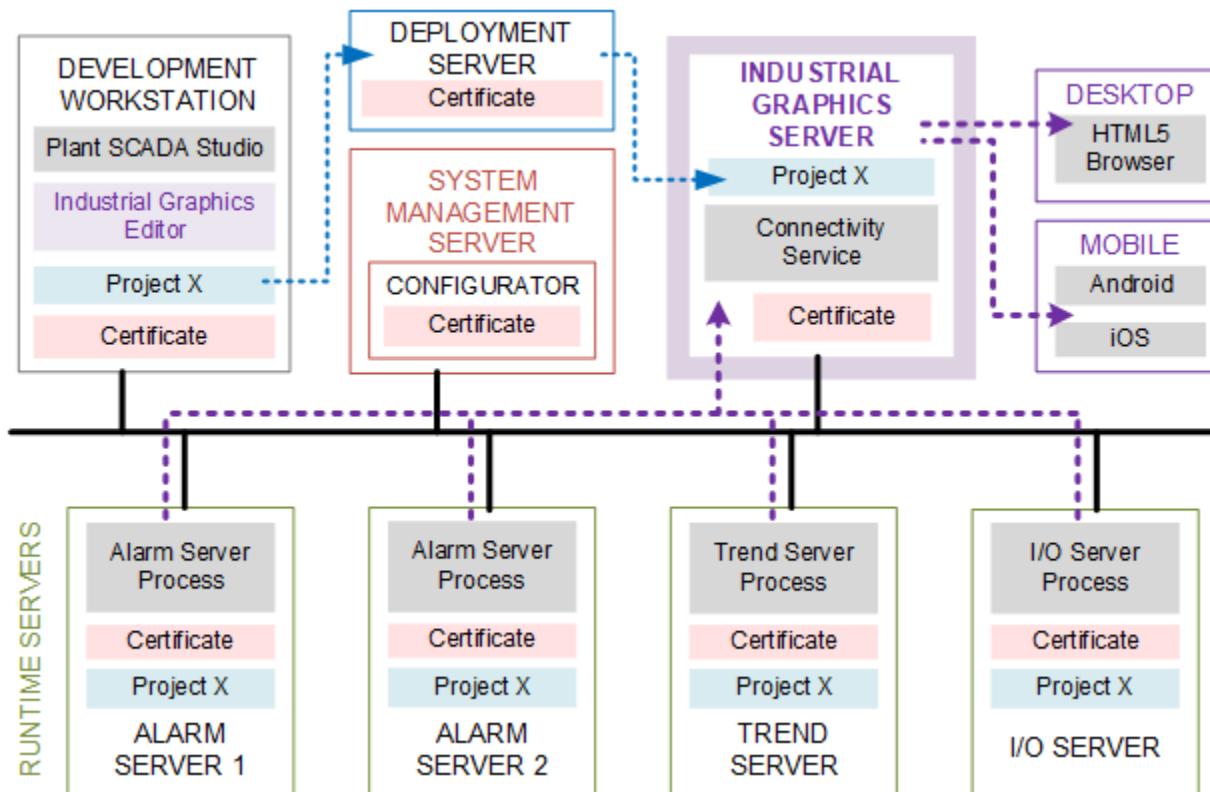

**Note:** The installation experience is not complete until after you exit Configurator. A restart request is likely to appear at this point. To avoid permission issues, you should close Configurator and confirm if a reboot is required before you run Plant SCADA.

To configure your system for deployment following installation, see the topics [Configure a Deployment Server](#)

and [Configure a Deployment Client](#).

## Install an Industrial Graphics Server

An AVEVA™ Industrial Graphics Server distributes HTML5 graphics to desktop and mobile browsers. It authenticates clients details and provides access to the graphical and functional content created using the Plant SCADA Industrial Graphics Editor.

**Note:** With this release of Plant SCADA, the Industrial Graphics Server has a number of functionality limitations. For example, it does not support alarms. For a full list of limitations, see [Industrial Graphics Server Functionality Limitations](#).

### ⚠️ WARNING

#### UNINTENDED EQUIPMENT OPERATION

A computer that hosts an Industrial Graphics Server must be configured to use an English regional locale. This ensures that any values with unit separators are interpreted correctly when entered by an operator.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

When you choose to install an Industrial Graphics Server, the following components are selected by default:

- Plant SCADA Industrial Graphics Server
- Plant SCADA Deployment Client.

The Deployment Client is required as Plant SCADA's Deployment functionality is used to deliver projects to the

Industrial Graphics Server.

**Note:**

- For runtime operation, it is recommended that you install an Industrial Graphics Server on a dedicated computer especially if it will be required to handle a large number of client requests.
- If you would like to review an Industrial Graphics application locally during development, you also need to have an Industrial Graphics Server installed locally on the development workstation.

Licensing for AVEVA Industrial Graphics is managed using the AVEVA Enterprise Licensing system, which means you may also need to install the Enterprise Licensing Server and/or the Enterprise Licensing Manager. For more information, see [AVEVA™ Enterprise Licensing](#).

If required, you can display the Industrial Graphics Web Client locally on the Industrial Graphics Server using the following address in a browser:

- `https://localhost/aig`

Be aware, however, that the connected System Management Server may be configured to use a non-default port (see [Advanced Configuration for a System Management Server](#)). This changes the port the AIG server uses to listen, which means you need to include the current **HTTPS Port** setting in the address as follows:

- `https://localhost:<HTTPS Port value>/aig`

**Note:** If the Plant SCADA compiler determines that your SCADA system tag names are not globally unique across all clusters, any tag subscriptions that do not specify a specific cluster will be rejected by the Industrial Graphics Server. If this occurs, you can use the parameter [\[General\]EnforceTagGlobalUniqueness](#) to diagnose which tags are not globally unique.

## See Also

[Industrial Graphics Server Installation Requirements](#)

[Industrial Graphics Server Installation Procedure](#)

[Use Configurator to Set Up an Industrial Graphics Server](#)

[Confirm the Settings for an Industrial Graphics Server](#)

## Industrial Graphics Server Functionality Limitations

With the current release of Plant SCADA, the Industrial Graphics Server has the following functionality limitations:

- Alarms are not supported.
- Only English locale is supported by the Industrial Graphics Server.
  - For decimal points you need to use "." (period).
  - For thousand separators you need to use "," (comma).
- The status of write operations is not reflected by the status element or quality styles applied to elements. Design your pages so that an operator can determine if a write has been set or rejected by displaying the current value.
- Local variables cannot be referenced.

- Alarm Properties as Tags are not exposed.
- Quality tag extensions are represented as a numeric value. Only OPC quality should be used for an Industrial Graphics application.
- Extended quality modes "Control Inhibit" and "Tag Override" are not available.
- Plant SCADA trends are not supported, however, instant trends via an I/O tag or AVEVA™ Historian are available.
- Web widgets are not supported.
- Industrial Graphics cannot be imported/exported between Plant SCADA and other AVEVA products.
- Native Plant SCADA graphics cannot be converted or imported into Industrial Graphics applications.
- Redundant Industrial Graphics Servers are not supported.

---

**Note:** It is recommended that you review the list of supported graphical elements and limitations before you start creating an Industrial Graphics application. See the topic [Supported Graphical Elements and Known Limitations](#) in the *AVEVA™ Industrial Graphics* section of the Plant SCADA documentation.

---

- [Use Configurator to Set Up an Industrial Graphics Server](#)
- [Confirm the Settings for an Industrial Graphics Server](#)

## Industrial Graphics Server Installation Requirements

This topic describes the hardware and software requirements for a computer that will host an Industrial Graphics Server.

Before you install Plant SCADA, it is recommended that you install the latest updates from Microsoft® for your operating system and system software.

---

**Note:** It is recommended to install the Industrial Graphics Server on a dedicated computer.

---

## Hardware Requirements

The hardware requirements for an Industrial Graphics Server are as follows:

- CPU PassMark®: > 5200 pts
- RAM: 16 GB
  - Each client session requires ~200 Mb of memory, depending upon graphics complexity.
- HDD: 500 Mb and space for the project's Industrial Graphics.
- Client connections: 10
  - Additional clients can be supported by increasing the number of CPU's, CPU speed, and Memory.

---

**Note:** The recommended requirements are suitable for a system with ten clients, browsing pages with approximately 40 dashboard/charting components with ~250 I/O tags on the page. Pages may take a longer time to display on the first visit. The display time depends on graphics and script complexity.

---

## Operating System Requirements

The following operating systems are supported (64-bit only):

- Windows 11 21H2 (or later)
- Windows 10 21H2 (or later)
- Windows 10 LTSC 1607 (or later)
- Windows Server 2016
- Windows Server 2019
- Windows Server 2022

Microsoft .NET Framework 4.8 is required. It will be installed by Plant SCADA if not detected.

When .NET installation is complete, you may be prompted to restart your computer. If this occurs, you should initiate a restart before you continue.

**Note:** Licensing for AVEVA Industrial Graphics is managed using the AVEVA Enterprise Licensing system. If you do not have access to an existing Enterprise License Server, you will need to include the **AVEVA Enterprise License Manager** and **AVEVA Enterprise License Server** to your Plant SCADA installation. For more information, see [AVEVA™ Enterprise Licensing](#).

- [Industrial Graphics Server Installation Requirements](#)
- [Use Configurator to Set Up an Industrial Graphics Server](#)
- [Confirm the Settings for an Industrial Graphics Server](#)

## Use Configurator to Set Up an Industrial Graphics Server

You can use [Configurator](#) to enable authentication for an Industrial Graphics Server. You can also adjust the refresh rates for any connecting clients. These settings are available on the following pages within the **Industrial Graphics Server** branch of the Configurator directory.

### Authentication Settings

#### System Management Server

You need to connect a computer that hosts an Industrial Graphics Server to a System Management Server (SMS). This will allow authentication and authorization requests to be handled by the SMS's Identity Manager.

When connected, the **System Management Server** field will display the name of the computer hosting the SMS.

If "not connected" is displayed, you will need to configure the connection to an SMS (see [Connect a Computer to a System Management Server](#)).

### Secure Gateway

If required, you can use a secure gateway to avoid directly exposing the Industrial Graphics Server to client computers that are not a part of your SCADA system network.

To use a secure gateway, enter the Fully Qualified Domain Name for the computer that hosts the secure gateway server you want to use. The computer you use should be located in a DMZ.

For more information, see the topic [Secure the Industrial Graphics Web Client](#).

## Client Settings

The Client Settings page allows you to specify the following settings for clients that connect to the Industrial Graphics Server.

### Graphic Refresh Rate

Allows you to specify (in milliseconds) how regularly graphics are refreshed in a connected Industrial Graphics Client. You can specify a **Refresh Rate** between 250 and 60000 milliseconds.

### Alarm Refresh Rate

This feature is not supported by Industrial Graphics applications in this version of Plant SCADA.

---

**Note:** Plant SCADA's Deployment functionality is used to deliver projects to the Industrial Graphics Server. For this reason, you will need to use Configurator's **Deployment Client** page to connect the Industrial Graphics Server to your system's Deployment Server. See [Configure a Deployment Client](#) for further instructions.

---

## Confirm the Settings for an Industrial Graphics Server

To confirm that an Industrial Graphics Server is ready for operation, you should check that you have completed the following steps.

### Connect all your Plant SCADA computers to a System Management Server

To connect a computer to a System Management Server, use the System Management Server page in **Configurator**. See [Connect a Computer to a System Management Server](#).

### Configure the authentication settings

The required settings are available on the **Authentication Settings** page within the **Industrial Graphics Server** branch of Configurator. See [Use Configurator to Set Up an Industrial Graphics Server](#).

### Set up deployment

If your Industrial Graphics Server is running on a remote computer, set it up for deployment.

- Set up a deployment server in your system (see [Configure a Deployment Server](#)).
- Configure a deployment client on the Industrial Graphics Server so that it can receive project versions from the deployment server (see [Configure a Deployment Client](#)).

## Enable encryption

An Industrial Graphics Server will only connect to your Plant SCADA servers over an encrypted connection. You need to confirm the following:

- Plant SCADA is configured to run with encryption enabled. This is achieved via the **Encryption** page in Configurator (see [Enable Encryption](#) in the Plant SCADA documentation).  
Running in mixed mode is acceptable as long the remaining prerequisites are also met.
- Runtime Manager needs to be configured to run as a service.  
This is required to enable encryption. The required settings are available on **Configurator's Computer Setup** page (see [Configure a Runtime Computer for Encryption](#) in the Plant SCADA documentation).
- In your project settings, confirm the **DNS Name** field is configured for each entry in the **Computers** activity. This is also required to enable encryption.
- Run the Computer Setup Wizard and confirm on the **Network Model** page that networking is enabled. This is required even if you are running the Industrial Graphics Server and the Plant SCADA servers on a single computer.

## Set up user authentication

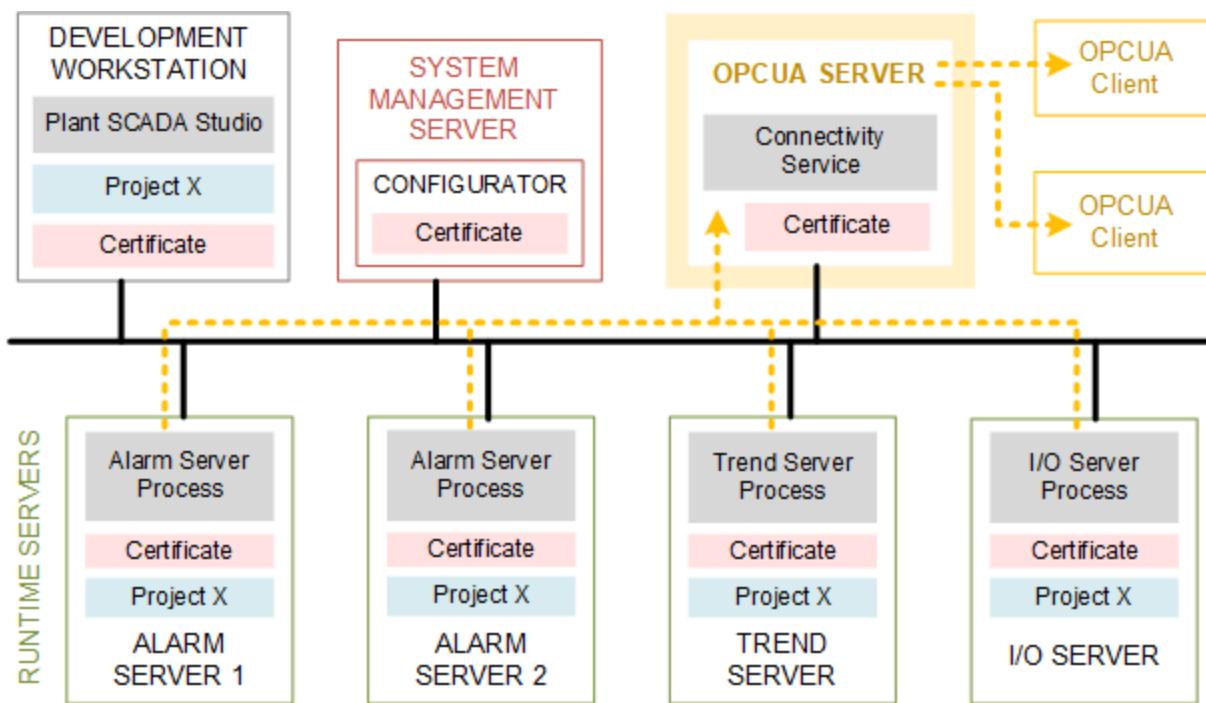

The Industrial Graphics Server only supports authentication with Windows® users. Plant SCADA users are not supported.

Authentication occurs in two places:

- To establish a connection to the Industrial Graphics Server, a user must be a member of a Windows group that is mapped to the "Industrial Graphics Users" security role (see [Security Roles](#)).
- The user must also be a member of a Windows group that is mapped to a valid Role within your Plant SCADA project. See the topic [Roles](#) within the *Runtime System Security* section of the Plant SCADA documentation.

## Install an OPC UA Server

An OPC UA server allows Plant SCADA's runtime system to function as a server to OPC UA client applications.

**Note:** In this release of Plant SCADA, the OPC UA server has the following functionality limitations:

- The server supports DA only.
- Quality tag extensions are represented as a numeric value. Only the OPC quality is exposed.
- Alarm Properties as Tags are not exposed.
- Extended quality modes "Control Inhibit" and "Tag Override" are not available.
- Redundant OPC UA servers are not supported.

Tag extensions are included in the OPC UA browse hierarchy. Of those presented, a client can subscribe to the following:

- Field
- Control Mode
- Override Mode
- Valid
- Status
- Override

Following installation, you can configure the OPC UA server via Configurator's **OPC UA Server** plugin under Plant SCADA. This has four configuration options:

- **Port number** – the port number the OPC UA server will listen on.
- **URL** – the URL to use to connect an OPC UA client to the OPC UA server (read only).
- **Enable Encryption** – This option allows encrypted communications between the OPC UA server and a connected client.
- **Allow Anonymous access** – Checking this option allows anonymous users to connect to the OPC UA server.

See [Use Configurator to Set Up an OPC UA Server](#).

If the OPC UA server is installed on a separate computer, you will need to configure a deployment server and

client to deploy the relevant project information to the OPC UA server. Once the project files have been deployed, the OPC UA server will start using the new configuration automatically.

To communicate with the Plant SCADA runtime system, you also need to connect the OPC UA server to a System Management Server to enable encrypted communication with the Plant SCADA servers.

**Note:** The OPC UA server requires the purchase of a specific license. Please contact your Plant SCADA distributor for more information.

## **WARNING**

### **UNINTENDED EQUIPMENT OPERATION**

If you update the Equipment Name or Equipment Item for a variable tag and restart the I/O server, any OPC UA clients that are subscribed to this tag via its old equipment name may show outdated values. After restarting the I/O server, perform the rebrowse operation in the OPC UA client and resubscribe to those variables tags.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** The OPC UA Server's browse functionality will always retrieve a tag name with the cluster prefix. However, if you manually subscribe to a Plant SCADA tag using its tag name, the OPC UA Server may reject the subscription request if a cluster is not explicitly defined. This will occur if the compiler determines that your SCADA system tags are not globally unique across all clusters. If this occurs, you can use the parameter [\[General\]EnforceTagGlobalUniqueness](#) to diagnose which tags are not globally unique.

## **See Also**

[OPC UA Server Installation Requirements](#)

[OPC UA Server Installation Procedure](#)

[Use Configurator to Set Up an OPC UA Server](#)

[Confirm the Settings for an OPC UA Server](#)

## **OPC UA Server Installation Requirements**

This topic describes the hardware and software requirements for a computer that will host an OPC UA Server.

Before you install Plant SCADA, it is recommended that you install the latest updates from Microsoft® for your operating system and system software.

It is also recommended that you install the OPC UA Server on a dedicated computer.

**Note:** The OPC UA server requires the purchase of a specific license. Please contact your Plant SCADA distributor for more information.

## **Hardware Requirements**

The hardware requirements for a OPC UA Server are as follows:

- CPU PassMark®: > 4000 pts
- RAM: 16 GB
- Changes per second: < 25,000

OPC UA in Plant SCADA supports a minimum sampling rate of 500 milliseconds, which means it can capture value changes for a tag at one second interval.

A higher number of changes per second can be supported, but this will require additional memory and CPU performance.

- Subscribed tags: < 100,000
- Maximum OPC UA clients in the system: < 10

Adding each OPC UA client to the connected OPC UA server increases the CPU and memory usage on both the OPC UA server and the I/O sever.

---

**Note:**

- Several systems with a large number of tags arranged in a flat architecture, or a hierarchy with many child nodes, will significantly impact the browse performance of a connected OPC UA client.
  - Plant SCADA now includes a connectivity service that manages tag subscriptions for the OPC UA Server and Industrial Graphics Server. This places an additional load on your I/O servers, particularly if a subscribed tag also specifies a property or extension. If this impacts I/O performance, you should consider distributing your I/O servers across a number of computers. You can also disable support for properties and extensions with the parameter [\[IOServer\]DisableConnectivityPropertiesAndExtensions](#).
- 

## Operating System Requirements

The following operating systems are supported (64-bit only):

- Windows 11 21H2 (or later)
- Windows 10 21H2 (or later)
- Windows 10 LTSC 1607 (or later)
- Windows Server 2016
- Windows Server 2019
- Windows Server 2022

Microsoft .NET Framework 4.8 is required. It will be installed by Plant SCADA if not detected.

When .NET installation is complete, you may be prompted to restart your computer. If this occurs, you should initiate a restart before you continue.

---

**Note:** The OPC UA Server does not support browse filtering by OPC UA Clients.

---

## OPC UA Server Installation Procedure

This section describes the pages displayed by the Plant SCADA installer and the settings required for an OPC UA Server. Use the **Back** and **Next** buttons to navigate through the included pages.

Installer Page	Notes
Installation Documentation	If required, view the available documents.
License Agreement	Accept the terms of the License Agreement.
What is the role of this computer?	Select <b>Server</b> .
Select the server(s) you want to install	<p>Select <b>Plant SCADA OPC UA Server</b>. If required, you can also select other server types.</p>
The selected products/components will be installed/upgraded.	<p>By default, the following components are selected when you install an OPC UA Server.</p> <ul style="list-style-type: none"> <li>• Platform Common Services</li> <li>• Plant SCADA OPC UA Server</li> </ul> <p>You can use this page to customize the list of selected components.</p>
Access Restriction	<p>This page provides information about the local Windows groups the installer will create to manage security (see the section <i>Windows User Groups and Security Roles</i> in the topic <a href="#">Installation Information</a>).</p> <p><b>Note:</b> This page will only appear if you are installing Plant SCADA on a clean computer (one that has not hosted an earlier version). If you are upgrading from an earlier version, equivalent user groups will already exist on the computer.</p> <p>If you want your current Windows user account to be included in the groups that are being created, select <b>Add the current Windows user to these groups</b>. A dialog will let you know that the group membership changes will not occur until after a restart.</p>
Firewall	<p>If the installer detects that the computer has Windows Firewall enabled, you will be asked if you would like the installer to modify your settings.</p> <p>If you select <b>Yes</b>, Plant SCADA Runtime will be added to the list of authorized programs.</p> <p>See the section <i>Windows Firewalls</i> in the topic <a href="#">Installation Information</a>).</p>
Customize the installation location	<p>This page identifies the destination folders for:</p> <ul style="list-style-type: none"> <li>• The selected Plant SCADA program files.</li> <li>• The Plant SCADA User and Data folders.</li> </ul>

Installer Page	Notes
	<p>You can modify the folder locations by clicking the <b>Change</b> buttons and selecting alternative locations.</p> <p>You can also <b>Reset</b> the default locations.</p> <p><b>Note:</b> The installation folder and the 'User and Data' folder cannot be the same, or a sub-directory of one another. You should also avoid selecting your Windows user folder.</p>
Ready to Install the Program	<p>This page lists the components that will be installed based on your selections.</p> <p>If required, use the <b>Back</b> button to make any modifications.</p> <p>Click <b>Install</b> to start the installation process.</p>

When installation is complete, a dialog will appear asking if you would like to launch [Configurator](#). This may take a few minutes if you have installed some external components (for example, AVEVA Enterprise Licensing components).

**Note:** The installation experience is not complete until after you exit Configurator. A restart request is likely to appear at this point. To avoid permission issues, you should close Configurator and confirm if a reboot is required before you run Plant SCADA.

## See Also

[OPC UA Server Installation Requirements](#)

[Use Configurator to Set Up an OPC UA Server](#)

[Confirm the Settings for an OPC UA Server](#)

## Use Configurator to Set Up an OPC UA Server

When your Plant SCADA installation is complete, a dialog will appear asking if you would like to launch [Configurator](#).

To set up an OPC UA Server, open Configurator and adjust the following settings on the **OPC UA Sever** page under Plant SCADA.

**Note:** The settings on this page will not encrypt communication with Plant SCADA runtime. You need to connect the OPC UA server to a System Management Server and have encryption enabled to allow communication with a runtime system. See [Enable Encryption](#).

## Address Configuration

- Enter the **Port Number** that you want to use for the OPC UA server. The value you enter will be reflected in the URL.
- The **URL** field shows the address that you need to use to connect an OPC UA client to the OPC UA server. You cannot edit this field. It defaults to:

opc.tcp://<computer name>:48031/plantscada.

The OPC UA server does not support OPC UA's discovery feature, so you need to manually enter this URL into a client application to connect to an OPC UA server.

## Encryption

Select **Enable encrypted communications** to protect the connection between the OPC UA server and any connected clients. This will set the security policy to Basic256Sha256 and the security mode to SignAndEncrypt.

For information on how to use certificates to enable encrypted communications between a Plant SCADA OPC UA server and an OPC UA client, see [Configure Client Certificates for an OPC UA Server](#).

---

**Note:** It is recommended that you enable encryption to help secure the OPC UA server.

## Authentication

Select **Allow anonymous connections** if you want to allow users to connect anonymously to the OPC UA Server.

If this option is not selected, a user will only be able to access the server if they are part of a Windows group that is associated with one of the [Security Roles](#) defined in your project. Plant SCADA users are not supported.

---

**Note:** It is recommended that you disable anonymous access to facilitate user-based security for the OPCUA server. Also, tag writes from an OPC UA client application are not supported if anonymous access is enabled.

## Browsing

Many OPC UA clients will only allow writes to occur on the leaf nodes in the OPC UA browse result. For OPC UA clients that support this functionality, you will need to select **Disable properties and extensions**.

## Configure Client Certificates for an OPC UA Server

You can use certificates to enable encrypted communications between a Plant SCADA OPC UA Server and an OPC UA client. To achieve this, both computers require access to the following certificates:

- The "<Computer Name> ASB OPC UA Server" certificate from the OPC UA Server
- The client certificate from the OPC UA client.

---

**Note:** The information provided in this topic is intended for a scenario where SMS certificates are used on computers contained within your SCADA system network. If you want to deliver information across multiple domains or externally via the internet, we recommend you seek professional advice on setting up an external web server.

To complete this setup, you will need to perform the following procedures.

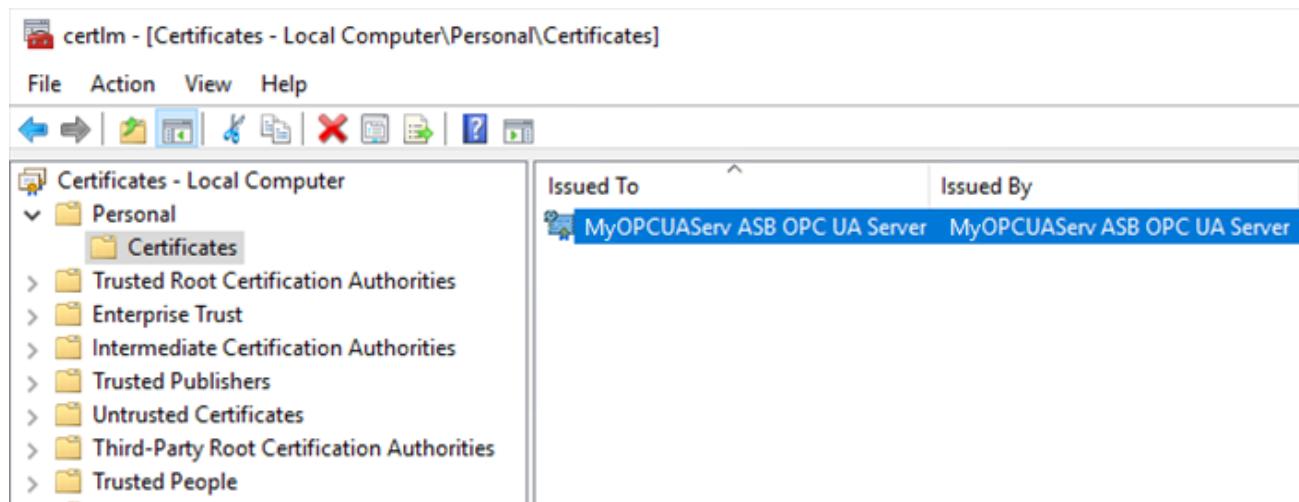

### Copy the OPC UA Server certificate to the OPC UA client

You initially need to export a copy of two certificates created by the SMS.

1. Open Windows™ Certificate Manager.

To do this, you can type "manage computer certificates" into the Windows **Search** bar.

2. In the tree view, go to the **Personal** branch then select **Certificates**.
3. Locate the certificate named "<computer name> ASB OPC UA Server".

4. Right-click on the certificate and select **All Tasks**, then **Export**. This will open the Certificate Export Wizard. Depending on the type of certificates that your client application uses, you will need to export the certificate as a CER file (if the client uses the Windows™ Certificate Store) or a DER file (if the client uses file-based certificates). These two formats are the same, only the file extension is different.
5. Use the following settings to export the certificate.
  - On the **Export Private Key** page, select **No, do not export the private key**.
  - On the **Export File Format** page, select **DER encoded binary X.509 (.CER)** or **Base-64 encoded X.509 (.CER)** (depending on the requirements of your client application).
  - On the **File To Export** page, enter a path and file name (for example, "c:\temp\<machine name> OPC UA Server.cer").
6. When you reach the Finish page, review the settings and click **Finish** to export a copy of the certificate.

Once the certificate has been exported, you may need to rename the file extension on the certificate from ".cer" to ".der" (if the client uses file-based certificates).

## Import the OPC UA Server Certificate on the Client Computer

OPC UA client applications will generally use one of the following mechanisms to manage certificates:

- Using the Windows™ Certificate Store
- Storing certificates in a specified folder (that is predefined by the OPC UA client application).

### Import a certificate into the Windows Certificate Store

Importing a certificate into the Windows Certificate Store requires administrator rights.

1. Copy the "<machine name> OPC UA Server.cer" file to an appropriate location on the client computer.
2. Right click on the CER file and select **Install Certificate**. This will open the Certificate Import Wizard.
3. Use the following settings.

- Under **Store Location**, select **Local Machine**.
  - On the **Certificate Store** page, select **Personal**.
4. When you reach the last page, review the settings and click **Finish**.

### Import a certificate into a specified location

Copy the "<machine name> OPC UA Server.der" file to the folder that is used by your OPC UA client application.

The table below includes the location of the certificate folder for some common OPC UA clients.

OPC UA Client	Manufacturer	Certificate Folder
Datafeed OPC UA Client	Softing	C:\ProgramData\Softing\OpcClient\pki\trusted\certs
UaExpert	Unified Automation	C:\Users\Admin\AppData\Roaming\unifiedautomation\uaexpert\PKI\trusted\certs
UA Client Getting Started	Unified Automation	C:\ProgramData\unifiedautomation\UaSdkNetBundleEval\pkiclient\trusted\certs
Matrikon	Matrikon	C:\Users\Admin\AppData\Local\Matrikon\OPCUAExplorer\pki\DefaultApplicationGroup\trusted\certs
KEPServer	Kepware	C:\ProgramData\Kepware\KEPServerEX\V6\UA\Client Driver\cert
Top Server	Software Toolbox	C:\ProgramData\Software Toolbox\TOP Server\V6\UA\Client Driver\cert

For more information, please refer to the documentation provided with your OPC UA client application.

### Configure the OPC UA client certificate on the OPC UA Server

The next step in this process is trust the OPC UA client certificate on the computer the OPC UA Server is running on.

The easiest way to do this is to attempt to connect an OPC UA client to the server. As the server will not trust the client certificate yet, the connection is expected to be unsuccessful. However, after this happens, any OPC UA client certificates that are not installed on the OPC UA Server computer will be put into the "Rejected Certificate" folder on the OPC UA Server. By default, this is in the following folder:

C:\ProgramData\AVEVA\PCS\OPC UA Rejected Client Certificates\certs"

Accessing this folder requires administrator rights.

## Import certificates from the Rejected Certificates folder

1. Browse to the rejected certificate folder.
2. Right click on the certificate for the OPC UA client that you want to trust and select **Install Certificate**. This will open the Certificate Import Wizard.
3. Use the following settings.
  - Under **Store Location**, select **Local Machine**.
  - On the **Certificate Store** page, select **Trusted People**.
4. When you reach the last page, review the settings and click **Finish**.

## Configure the OPC UA Server ports

OPC UA communicates via a single TCP port. This is specified in the **Endpoint Connection** setting for the OPC UA Server.

This defaults to port 48031.

You will need to confirm that this port is not blocked by any firewall software installed on your computer.

## See Also

[Confirm the Settings for an OPC UA Server](#)

## Confirm the Settings for an OPC UA Server

To confirm that an OPC UA Server is ready for operation, you should check that you have completed the following steps.

## Connect all your Plant SCADA computers to a System Management Server

The System Management Server facilitates encrypted communications for your Plant SCADA system. To connect a computer to a System Management Server, use the System Management Server page in **Configurator**. See [Connect a Computer to a System Management Server](#).

## Set up deployment

If your OPC UA Server is running on a remote computer, set it up for deployment.

- Set up a deployment server in your system (see [Configure a Deployment Server](#)).
- Configure a deployment client on the OPC UA Server so that it can receive project versions from the deployment server (see [Configure a Deployment Client](#)).

## Confirm the Configurator settings for the OPC UA Server

The required settings are available on the **OPC UA Server** page within the **Plant SCADA** branch of Configurator. See [Use Configurator to Set Up an OPC UA Server](#).

## Enable encryption

An OPC UA Server will only connect to your Plant SCADA servers over an encrypted connection. You need to confirm the following:

- Plant SCADA is configured to run with encryption enabled. This is achieved via the **Encryption** page in Configurator (see [Enable Encryption](#)).

Running in mixed mode is acceptable as long the remaining prerequisites are also met.

- Runtime Manager needs to be configured to run as a service.

This is required to enable encryption. The required settings are available on **Configurator's Computer Setup** page (see [Configure a Runtime Computer for Encryption](#)).

- In your project settings, confirm the **DNS Name** field is configured for each entry in the **Computers** activity. This is also required to enable encryption.
- Run the Computer Setup Wizard and confirm on the **Network Model** page that networking is enabled. This is required even if you are running the OPC UA Server and the Plant SCADA servers on a single computer.

## Set up user authentication

If **Enable Anonymous Access** is disabled for the OPC UA Server, a user name and password will be required to connect to the OPC UA server. Only authentication with Windows® users is supported (Plant SCADA users are not supported).

The user must also be a member of a Windows group that is mapped to a valid Role within your Plant SCADA project. See the topic [Roles](#) within the *Runtime System Security* section of the Plant SCADA documentation.

Anonymous access needs to be disabled to support tag writes from an OPC UA client application.

## Enable tag writes for your variable tags

Your variable tags can be configured to support writes from an OPC UA client application.

---

**Note:** Tag writes will only work if anonymous access is disabled for the OPC UA Server.

To enable tag writes, you need to set the **Write Roles** property for each variable tag that will have writes enabled. The Property Grid allows you to select one of the roles configured in your Plant SCADA project, or you can manually enter a comma-separated list to include multiple roles.

To write to a variable tag, the user that is currently logged in to the OPCUA client application needs to be part of a Windows™ domain group that is associated with the role specified in the **Write Roles** property.

---

**Note:**

- Plant SCADA runtime does not support online changes for variables, which means any changes you make to the Write Roles setting for a variable tag will not be implemented until you restart the I/O server.
- If you have renamed any Roles, you should also restart the I/O server to synchronize the changes at runtime, particularly if you use the Cicode function [UserUpdateRecord](#) to recompile a local project configuration.

## OPC UA Client Driver

The **OPC UA Client Driver** page appears under Plant SCADA in [Configurator](#), when the Plant SCADA OPCUA driver

is installed. This is one of the communication drivers that is installed with Plant SCADA by default (see [Install Communication Drivers](#)).

---

**Note:** The Configurator's OPC UA Client Driver page is used to manage secure device communications via an external OPC UA server. It is not related to the Plant SCADA OPC UA Server, which delivers runtime data to third-party OPC UA clients.

Plant SCADA's OPCUA driver supports the use of user credentials when connecting to a device. It allows you to establish a secure connection between the driver and an external OPC UA server using X509 client and server certificates. The driver needs access to the server certificate and the server needs access to the driver's client certificate.

To support this, the OPC UA Client Driver page under Plant SCADA in Configurator allows you to:

- Create security settings.
- Select the client certificate from the Windows® certificate store.
- Import the client certificate from a file into the Windows certificate store.
- Issue a Plant SCADA OPC UA client certificate, store it in the Windows certificate store and export it to a file.
- Import the server certificate from the file into the Windows certificate store.
- Test connection to the OPC UA server.

For further instructions, see the topic *Security Configuration* in the OPCUA driver documentation. You can access the driver documentation via the **Driver Reference Help** toolbar button in Plant SCADA Studio's **Topology | I/O Devices** view.

## Install a Runtime-only Client

You can use the Plant SCADA installer to set up a runtime-only client. This will create dedicated runtime display client that does not include the components required to configure a project.

### See Also

- [Runtime-only Client Requirements](#)
- [Runtime-only Client Installation Procedure](#)
- [Use Configurator to Set Up a Runtime-only Client](#)

## Runtime Only Client Installation Requirements

This section describes the hardware and software requirements for a Runtime Only Client.

Before you install Plant SCADA, it is recommended that you install the latest updates from Microsoft® for your operating system and system software.

### Hardware Requirements

The hardware requirements for a Runtime Only Client are as follows.

CPU PassMark®	2000
Cores	2
RAM	4 GB
HDD	10 GB
Graphics	DirectX 11 or later with WDDM 1.0 Driver. 128 MB of dedicated VRAM.
Screen Resolution	1920 x 1080
Network	100 Mb

The complexity of your pages such as the number of graphical animations and Cicode running in the background will impact your client CPU choice. It is recommended to use a higher performing PC with high clock speed when building complex user interfaces.

As a guide, the following will require high clock speed to maintain a client CPU load of less than 25% on a single core:

- HD user interface with 50 complex Genies
- UHD4K user interface with 100 complex Genies.

If the deployment feature is being used, the HDD needs to have the required space for the number of configured project versions + 2. You should remove unused project versions periodically to reduce HDD usage.

The suggested screen resolution supports lower and higher resolutions including 4K UHD (3840 x 2160). However, 4K UHD will require a high clock speed CPU. A multi-monitor client may also require a higher clock speed CPU and more memory.

## Operating System Requirements

The following operating systems are supported (64-bit only):

- Windows 11 21H2 (or later)
- Windows 10 21H2 (or later)
- Windows 10 LTSC 1607 (or later)
- Windows Server 2016
- Windows Server 2019
- Windows Server 2022

Microsoft .NET Framework 4.8 is required. It will be installed by Plant SCADA if not detected.

When .NET installation is complete, you may be prompted to restart your computer. If this occurs, you should initiate a restart before you continue.

## See Also

- [Runtime-only Client Installation Procedure](#)
- [Use Configurator to Set Up a Runtime-only Client](#)

## Runtime Only Client Installation Procedure

This section describes the pages displayed by the Plant SCADA installer and the setting required for a Runtime Only Client. Use the **Back** and **Next** buttons to navigate through the included pages.

Installer Page	Notes
Installation Documentation	If required, view the available documents.
License Agreement	Accept the terms of the License Agreement.
What is the role of this computer?	Select <b>Runtime Only Client</b> .
The selected products/components will be installed/upgraded.	<p>By default, only the following component is selected when you install a Web Server.</p> <ul style="list-style-type: none"><li>• AVEVA Plant SCADA<ul style="list-style-type: none"><li>• Plant SCADA Runtime</li><li>• Extensions</li><li>• Software Update Tool</li></ul></li></ul> <p>You can use this page to customize the list of components selected for installation.</p>
Access Restriction	<p>This page provides information about the local Windows groups the installer will create to manage security (see the section <i>Windows User Groups and Security Roles</i> in the topic <a href="#">Installation Information</a>).</p> <p><b>Note:</b> This page will only appear if you are installing Plant SCADA on a clean computer (one that has not hosted an earlier version). If you are upgrading from an earlier version, equivalent user groups will already exist on the computer.</p> <p>If you want your current Windows user account to be included in the groups that are being created, select <b>Add the current Windows user to these groups</b>.</p> <p>A dialog will let you know that the group membership changes will not occur until after a restart.</p>
Firewall	If the installer detects that the computer has Windows Firewall enabled, you will be asked if you would like the installer to modify your settings.

Installer Page	Notes
	<p>If you select <b>Yes</b>, Plant SCADA Runtime will be added to the list of authorized programs.</p> <p>See the section <i>Windows Firewalls</i> in the topic <a href="#">Installation Information</a>).</p>

---

**Note:** The installation experience is not complete until after you exit Configurator. A restart request is likely to appear at this point. To avoid permission issues, you should close Configurator and confirm if a reboot is required before you run Plant SCADA.

---

## See Also

[Use Configurator to Set Up a Runtime-only Client](#)

## Use Configurator to Set Up a Runtime-only Client

When your Plant SCADA installation is complete, a dialog will appear asking if you would like to launch [Configurator](#). For a runtime-only client, you can use the Configurator's **Computer Setup** page under Plant SCADA to adjust the following runtime environment settings for a computer.

## Project Run Path

This setting allows you to specify whether or not the computer will receive project versions from a Deployment Server.

**To set the Project Run Path:**

1. In the panel on the left side of the **Configurator**, select **Plant SCADA | Computer Setup**.  
The **Computer Setup** page appears.
2. Navigate to the **Project Run Path** section.

**Project Run Path**

*Runtime can run the project selected in Plant SCADA Studio, or the project that has been deployed by the Deployment Server*

- [Run the project selected in Plant SCADA Studio](#).  
 [Run the project deployed from the Deployment Server](#).

3. Select one of the following options to determine which project will be launched by Runtime Manager:
  - **Run the project currently selected in Plant SCADA Studio** — This is selected by default and will run the project from Plant SCADA Studio.
  - **Run the project deployed from the Deployment Server** — Select this option to set up a computer for deployment. This option allows you to run the deployed projects from the deployment server.
4. To apply your settings, click the **Configure** button.

**Note:** If Plant SCADA Runtime is running as a service and the **Project Run Path** option in the Configurator is changed to **Run the project deployed from the Deployment Server**, you need to restart the Runtime Manager service for deployment to function correctly.

If you intend to use Plant SCADA's Deployment feature to distribute project versions to this client, you will need to use Configurator to connect the computer to a Deployment Server. See [Configure a Deployment Client](#).

## Runtime Manager Configuration

The Runtime Manager can be configured to run as a Windows® service. This allow a project to be deployed and run on a computer without having to change other settings.

You need to select **Run Runtime Manager as a service** under the following circumstances:

- When a deployment client is configured on a computer and you want to push project updates using "Force" mode.
- If you are using encrypted communications, and the current user on a deployment client may not have required privileges.

**Note:** The current user on a deployment client needs to be a member of the **Configuration Users** security role to run the deployment client (see [Security Roles](#)).

**To run Runtime Manager as a service:**

1. In the panel on the left side of the **Configurator**, select **Plant SCADA | Computer Setup**. The **Computer Setup** page appears. Navigate to the **Runtime Manager Configuration** section of the dialog.

### Runtime Manager Configuration

The Runtime Manager can be configured to run as a service or as a standard process. When run as a service, Runtime Manager allows projects to be deployed to the machine without having to change any other settings.

Run Runtime Manager as a service

#### 2. Select **Run Runtime Manager as a Service**.

**Note:** If you are using Deployment to run a project and do not select the **Run Runtime Manager as a Service** option, you will need to manually start the Plant SCADA Runtime Manager before deploying the project.

#### 3. To apply your settings, click the **Configure** button.

**Note:** If you have configured a Plant SCADA OPC DA server on a computer that is running Plant SCADA as a Windows service, you will need to make the additional configuration changes. See the topic [Running an OPC DA Server as a Service](#) in the *Runtime* section of the Plant SCADA documentation.

## AVEVA™ Enterprise Licensing

The AVEVA Enterprise Licensing system is a common platform that allows you to manage AVEVA Enterprise Software product licenses.

The system was introduced to allow centralized license management, remove the need for dongles, and increase license security by use of activated licenses. It supports flexible topologies for any size system.

The following describes the components of the AVEVA Enterprise Licensing system.

### License Manager

The License Manager allows you to access and maintain licenses for certain AVEVA Enterprise Software products in your different environments using its scalable, flexible design features:

- Browser-based for scalability and ease of use; can be remotely accessed by any of the supported web browsers.
- Light-weight, standalone software you can install on the same node as the License Server computer, or on any other node based on your deployment needs.
- Manage one or multiple License Servers to organize the licensing requirements for your environment.
- Access details about your licenses, such as usage information, from the License Manager interface.

You can use Plant SCADA Studio to launch Enterprise License Manager from any installed location within your Plant SCADA system. See [Launch Enterprise License Manager from Plant SCADA Studio](#).

### License Server

License Server provides the functionality to acquire, store, maintain, and serve licenses to your installed AVEVA Enterprise software.

- Licenses are hosted and maintained on the License Server.
- Securely serve any type of software applications being licensed, including Windows browsers, tablets, and mobile devices.

- Provide current license usage information.

**Note:** Plant SCADA 2023 R2 allows you to run your AVEVA Enterprise License Server in **Secure Mode**. This facilitates encrypted communication for any Plant SCADA computers that connect with your license server to acquire licenses. For more information, see *Running in Secure Mode* in the topic [Use Configurator to Set Up an Enterprise License Server](#).

### Activation Server

Activation Server is a cloud-based Internet-accessible server to which the License Manager connects for license activation. The License Manager connects to the AVEVA Activation Server in the Cloud only temporarily during the activation process.

### Installed Products

Once the AVEVA Enterprise Software product is installed it relies on the licensing system to enable its functionality. Following installation, you use Configurator to specify from which License Server you want the product to get its license.

- If a License Server is installed on the same computer as the product, it will be selected in Configurator by default.
- If the product is installed on a different computer than the License Server, you can use Configurator to point the product to the required License Server computer.

You need to configure the connection to the License Server for any computers that need to acquire licenses. See [Use Configurator to Set Up an Enterprise License Server](#).

All AVEVA products installed on the same computer need to point to the same License Server.

If you are implementing a distributed topology, we recommend creating a network diagram as an initial step. This will allow you to visually model your system before you decide where to install the License Manager and License Server components. For more information, see [AVEVA™ Enterprise Licensing Topologies](#).

**Note:** When working with virtual environments, you need to deactivate all licenses in a License Server before cloning a virtual machine. If this is not done, the cloned License Server will go into Grace Period mode of 15 days, after which it will cease serving licenses.

[Enterprise License Server Installation Requirements](#)

[Enterprise License Server Installation Procedure](#)

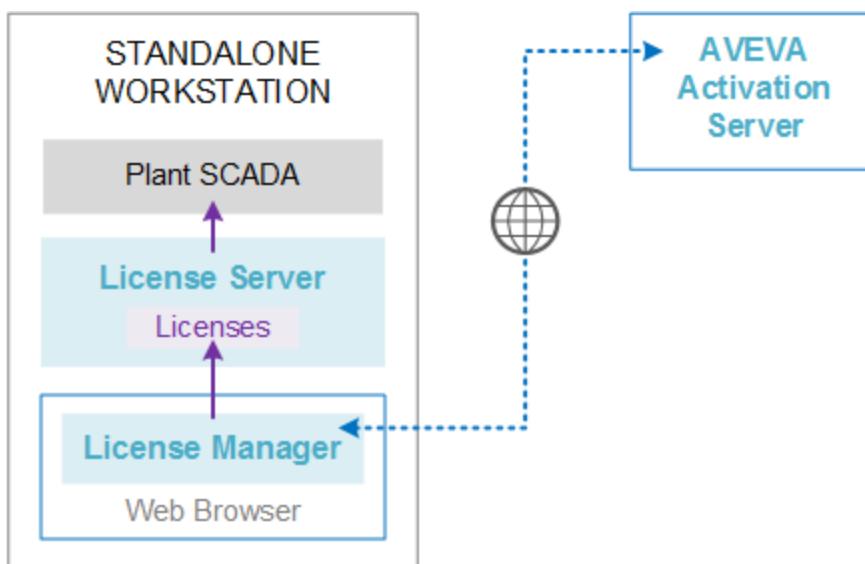

## AVEVA™ Enterprise Licensing Topologies

Use the models described in this topic to design the topology for your [AVEVA™ Enterprise Licensing](#) platform. This will help you decide where you need to install the License Manager and License Server components.

There are three topology types to consider.

### Single Node Topology

A single node topology involves a computer with Plant SCADA, License Manager, and License Server installed. In this configuration, the communication between the server components, License Server, and License Manager is local. Internet access is required to connect to the Activation Server.

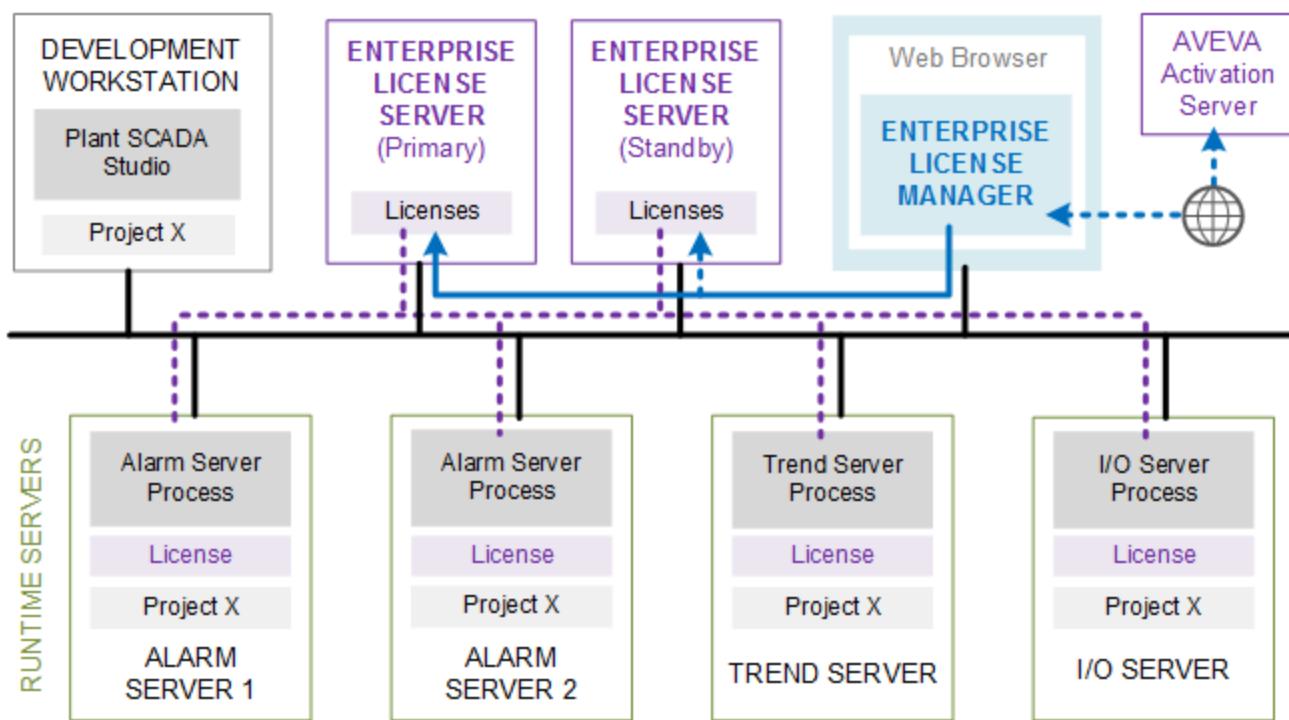

Typically a single node topology would be used to test a project on a development workstation. It can also be used for training or evaluation purposes.

### Distributed Topology

The licensing components can be installed on separate computers as long as there is reliable network connectivity between them. This type of topology is suitable for systems where you need to manage licenses for multiple installations of Plant SCADA across a distributed runtime system.

In the following example:

- The **Enterprise License Manager** components are installed on a computer with Internet access to the Activation Server. The interface runs locally in a web browser.
- The **Enterprise License Server** components are installed on two separate computers that are acting as a redundant pair.
- The Plant SCADA runtime computers each require network access to the License Servers.

This type of topology allows you to manage multiple License Servers for a runtime system from a single License Manager browser interface.

License Server redundancy is highly recommended when centralizing your licenses. It is available at no additional cost. A paired set of License Servers keeps licenses, reservations and the status of licenses synchronized to help maintain stability for the runtime system.

If you use clustering to manage a system that is physically distributed across multiple sites, it is recommended that you have a pair of redundant license servers at each location.

For information and procedures about implementing redundancy, see the topic *Working With License Server Redundancy* in the AVEVA Enterprise Licensing documentation in [AVEVA™ Help](#).

#### [Disconnected Topology](#)

This topology is required if an internet connection is not available. For example, a firewall or other constraints may exist between the License Manager components and the Activation Server.

In this scenario, you need to set up a separate computer with Internet access to the License Activation Web Page and Activation Server and then complete the activation process in "offline" mode. For more information, see the topic *Activating Licenses in Offline Mode* in the AVEVA Enterprise Licensing documentation in [AVEVA™ Help](#).

---

**Note:** If you are planning to run a system that includes a combination of client, server, and HMI licenses, you need to confirm that your Plant SCADA computers have the appropriate role configured. This will allow an Enterprise License Server to correctly allocate different license types. Computer roles are configured using the [Computer Role Setup](#) page of the Setup Wizard.

For an example of how to acquire, activate and distribute your licenses, see [AVEVA™ Enterprise Licensing Workflow](#) in the Plant SCADA documentation.

For more detailed information see the AVEVA Enterprise Licensing documentation in [AVEVA™ Help](#).

## AVEVA™ Enterprise Licensing Workflow

The following example of the AVEVA Enterprise Licensing workflow assumes that both License Manager and License Server are installed on the same computer, and that the computer can connect to the Internet.

### 1. Purchase one or more AVEVA Enterprise Software products

Along with your installation media or downloads, you will receive one or more entitlement files containing license details.

### 2. Start License Manager

It opens in a browser window and accesses the installed License Manager components.

### 3. Select the License Server

Use the License Manager to select an available server to host the licenses you want to activate. You can also add a new license server.

---

**Note:** You need to configure the connection to the License Server on any computer that needs to acquire licenses. See .

---

### 4. Import the entitlement file

Once you import the entitlement file, the License Manager displays the available licenses.

The entitlement file contains information for specific product licenses that are imported into the License Manager to activate purchased licenses. It is sent to you in an email upon purchase of your product licenses. It is in a zipped .xml file format.

### 5. Activate licenses

License Manager connects to the AVEVA Enterprise Activation Server over the Internet to activate the selected licenses on the License Server. The Activation Server activates licenses on the License Server.

### 6. Manage your licenses

Licenses are now available for their respective product to use. You can now:

- Activate new licenses
- Deactivate current licenses
- Reserve and unreserve licenses
- Checkout licenses.

In some cases, you may need to reserve a license for a specific computer using the device reservation feature. For example, it is recommended that you checkout a license for any critical runtime computers. For more information, see [Allocating AVEVA™ Enterprise Licenses](#).

---

**Note:** Plant SCADA only supports device reservations. You cannot reserve licenses for specific users.

---

### 7. Install and configure Plant SCADA

When running, Plant SCADA will acquire licenses from the License Server selected in Configurator (see Use Configurator to Set Up an Enterprise License Server). They will release them when no longer needed.

---

**Note:** For more detailed information see the AVEVA Enterprise Licensing documentation in [AVEVA™ Help](#).

---

## Enterprise License Server Installation Requirements

This section describes the hardware and software requirements for a computer that will host an AVEVA™

Enterprise License Server.

Before you install this component, it is recommended that you install the latest updates from Microsoft® for your operating system and system software.

## Hardware Requirements

The hardware requirements for a Enterprise License Server are as follows:

Cores	4
Memory	4 GB

## Operating System Requirements

The following operating systems are supported (64-bit only):

- Windows 11 21H2 (or later)
- Windows 10 21H2 (or later)
- Windows 10 LTSC 1607 (or later)
- Windows Server 2016
- Windows Server 2019
- Windows Server 2022

Microsoft .NET Framework 4.8 is required. It will be installed by Plant SCADA if not detected.

**Note:** Plant SCADA 2023 R2 installs version 4.0 of AVEVA Enterprise Licensing. If your system includes computers that are not upgraded to AEL 4.0, you will need to install **AVEVA Enterprise Licensing Server Legacy Support** on your Enterprise License Server. This enables backwards compatibility for clients nodes that are running an earlier version of AEL. You can select this option on the products/components page on the Plant SCADA installer. You should also check the **Legacy Server Port** setting in Configurator. See [Use Configurator to Set Up an Enterprise License Server](#).

## See Also

[Enterprise License Server Installation Procedure](#)

## Enterprise License Server Installation Procedure

This section describes the pages displayed by the Plant SCADA installer and the settings required for an AVEVA™ Enterprise License Server. Use the **Back** and **Next** buttons to navigate through the included pages.

Installer Page	Notes
Installation Documentation	If required, view the available documents.
License Agreement	Accept the terms of the License Agreement.

Installer Page	Notes
What is the role of this computer?	Select <b>Server</b> .
Select the server(s) you want to install	Select <b>AVEVA Enterprise License Server</b> . If required, you can also select other server types.
The selected products/components will be installed/upgraded.	<p>By default, the following components are selected when you install an Enterprise License Server.</p> <ul style="list-style-type: none"><li>• AVEVA Enterprise License Manager</li><li>• AVEVA Enterprise License Server.</li></ul> <p>If you are going to connect the computer to a License Server on a remote computer, you only need to install the License Manager.</p> <p><b>Note:</b> Plant SCADA 2023 R2 installs version 4.0 of AVEVA Enterprise Licensing. If your system includes computers that are not upgraded to AEL 4.0, you will need to install <b>AVEVA Enterprise Licensing Server Legacy Support</b> on your Enterprise License Server. This enables backwards compatibility for clients nodes that are running an earlier version of AEL.</p>
Access Restriction	<p>This page provides information about the local Windows groups the installer will create to manage security (see the section <i>Windows User Groups and Security Roles</i> in the topic <a href="#">Installation Information</a>).</p> <p><b>Note:</b> This page will only appear if you are installing Plant SCADA on a clean computer (one that has not hosted an earlier version). If you are upgrading from an earlier version, equivalent user groups will already exist on the computer.</p> <p>If you want your current Windows user account to be included in the groups that are being created, select <b>Add the current Windows user to these groups</b>.</p> <p>A dialog will let you know that the group membership changes will not occur until after a restart.</p>
Firewall	<p>If the installer detects that the computer has Windows Firewall enabled, you will be asked if you would like the installer to modify your settings.</p> <p>If you select <b>Yes</b>, Plant SCADA Runtime will be added to the list of authorized programs.</p> <p>See the section <i>Windows Firewalls</i> in the topic <a href="#">Installation Information</a>).</p>

Installer Page	Notes
Customize the installation location	<p>This page identifies the destination folders for:</p> <ul style="list-style-type: none"><li>• The selected Plant SCADA program files.</li><li>• The Plant SCADA User and Data folders.</li></ul> <p>You can modify the folder locations by clicking the <b>Change</b> buttons and selecting alternative locations.</p> <p>You can also <b>Reset</b> the default locations.</p> <p><b>Note:</b> The installation folder and the 'User and Data' folder cannot be the same, or a sub-directory of one another. You should also avoid selecting your Windows user folder.</p>
Ready to Install the Program	<p>This page lists the components that will be installed based on your selections.</p> <p>If required, use the <b>Back</b> button to make any modifications.</p> <p>Click <b>Install</b> to start the installation process.</p>

When installation is complete, a dialog will appear asking if you would like to launch [Configurator](#). This may take a few minutes if you have installed some external components (including AVEVA Enterprise Licensing components).

---

**Note:** The installation experience is not complete until after you exit Configurator. A restart request is likely to appear at this point. To avoid permission issues, you should close Configurator and confirm if a reboot is required before you run Plant SCADA.

---

## See Also

[Use Configurator to Set Up an Enterprise License Server](#)

## Use Configurator to Set Up an Enterprise License Server

You need to configure a connection to a License Server on any computer that needs to acquire licenses.

To configure an Enterprise License Server, open [Configurator](#) and go to the **Select License Server** page located under **AVEVA Enterprise Licensing**.

---

**Note:** Before running the Configurator, make sure that ports 55559 and 59200 are open. If you have also installed **AVEVA Enterprise Licensing Server Legacy Support** (see **Legacy Server Port** below), enable port 55555.

---

- **Primary Server Name**

By default, the installation process identifies the local computer as the primary server and enters the computer name as the Primary Server Name.

If you want to point the local computer a different License Server on your network, you will need to manually enter the computer name as Plant SCADA does not support network discovery for Enterprise License Servers.

- **Server Port**

The default Server Port is 55559. You can specify a different port, if necessary.

- **Agent Port**

The default Agent Port is 59200. You can specify a different port, if necessary.

- **Legacy Server Port**

Plant SCADA 2023 R2 installs version 4.0 of AVEVA Enterprise Licensing. If your system includes computers that are not upgraded to AEL 4.0, you can enable backwards compatibility by installing **AVEVA Enterprise Licensing Server Legacy Support** on your Enterprise License Server. This is achieved via the products/components page of the Plant SCADA installer.

The **Legacy Server Port** represents the port used by legacy client nodes to acquire licenses from the license server. The default value is 55555.

You can test your connection to the License Server by selecting **Test Connection**.

Press **Configure** to save all your changes.

---

**Note:** If you disconnect a computer from an Enterprise License Server, the licenses that have been acquired from the server will be released.

## Running in Secure Mode

Plant SCADA 2023 R2 allows you to run your AVEVA Enterprise License Server in **Secure Mode**. This facilitates encrypted communication for any Plant SCADA computers that connect with your license server to acquire licenses.

Secure Mode is enabled by default when your Enterprise License Server is connected to a System Management Server. You can check if Secure Mode is enabled by viewing the **Secure** page in the **AVEVA Enterprise Licensing** branch of Configurator.

This page will indicate if the license server is currently configured to support Secure Mode. If it is not, it will provide instructions on how to set it up.

## Install OPC Factory Server

Plant SCADA allows you to install a copy of Schneider Electric's OPC Factory Server.

Based on the OPC protocol, OPC Factory Server enables Windows-based OPC client applications to communicate with the following Schneider Electric PLCs:

- TSX Compact
- Micro
- TSX Momentum
- TSX/PCX Premium
- Quantum
- M340
- TSX Series 7
- TSX S1000.

---

**Note:** A Plant SCADA server license includes an OFS license. This means you need to install Plant SCADA before you install OPC Factory Server so it can be licensed using the Plant SCADA license. This will allow the correct part and serial number combination to be registered.

---

OPC Factory Server can be installed on the following operating systems (64-bit only):

- Windows® Server 2022
- Windows® Server 2019
- Windows® Server 2016
- Windows 11 21H2 (or later)
- Windows 10 21H2 (or later)
- Windows 10 LTSC 1607 (or later).

To install OPC Factory Server, run the **Setup.bat** file located in the following folder in Plant SCADA's installation media:

...InstallFiles\Extras\OFS vX.XX [SPn]

Details on the installation options for OPC Factory Server can be found in the **Documentation** folder within this directory.

## Installation Troubleshooting

Log files are available for a Plant SCADA installation. Each installed component has one or more log files in their respective "ID" folder. For example, Plant SCADA creates the following installation log files:

C:\Program Files (x86)\Common Files\ArchestrA\Install\{692B4E4F-CC1F-4AA4-AEE8-1C22F7BA336B}\ILog<DateTimeStamp>.log

C:\Program Files (x86)\Common Files\ArchestrA\Install\{692B4E4F-CC1F-4AA4-AEE8-1C22F7BA336B}\MSI<DateTimeStamp>.log

The log files will notify you if Plant SCADA's security configuration was not successful during installation. You should take the action described below if one of the following warning messages is displayed.

- **Installation successfully created the local Windows groups but was not able to add the current user to them. You can manually add the user to the groups.**

The account that was logged in during installation was not added to the Windows groups created by Plant SCADA (see *Windows User Groups and Security Roles* in the topic [Installation Information](#)).

If required, you can use the **Security Roles** page in Configurator to associate this user with the required security roles (see [Modifying the Members of a Security Role](#)).

- **One or more of the members of a security role could not be validated. Please check the Security Roles tab in the Configurator.**

This indicates the users and local user groups associated with Plant SCADA's Security Roles could not be validated. For example, the domain server may have been unreachable or a user name was not valid.

To fix this, go to the **Security Roles** page in Configurator. Verify the users and local user groups associated with each security role, then click **Configure**. The Configurator Messages panel will indicate if any further configuration changes are required. See [Modifying the Members of a Security Role](#).

- **An error occurred applying security to resources. Please check the Security Roles tab in the Configurator.**

Plant SCADA will attempt to restrict access to some folders and services that need to be secured. This message indicates that the required security settings were not successfully applied.

To fix this, go to the **Security Roles** page in Configurator. Select **Configure** to re-apply the security settings.

- **Could not initialize security model because AVEVA Data Store service is not running. Please check the AVEVA Data Store service is running in the Windows Services Manager.**

Locate **AVEVA Data Store** in Windows Services Manager and confirm that its **Status** indicates it is "Running". You can **Restart** the service if required. Its **Startup Type** should also be set to "Automatic".

## Unattended Silent Installation

The installation of Plant SCADA can be executed via a command line with the required components specified via a configurable response file.

**Note:** A silent installation will only work on a clean computer. If you have any existing dependent components on a computer from an earlier installation (such as Operations Control Logger or Platform Common Services), a silent install will not be successful. If this occurs, you can complete your installation by manually running the Plant SCADA Installer.

### Response File

A response file specifies the set of components that will be installed during a silent installation. It represents the forms normally seen when interacting with the user interface of the Plant SCADA installer. The available options for each form are configured via a set of properties.

Four preconfigured response files are available for use:

- **All.txt** – installs all components
- **DevelopmentWorkstation.txt** – installs components for a development workstation
- **RuntimeClient.txt** – installs components for a runtime client
- **Server.txt** – installs components for a runtime server.

These can be used to install a typical set of components, or they can be used as reference for your own customized response file (see [Customize a Response File](#)).

The four files are available from the following directory within the Plant SCADA installation media:

#### InstallFiles\ResponseFiles

The following example shows the content of the Server.txt response file.

```
<responsefile>
  <install>
    ComputerRoleSelectionForm.SelectedComputerRoleName=Server
    ServerRoleSelectionForm.ServerRolesList=RuntimeServer,DeploymentServer,
    IndustrialGraphicsServer,OPCUAServer,EnterpriseLicenseServer
    FeaturesForm.SFeatureList=AVEVA Plant SCADA.Configuration,AVEVA Plant SCADA.Runtime,
    AVEVA Plant SCADA.InTouchWebClient,AVEVA Plant SCADA.OpcUaServer,
    AVEVA Plant SCADA.DeploymentServer
    SecurityGroupForm.AddUserToGroups=true
    FirewallForm.ModifyFireWall=true
    CustomDestinationSelectionForm.InstallDirPath=C:\Program Files (x86)\AVEVA Plant
```

```
SCADA
CustomDestinationSelectionForm.ProgramDataPath=C:\Program Data\AVEVA Plant SCADA 2023
R2
</install>
</responsefile>
```

You can also specify Configurator settings within a response file. See [Add Configurator Settings to a Response File](#).

## Silent Install/Uninstall Commands

The following commands can be executed from a command prompt:

- **Command for installation:**

```
Setup.exe /silent "<Response File Path>"
```

The specified response file needs to be text-based. A full absolute path needs to be provided. For example:

```
Setup.exe /silent "D:\PlantSCADA\MyResponseFiles\All.txt"
```

You can also use the "silentnoreboot" option to suppress a machine reboot after installation completes, for example:

```
Setup.exe /silentnoreboot "<Response File Path>"
```

- **Command for uninstallation:**

```
Setup.exe /silentuninstall <ID of Plant SCADA>
```

For example:

```
Setup.exe /silentuninstall {XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX}
```

The ID for Plant SCADA can be retrieved from the **Setup.xml** file, located in the **InstallFiles** directory within the installation media.

Search for the ID value within the **<mainproduct>** tags.

**Note:** Do not manually uninstall any non-core components (such as AVEVA Enterprise Licensing, the Sentinel Driver, PCS, Operation Control Logger or AVEVA Help) prior to running a silent uninstall of Plant SCADA as the silent uninstall may not be successful.

When you run a silent uninstallation, you need to follow the procedure below when also uninstalling any non-core components.

1. Uninstall AVEVA Plant SCADA's core components (using the silent uninstall command).
2. Uninstall AVEVA Enterprise Licensing components:
  - AVEVA Enterprise License Server
  - AVEVA Enterprise License Manager
  - AVEVA Enterprise Licensing Platform.
3. Uninstall Schneider Electric Software Update.
4. Uninstall Sentinel System Driver Installer.
5. Uninstall AVEVA Platform Common Services.
6. Uninstall Operations Control Logger.
7. Uninstall AVEVA Help.

**Note:** You can also use a command to silently install a Plant SCADA update. See [Silently Install a Plant SCADA Update](#).

## Customize a Response File

To create a customized set of options for a silent installation of Plant SCADA, you should start by creating a copy of one of the provided response files. Four are available for use:

- **All.txt** – installs all components (including all communication drivers)
- **DevelopmentWorkstation.txt** – a typical set of components for a development workstation
- **RuntimeClient.txt** – a typical set of components for a runtime client
- **Server.txt** – a typical set of components for runtime server.

These are available from the following directory within the Plant SCADA installation media:

### InstallFiles\ResponseFiles

You can then use the following set of properties to specify the settings for the forms normally seen when interacting with the Plant SCADA installer.

Form Name	Properties	Allowable Values
ComputerRoleSelectionForm	SelectedComputerRoleName	One of the following values: <ul style="list-style-type: none"><li>• DevelopmentWorkstation</li><li>• Server</li><li>• RuntimeOnlyClient</li></ul>
ServerRoleSelectionForm	ServerRolesList	Multiple server names separated by commas: <ul style="list-style-type: none"><li>• RuntimeServer</li><li>• DeploymentServer</li><li>• IndustrialGraphicsServer</li><li>• OPCUAServer</li><li>• EnterpriseLicenseServer</li></ul>
FeaturesForm	SFeatureList	ALL or multiple feature names separated by commas (see below).
SecurityGroupForm	AddUserToGroups True adds the current Windows user to created groups.	True or False
FirewallForm	ModifyFireWall	True or False
CustomDestinationSelectionForm	InstallDirPath	A valid absolute folder path

	ProgramDataPath	A valid absolute folder path
--	-----------------	------------------------------

**Note:** A response file needs to include an entry for each of the six forms it represents. If you remove any of the forms, installation will not succeed.

To specify the features that are installed via the **FeaturesForm.SFeaturesList** property, you can enter the following as a comma separated list.

Components	Description	SFeaturesList setting
All components	Includes all components listed below.	ALL
Runtime client	Provides runtime client display and server level processing of I/O, trends, alarms, reports, and CtAPI.	AVEVA Plant SCADA.Runtime
Configuration Environment	Plant SCADA Studio, graphics, Cicode Editor and other configuration tools for building your system.  This option also requires the Runtime and Platform Common Services components.	AVEVA Plant SCADA.Configuration
Deployment Server	Provides server functionality for managing the runtime versions of your system and deployment to runtime computers.	AVEVA Plant SCADA.DeploymentServer
Industrial Graphics Web Server	Provides server functionality for managing the runtime versions of your system and deployment to runtime computers.	AVEVA Plant SCADA.InTouchWebClient
OPC UA Server	Provides server functionality that allows OPC UA clients to browse and subscribe to Plant SCADA I/O data.	AVEVA Plant SCADA.OpcUaServer
Project DBF Add-in for Microsoft Excel	Provides bulk editing of configuration databases in Microsoft Excel.	Extensions.BinFiles
Software Update by Schneider Electric	Provides notification of updates, new versions and telemetry information.	Extensions.SEP_Features
AVEVA License Server	Provides server functionality to acquire, store, maintain, and serve licenses to your installed AVEVA	AVEVA Common Components.AELicenseServer

	software.	
AVEVA License Manager	Browser-based client application for accessing and maintaining licenses for AVEVA Enterprise Software products.	AVEVA Common Components.AELicenseManager
Platform Common Services  <b>Note:</b> You only need to include this component in a response file if you are setting up a computer as a standalone System Management Server. It will automatically be installed as a prerequisite for any other Plant SCADA components.	Provides the following services: System Management Server Identity Management Service Data Storage Service Diagnostic Portal	AVEVA Common Components.ASBRuntime
Plant SCADA Communications Drivers  These can include:  ABCLX ABMLXEIP ABTCP BACNET CTICMP DNPR GETCP IEC870IP KNX MELSECQ MODBUS MODBUA MODNET OFSOPC OMFINS OPC OPCLX OPCUA S7TCP SNMPII	Installs software to enable communication with I/O devices using a specific protocol.	AVEVA Plant SCADA Communication Drivers.<driverName>Driver  For example: AVEVA Plant SCADA Communication Drivers.BACNETDriver

**Note:** You can also specify Configurator settings within a response file. See [Add Configurator Settings to a Response File](#).

#### Example

The following demonstrates the response file you could use to install a development workstation with all available features.

```
<responsefile>
<install>
ComputerRoleSelectionForm.SelectedComputerRoleName=DevelopmentWorkstation
```

```
FeaturesForm.SFeatureList=ALL
SecurityGroupForm.AddUserToGroups=true
FirewallForm.ModifyFireWall=true
CustomDestinationSelectionForm.InstallDirPath=C:\Program Files (x86)\AVEVA Plant SCADA
CustomDestinationSelectionForm.ProgramDataPath=C:\Program Data\AVEVA Plant SCADA 2023 R2
</install>
</responsefile>
```

**Note:** You can determine if the silent configuration of plugins has been successful at the end of an installation using the XML log file located at:

**C:\Program Files (x86)\Common Files\ArchestrA\SilentConfigurator**

## See Also

[Unattended Silent Installation](#)

## Add Configurator Settings to a Response File

You can add a section to a response file that allows you to preconfigure the settings that are available in [Configurator](#) for Plant SCADA (and other AVEVA components).

To do this, define a new section within a response file using the following tags:

```
<configurator> <configurator/>
```

You can then use the information in the following tables to define the settings for each page in Configurator when running a silent installation.

**Note:** You cannot configure the authentication settings for an Industrial Graphics Server during a silent installation. If you silently install an Industrial Graphics Server, you will need to manually adjust its settings in Configurator. See [Use Configurator to Set Up an Industrial Graphics Server](#).

You can determine the success of a silent installation using the XML log file located at:

**C:\Program Files (x86)\Common Files\ArchestrA\SilentConfigurator**

### Security Roles page

Configurator Setting	Options	Response file syntax
Security Role Members	<p>Role:User,User; Role:User,User;</p> <p><b>Role</b> needs to be one of the following:</p> <ul style="list-style-type: none"><li>• ConfigUsers</li><li>• ServerUsers</li><li>• RuntimeUsers</li><li>• DeploymentAdmins</li><li>• DeploymentUsers</li><li>• DeploymentUploaders</li><li>• AIGUsers</li><li>• AIGUsersRW</li></ul> <p><b>User</b> needs to be:</p> <ul style="list-style-type: none"><li>• A local user: ".\&lt;UserName&gt;" or</li></ul>	<p>Plant SCADA.</p> <p>SecurityConfiguration.RoleMembers=</p> <p><b>Examples</b></p> <p>To add UserA and UserB to ConfigUsers:</p> <pre>Plant SCADA. SecurityConfiguration.RoleMembers= ConfigUsers:MyComputer\UserA,MyComputer\UserB;</pre> <p>To add UserA and UserB to ConfigUsers and ServerUsers:</p>

	"<ComputerName>\<UserName>" <ul style="list-style-type: none"> <li>• A local Windows group: ".\&lt;GroupName&gt;" or</li> <li>"&lt;ComputerName&gt;\&lt;GroupName&gt;"</li> </ul> <ul style="list-style-type: none"> <li>• A domain group user: "&lt;DomainName&gt;\&lt;UserName&gt;"</li> <li>• A domain group: "&lt;DomainName&gt;\&lt;GroupName&gt;"</li> </ul>	Plant SCADA. SecurityConfiguration.RoleMembers= ConfigUsers:MyComputer\ UserA,MyComputer\ UserB;ServerUsers:MyComputer\ UserA,MyComputer\UserB;
--	---	--

Using a response file to add members to a security role has the following limitations:

- Adding NT Service accounts is not supported.
- If you modify a role, all existing users will be removed (except for any existing NT Service accounts).
- If no valid users are specified for a role, the role will not be modified.
- If the limit of 10 users per role is exceeded in the response file, only the first 10 users will be added. This means if you try to add 12 users, the last two will be ignored.

#### Computer Setup page

Configurator Setting	Options	Response file syntax
Configure Server Password	True or false.	Plant SCADA. ComputerSetup.PartOfTrustedNetwork=
Password / Confirm Password	A valid password.	Plant SCADA.ComputerSetup.ServerPassword=
Project Run Path	True = Run the project deployed from the Deployment Server. False = Run the project selected in Plant SCADA Studio.	Plant SCADA.ComputerSetup.DeploymentEnabled=
Run Runtime Manager as a Service	True or false.	Plant SCADA.ComputerSetup.RuntimeAsService=

## Uninstall or Change Components

You can uninstall or change Plant SCADA's core components and its supporting applications using the **Programs and Features** page in Windows® Control Panel.

Following a Plant SCADA installation, the list of programs can include any of the following components:

- AVEVA Enterprise License Manager
- AVEVA Enterprise License Server
- AVEVA Enterprise Licensing Platform
- AVEVA Help
- AVEVA Plant SCADA 2023 R2

- AVEVA Platform Common Services
- Sentinel System Driver Installer
- Schneider Electric Software Update.

---

**Note:** The entry for AVEVA Plant SCADA provides access to all core components including the configuration environment, runtime components, communications drivers, OPC UA components, Industrial Graphics components and extensions.

---

### To uninstall or change a Plant SCADA installation:

1. From the Windows **Start** menu open **Control Panel**.
2. Go to **Programs** then **Programs and Features** to display the **Uninstall or Change a Program** page.  
**Note:** The change/modify option is not available via the **Apps & Features** settings in Windows. You can only use the Programs and Features page in Control Panel.
3. Locate the program you want to remove or modify and select **Uninstall/Change**.
4. Select one of the following options from the dialog that appears:
  - **Modify** — this option allows you to add components that were not installed during the original installation, or remove selected components.
  - **Repair** — this will reinstall all non-customizable files in the same location as the previous installation. If any of the files were accidentally deleted or modified, then this option will restore the software back to its original state.
  - **Remove** — This will remove any files associated with the selected component and its registry entries.
5. Click **Next**.
6. If you chose **Modify**, select the features that you would like to add or remove and click **Next..** The following page will confirm the changes you have requested. Select **Modify** to continue.

If you chose **Repair** or **Uninstall**, the following page will ask you to confirm your selection.

The installer will indicate when the selected process is complete.

---

**Note:** Only reinstall PCS if the support team advises it, or if you get a notification from the troubleshooting tool in the Common Services portal. Do not install PCS on a computer where it was not previously installed.

---

## Manage Updates

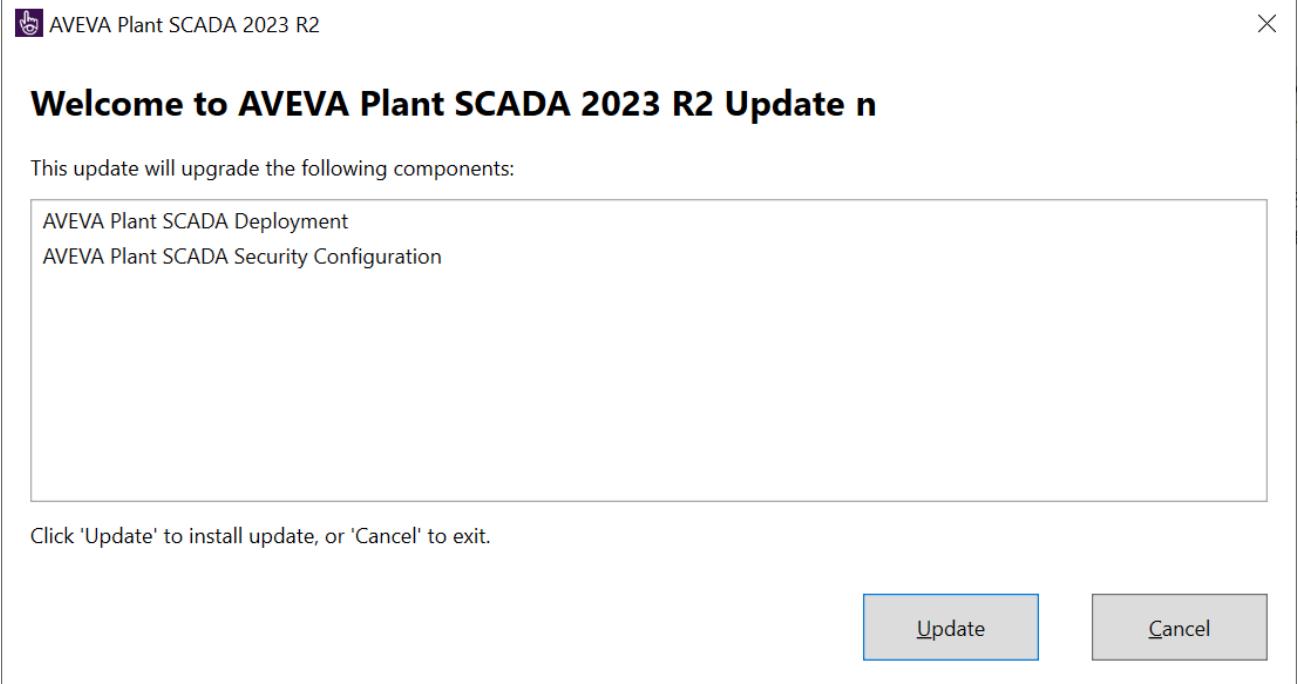

AVEVA will periodically publish software updates for Plant SCADA. You can download these updates from the **Product Hub** page of the [AVEVA™ Knowledge & Support Center](#) website at:

<https://softwaresupport.aveva.com/#/producthub>.

### To install a Plant SCADA software update

1. Go to the location where the update media was saved.
2. Run the executable file named "Plant SCADA <VersionNumber> Update *n*.exe".

The following dialog will appear. It lists the components that will be updated.

3. Select **Update** to proceed.

If any Plant SCADA services or processes are using files that need to be updated, an additional dialog will appear asking if you want to automatically shut everything down or reboot after the update is installed.

4. Make your selection and click **OK** to complete the installation.

A monthly update may include prerequisite upgrades to one or more AVEVA common components (such as Platform Common Services).

If an update contains such prerequisites, and the component has not already been upgraded on your computer, the following dialog will be shown (before the dialog from step 2 above).

AVEVA Plant SCADA 2023 R2

## Welcome to AVEVA Plant SCADA 2023 R2 Update n

This update requires the following components to be upgraded first.

Note: Once upgraded, these components can not be reverted to the previous version without uninstalling and reinstalling them.

Component	Version
AVEVA Platform Common Services	8.1.23456.1
AVEVA Enterprise License Server	4.0.2

Press 'Upgrade' to upgrade all required components, or 'Cancel' to exit.

[Upgrade](#)[Cancel](#)

Select **Upgrade** to proceed with upgrading the components. If all prerequisites are upgraded successfully, the update will display the dialog from step 2, otherwise an error will be displayed.

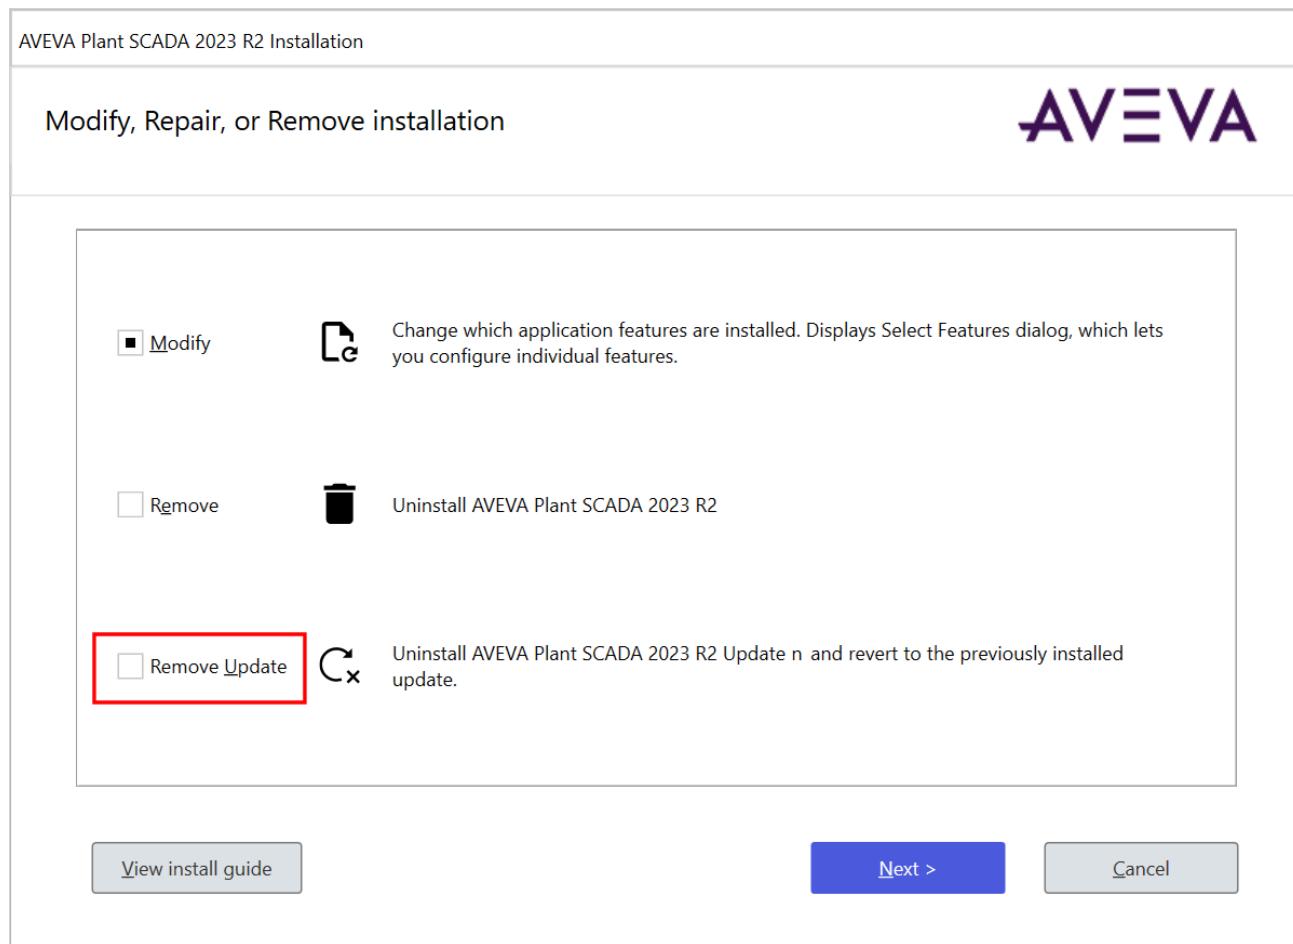

**Note:** Unlike updates to Plant SCADA components, upgrades of common components cannot be reverted without a full uninstall and reinstall of the component.

### To uninstall a Plant SCADA software update

You can uninstall Plant SCADA updates from the **Uninstall or change a program** page of Windows® Control Panel. The entry for Plant SCADA will display the most recent update that has been applied.

AVEVA Help	AVEVA Software, LLC
AVEVA Plant SCADA 2023 R2 Update n	AVEVA Software Australia Pty Ltd
AVEVA Platform Common Services 8.0	AVEVA Software, LLC

1. Select the **Uninstall/Change** option for AVEVA Plant SCADA.
2. When the **Modify, Repair, or Remove** page appears, select the **Remove Update** option.

### 3. Click **Next**, then **Uninstall**.

When the uninstallation process has completed, the entry for Plant SCADA in the Control Panel programs list will be updated to reflect the changes that have been made. If an earlier update was installed, it will indicate that the previous update is now the most recent.

**Note:** You can also use a command to silently install a Plant SCADA update. See [Silently Install a Plant SCADA Update](#).

## Silently Install an Update

To silently install a monthly update, run the following command from the command line (assuming the update executable is in the current directory):

```
"Plant SCADA 2023 R2 Update <n>.exe" -sp/silent
```

Replace <n> with the update number and date to match the name of the update executable.

This command will return immediately without waiting for the update to finish installing. To wait for the update to install (for example, when installing from a batch file), use the built-in start command:

```
start /w "" "Plant SCADA 2023 R2 Update <n>.exe" -sp/silent
```

**Note:** The empty "" are important to tell the start command to interpret the quoted update name as the executable to run (instead of the window title). The quotes are required on the update name as it contains spaces.

Any required prerequisites (for example, Platform Common Services) will be installed.

Any running Plant SCADA services will be automatically stopped by the update and restarted again when complete. Any other running Plant SCADA programs, such as Plant SCADA Studio or Plant SCADA Runtime in non-service mode, will not be stopped. If this occurs, the update will not be successful.

## Return Values

The update executable will return 0 to indicate the update was installed successfully.

If 3010 is returned, it indicates that the update was installed successfully but a reboot is required to complete installation.

Any other non-zero value will indicate an error (see the table below).

Use the %ERRORLEVEL% environment variable to check the return code. The start command must be used to retrieve the return code properly.

Return value	Description
1603	<ul style="list-style-type: none"><li>• One or more non-service Plant SCADA processes are running.</li><li>• An error occurred launching Windows Installer or setup.exe to install a prerequisite or patch file.</li></ul>
1605	The version of Plant SCADA this update is intended for is not installed.
1638	A newer monthly update is already installed.
Other	The error code returned by Windows Installer or setup.exe if an error occurs when installing a prerequisite or patch file.

## Upgrade Plant SCADA

This chapter describes the process required to migrate from an existing installation of Citect SCADA or Plant SCADA to the latest version of Plant SCADA.

**Note:** Cross version compatibility is not available for alarms version v7.20 onwards.

When updating the computer with a new product version, backup the existing projects and uninstall the existing installation. For instructions, consult the documentation for the existing version. You can then install the new version and restore your projects.

**Note:** The new version you are installing may have updates available. The update may have a fix for the automatic upgrade and may be required to be installed before restoring the project. Please refer to the **Product Hub** page of the **AVEVA Knowledge & Support Center** (<https://softwaresupport.aveva.com>).

Before you review this information, check that you have the necessary hardware and software required to run this version. See the requirements specified for the type of SCADA system computer you are upgrading in the relevant section of the Install Guide.

When upgrading to Plant SCADA 2023 R2 you need to consider the following:

- **Upgrade Method:** Depending on whether your system can afford downtime and loss of data, choose an upgrade method: offline or online.
- **Upgrade Path:** Upgrade path refers to the number of versions to which you need to upgrade to get from your current version of Citect SCADA/Plant SCADA to the latest version. For upgrading to intermediate versions specified in the upgrade path (for example, v2015 or v2016), refer to the documentation for those versions.

---

**Note:** With the release of Plant SCADA 2023, Schneider Electric's Floating License Manager is no longer supported. Existing users of the Floating License Manager will need to migrate their systems to [AVEVA™ Enterprise Licensing](#).

---

## See Also

- [What's New in Plant SCADA](#)
- [Offline Upgrade](#)
- [Online Upgrade](#)

## Upgrade Method

Before you plan to upgrade Plant SCADA, consider whether your SCADA system can afford downtime and whether your historical information needs to be available. The upgrade method you choose will depend upon this.

Upgrade methods are of the following types:

- This method requires your system to be shut down for the duration of the upgrade. If your system can afford downtime and depending on whether historical information needs to be available, this method is suitable for you. This is the basic upgrade process that will be required even if you use the online upgrade method.
- If you need your system to be available, this method is suitable for you. To be able to conduct an online upgrade, you need to have at least one pair of redundant servers (for details and other pre-requisites, see [Pre-requisites for Online Upgrade](#)).

## See Also

- [Upgrade Path](#)
- [Offline Upgrade](#)
- [Online Upgrade](#)

## Upgrade Path

Upgrade path refers to the versions you need to install to get from your current version of Citect SCADA to the latest version of Plant SCADA.

Some versions of Citect SCADA included substantial changes to the product, which require incremental upgrades involving intermediate steps between versions. The number of necessary steps will depend on whether you do an offline or online upgrade.

- For an [Offline Upgrade](#), you can upgrade a project directly from any version of Citect SCADA from 5.21

onwards.

- For an [Online Upgrade](#), you can go directly from the following versions:
  - Citect SCADA v2020 R2 Update 2 (March 2022) or later.
  - Plant SCADA v2023 (or later).

If you would like to perform an online upgrade from an earlier version, you will firstly need to temporarily upgrade your system to one of the versions listed above. For more information, see the Installation Guide for the version you choose.

You can download the installers for earlier versions from the **Product Hub** page of the **AVEVA Knowledge & Support Center** (located at <https://softwaresupport.aveva.com/>).

For both offline and online scenarios you need to:

- Apply the latest patch to the version you are upgrading from.
- Perform the upgrade to Plant SCADA 2023.
- Apply the latest updates to Plant SCADA 2023.

---

**Note:** Any patches released from July to October 2020 should not be used in an online upgrade scenario.

---

## Offline Upgrade

---

**Note:** This is the basic upgrade process. You will need to perform these steps even if you choose to use the Online Upgrade method.

---

An Offline Upgrade to Plant SCADA comprises the following steps:

### 1. Backup your current project and relevant files.

Perform a backup of your project and other relevant files. For the upgrade to complete smoothly, you need to back up a number of files/folders from your system other than your project files. The number of files you need to back up depends on your system configuration. For more information about performing a backup, refer to the Backing Up a Project section in the online help of your current version.

---

**Note:** With the release of Plant SCADA 2023 R2, the CSV\_Include project is no longer supported as a system project. If you have any projects based on the CSV\_Include templates, you will need to create a separate backup of the CSV\_Include project and restore manually it in version 2023 R2 (or later). You can then include it as a user project.

---

The following files need to be backed up:

File	Description
Project backup (.ctz file)	This is the main file to back up. For information about backing up a project, refer to your current version's online help. You need to have the <b>Save sub-directories</b> and <b>Save configuration files</b> options selected in the Backup dialog.
Citect.ini	This file is located in the config folder.

File	Description
Deployment configuration files	<p>If you have deployment configured, back up the following files:</p> <ul style="list-style-type: none"> <li>• SE.Asb.Deployment.Server.WindowsService.exe.config</li> <li>• SE.Asb.Deployment.Node.WindowsService.exe.config.</li> </ul> <p>These are located in the path [CtEdit]Config.</p>
Data directory	This file is found on the path [CtEdit]Data.
Deployment database	<p>This is located in the Deployment directory. For example:</p> <p>%PROGRAMDATA%\AVEVA Plant SCADA 2023\Deployment.</p>
Alarm Database (for v2015 or later)	<p>The Alarm Database is located in the Data directory: [Data]\&lt;Project Name&gt;\&lt;ClusterName.AlarmServerName&gt;.</p> <p>For each alarm server you have in your system, a corresponding Alarm Database will exist. You need to backup all alarm databases.</p>
Trend files: *.HST and *.00X	<p>The path and names of these files are defined on the trend tag itself and created in the Data directory defined in [CtEdit]Data. The files will be named after the trend name and number of files. For example, if the trend name is CPU, file names will be CPU.HST, CPU.001, CPU.002 and so on.</p>
Report Files	<p>These files contain the code that is executed on your reports. They are located in the [CtEdit]User\&lt;Project Name&gt; folder.</p>
Custom ActiveX Controls (.OCX)	<p>Plant SCADA includes some ActiveX controls, which will be available with the 2023 installation. However, you need to take a backup of your custom ActiveX controls.</p> <p>Check your ActiveX.dbf file in the [CtEdit]User\&lt;Project Name&gt; folder. This file contains a list of the ActiveX controls in your project and their GUID. Using the GUID, find the path of an ActiveX control using the Windows Registry key:</p> <p>KEY_LOCAL_MACHINE\SOFTWARE\Classes\CLSID\"GUID"\InProcServer32\.</p> <p>The default value for this key is a path to the .DLL or</p>

File	Description
	.OCX file you need to back up.
Process Analyst files	Backup the main <Project Folder>\Analyst Views and <Project Folder>\Dictionary folders.
Device logs	These files contain any logging (alarm logs, report logs) you have configured in your project. You will find their location in the Devices dialog. Refer to your online help for more information.
Additional Files	Check your Citect.ini file or use the <b>Setup Editor, Paths</b> section as it could contain runtime files used by custom code in the project.
Driver Hotfixes	<p>If you are aware of any driver hotfix in your system, backup this driver DLL which is located in the Bin directory where Plant SCADA is installed.</p> <p><b>Note:</b> The fixes contained in this hotfix may have been included in the drivers which ship with Plant SCADA 2023.</p>

**Note:** Before you backup a project from version 2016 (or earlier) for upgrade to version 2018 R2 (or later), you should check if the Citect.ini file uses the parameter [CtEdit]ANSIToOEM. If so, confirm that the parameter is set to the required value. Then perform an **Update Pages** with the **Fast Update Pages** option disabled. This will back up the correct ANSI character values. Be aware that the Fast Update Pages option is not available from version 2018. If you are using a later version and have noticed inconsistencies due to the misconfiguration of [CtEdit]ANSIToOEM prior to an upgrade, contact technical support.

## 2. Upgrade your licenses

In order to do this, you will either need to have a valid support agreement or you will need to purchase a license upgrade. You can upgrade your key or soft license on the **License Activation** page of the AVEVA Knowledge and Support Center website at <https://softwaresupport.aveva.com>. You can also check the support status.

If your license is out of support, contact your local authorized AVEVA distributor. If you don't know who your local distributor is, send an email to [scada.orders@aveva.com](mailto:scada.orders@aveva.com) with your license and site ID details. For more information about licensing in Plant SCADA, refer to the [Licensing](#) section of the Plant SCADA documentation.

**Note:** With the release of Plant SCADA 2023, Schneider Electric's Floating License Manager is no longer supported. Existing users of the Floating License Manager will need to migrate their systems to [AVEVA™ Enterprise Licensing](#).

## 3. Install Plant SCADA

Uninstall the current version of Citect SCADA completely and install Plant SCADA 2023.

**Note:** Do not uninstall Platform Common Services (PCS) if upgrading from Plant SCADA 2018 R2.

## 4. Configure the Server Password

Configure the Server Password using the Configurator's **Computer Setup** page under Plant SCADA. For more information, see [Use Configurator to Set Up a Runtime Server](#).

## 5. Configure the System Management Server

Configure the System Management Server in the Configurator's System Management Server page under Plant SCADA. For more information, see [Configure a System Management Server](#) in the Plant SCADA documentation.

## 6. Restore your project

Restore your project. For instructions on restoring your project, refer to the Plant SCADA documentation.

## 7. Upgrade your project

As a default, when you restore your project from a previous version, Plant SCADA will force an update, and you will get a warning message. Click **Yes** to proceed with project upgrade.

If this message is not displayed, you can force an update of all projects by setting the [\[CtEdit\]Upgrade](#) INI parameter to 1. Close and re-open Plant SCADA Studio. Once you re-open Plant SCADA Studio, you will get a warning message. After clicking **Yes** all projects will be upgraded.

## 8. Migrate your project

The automatic project upgrade does not fully upgrade your projects and needs to be followed by the Migration Tool. The [Project Migration Tool](#) is a separate application that runs automatically after the project upgrade has been executed. It adds computers from the existing topology. You may need to run the Migration Tool separately for other components.

## 9. Merge your INI file

If you have defined any project-specific parameters in your Citect.ini file, merge them into the new version's INI file.

Merge any driver parameters from your old INI file as they will most likely be necessary to interface with your I/O network. For a list of changes to .INI parameters, refer to the topic [Citect.ini Parameters in Plant SCADA 2023](#) in the Plant SCADA documentation.

## 10. Compile your project

After upgrading your project and running the Migration tool, compile your project to ascertain that runtime functionality works as expected. It is very likely that you may encounter errors when you compile your project. One of the common sources of errors when upgrading is Cicode functions. This is because functions may have changed, deprecated or simply because the compiler code has been updated to prevent runtime errors. You can find a list of updates to Cicode functions in the *What's New* section of the Plant SCADA documentation.

Refer to the Plant SCADA documentation for instructions on compiling your project.

---

**Note:** If you are upgrading from version 2018 R2, the compiler warning message W1041 will be generated if the **Address** field for your network address is an IP address. If this occurs and you want to use encryption, you need to set the **DNS Name** field in the **Topology|Computers** view for the matching network address to the **DNS Name** of the computer.

---

## 11. Run the Setup Wizard

Before running your project, run the Setup Wizard to configure the Runtime Manager and other settings that are relevant to the runtime process. The Setup Wizard will automatically determine the role of your computer based on the network addresses defined in your project. After finishing the Setup Wizard, restore your historic data and other files, and run your project.

## 12. Restore runtime files

After compiling your project, place the files necessary for runtime in the correct directories. Refer to point 1 in this topic for the list of files you need to place in the corresponding directories as defined in your Citect.INI file and project configuration.

## 13. Restore historical data files

Restore the historical data files before running your upgraded projects.

### Alarms

Convert your alarm database in the Data directory with the following steps:

1. Check that you have placed your backed-up alarm database in the directory defined by the [CtEdit]Data parameter.
2. Delete any legacy database files.

Prior to version 7.30, Citect SCADA used the following alarm database files:

- <project>\_<cluster>\_ALMSAVE.DAT
  - <project>\_<cluster>\_ALMINDEXSAVE.DAT
- Or:
- ALMSAVE.DAT
  - ALMINDEXSAVE.DAT.

If you are upgrading from a version prior to 7.30, these legacy files are converted to a new alarm database format when the alarm server is launched. Once this occurs, these files are no longer required.

If you are upgrading from a version later than 7.30 (2015 or later), you should delete these files prior to starting the alarm server. Confirm that the directory specified by the [Alarm]SavePrimary parameter does not contain the legacy alarm database files listed above.

---

**Note:** If you do not delete these files, in some circumstances the legacy data from these files may replace or merge into your current alarm database when you launch the alarm server.

---

### Trends

Follow these steps to convert the files:

1. Create the same file hierarchy on the new system.
2. Place the files in the same folders.
3. If you want to change the folder location or you cannot replicate the same file hierarchy, edit the trend tag definitions to match the new file paths.

## 14. Run your project

Run your project to check that the functionality works as intended:

- Check any Cicode that you needed to modify in order to compile your project.
- Test communications to your I/O devices, alarm triggering and trend capture.

### See Also

[Migrate to Production](#)

[Troubleshooting an Offline Upgrade](#)

[Online Upgrade](#)

## Migrate to Production

Review the following information to complete your Offline Upgrade process and apply the changes to your production system.

### Testing Considerations

After the upgrade and configuration changes to the project are complete, it is recommended to perform system testing of the new project version. This is to check that functionality and operation behaves as expected before applying the new project to the production environment.

### Licensing

When changing to use a newer product version, the hardware/software key may need to be updated. The hardware key is a physical key that plugs into either the parallel port or USB port of your computer. To upgrade the key, a new authorization code is required which can be created by using the AuthCode Generator. To prepare the system, it is recommended to update the production machine keys before the project is updated on the production machines as the updated key will still license the previous version. You can update the hardware/software key in the Licensing activity in Plant SCADA Studio.

---

**Note:** With the release of Plant SCADA 2023, Schneider Electric's Floating License Manager is no longer supported. Existing users of the Floating License Manager will need to migrate their systems to [AVEVA™ Enterprise Licensing](#).

---

### Prepare Configuration [INI] Files

Before beginning any changes to the production computers, it is recommended that you back up the configuration [INI] files for each machine as they may be required for reference.

The current configuration file can be used with the new product version after the path parameters have been updated to the new version file locations. Refer to the setup of the development environment section of the specific version for further parameter information.

The Setup Editor and Setup Wizard can be used to finalize the configuration of the computer setup.

## Server Addresses

During a migration with an existing system, it may be useful to use a new set of IP addresses and computer names for the new version. This is typically done when there is a need to provide isolation between the system project versions to allow the two systems to individually co-exist on the network for a period of time. When isolated, the systems will be independent and not cross communicate or synchronize between the existing and new versions. This type of upgrade would have the new version start with a snapshot of the historical data from the previous system and then run in parallel.

## Communication Drivers

The project may be using specialty drivers. If so, it is recommended that you back up the driver files located in the product 'bin' directory. Existing specialty drivers that are used may be required for the new version. The Connectivity Hub on the [AVEVA Knowledge & Support Center](#) can be checked for driver availability and compatibility.

**Note:** Plant SCADA 2020 R2 introduced a classification system for the driver portfolio that reduced the number of drivers included by default with the Plant SCADA installation media. Some drivers may need to be downloaded from the **Connectivity Hub** at the AVEVA Knowledge and Support Center.

## Specialty Software

The project may be using specialty software to provide certain system functionality. These applications may be required to be updated or re-installed during the upgrade process and considered in the context of the upgrade.

## Format File

The project may be using custom configuration forms in the product. This configuration is located in the FRM file which may be required in the new installation. For further information, check the Tech Note "Upgrading with a modified CITECT.FRM file" (TN3795) on the AVEVA Knowledge & Support Center.

## Trend and Alarm Data

A project upgrade may also require the trend and alarm data to be updated based on the new product features. It is recommended to keep a backup of the existing production trend data files and the alarm save data file from the original.

Once the data files have been upgraded, the updated data files may not be compatible with the previous version. It is not recommended to change the directory path of the trend data files during the project upgrade as this may affect the trend operation. The default data directory may be changed between product versions and may need to be considered in the context of the install and upgrade with regards to the trend file location.

## See Also

[Troubleshooting Offline Upgrade](#)

## Troubleshooting an Offline Upgrade

This section lists common issues you might encounter during your [Offline Upgrade](#), which may be compiling errors or any other pre-runtime issues.

### Not able to upgrade license key

- Check that you have correctly installed the latest versions of **CiUSafe** and the **Sentinel Driver** via the [License Activation](#) page of the AVEVA Knowledge and Support Center.
- Check that the Authorization code matches the Key you are trying to upgrade. If you still cannot upgrade your license, please check the Tech Note "CIUSafe Error Return Codes" (TN5882) on the [Knowledge Base](#) page of the [AVEVA Knowledge and Support Center](#).

### Compiler errors and warnings not related to deprecated functions

As Plant SCADA evolves, the compiler feature becomes stricter in order to maintain project quality and runtime success. The fact that you are getting compiling errors that were not appearing before is because of stricter compilation, which will result in more predictable and stable runtime. Refer to the error code in the error message to resolve any errors and warnings. You can search the online help using the error code for more information about a specific error code.

## Online Upgrade

An online upgrade takes advantage of Plant SCADA's native server redundancy to avoid loss of data and minimize downtime on a production system.

---

**Note:** An online upgrade is only supported from versions that are currently in mainstream support.

---

There are two ways to perform an online upgrade:

- Upgrade one by one — firstly primary servers, then clients and then standby servers.
- Upgrade side by side — where a new set of server and clients runs in parallel.

If the primary server has a lower version of AVEVA Plant SCADA than the standby server, then the server communication will be lost. So, make sure to avoid the following scenarios during online upgrade:

- Shutting down the upgraded primary server before the standby is upgraded.
- Stopping both the servers when the upgrade is in progress.
- Starting up the non-upgraded standby server, when the upgraded primary server is running.

Similar to the [Offline Upgrade](#), you will need to follow the upgrade path, and repeat the process as many times as the number of steps in your upgrade path.

---

**Note:** With the release of Plant SCADA 2023, Schneider Electric's Floating License Manager is no longer supported. Existing users of the Floating License Manager will need to migrate their systems to [AVEVA™ Enterprise Licensing](#).

---

The required patches for an online upgrade are:

- For Plant SCADA 2020 R2, Update 2 (March 2022) or later is required.

For Plant SCADA 2023, you can upgrade from an RTM installation or a later installed update.

Refer to the following sections for specific instructions on how to upgrade from your current version.

- [Upgrading from v2020 R2](#)
- [Upgrading from v2023](#).

## See Also

[Pre-requisites for Online Upgrade](#)

[Troubleshooting an Online Upgrade](#)

## Pre-requisites for Online Upgrade

As mentioned earlier, an online upgrade will allow you to avoid downtime and loss of data. It is important that you take into consideration the complexity and size of your project when planning for this upgrade. It is recommended that you review the following pre-requisites before you start an online upgrade:

1. **At least one pair of redundant servers:** This is to upgrade one server at the time while the redundant server assumes primary operation, avoiding downtime and loss of data.
2. **Upgraded project:** Check that your project runs and works properly on Plant SCADA 2023 before migrating to production and starting the online upgrade. If your project is complex, it is recommended that you have a test environment as the offline upgrade could be complex and could involve a long server downtime if done on your production system.
3. **Restore runtime files:** Check that you have restored the necessary files for runtime onto the appropriate directories to avoid any disturbances on the upgraded live system.
4. **Capture data files:** To allow historic data to be restored into the new version, you need to assess and move data files to the required location during the upgrade process. This is described in detail in the online upgrade steps in the relevant sections.
5. **Configure your running system for online upgrade:** We recommend leveraging your current redundant system and adding the following Citect.ini parameters before the online upgrade:
  - **[LAN]EarliestLegacyVersion:** Use 8300 for v2020 R2, or 8400 for v2023. This will allow your upgraded servers to accept connections from the older version.
  - **[Alarm]EnableStateLogging:** Set this parameter to 1 to allow logging the alarm synchronization messages into the syslog file.
  - **[Debug]Kernel = 1 (optional):** This allows you to use the Kernel to monitor progress during the upgrade.

---

**Note:** Before you perform an online upgrade from Plant SCADA version 2020 R2, you need to install Update 2 (March 2022) or later. Updates for Plant SCADA are available from the **Product Hub** page of the AVEVA Knowledge & Support Center website at <https://softwaresupport.aveva.com>.

---

## Upgrading from v2020 R2

**Note:** For an online upgrade from Plant SCADA 2020 R2, Update 2 (March 2022) or later is required.

### To upgrade from v2020 R2:

1. Check that you have added the following parameter in the .INI file to all your server nodes before you start the online upgrade.

**[LAN]EarliestLegacyVersion = 8300.**

Restart the servers after adding the parameter for the changes to take effect.

2. Shutdown SCADA runtime on the primary server.
3. Upgrade Plant SCADA on this server according to the [Offline Upgrade](#).

**Note:** Do not uninstall Platform Common Services (PCS) if upgrading from Plant SCADA 2020 R2.

4. Set up the Server Password in Configurator's **Computer Setup** page. See [Use Configurator to Set Up a Runtime Server](#).

5. Configure your System Management Server and encryption settings based on your requirements.

**Note:** The encryption settings in version 2023 R2 need to be configured to align with the settings as they were in 2020 R2, otherwise communications may not be successful.

The following table indicates the encryption settings that will align successfully across version 2023 R2 and 2020 R2.

		Encryption setting on Plant SCADA 2023 R2		
		Unencrypted	Mixed Mode	Encrypted
Encryption setting on 2020 R2	Unencrypted	Communication OK	Communication OK	Communication unsuccessful
	Mixed Mode	Communication OK	Communication OK	Communication OK
	Encrypted	Communication unsuccessful	Communication OK	Communication OK

6. Place the backed-up Alarm database in the [CtEdit]Data directory. This will allow a quicker synchronization of alarm servers.
7. Restart the primary server, which is now upgraded.
8. The upgraded server will synchronize its alarm database with the running v2020 R2 server. You need to wait for the synchronization process to finish, and this will depend on the size of your alarm database. The synchronization information is available from the main kernel window of the Alarm Process as well as the syslog.
9. Upgrade your client nodes one by one.
10. Configure your System Management Server and encryption settings based on your requirements.
11. Check the **Server Authentication** section of the Computer Setup page in Configurator, under Plant SCADA. If you have selected **Configure Server Password**, make sure you use the same password as the one defined above in step 5.
12. Shutdown runtime on the standby server.

13. When the newly upgraded server assumes the primary server role it will migrate the entire alarm database to the new format, and you should now be able to see Alarm Summary data on all migrated clients.
14. Upgrade Plant SCADA on this server according to the [Offline Upgrade](#).
15. Set up the Server Password in the Configurator, Plant SCADA, Computer Setup page.
16. Configure your System Management Server and encryption settings based on your requirements.
17. Restart the standby server, which is now upgraded.
18. Check functionality of the system as a whole.
19. Test redundancy by switching off the primary server and checking that the standby takes over and clients switch over.

## Upgrading from v2023

### To upgrade from v2023:

1. Check that you have added the following parameter in the .INI file to all your server nodes before you start the online upgrade.

**[LAN]EarliestLegacyVersion = 8400.**

Restart the servers after adding the parameter for the changes to take effect.

2. Shutdown SCADA runtime on the primary server.
3. Upgrade Plant SCADA on this server according to the [Offline Upgrade](#).

---

**Note:** Do not uninstall Platform Common Services (PCS) if upgrading from Plant SCADA 2023.

---

4. Set up the Server Password in Configurator's **Computer Setup** page. See [Use Configurator to Set Up a Runtime Server](#).
5. Configure your System Management Server and encryption settings based on your requirements.

---

**Note:** The encryption settings in version 2023 R2 need to be configured to align with the settings as they were in 2023, otherwise communications may not be successful.

---

The following table indicates the encryption settings that will align successfully across version 2023 R2 and 2023.

		Encryption setting on Plant SCADA 2023 R2		
		Unencrypted	Mixed Mode	Encrypted
Encryption setting on 2023	Unencrypted	Communication OK	Communication OK	Communication unsuccessful
	Mixed Mode	Communication OK	Communication OK	Communication OK
	Encrypted	Communication unsuccessful	Communication OK	Communication OK

6. Place the backed-up Alarm database in the [CtEdit]Data directory. This will allow a quicker synchronization of alarm servers.
7. Restart the primary server, which is now upgraded.
8. The upgraded server will synchronize its alarm database with the running v2023 server. You need to wait for

the synchronization process to finish, and this will depend on the size of your alarm database. The synchronization information is available from the main kernel window of the Alarm Process as well as the syslog.

9. Upgrade your client nodes one by one.
10. Configure your System Management Server and encryption settings based on your requirements.
11. Check the **Server Authentication** section of the Computer Setup page in Configurator, under Plant SCADA. If you have selected **Configure Server Password**, make sure you use the same password as the one defined above in step 5.
12. Shutdown runtime on the standby server.
13. When the newly upgraded server assumes the primary server role it will migrate the entire alarm database to the new format, and you should now be able to see Alarm Summary data on all migrated clients.
14. Upgrade Plant SCADA on this server according to the [Offline Upgrade](#).
15. Set up the Server Password in the Configurator, Plant SCADA, Computer Setup page.
16. Configure your System Management Server and encryption settings based on your requirements.
17. Restart the standby server, which is now upgraded.
18. Check functionality of the system as a whole.
19. Test redundancy by switching off the primary server and checking that the standby takes over and clients switch over.

## Troubleshooting an Online Upgrade

This section lists common issues you might encounter during your Online Upgrade, which may be related to runtime issues and redundancy connectivity.

### Redundant servers do not communicate

I cannot make my redundant servers communicate and I keep getting the hardware alarm "Redundant Server not found".

1. Check that you have set your [LAN]EarliestLegacyVersion parameter correctly.
  - If upgrading v2020 R2 use [LAN]EarliestLegacyVersion=8300.
  - If upgrading v2023 use [LAN]EarliestLegacyVersion=8400.
2. Check that you have run the Setup Wizard and set both servers to Networked mode.
3. Set the same server password on both servers in the Setup Wizard.
4. If security is enabled, check that Plant SCADA Runtime Manager is running as a Windows service.
5. Check that the **Accept encrypted and non-encrypted connections (mixed mode)** option is selected in the Configurator, Plant SCADA, Encryption page.

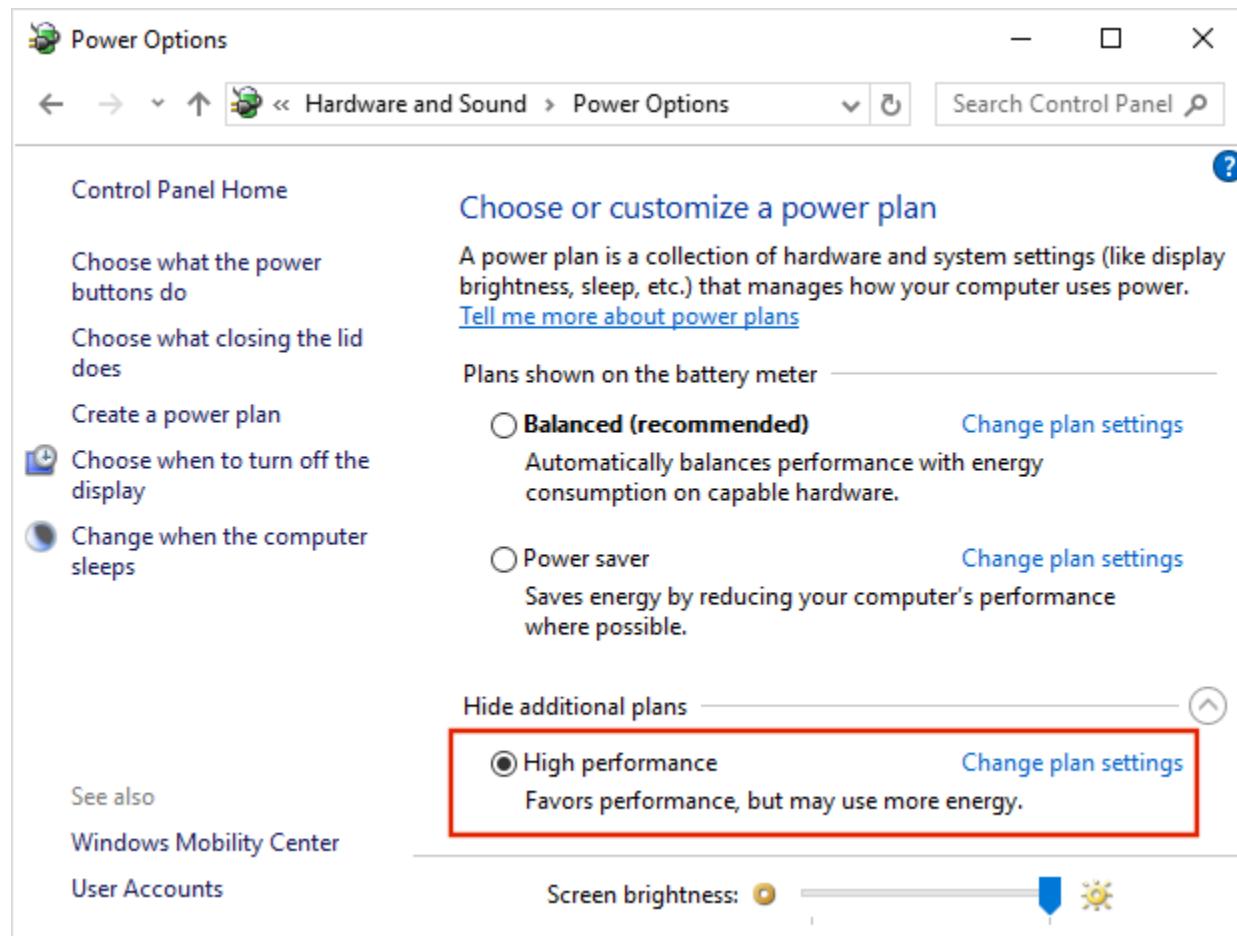

---

**Note:** The current version should not have encryption enabled with **Accept encrypted and non-encrypted** not selected, otherwise the servers will not be able to communicate. **Mixed Mode** should be used, or encryption should be disabled.

---

## My system is performing slowly even though Hardware and software requirements are met

Check your system's power options: **Control Panel, Power Options**.

## Remove Upgrade related parameters

After finalizing the upgrade process and confirming that runtime is fully functional, we recommend removing or updating the following .INI parameters. You will need to restart the servers after changing the parameters for the changes to take effect.

- **[Debug]Kernel = 0:** this is to enhance security and keep operators out of the kernel.
- **[LAN]EarliestLegacyVersion:** remove this parameter.

## Upgrade Deployment from Plant SCADA 2020 R2

The deployment architecture installed with Plant SCADA 2023 and 2023 R2 is no longer compatible with deployment servers running an earlier version. This means:

- You cannot use a 2023 R2 version of Plant SCADA Studio to add projects to a deployment server that is running Plant SCADA 2020 R2 (or earlier).

- You cannot deploy a project from a deployment server running 2023 R2 to a deployment client that is running Plant SCADA 2020 R2 (or earlier).

If you have a distributed system that includes some computers on Plant SCADA 2020 R2 (or earlier), you should retain your existing deployment server to distribute projects to these computers until the roll out of 2023 R2 is complete. You will also need to configure a new deployment server to deploy 2023 R2 projects to any upgraded computers.

---

**Note:** If you want to maintain your existing deployment server and client configurations from 2020 R2 (or earlier), you need to confirm that you have a backup of the Plant SCADA \Config folder (for example, C:\ProgramData\AVEVA Plant SCADA 2020 R2\Config) prior to upgrading to version 2023 R2.

---

Additional steps are required if you are upgrading deployment directly from Citect SCADA 2018 to Plant SCADA 2023 R2. For more information, see *Upgrade deployment directly from Citect SCADA 2018* below.

### To migrate your deployment configuration from 2020 R2 (or earlier) to a 2023 R2 deployment server.

1. Confirm the System Management Server configuration has been upgraded correctly.
2. In Configurator, confirm that Computer Setup is configured correctly.
3. On Configurator's Deployment Server page, select **Import Configuration file from previous version of Deployment Server**.

If this option is not available, you need to close Configurator and delete the following files from Plant SCADA's \Config folder:

- For a deployment client, delete SE.Asb.Deployment.Node.WindowsService.exe.config
- For a deployment server, delete SE.Asb.Deployment.Server.WindowsService.exe.config.

You then need to restart Configurator and attempt step 3 again.

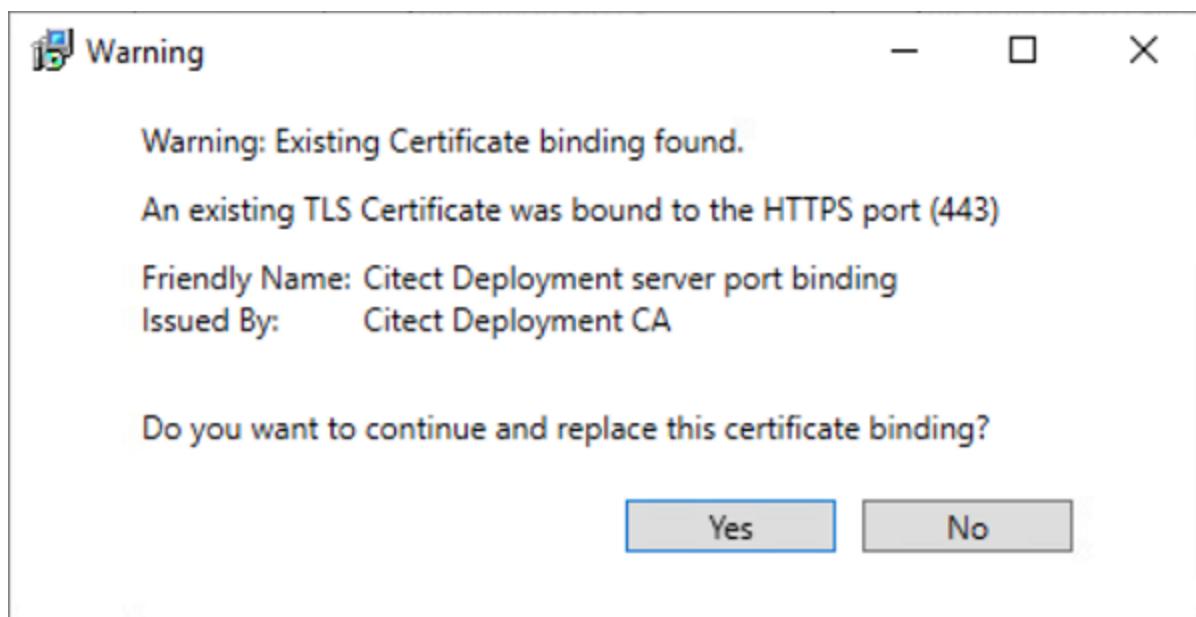

4. Using the browse dialog, locate the deployment server configuration file from your previous version. For example:  
C:\ProgramData\AVEVA Plant SCADA 2020 R2\Config\  
SE.Asb.Deployment.Server.WindowsService.exe.config
5. Open the file.
6. Click the **Configure** button to complete configuration of the deployment server.

The same steps should be taken for configuration of the new deployment clients.

When you check the Computer Setup settings for a deployment client in Configurator, confirm that the **Run the project deployed from the Deployment Server** setting is selected, otherwise the deployment client will not appear in Plant SCADA Studio's Deployment view.

### Upgrade deployment directly from Citect SCADA 2018

In this scenario, a deployment server from Citect SCADA 2018 will have taken port 443 by default. The following warning message displays if the 2023 R2 System Management Server is also configured with the default port 443.

If this occurs, you need to select **Yes** to enable the new System Management Server to take over the deployment certificate authority role. This also allows your deployment history to be persisted.

You can then follow the step in the procedure above.

## See Also

[Install a Deployment Server](#)

## Project Migration Tool

The automatic update that occurs when you initially launch Plant SCADA does not fully upgrade your projects, and needs to be followed by the use of the Project Migration Tool (if migrating from v7.x this is particularly noteworthy). The automatic update is a passive action which updates the database field definition for any database that has been changed between the two versions and copies new files that are required.

The Migration Tool is a separate application which has to be run manually after the automatic upgrade has been executed. It can be initiated after you have prepared the project for final migration. This tool will accommodate the changes in project functionality that are incorporated in 7.x and subsequent versions.

### **⚠ WARNING**

#### **UPGRADE ALTERS COMMUNICATIONS CONFIGURATIONS**

After upgrading, confirm and adjust the configuration of I/O devices in your project.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

## See Also

[Using the Project Migration Tool](#)

## Using the Project Migration Tool

**Note:** Before you use the Project Migration Tool, is recommended that you familiarize yourself with the process that it performs, and the preparatory steps that you need to carry out with your existing projects.

### To run the Project Migration Tool:

1. Backup the projects that you need to migrate.
2. Navigate to the Project activity in Plant SCADA Studio, select **Home, Migration Tool** to display the Project Migration dialog.
3. Either accept the project displayed in the edit box, or browse for the project that you wish to upgrade.
4. Specify the changes you would like to implement during the migration process by selecting from the options described in the following table.

Option	Description
Remove obsolete Memory and Alarm devices	<p>Select this check box if you wish to delete these types of devices after successful migration (see <a href="#">Remove Obsolete Memory and Alarm Devices</a>).</p> <p><b>Note:</b> Do not select this check box when you run the tool for the first time on a project that contains any included projects which are shared with more than one master project. If you want to delete obsolete devices under these circumstances, you can run the tool a second time using this option if the migration is successful after it is run the first time.</p>
Append to existing log file	<p>Use this option to append information about the migration process to the existing Migration Tool log file (located in Plant SCADA's User directory). If this option is not selected, a new log file will be created when migration is complete.</p>
Create unique IDs for Variables and Equipment	<p>Select this option to add a unique ID to the variable tags, equipment and equipment types in your project.</p> <p>Unique IDs were added to variable tags in Plant SCADA 2023 and equipment in 2023 R2. This setting should be applied to any projects that you migrate.</p> <p>You can also use it to repair a project if you are seeing compiler warning W1050 (Unique ID expected).</p>
Create roles from User security information	<p>Select this option if you wish to migrate the users database from an existing project (see <a href="#">Creation of Roles for Existing Users</a>).</p>
Copy XP_Style menu into Tab_Style menu	<p>Select this option to convert legacy menu entries to</p>

Option	Description
	the format necessary for the new menu configuration system. By default, this option is unchecked to avoid potential compile errors that may occur if the legacy menu.dbf contains functions which have been removed.
Migrate included projects	Select this option to migrate the included projects associated with the selected project (see <a href="#">Migrate Included Projects</a> ).
Migrate Equipment database, Types and Parameters	<p>You should check this option to migrate your equipment to use configuration parameters, introduced in Plant SCADA 2023 to replace custom parameters. Configuration parameters support the same functionality as the legacy custom parameters, but they are stored in a dedicated configuration parameter database that removes the 256 character limitation. See <a href="#">Migrate Custom Parameters to the Configuration Parameters Database</a>.</p> <p>You should also select this option if you have an existing database that you want to migrate into this version. When upgrading from an earlier version, and the "PARENT" field of the equipment table was used, you should select this check box. Otherwise existing data from the PARENT field will be ignored. If runtime browsing is used, the PARENT field will return the equipment parent (the substring of the equipment name without the last '.' and anything after that).</p> <p>To retrieve information that was stored in the previous "PARENT" field the "COMPOSITE" field should be used.</p>
Migrate ABCLX to OPCLX	<p>Select this option if you want to migrate devices that currently use the ABCLX driver to the OPCLX driver. Select the <b>Configure</b> button to indicate which I/O devices you would like to migrate.</p> <p><b>Note:</b> You should confirm that the OPCLX driver is installed before you use this option.</p>
Migrate Trend/SPC storage method	If you select this option, the storage method will be set to scaled (2-byte samples) for all trends that have no storage method defined. Use this option to stop the compiler error message "The Storage Method is not defined". In previous versions, a blank storage method would default to scaled.

Option	Description
	However, this is no longer supported, resulting in the compile error message.
Create computers from Network Addresses	If you select this option, computers will be created from the servers and network addresses that you have configured for a project and its include projects. This option distinguishes whether a computer has multiple IP addresses.

**Note:** If 'Copy XP Style menu into Tab\_Style Menu' and 'Migrate Included Projects' are both selected when the migration tool runs, the following message will be displayed: "Copying menus of included projects may lead to conflicts. Any conflicts will need to be manually corrected". To avoid this from occurring, it is recommended you run the migration tool twice. In the first instance just select the option 'Copy XP\_Style menu into Tab\_Style Menu', and in the second instance just select the option 'Migrate Included Projects'.

- Click **Migrate** to begin the migration process.

A progress dialog will display indicating the stage of the conversion and the name of the project being migrated. If you wish to cancel the migration at this point click the **Abort** button.

**Note:** Aborting a migration will stop the migration process, and any changes already completed will not be rolled back. You will have to restore your project from the backup created in the first step.

When the migration process is concluded, a confirmation dialog box will display indicating the number of variables converted and the number of I/O devices deleted (if device deletion was selected at the start of migration).

- Click the **Close** button to close the dialog.

## Remove Obsolete Memory and Alarm Devices

When you use Plant SCADA's Migration Tool, the **Remove obsolete Memory and Alarm devices** option adjusts the following:

**Memory tags to local variables:** tags that are on an I/O device that are configured to use a 'memory' port.

**Note:** If there are real I/O devices in your project that have been set to use a 'memory' port during testing, these can be changed before running the migration tool to avoid those tags getting adjusted.

**Alarm devices:** can remove I/O devices that have a protocol set to 'Alarm', which was needed in earlier versions to enable alarm properties as tags. In version 7.x, the alarm properties are enabled via a setting on the alarm server configuration form.

## See Also

[Memory Devices](#)

[Alarm Devices](#)

[Converting Memory Variables](#)

[Inserting New Local Variables](#)

[Deleting Variable Tags](#)

[Deleting Obsolete I/O Devices](#)

## Memory Devices

In previous versions of Plant SCADA an I/O Device could be defined as a memory device by setting the port value to "Memory". This was generally done for one of the following purposes:

- To provide for future devices that were not currently connected to the system, but their points needed to be configured at this stage of project.
- For virtual devices where there was no corresponding physical I/O Device and you needed data storage with the entire functionality normally associated with I/O variables such as alarms.
- To act as a variable which was local to the process being used in place of Cicode global variables.

You can still use I/O Devices for future or virtual devices in version 7.0, but manually set the Port parameter to an unused value other than Memory, and set the Memory property of the device to True to indicate that it is an offline in-memory device before running the Migration Tool.

You need to review your project to identify which memory I/O Devices are local variable holders and which ones need to be changed to non-memory so that the Migration tool does not convert their variables.

The Migration Tool will set any I/O Device's port which is identified as a Memory device to the new Local Variable, and the original device record will be deleted.

## See Also

[Alarm Devices](#)[Converting Memory Variables](#)

## Alarm Devices

In previous versions of Plant SCADA Alarm devices were defined as devices with their Protocol property set to "Alarm". In version 7.0 the function of configuring such a device is now replaced by setting the Publish Alarm Properties property to True on the Alarm Server.

Alarm devices with their Protocol property set to "Alarm" will be deleted from I/O Devices table by the Migration Tool.

The Migration tool can delete memory and alarm device records. If you want to delete the devices at a later time, deselect the "Remove obsolete Memory and Alarm Devices" option.

---

**Note:** Alarm devices with their Protocol property set to "Alarm" are no longer used and will be removed by the Migration Tool. The Alarm Servers will now publish Alarm Properties.

---

## See Also

[Converting Memory Variables](#)

## Converting Memory Variables

A memory variable is a variable with its I/O Device Port property set to either "Memory" or "MEM\_PLA".

If there are multiple I/O Devices with the same name, possibly on different I/O Servers, the device would not be considered as a memory device regardless of its port value. In other words, the Migration tool will not process the variables for memory devices with duplicate names.

## See Also

[Inserting New Local Variables](#)  
[Deleting Variable Tags](#)

### Inserting New Local Variables

When the Migration Tool runs, a local variable record will be inserted for each identified memory variable, and the variable data will be copied into the new local variable.

Local variables have fewer fields than variables; the following table shows the mapping from variable to local variable when copying their data.

Variable Tag Parameter or Constant Value	Local Variable Parameter
Variable Tag name	Name
Data Type	Date Type
(Empty)	Array Size
Eng. Zero Scale	Zero Scale
Eng. Full Scale	Full Scale
Comment	Comment

With the exception of the Array Size, which has been introduced in version 7.0 exclusively for local variables, every field receives its value from the same or similar field.

## See Also

[Deleting Variable Tags](#)

### Deleting Variable Tags

Once the Migration Tool has created the local variable records it will insert those variable tag records that have been converted in the previous step, and delete the original variable tag.

If an error is detected during the insertion of the local variables, the deletion of the variable tags will not be performed. If this occurs it is possible to have two records with same name and data, one in the local variable (the newly inserted record) and one in the variable tags (the original record that has not been deleted). You need to delete either of the variables manually, or restore the backed up project after removing the cause of the error then run the Migration Tool again.

## See Also

[Deleting Obsolete I/O Devices](#)

### Deleting Obsolete I/O Devices

Deleting obsolete I/O Devices is an optional step in the Migration Tool and will be performed after the memory variables are converted. If the delete option is chosen, obsolete Memory devices and Alarm devices will be deleted as the final step of the Migration Tool operation.

## Creation of Roles for Existing Users

When upgrading an existing project using the migration tool, a new role will be created (if needed) for every existing user. The new role will have the same security settings that were defined for that user and be given a generic name such as Role\_1, Role\_2 etc. During the upgrade process, if a role exists with the same security settings as the user, then the existing role will be assigned to the user being upgraded. For example; If Role\_1 exists and matches the security settings of the upgraded user then that user will be assigned Role\_1 also.

If you do not want to migrate users from an existing project, clear the option **Create Roles from User security information** from the migration tool dialog before running it.

## See Also

[Migrate Included Projects](#)

### Migrate Included Projects

Each project may contain multiple included projects. Additionally, any included project may contain its own included project so creating a cascading project.

The Migration Tool needs to process the original project and included projects in a single step. The reason for this is that variables can be defined in one project that refer to I/O Devices defined in another included project.

The Migration Tool performs this procedure sequentially on the "master" project then each included project.

In the case where two master projects share the same project as an included project, you should not select the "Remove obsolete Memory and Alarm devices" check box when you process a project that contains shared included projects. This is because the removal is performed at the conclusion of the migration process on each master and included projects sequentially. This could cause the deletion of an I/O Device in the first master project which is referenced by a tag in a shared included project which is processed in a later step.

If two separate "master" projects contain the same included project, run the Migration Tool on each "master" project without selecting to delete obsolete devices.

#### UPGRADE ALTERS COMMUNICATIONS CONFIGURATIONS

After upgrading, confirm and adjust the configuration of all I/O devices in your project.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

To remove obsolete devices, it is recommended that once the Migration Tool has completed successfully (without the check box being selected), run it a second time with the check box selected. This will remove the devices since every tag conversion were completed in the first pass of the Migration Tool.

## Default Scale

The Scale properties in both variable tags and local variables are optional. If a Scale value is not specified, the default value is indicated by a parameter in the Citect.ini file. The parameter name is "DefaultSliderScale" under the [General] section in the Citect.ini file. The default values for Scale is 0-32000, unless the default slider scale is true in which case the default value depends on the type, for example, Integer, String, or so on.

The Migration Tool will read this parameter and if it is not set, or set to false, then it will explicitly set any empty Scale property to a value into the range of 0 to 32000. This will be done even if either of the Zero Scale or Full Scale parameters has a value, in which case the empty Scale parameter will receive the default value.

If the DefaultSliderScale in the Citect.ini file set to True, the Scale parameters will not be populated with a default value if they are empty, rather they will be interpreted at runtime.

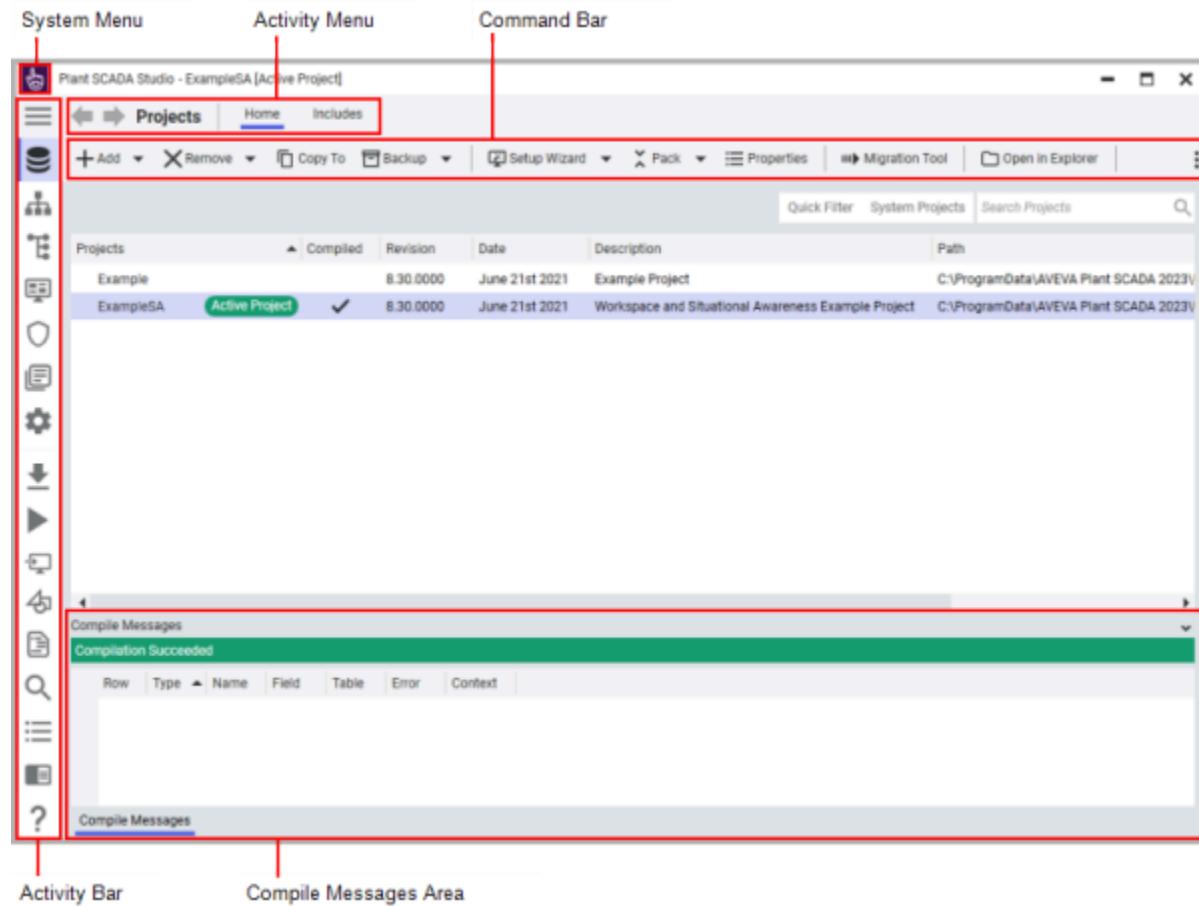

# Plant SCADA Studio

Plant SCADA Studio allows you to create and set up a logical representation of your plant environment. The configured environment can then be used to supervise and control the plant at runtime.

See [About Plant SCADA Studio](#).

## About Plant SCADA Studio

Plant SCADA Studio is divided into several [Plant SCADA Activities](#) (such as **Projects**, **Topology**, **System Model** and **Deployment**), allowing you to access different SCADA functions through a single interface.

- **Activity Bar** — allows you to navigate between the different activities, and also provides access to important global commands like **Compile** and **Run**.
- **Activity Menu** — within each activity, the Activity Menu allows you to configure different aspects of the associated functionality via a set of Activity Tabs. There may be multiple menus in an activity.
- **Command Bar** — each Activity Menu displays a Command Bar with several options for performing specific tasks within that activity. Frequently used Command Bar options (such as **Save** and **Discard**) are available in

more than one activity.

- [Compile Messages Area](#) — this area is available to view at any time, and shows messages pertaining to errors encountered when a project is compiled.
- [The System Menu](#) — this menu can be accessed by clicking the following icon in the top left corner:

Plant SCADA Studio displays the **Projects** activity when it is launched. All projects in your system are displayed, and the name of the selected project is displayed on the title bar of the Plant SCADA Studio. To select a different project, click on the required project name.

[Command Bar](#)

## Activity Bar

The Activity Bar is located on the left hand side of Plant SCADA Studio. It displays a set of icons that provide access to various project engineering activities such as **Projects**, **Topology**, **Security**, and so on.

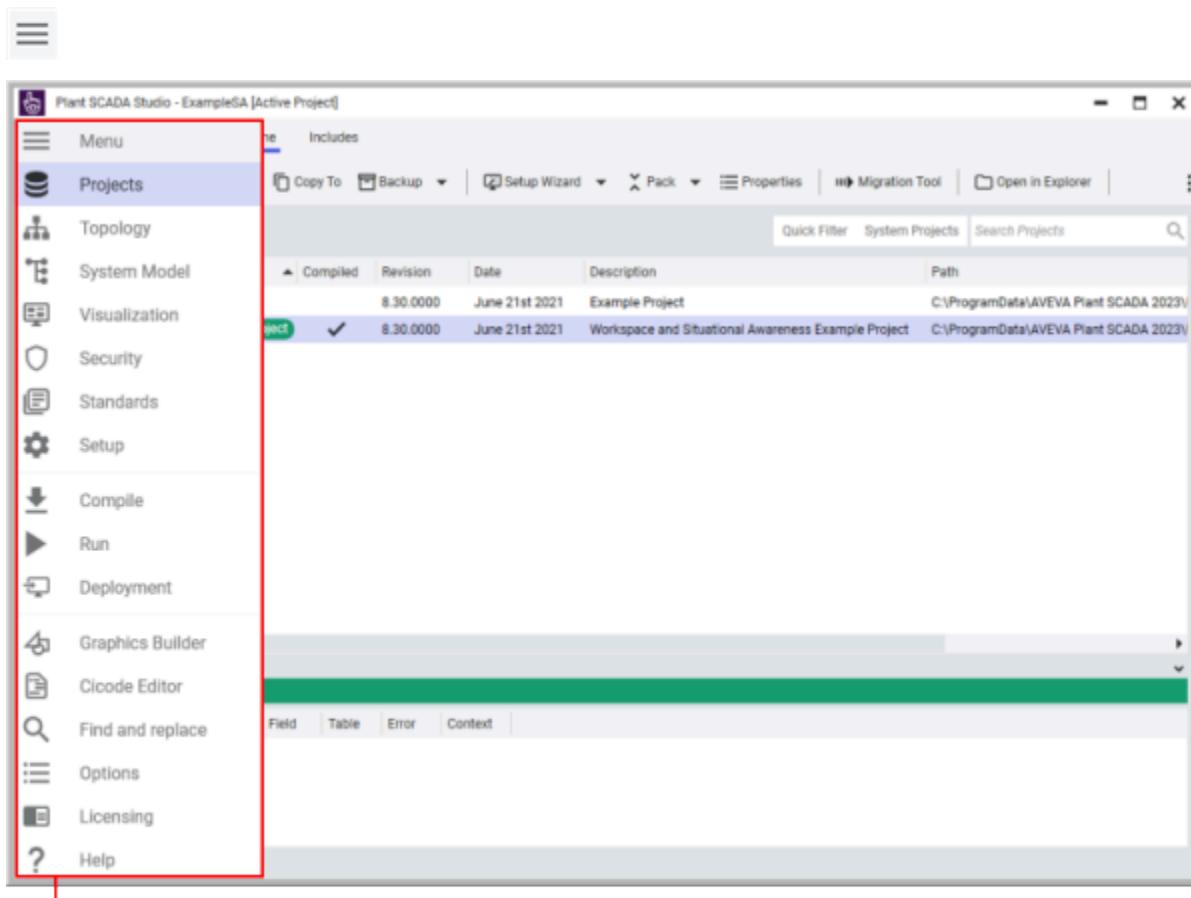

For example, clicking on the following icon on the Activity Bar displays the **Projects** activity.

Each icon displays a tooltip for easy identification.

Selecting the following icon displays the Activity Bar as a menu, which provides a description of each icon.

The Activity Bar is always visible. Selecting an option in the Activity Bar displays the corresponding [Plant SCADA Activities](#) and [Activity Menu](#).

You can also use the Activity Bar to perform the following tasks:

- Run, compile and deploy the current project
- Switch to an editor, for example, the Graphics Builder or Cicode Editor
- Set options for Plant SCADA
- Access the Plant SCADA help.

## See Also

[Plant SCADA Studio Options](#)

## Activity Menu

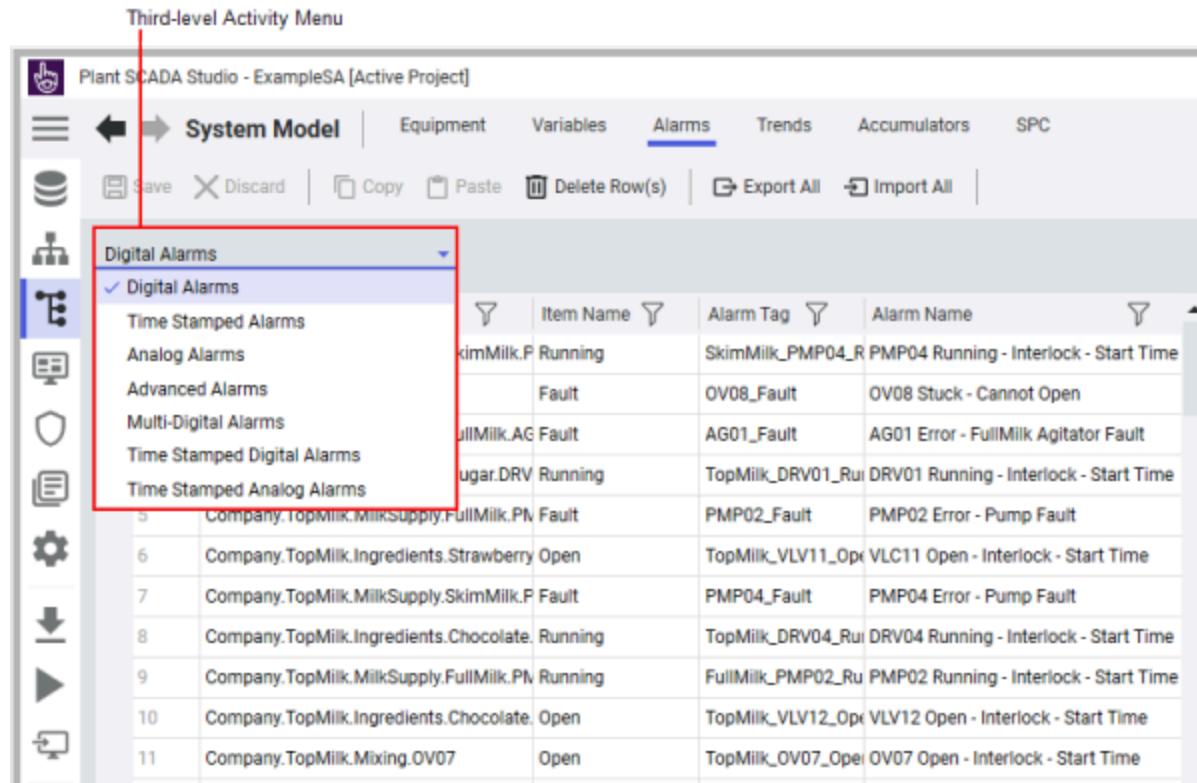

The Activity Menu displays at the top of the window in an activity. It includes tabs for each function associated with the selected activity.

The name of the currently selected activity is displayed on the left. Next to it, **Back** and **Forward** buttons are provided to navigate directly to activities and views that have recently displayed. The selected Activity Menu tab is displayed with an underline.

For example, when you select **System Model** on the Activity Bar, the **System Model** activity is displayed with its associated Activity Menu. In the example below, the **Alarms** tab is selected on the Activity Menu.

An Activity Menu tab may have a third-level of navigation displayed below the **Command Bar**. The third-level menu is displayed as a drop-down list from which you can select an option. For example, **System Model | Alarms** displays the following menu, which can be used to select the type of alarms to configure.

[The Grid Editor](#)

## Command Bar

The Command Bar is located below the [Activity Menu](#). It displays commands that represent one or more actions that can be performed within the selected activity.

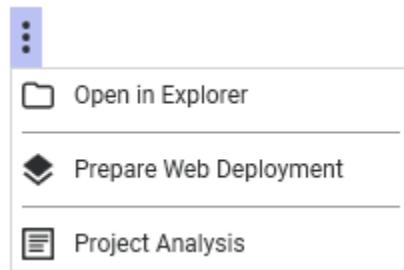

Each option (button) on the Command Bar performs a specific task. Command Bar options may have one or more sub-options accessed via a drop down control. For example, the **Add** option in the **Home** tab consists of the following tasks/commands as shown below.

If Plant SCADA Studio's current size does not allow enough space to display all the commands for an activity, the following icon will display on the right-hand side of the Command Bar.

Clicking on this icon will provide access to any commands that are currently not displayed.

# Compile Messages Area

The Compile Messages area is located at the bottom of every view in Plant SCADA Studio. It displays error messages when compiling a project.

To view these messages, click **Compile Messages**. Messages are displayed in a tabular format. To go to a record that relates to a compile message, double click within the message row. The Grid Editor will display with the associated field selected.

To close the **Compile Messages** area, click the arrow located in the top right corner of the Compile Messages area.

**Note:** You can sort the messages by clicking on one or more column names.

## Plant SCADA Studio Options

Plant SCADA Studio is supported by a set of options that allow you to change the way the project configuration environment operates.

**To set the Plant SCADA Plant SCADA Studio options:**

1. Open Plant SCADA Plant SCADA Studio.

2. On the [Activity Bar](#), select **Options**.

The **Options** dialog box appears. Select the required options (see below for a description of the options).

3. Make any required changes.

4. Click **OK**.

**Plant SCADA Studio Options**

Option	Description
<b>Incremental compile</b>	Enables the incremental compilation of the project.
<b>Incremental equipment update</b>	Enables an incremental equipment update that only includes equipment and equipment types that have been modified since the last update occurred. See <a href="#">Update Equipment in Plant SCADA Studio</a> .
<b>Disable user functions search</b>	When you use a combo box to select a function (for a command or expression field), a list of built-in Cicode functions and user-written functions displays. If you disable user functions, only the built-in functions are displayed in the list.
<b>Confirm on project packing</b>	Enables the "Packing databases may take a long time" message window to appear when packing a database.
<b>Compile enquiry message</b>	Enables the "Do you want to compile?" message window to appear when the project has been modified and Run is selected from the File menu. Normally, Plant SCADA compiles the project automatically (if the project has been modified) when Run is selected.
<b>Prompt on tag not exist</b>	Enables the "Some variable tags were not found" message window to appear when a variable tag or tag reference is specified that does not exist in the database.
<b>Prepare for Web deployment</b>	Automatically runs the Web Deployment Preparation tool every time you compile a project. Please be aware that this dramatically increases the amount of time taken for each compile, particularly for large projects.
<b>Log deprecated warnings during compile</b>	If you select this option, the compiler will generate an alert message to identify any deprecated elements it

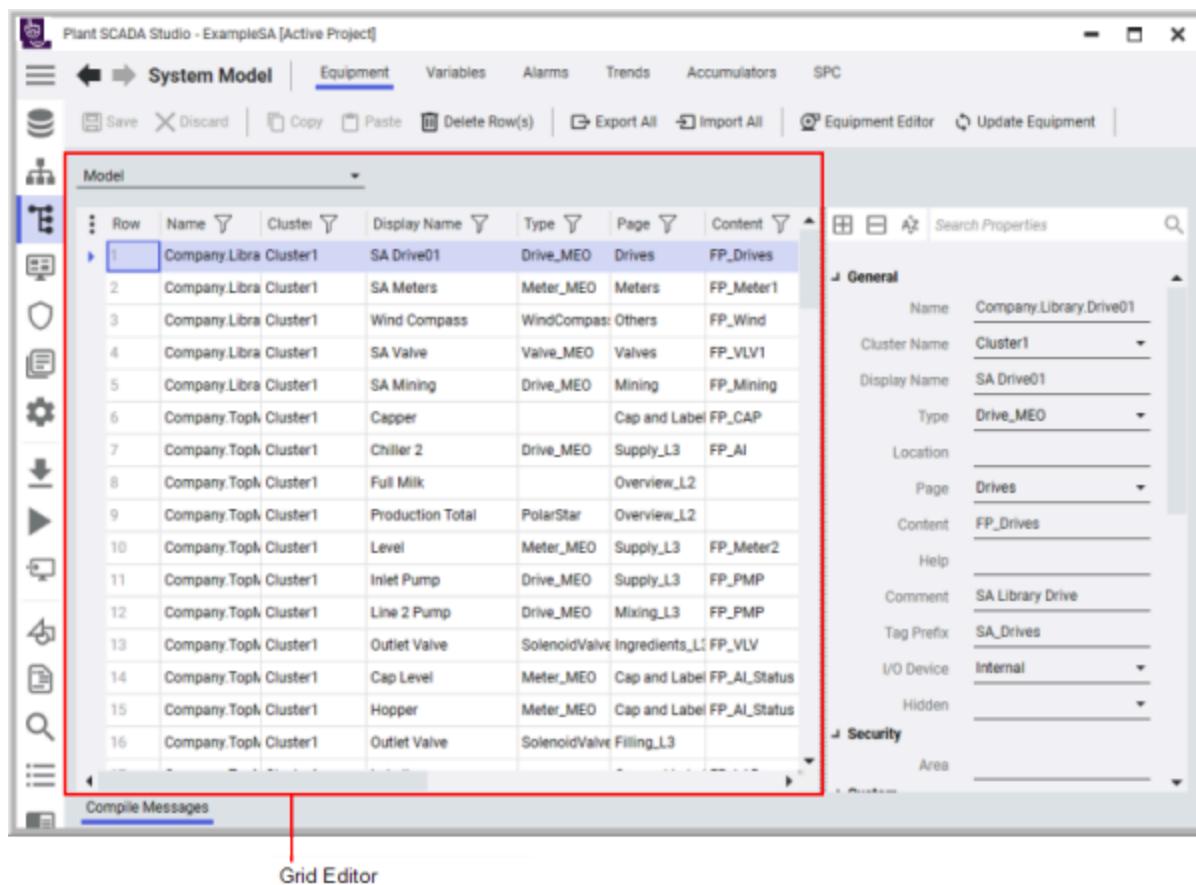

Option	Description
	<p>detects in a project, that is any functions, parameters, or Kernel commands that are no longer supported.</p> <p>By deselecting this option, the alert messages are still included in the displayed alert count, but they are not added to the error log.</p>
<b>Check Computer Setup status before running project</b>	<p>When you run a project, Plant SCADA can check if the local computer was previously set up for a project that is different to the one you have chosen to run. If this is the case, a dialog will prompt you to run the Computer Setup Wizard. Select this option if you want this check to occur.</p>
<b>Info popup time</b>	<p>The delay (in seconds) from the beginning of a database search until a search information window displays. The search information window displays the number of the traced records and allows you to cancel the search. You can cancel the search by selecting the Cancel button in the information window.</p>
<b>Report Editor</b>	<p>The editor that is used for editing Report Format Files. You need to enter the name of the executable file in this field. The default editor is Write (write.exe). If you are using Rich Text Format (RTF) reports, verify that your editor is RTF capable.</p>
<b>Maximum list box items</b>	<p>The maximum number of records that are displayed in drop-down combo boxes.</p>
<b>Warn about unused tags during full compile</b>	<p>Enables the generation of alert entries for unused tags that are not used directly in a project. The alert entries are included in the Compile Messages panel when a full compile is run. By default this option is not selected.</p> <p><b>Note:</b> For this option Alert entries are generated only for a full compile, not an incremental compile.</p>
<b>Log "tag not defined" warnings during compile</b>	<p>If you select this option, the compiler will generate a 'tag not defined' alert in the error log for any tags detected that are not defined in the variable database. As Plant SCADA allows you to include undefined tags on your graphic pages, this alert may be redundant and impractical. By deselecting this option, the alerts are still included in the displayed count, but they are not added to the error log.</p>
<b>Display equipment items when populating tag list</b>	<p>This option is selected by default. Equipment.Item tag</p>

Option	Description
	<p>references will populate 'insert tag' list when adding objects to a graphics page. If not set the variable tag list will be populated.</p> <p><b>Note:</b> If this option is selected and no equipment has been configured, the list will be empty.</p>
<b>Cascade changes across the system</b>	<p>Select <b>Always</b> to cascade field value changes through to all associated references within the Grid Editor. For example, if you change the <b>Tag Name</b> for a variable, any alarms that reference the variable as a trigger will also be updated with the new name.</p> <p>Select <b>Never</b> to limit a field value change to only the current view.</p> <p>Select <b>Prompt</b> to display the Cascade Changes message window where you can choose to cascade changes or limit it to the current view.</p> <p><b>Note:</b> This option will be disabled if the [General]ClusterReplication citect.ini parameter is enabled. This is to prevent changes from being cascaded across clusters and replacing values incorrectly.</p>

## The Grid Editor

The Grid Editor is an interface that displays information in a tabular format in numbered rows. Use the Grid Editor to [Add Rows to the Grid](#), [Edit Values in the Grid Editor](#) or [Delete Rows from the Grid](#) values individually or in bulk.

For example, the image below shows the Grid Editor with the equipment defined for the active project.

You can change the way data is displayed by changing the column on which the information is sorted or by changing the sort order. You can also [Customize Grid Editor Columns](#) by adding columns to or removing columns from the grid. To revert to the default display of the Grid Editor, select **Reset to Default Columns**.

You can also [Export to Microsoft™ Excel](#) and [Import from Microsoft Excel](#) data rows in the Grid Editor.

## Grid Editor Operations

The following table lists operations that are allowed in the Grid Editor.

Operations Allowed in the Grid Editor	Comments
<a href="#">Change the Default Sorting</a>

[Command Bar](#)

## Change the Default Sorting

By default, information displayed in the Grid Editor is sorted by the project name. Information in the grid can be sorted in one of three ways:

- Unsorted (the way the information was added)
- Ascending
- Descending.

---

**Note:** Sorting may take longer depending upon the volume of data in your system.

---

### To change the sorting:

1. Click the column header of the field that you want to use for sorting. For example, if you wish to sort data by **Name**, click the header **Name**. Data is sorted in ascending order by Name.

The screenshot shows the 'Equipment' tab selected in the top navigation bar of the 'System Model' interface. Below the toolbar, there are buttons for Save, Discard, Copy, Paste, Delete Row(s), Export All, Import All, and Equipment Editor. A dropdown menu labeled 'Model' is open. The main area is a grid table with columns: Row, Name, Cluster Name, Display Name, and Type. The 'Name' column header has a dropdown arrow pointing down, with a tooltip saying 'Click to change sort order. Click and drag to re-order.' The data rows are:

Row	Name	Cluster Name	Display Name	Type
1	Company.TopMilk.Production.Recipe.Sugar	Cluster1	Sugar	
2	Company.TopMilk.Production.Recipe.Straw	Cluster1		
3	Company.TopMilk.Production.Recipe.SkimMilk	Cluster1	Skim Milk	
4	Company.TopMilk.Production.Recipe.PreMixTime	Cluster1		
5	Company.TopMilk.Production.Recipe.MixTime	Cluster1		
6	Company.TopMilk.Production.Recipe.MixSpeed	Cluster1		
7	Company.TopMilk.Production.Recipe.Malt	Cluster1	Malt	

2. To reverse the sort order, click the column header again. Data is now sorted in descending order.
3. Click the header again to return the column to "unsorted".

**Note:** You can also sort by multiple columns by holding the **SHIFT** key down and clicking on the columns you want.

[The Grid Editor](#)

[Plant SCADA Studio](#)

## Customize Grid Editor Columns

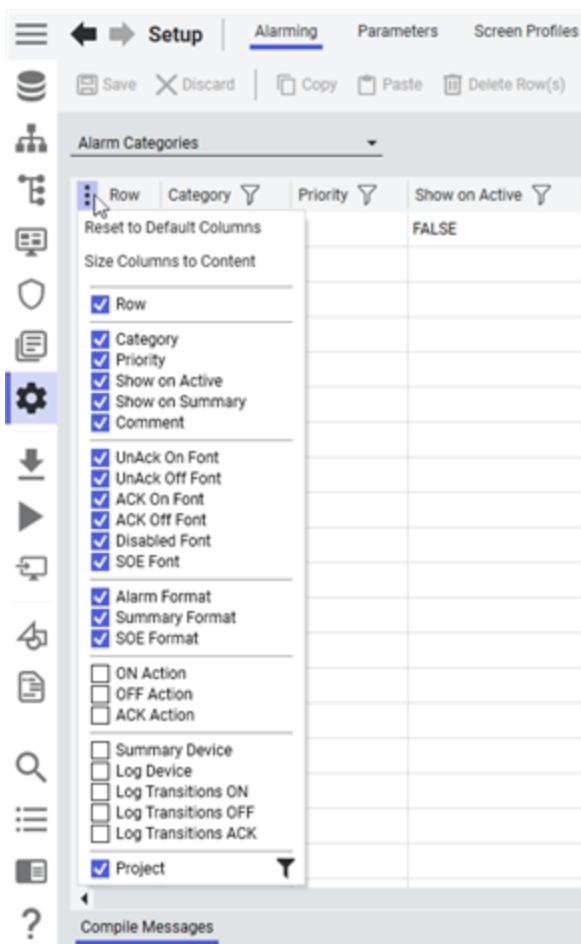

The Grid Editor displays a default selection of columns in the grid. However, this selection can be customized to suit your requirements.

### To customize the Grid Editor columns:

1. Click the icon displayed on the top left-hand side of the Grid Editor.

A list of available columns is displayed.

2. To select a column for display, select the check box next to the column name. To hide a column, clear the check box next to column name. Repeat this step until you have chosen the required columns. Columns are displayed or hidden as soon as you select or clear the selection of a check box.

**Note:** To hide row numbers, clear the check box next to the column name "Row".

3. To return to the default display, select **Reset to Default Columns**. Selecting this option will remove any filters applied to the grid.
4. To re-size columns according to their content, select **Size Columns to Content**.

To change the order in which the columns are displayed in the Grid Editor, click the column header, hold the left-mouse button down and drag the column to the desired location. Release the left-mouse button.

**Note:** The "Row" column cannot be moved.

[Import from Microsoft Excel](#)

## Filtering

By default, the Grid Editor displays data for the selected project and its include projects. You can filter data displayed in a grid by one or more columns. The Filter icon on each column indicates the filter status:

Filter Button	Filter Status
	A filter has <b>not</b> been applied to the column.
	A filter has been applied to the column. This icon is also displayed next to the column name in the list of columns if a filter has been applied to a column.
	A change has been made to filtered data in the grid, which prevents you from making changes to the filtering and sorting until you save the changes.

### To filter data:

1. Click in the column by which you wish to filter. The Filter control is displayed and the "Contains" operator is selected by default.
  2. Select the required operator (the table below describes the available operators).
  3. In the area below the operator, type the text for the filter.
  4. Click **Apply**.
- To reset the filter, click **Clear**.
5. Click the **x** button to close the Filter control.

Filtering may take longer depending upon the volume of data in your system.

---

**Note:** On filtering data in the grid, row numbers are re-calculated.

---

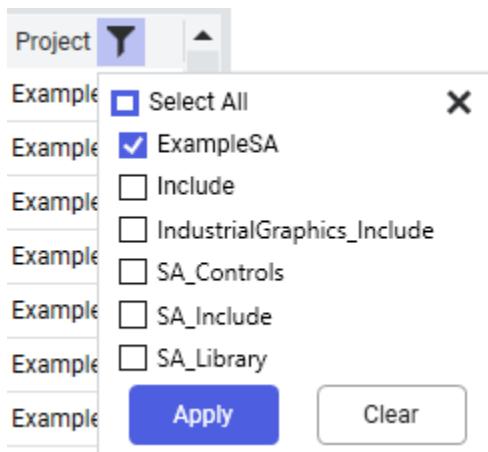

## Filter Operators

Filter Operator	Use Operator to Search for...
Contains	A numeric or alphanumeric value that includes the search text.
Does not contain	A numeric or alphanumeric value that does not include the search text.
Ends with	A numeric or alphanumeric value that ends with the search text.
Is contained in	A numeric or alphanumeric value that appears within

Filter Operator	Use Operator to Search for...
	the search text.
Is not contained in	A numeric or alphanumeric value that does not appear within the search text.
Is empty	Values that have not been specified (empty) within the column.
Is not empty	Any value within the column that is not empty.
Is equal to	A numeric or alphanumeric value that is identical to the search term.
Is not equal to	A numeric or alphanumeric value that is not identical to the search text.
Starts with	A numeric or alphanumeric value that begins with the search text.

### To filter data by project:

1. Click  in the Project column. A list of all projects is displayed.
2. Select the check box next to the project(s) for which you want to view data.

3. Click **Apply**.
- To reset the filter, click **Clear**. The Grid Editor displays data for the selected projects. If no project is selected, the grid will not display any data.
4. Click the **x** button to close the list of projects.

## Add Rows to the Grid

You can add as many rows as you wish to a grid in Plant SCADA Studio.

### To add rows to a grid:

1. Scroll to the last row in the grid.
2. Type the information in each column (see [Edit Values in the Grid Editor](#)), or in the boxes provided for each field in the Property Grid (see [Edit Values in the Property Grid](#)).  
Alternatively, you can [Cut/Copy and Paste Rows and Columns](#) into grid rows.
3. Click **Save**. For more information, see [Save Changes](#).

## See Also

[The Grid Editor](#)

[Edit Values in the Grid Editor](#)

[Delete Rows from the Grid](#)

[Cut/Copy and Paste Rows and Columns](#)

## Edit Values in the Grid Editor

Values in a grid can be edited directly in the grid or through the Property Grid.

### To edit values in the Grid Editor:

1. Select the field that contains the value you would like to edit
2. Click on the field a second time to highlight the value.
3. To select multiple fields, select the first field. Then, hold the SHIFT key and use the arrow keys or click the left mouse button to select additional fields.
4. Make the required change to the value. If a field is read-only, you will not be able to edit it.

---

**Note:** If the selected field values are different, they will be overwritten by the value you specify in the field that you edit.

---

5. Click **Save** to keep the change, or **Discard** to undo the change.

---

**Note:** Some changes you save will cascade through to all associated references within the Grid Editor. For more information, see [Cascade Changes](#).

---

Grid Editor values are also updated when changes are made in the Property Grid (see [Edit Values in the Property Grid](#)). You can also use the [Property Grid](#) to edit multiple rows at the same time (see [Edit Multiple Values](#)).

## Cut/Copy and Paste Rows and Columns

### Delete Rows from the Grid

Rows in a grid may be deleted if required.

#### To delete rows from the grid:

1. Click in the first column on the left hand side of the row you want to delete. The current row is selected.
2. To delete multiple rows, hold down the **Shift** key, and use the **Up/Down** arrow keys or the **Shift** key to select additional rows for deletion.
3. Press the **Delete** key or click the **Delete Row(s)** button on the Command Bar. A strike through appears in the selected row(s).

The screenshot shows the 'System Model' tab selected in the top navigation bar. Below it is a toolbar with buttons for Save, Discard, Copy, Paste, Delete Row(s), Export All, Import All, and Equipment Editor. The main area is a grid titled 'Model' with columns: Row, Name, Cluster Name, Display Name, and Page. Rows 1 through 4 are highlighted with a blue selection box, indicating they are selected for deletion. The other rows (5, 6, 7) are visible but not selected.

Row	Name	Cluster Name	Display Name	Page
1	Company.TopMilk.Production.Recipe.Sugar	Cluster1	Sugar	Overview_L2
2	Company.TopMilk.Production.Recipe.Strawberry	Cluster1		Overview_L2
3	Company.TopMilk.Production.Recipe.SkimMilk	Cluster1	Skim-Milk	Overview_L2
4	Company.TopMilk.Production.Recipe.PreMixTime	Cluster1		Overview_L2
5	Company.TopMilk.Production.Recipe.MixTime	Cluster1		Overview_L2
6	Company.TopMilk.Production.Recipe.MixSpeed	Cluster1		Overview_L2
7	Company.TopMilk.Production.Recipe.Malt	Cluster1	Malt	Overview_L2

4. Click **Save** to complete the deletion.

### See Also

[The Grid Editor](#)

[Add Rows to the Grid](#)

[Cut/Copy and Paste Rows and Columns](#)

## Cut/Copy and Paste Rows and Columns

Rows in a grid can be copied and pasted in a different grid.

#### To copy a subset of columns or rows and paste it in the grid:

1. Select the required row by clicking the box to the left of the row. To select multiple rows, select the first row and hold the **Shift** key while you select additional rows with the **Up/Down** arrow keys or click to select additional rows.

To select a column value, click in the column cell. To select multiple values, hold the left mouse button down

and drag up or down and/or right/left to select additional values.

2. Press **Ctrl + C** on the keyboard to copy the selected columns or rows. To move the columns or rows to a different location in the grid, press **Ctrl + X**.
3. Navigate to the column or row in the grid where you wish to paste the rows.
4. Press **Ctrl + V** to paste the rows.

**Note:** You can move rows of data between projects by using the **Cut** operation in the source project, which you can **Paste** into a destination project. When you do this, the rows that you selected to move will be deleted from the source project.

## See Also

[The Grid Editor](#)

[Add Rows to the Grid](#)

[Delete Rows from the Grid](#)

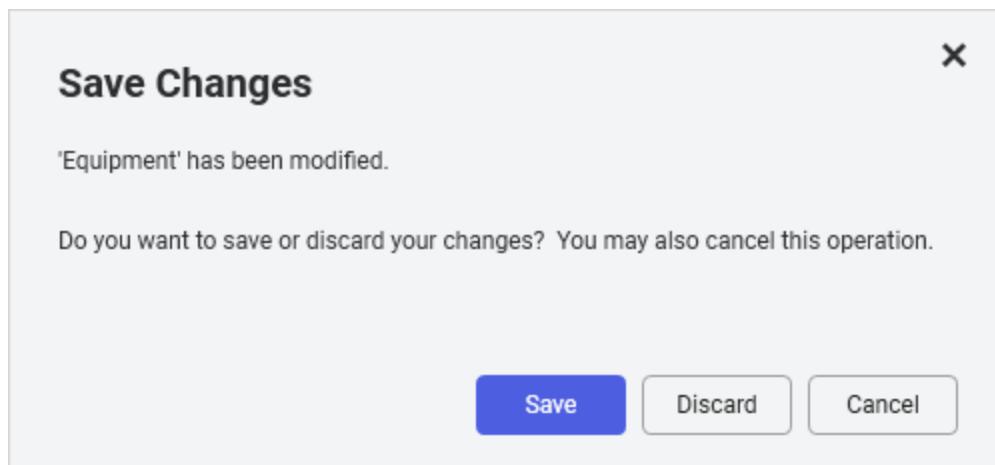

## Save Changes

After updating information in the Grid Editor, click **Save** on the Command Bar. To revert to the previous value(s) without saving your updates, click **Discard** on the Command Bar.

The screenshot shows the AVEVA Plant SCADA Grid Editor interface. At the top is a navigation bar with icons for back, forward, and search, followed by the title "System Model". Below the title is a toolbar with buttons for Save (highlighted with a red box), Discard, Copy, Paste, Delete Row(s), Export All, Import All, and Equipment Editor. The main area is a data grid titled "Model" with the following columns: Row, Name, Cluster Name, Display Name, and Page. The data rows are:

Row	Name	Cluster Name	Display Name	Page
1	Company.TopMilk.Production.Recipe.Sugar	Cluster1	Sugar	Overview_L2
2	Company.TopMilk.Production.Recipe.Strawberry	Cluster1		Overview_L2
3	Company.TopMilk.Production.Recipe.SkimMilk	Cluster1	Skim Milk	Overview_L2
4	Company.TopMilk.Production.Recipe.PreMixTime	Cluster1		Overview_L2
5	Company.TopMilk.Production.Recipe.MixTime	Cluster1		Overview_L2
6	Company.TopMilk.Production.Recipe.MixSpeed	Cluster1		Overview_L2
7	Company.TopMilk.Production.Recipe.Malt	Cluster1	Malt	Overview_L2

If you attempt to navigate away from the view without saving changes, the following message is displayed.

Click **Save** to keep your changes, and remain in the current activity.

Click **Discard** to cancel your changes, and navigate away from the current activity.

Click **Cancel** to stay in the same view without saving your changes. The changes you have made will continue to be displayed.

[The Grid Editor](#)

[Cascade Changes](#)

[Edit Values in the Grid Editor](#)

[Edit Values in the Property Grid](#)

[Edit Multiple Values](#)

## Cascade Changes

Changes can be cascaded through to all associated references within the Grid Editor.

For example, if you change the cluster or tag name for a variable, any alarms or expressions that reference the variable as a trigger will also be updated with the new name.

**Clusters** context is a key determinant for changes being cascaded. When you change a tag name, the cluster associated with it will be used as a filter, and changes will be cascaded to alarms or expressions for that cluster only. If a cluster is not defined for a tag, the cluster name will be determined by the cluster specified for the associated I/O device, or the I/O server if the I/O device does not have a cluster specified. If you change the name of an I/O device in the grid, the cluster name of linked I/O server will be used for cascading changes to linked references.

Plant SCADA does not consider case sensitivity when it determines what needs to be changed.

Cascading changes are not supported for the following:

- Labels, groups, equipment states and remapping
- Alarm categories
- Equipment.item references used in expressions.

**Note:** Cascading changes are only passed through to associated references within the Grid Editor. References

that occur in locations such as graphics pages and Cicode files will not be automatically updated. Changes will not be cascaded if grid data is manipulated externally, for example through a tag import or modifications made through the Equipment Editor.

**To cascade changes on update:**

1. Open the Options dialog from the Activity Bar.
2. Set the Cascade changes across the system option to Always.

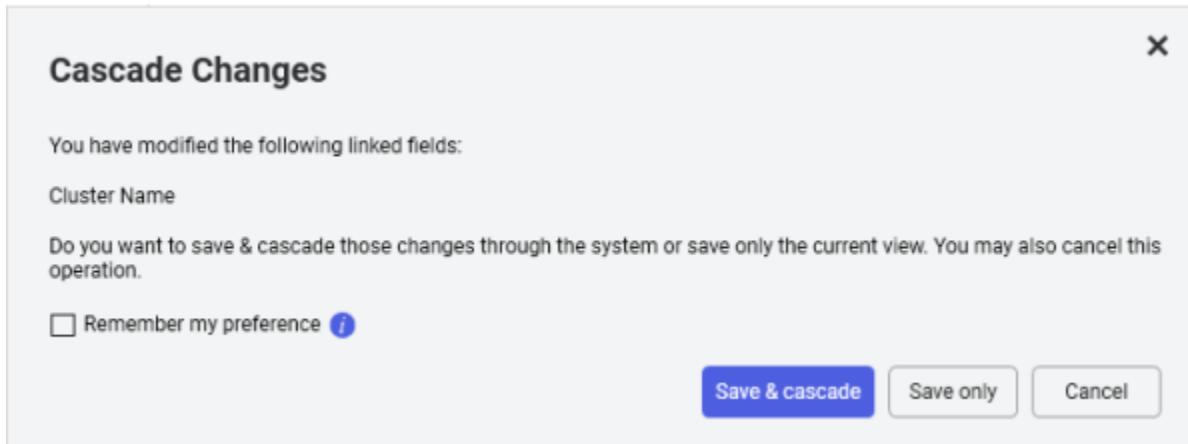

**To disable cascading changes:**

1. Open the Options dialog from the Activity Bar.
2. Set the Cascade changes across the system option to Never.

**To receive a message before you cascade changes:**

1. Open the Options dialog from the Activity Bar.
2. Set the Cascade changes across the system option to Prompt.

If you select the Prompt option, the following message will be displayed when you save your changes.

- Click **Save & cascade** to save the change and update the field value across the system.

**Note:** Details of unsuccessful cascaded changes are logged in a Change Log, which is located in the %PROGRAMDATA%\AVEVA Plant SCADA <VersionNumber>\Logs\ChangeLogs. A cascading change may be unsuccessful if you update a field with a value that exceeds the maximum number of characters the field can hold, if duplicated tag references occur, or if the database file that needs to be updated is inaccessible.

- Click Save only if you want to save the updated field value for the current view only.
- Click Cancel to stay in the same view without saving your changes. The changes you have made will continue to be displayed.
- Select the Remember my preference option to automatically use the currently selected option for subsequent save operations. Whenever required, you can switch to a different option using the Options window.

**Note:** Changes that are cascaded across the system are not applied to system projects.

## Export to Microsoft™ Excel

You can export all the information in the current grid to Microsoft Excel. Any filters or grid selections will not apply, all data will be exported.

### WARNING

#### LOSS OF DATA

If you make an incorrect selection when you chose to import a CSV file into Plant SCADA Studio, you may overwrite your data with outdated or inappropriate values.

To avoid this situation, it is recommended that you use a naming convention for exported CSV files that clearly describes the content included in the file.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

#### To export all records:

1. On the Command Bar, click **Export All**. The Export data to CSV file dialog box is displayed.
2. Select the folder in which you want to save the CSV file, and specify a name for the file.
3. Click **Save**. The data is exported to a Comma Separated Values (CSV) file. A message is displayed on successful export. You can now open the CSV file in Microsoft Excel.

## See Also

- [The Grid Editor](#)
- [Add Rows to the Grid](#)
- [Delete Rows from the Grid](#)

## Import from Microsoft Excel

Data from Microsoft Excel can be imported into your Plant SCADA project. When you import a CSV file, data in the grid will be overwritten only for those projects that have corresponding data in the CSV file. Data for other projects will not be affected.

**WARNING****LOSS OF DATA**

If you make an incorrect selection when you chose to import a CSV file into Plant SCADA Studio, you may overwrite your data with outdated or inappropriate values.

To avoid this situation, it is recommended that you use a naming convention for exported CSV files that clearly describes the content included in the file.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

---

**Note:** Read-only records will remain read-only after an import even if these values are modified prior to an import. Modified values will result in a mismatch between values generated by the Equipment Editor or a tag import and those in the Grid Editor.

**To import all data from a CSV file:**

1. Save the data from in Microsoft Excel file to a Comma Separated Values (CSV) file.
2. Click **Import** in Plant SCADA Plant SCADA Studio. The Import Data from CSV file dialog box appears.
3. Select the file you want to import, and click **Open**. A warning message is displayed indicating that the entire database will be overwritten on import.
4. Click **OK** to proceed with the import. A message is displayed on successful import.

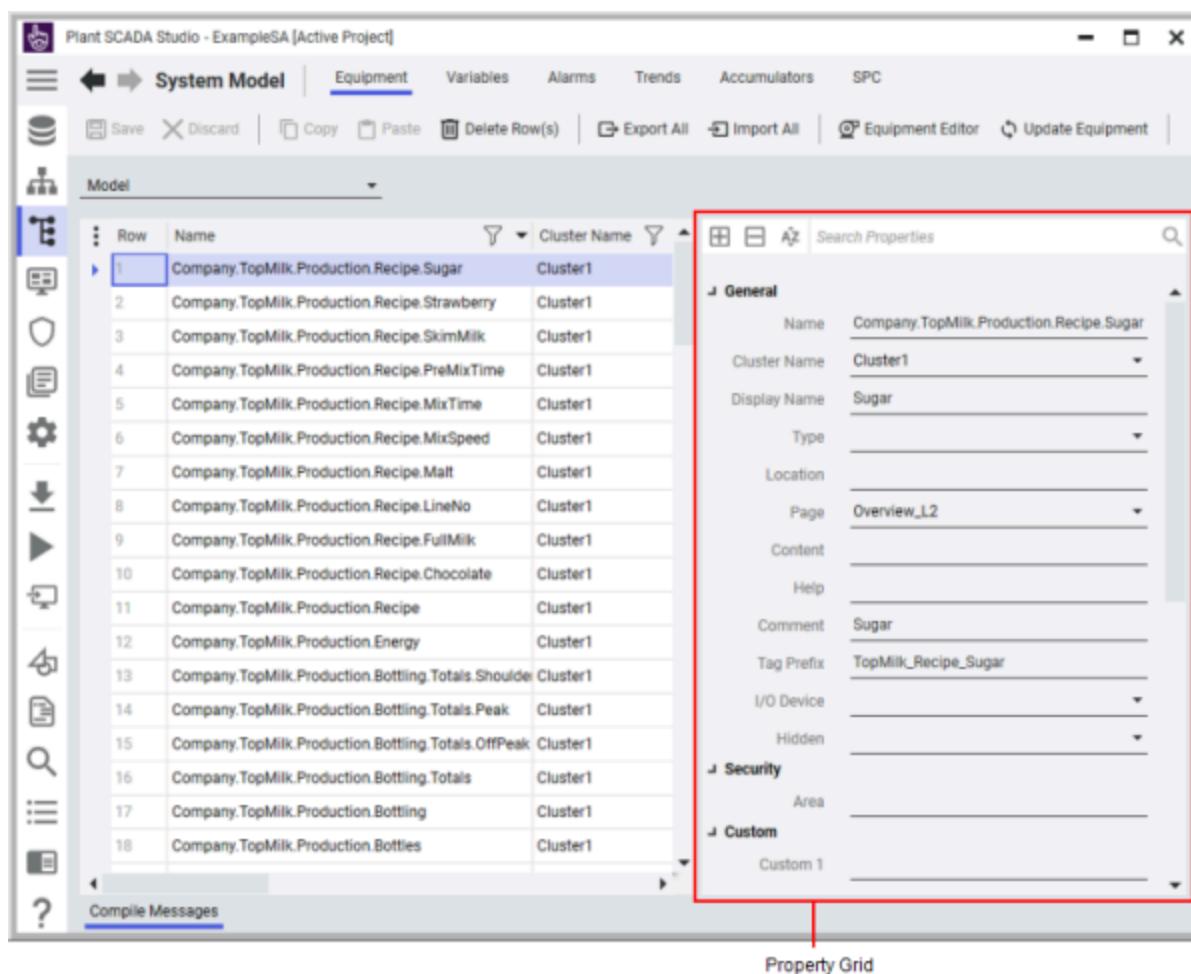

**Note:**

- If the data in the imported file is not valid (for example, it contains entries for a project that does not exist in your active project hierarchy), an error message is displayed and data import does not go through.
- If the imported file does not contain any entries for a particular project in your active project hierarchy, the data for that particular project will not be overwritten.

**See Also**[The Grid Editor](#)[Add Rows to the Grid](#)[Delete Rows from the Grid](#)

## Property Grid

The Property Grid is displayed to the right of a grid or browsing view. It displays details of the selected item(s). For example, if you have selected a piece of equipment in the System Model activity, the associated properties will display in the Property Grid.

By default, properties of the selected item are displayed as a categorized list.

- To collapse the categories, click
- To expand the categories, click
- To view properties as a flat list, click
- To return to the categorized list view, click

You can [Edit Values in the Property Grid](#), or you can use the Property Grid to edit multiple items at the same time (see [Edit Multiple Values](#)).

## See Also

[The Grid Editor](#)

## Edit Values in the Property Grid

### To edit values in the Property Grid:

1. In the Grid Editor, select the row that you would like to edit.

Or

In the **Visualization | Pages** view, select the page you would like to edit (see [Browse Pages in Plant SCADA Studio](#)).

The values associated with the selected item will appear in the Property Grid to the right.

2. Click on the field you want to edit in the Property Grid and make the required changes. If a field is read-only, you will not be able to edit it.
3. Press the **Enter** key (or click away from the field) to load the changes.
4. Click **Save** to keep the changes, or **Discard** to remove them.

Some saved changes will cascade through to all associated references. For more information, see [Save Changes](#).

**Note:** You can also use the Property Grid to simultaneously [Edit Multiple Values](#). If multiple items are selected and their property values differ, the Property Grid will display "Values differ" in the associated field.

## See Also

[Property Grid](#)

## Edit Multiple Values

### To simultaneously edit multiple values in the Property Grid:

1. In the Grid Editor, select the rows you would like to edit.

To select multiple rows, select the first row and hold the **Shift** key while you select additional rows with a mouse-click or with the up or down arrow keys.

Row	Name	Cluster Name	Page
4	SteelMill.Welder	Cluster1	SteelMill
5	SteelMill.EntryAccumulator	Cluster1	SteelMill
6	Loops.Level	Cluster1	LoopPage
7	Loops.Temperature	Cluster1	LoopPage
8	Loops.Density	Cluster1	LoopPage
9	Building	Cluster1	
10	Building.External	Cluster1	
11	Building.External.Light1	Cluster1	
12	Building.External.Light2	Cluster1	
13	Building.External.Light3	Cluster1	
14	Building.External.Light4	Cluster1	
15	Building.External.Light5	Cluster1	
16	Building.Level1	Cluster1	

**General**

Name	Values differ
Cluster Name	Cluster1
Display Name	
Type	Building light
Location	
Page	
Content	
Help	
Comment	Values differ
Tag Prefix	Values differ

If you are using the **Visualization | Pages** view, select the pages you would like to edit (see [Browse Pages in Plant SCADA Studio](#)).

If any corresponding fields in the selected items share common values, these values will appear in the Property Grid. For example, if you selected the three rows displayed above, "Cluster1" would appear in the **Cluster** field, and "Building light" would appear in the **Type** field.

If the selected field values are different, the text "Values differ" will be displayed for the corresponding fields in the Property Grid. If a field is read-only, you will not be able to edit it.

- To edit the values for the selected items, enter the changes in the fields in the Property Grid and press the **Enter** key.
- Click **Save** to keep the changes, or **Discard** to undo them.

---

**Note:** By default, any changes you save will cascade through to all associated references. For more information, see [Save Changes](#).

---

## See Also

[Property Grid](#)

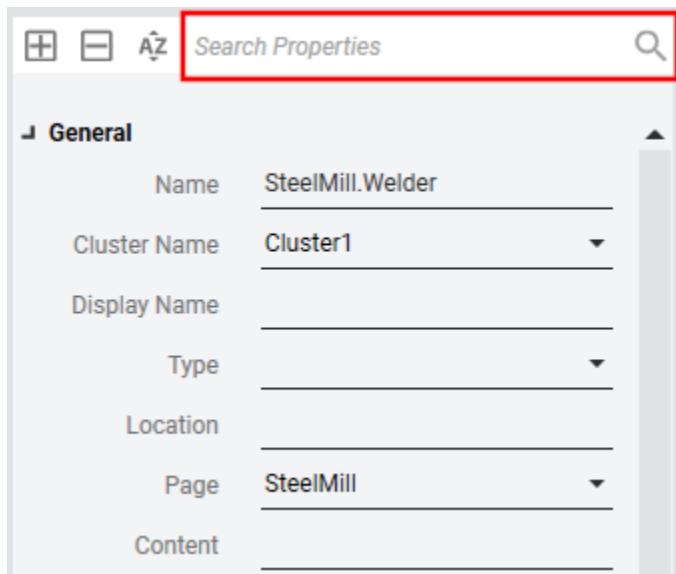

## Search for a Property

You can search for properties in the Property Grid. Instead of going through a long list of properties to edit a single property, you can search for the required property by name.

### To search for a property

- Click anywhere in the [The Grid Editor](#) or Pages view.

2. Type the entire property name or part of the property name in the **Search Properties** box.

All properties that contain the search term will be displayed. For example, to locate the Cluster Name property, you can type "clu", "clus" or "cluster" in the **Search Properties** box. If you search for "at", the properties Data Type and Format will be displayed.

## See Also

[Property Grid](#)

## Using Find and Replace

You can use the **Find and Replace** functionality to locate specified text in your projects, graphics and views. You can perform global text replaces as well as export search results.

This is explained in the following topics:

- [The Find and Replace Window](#)
- [Specify Search Coverage](#)
- [Use the Results List](#)
- [Remove Results](#)
- [Export Results](#)
- [Jumping to a Result \(Go To\)](#)
- [Replace Results](#)
- [Find and Replace Error Messages](#)

There is also a topic on [Troubleshooting Searches](#) to help determine if a search has been correctly configured when unexpected results are returned.

## The Find and Replace Window

You can open the **Find and Replace** window from:

- **Plant SCADA Studio** — used to find and replace text strings in your projects, included projects, graphics and Plant SCADA Studio views.
- **Graphics Builder** — used to find and replace text within a single graphics page, template, or Genie (including fields on the Metadata and Associations tabs, apart from the "In Use" field).

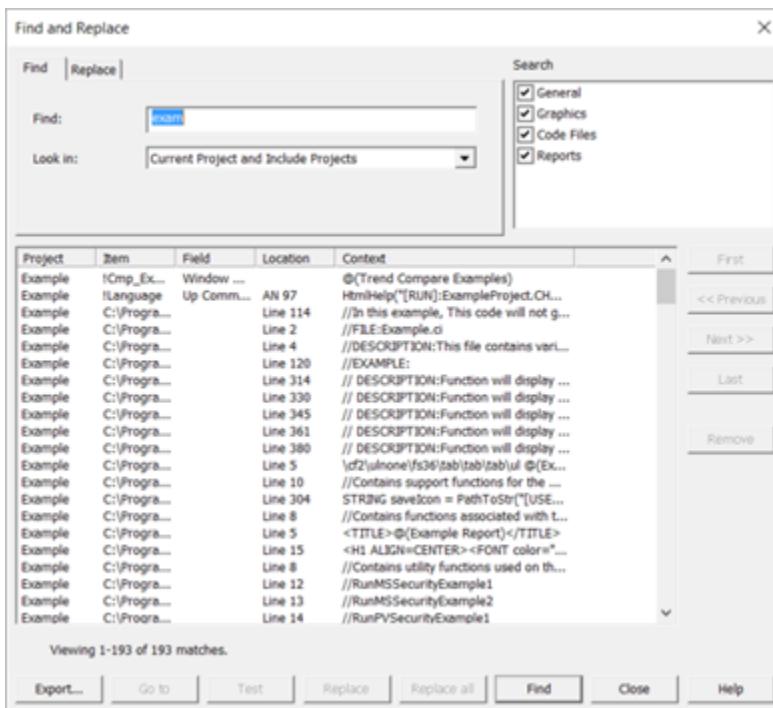

You can configure your search coverage, view your results, replace results, or open a search result for more information.

### To display the Find and Replace window:

1. From Plant SCADA Studio, click the following icon on the Activity Bar.

2. From Graphics Builder, click **Edit | Find or Edit | Replace**. The window box appears with either the **Find** tab or **Replace** tab selected, depending on which command you selected.
3. From Plant SCADA Studio or Graphics Builder, press **CTRL + F** on the keyboard.

### To search for text:

1. In the **Find** box, type the text string you want to search for. The search is not case-sensitive, so it doesn't matter whether you enter lower- or uppercase letters.

You can enter an entire string or a portion of the string you want to find. For example, typing BIT will return any string containing BIT, such as BIT\_1, BITE, HABIT, HABITS, and so on. You cannot enter wildcard

characters, but you can include special characters, as well as spaces if you want.

2. Specify your [Specify Search Coverage](#) using the **Look in** and **Search options** lists.
3. Click **Find**. Search results appear in the [Use the Results List](#) when the search completes. The status text under the results list indicates the progress of the search.

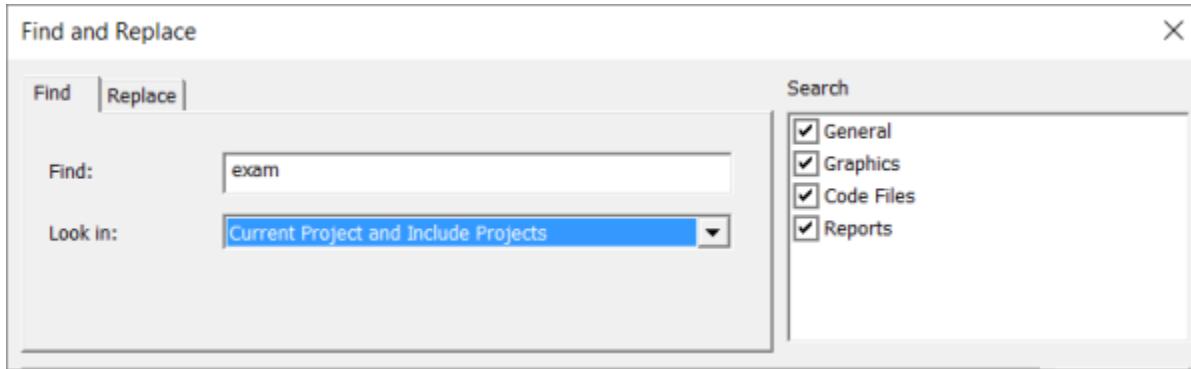

**Note:** When you start a search, the **Find** button changes to a **Stop** button you can use to exit the search. If you stop a search, a partial list of the results is displayed.

#### To replace text:

1. Click the Replace tab.
2. In the **Find** box, type the text you want to search for.
3. Specify your search coverage test
4. Specify your [Specify Search Coverage](#) using the **Look in** and **Search options** lists.
5. In the **Replace with** box, enter the replacement text.
6. Click **Find**.
7. View the [Use the Results List](#).
8. Replace Results using **Replace** or **Replace All**.

## Specify Search Coverage

You can specify search coverage using the **Look in** and **Search options** lists.

When you choose a **Look in** option, the **Search options** change. Each time you select a **Look in** option, associated **Search conditions** are selected by default. The **Look in** options work with the **Search options** as follows.

- Selecting **Current Project** or **Current Project and Include Projects** displays the options described below.
  - **General:** Searches configuration databases associated with a project as well as included projects (if that option is selected).
  - **Graphics:** Performs an "express search" for graphics pages only (the graphics page does not have to be currently open). *This search will not find text in symbols, Genies, or templates if they have not been used on a page.* If you don't find the text you want, try the more comprehensive graphics search by opening a page, Genie, symbol, or template and selecting **Current Graphic** as the **Look in** option (see below).
  - **Code Files:** Searches Cicode/VBA files in the current project (and included projects, if that option is selected).

- **Reports:** Searches report files within the project folder and included projects (if that option is selected).
- Selecting **Current Graphic** makes the options described below available. (This search is a more extensive search than that performed by the **Current Project:Graphics** search described above, and will search graphics documents that are currently open.)
  - **Inside Genies and Symbols** includes graphics objects contained within a Genie or symbol.
  - **Inside Templates** includes objects contained within a page template.
- Selecting **Current Unfiltered View:** Searches the current Grid Editor view. For example, if you are viewing variable tags, the search will be conducted within all variable tags for the Active project and all its includes.

**Note:** Searching the current filtered view does not take into account any project or column filters that have been applied to the view.

## Use the Results List

As matches are found they are listed in the results list. The results list shows an overview of items that match the string entered in the search.

The results list can display a maximum of 200 results per page, sorted by project and then item (you cannot change the sort order).

Project	Item	Field	Location	Context
Example	!Cmp_Ex...	Window ...		@(Trend Compare Examples)
Example	!Language	Up Comm...	AN 97	HtmlHelp("[RUN]:ExampleProject.CH...")
Example	C:\Progra...		Line 114	//In this example, This code will not g...

Example	C:\Progra...		Line 12	//RunMSSecurityExample1
Example	C:\Progra...		Line 13	//RunMSSecurityExample2
Example	C:\Progra...		Line 14	//RunPVSecurityExample1

The results list contains the following columns:

Column	Description
<b>Project</b>	The name of the project in which the found text occurs.
<b>Item</b>	Depends on the type of document in which the item occurs. If the document type is a: <b>Database</b> - User-friendly name of the database.

Column	Description
	<b>Page</b> - Name of the page. <b>Cicode/VBA</b> - Name and path of the Cicode/VBA file. <b>Report</b> - Name of the report.
<b>Field</b>	Identifies that portion of the document/database in which the found item occurs in. For example, if the found item appears in a database, this refers to the column name in the database. Be aware that the search covers both expression/command as well as numeric properties.
<b>Location</b>	Shows the specific record number, AN, or line number on which the found item occurs within the document/database.
<b>Context</b>	An example of the context in which the found item occurs within the project. For example, if the document type is a: <b>Database</b> - a search result of BIT* might have a context of BIT_!. <b>Page</b> - BIT* might have a context of Toggle(BIT_!). <b>Cicode/VBA</b> - UserName might have a context of FUNCTION GetUserName() <b>Report</b> - PUMP* might have a context of @(Pump A)

You can toggle between the Find and Replace functionality without losing the search results, but if you close the Results page, your search results are lost.

---

**Note:** You can re-size list columns by moving your mouse cursor onto the separator between the list columns. When the mouse cursor changes shape to a black bar with arrows, drag the column to the new size. You can also double-click the vertical bar between fields to re-size that field to fit the widest item.

---

## Remove Results

You can remove a search result from the Results window. Results that are removed are not included in exports or in replacement operations. Removing a result does not delete it, but merely removes it from the Results window.

**To remove a result:**

1. Click to select the result you want to remove and click **Remove**.  
The result is removed from the Results window.

## Export Results

You can export search results in a tab-delimited format to a specified location. Results are exported in the format:

<Project> <Item> <Field> <Location> <Context>

If the Results window contains more than 200 results, every result is exported, not just the ones currently displayed. If you remove an item from the results list, it will not be exported. (For details on removing results, see [Remove Results](#).)

If you export an item that has a context, the context string is stripped of tabs and new line characters.

Results exported are in Unicode format. Because of this, two leading characters and two trailing characters are added to the file, but in most cases will remain hidden. When exporting results, you need to use a viewing tool that supports Unicode.

#### To export results:

1. With the search results you want to export listed in the Results window, click **Export**.
2. Specify the location in the window and then click **Save**. If the file already exists, you're given the option to overwrite the file. Status text under the results list indicates the progress of the export.

---

**Note:** If you want to stop the export, click **Stop**. You cannot perform a partial export, so clicking **Stop** cancels the export entirely.

---

## Jumping to a Result (Go To)

You can jump to an individual result to see where the result occurs. Depending on the type of document that contains the search result, the following occurs:

- **Grid:** The relevant grid is displayed. If you attempt to go to a result that is hidden by a filter, a message that you cannot view the result is displayed.
- **Cicode/VBA:** The document opens within the Cicode Editor and the text string is highlighted.
- **Graphic:** The page opens in the Graphics Builder and the Properties dialog box appears for the object that contains the text string. The property containing the text string is displayed. If the string occurs on or inside a Genie, the Genie form also appears.

#### To navigate to a result:

1. With the search result you want to navigate to selected in the Results window, click **Go To**.  
The document or form containing the occurrence opens.

## See Also

[Replace Results](#)

## Replace Results

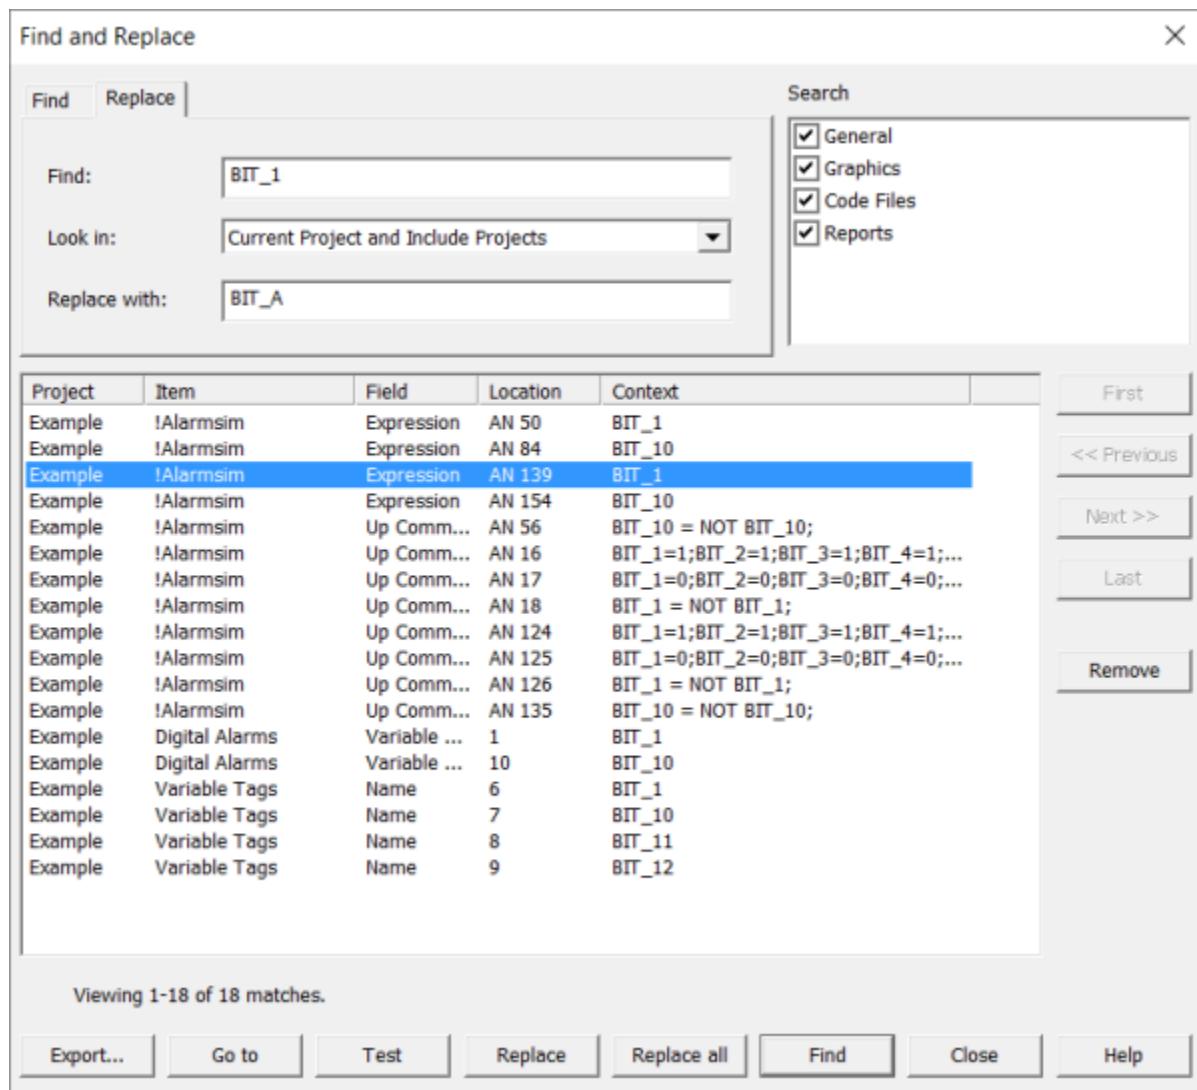

You can replace single results or multiple results with the replacement text string you specified. You can also test a single result before replacing it. Depending on the type of document that contains the search result, the following occurs when a replacement is made:

- **Database:** The result is replaced with the replacement text and the database record updated. The form containing the search result is not opened; to see the location of the search result before or after the

replacement is made, use the .

- **Cicode/VBA:** The Cicode file containing the matched text loads (if it is not loaded already), the replacement is made, and the file saved.
- **Graphic:** The page opens in the Graphics Builder (if it is not already) and the replacement made. If the page is open and contains unsaved changes, you're instructed to save or discard the changes before making the replacement. If there are multiple changes to be made to the same graphics page, the page remains open until every change has been made.
- **Report:** The found text is replaced with the replacement text and the file is saved.

**Note:** Replacements cannot be undone once performed. Take care to check your replacements before making them, especially when working with multiple replacements.

### To test a result:

1. With the result you want to test highlighted, click **Test**. A dialog box appears showing the result of the text replace.
2. Click **Accept** to accept the text replacement, or click **Cancel**.

**To replace a single result:**

1. With the result you want to replace highlighted, click **Replace**. The replacement is made and the result removed from the Results window. The next result in the list is then selected.

**To replace multiple results:**

1. With the search results you want to replace listed in the Results window, click **Replace All**. A confirmation dialog appears.
2. The replacements are made and removed from the Results window. (Replacements that are not made remain in the results list. This will occur if, for example, you try to replace a property that is read-only.)

---

**Note:** Clicking Stop during this process does not undo any replacements already made.

---

When attempting to make a replacement, you might encounter an alert message. For details, see [Find and Replace Error Messages](#).

## Find and Replace Error Messages

Find and Replace will display one of the following errors messages if it cannot replace a text string:

### File in Use

This alert message appears if the database or file that is necessary for writing to has become unavailable. This may be the case if the database/file is being used by a third-party application.

Do one of the following:

- Click **Try Again** (Default) to repeat the operation on the database/file.
- Click **Ignore** to skip the operation on this file.
- Click **Ignore All** button to skip any operations on files that are currently in use; this option causes this message not to reappear.

### Replaced Text Truncated

This alert message appears if performing the text replacement in a DBF field exceeds the field width limits. For example, if an Engineering Units field containing % is replaced with "%LONGTEXTSTRING", a "replaced text truncated" alert message appears because this field has a max width of 8. The replacement text would therefore be "%LONGTEX".

This alert message does not occur if searching the current graphics page.

Do one of the following:

- Click **Yes** to commit the truncated text to the database. Usually this will generate a compilation alert message when the project is compiled.
- Click **Yes to All** to commit every change to fields regardless if truncation exists without displaying the alert again.
- Click **No** (default) to leave the text as is.

- Click **No to All** button to leave truncated fields as is.

## Original Text Not Found

This alert message appears when attempting to replace an item on the current graphics page when the animation could not be found or the text could not be found. This would occur if the animation was deleted, or if the text found in an animation's field was changed after the find but before replacing the item.

In the example below, the Fill Level Maximum contained a value of 23, and the search text was 23. Before replacing the record, it was changed to 66.

Do one of the following:

- Click **Ignore** to skip this operation, leave the entry in the list, and move on to the next replacement if it exists.
- Clicking **Ignore All** acts like the **Ignore** button, except that it skips all occurrences.
- Click **Stop** to stop the replacement at the current record.

## Replaced Text Out of Range

This alert message appears when carrying out a replacement on the current graphics page in two different circumstances:

1. The field is text and is too long for the allowable field width.
2. The field is a numeric field, and would be out of the allowable range for a replacement value.

In the example below, the Fill Level Maximum allows a range of 0-100, and the value was 23 and is being replaced with 101, which would be out of range.

Do one of the following:

- Click **Ignore** to skip this operation, leave the entry in the list, and move on to the next replacement if one exists.
- Clicking **Ignore All** acts like the **Ignore** button, except that it skips all occurrences.
- Click **Stop** to stop the replacement at the current record.

## Replacement Text Not Numeric

This alert message will appear when carrying out a replacement on the current graphics page when the field being replaced is a numeric field, and the replacement text contains a non-numeric value.

In the example below, the Fill Level Maximum contained a value of '23', and the replacement text was 'fred'.

Do one of the following:

- Click **Ignore** to skip this operation, leave the entry in the list, and move on to the next replacement if it exists.
- Clicking **Ignore All** acts like the **Ignore** button, except that it skips all occurrences.
- Click **Stop** to stop the replacement at the current record.

## Field is Read-only

This alert message appears when replacing an item on the current graphics page when the field being replaced is part of a linked object like a Genie or template.

In the example below, the Expression field was part of an object that was part of a genie.

Do one of the following:

- Click **Ignore** to skip this operation, leave the entry in the list, and move on to the next replacement if it exists.
- Clicking **Ignore All** acts like the **Ignore** button, except that it skips all occurrences.
- Click **Stop** to stop the replacement at the current record.

## Undetermined error

This alert message appears when carrying out a replacement on the current graphics page when a general error is detected, and not happen in normal operation.

Do one of the following:

- Click **Ignore** to skip this operation, leave the entry in the list, and move on to the next replacement if it exists.
- Clicking **Ignore All** acts like the **Ignore** button, except that it skips all occurrences.
- Click **Stop** to stop the replacement at the current record.

## Troubleshooting Searches

If you do not find a result that you expected to find, check the following points and then perform your search again.

- Did you spell the text string correctly?
- Did you include the correct number of spaces?
- Are you using the appropriate Look in option?
- Are you using the appropriate Search options?
- Are you searching in the correct project?
- Are you using the correct graphics search?
- If you are using the graphics page search, do you have the correct graphics page open?

## Projects

Plant SCADA projects are repositories that hold the configuration information for your system that includes information such as I/O devices, tags, alarms and graphic pages that are used to build a runtime system.

The configuration for a runtime system can be spread across multiple projects depending upon the scale of operations. Small, simple operations may require only a single project that houses all components required for runtime. For larger, complex operations or multi-site operations, several projects can be created based on specific plant areas, engineering processes or libraries, which are "included" together to form a single merged configuration used at runtime.

## Project Types

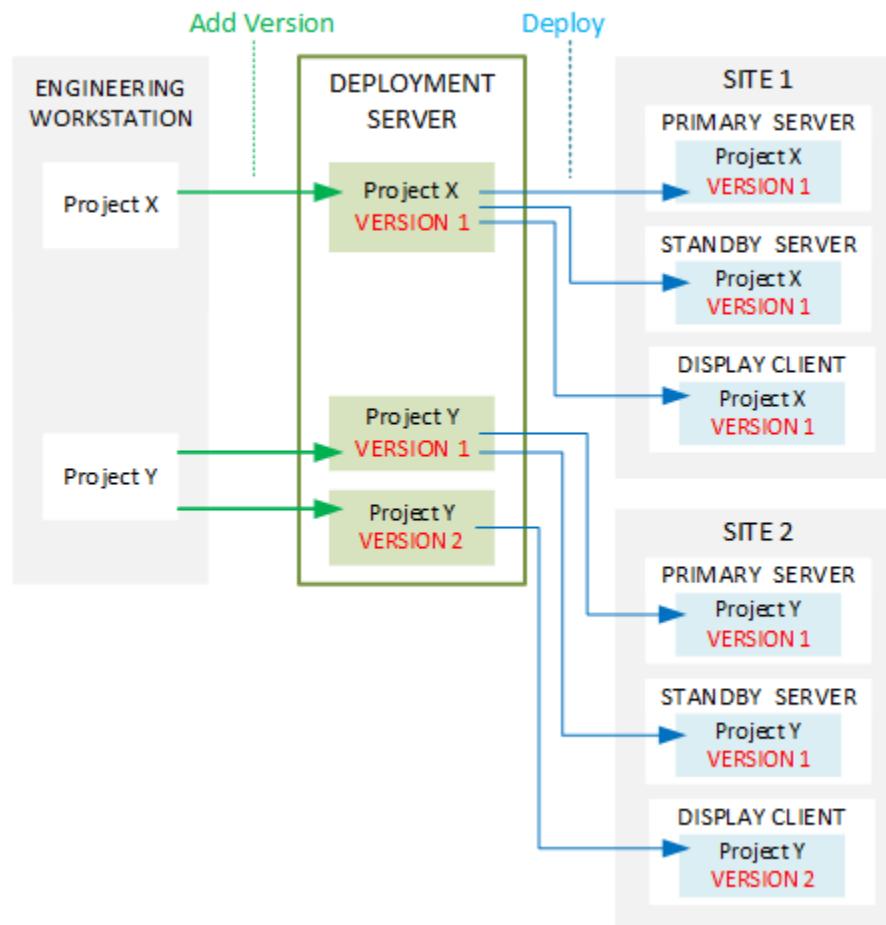

Projects created by you are referred to as "user" projects. In addition, Starter and System projects are also available for use.

- Starter projects initialize configuration in a newly created project to get you started quickly and can be run and/or deployed straight away. A Starter project can be selected when you [Create a Project Using a Starter Project](#).
- System projects provide internal, out-of-the-box content such as pages, settings and in-built functions that can assist with the building of your projects. System projects should not be modified as they are updated and replaced with each new version of Plant SCADA.

See [Project Types](#).

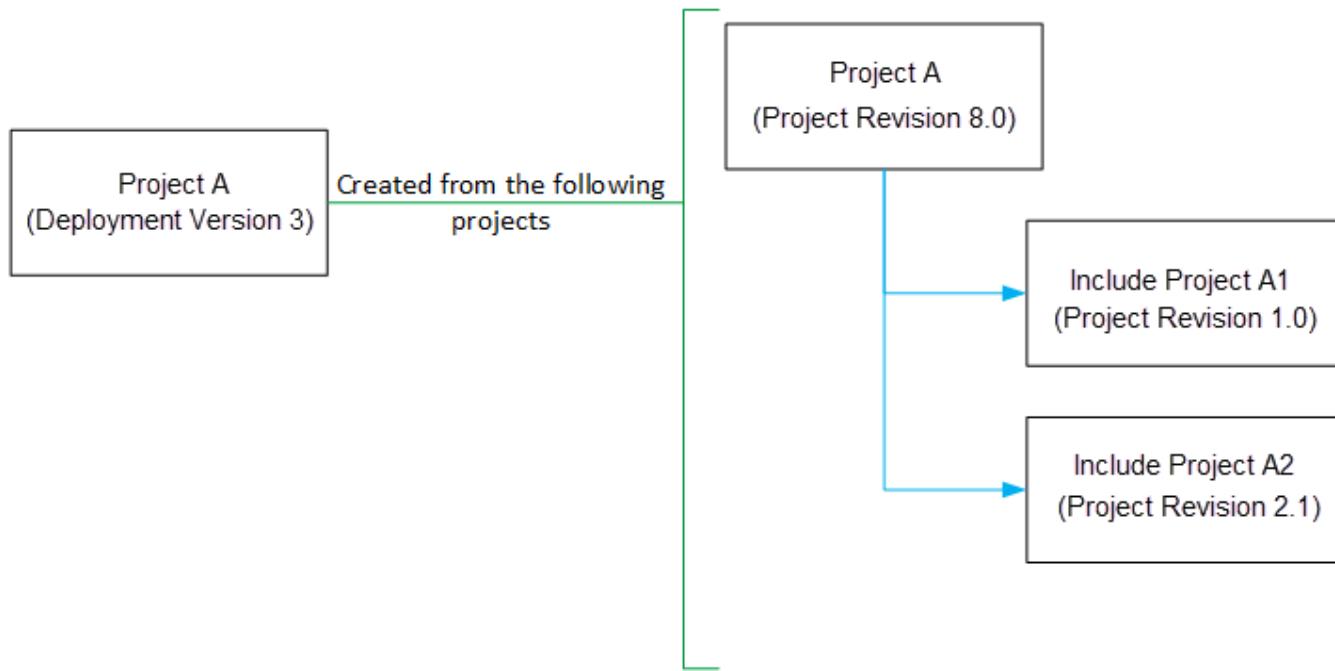

## Project Deployment

Multiple projects can be used to segregate different operational functions and plant areas, as well as simplifying the process of deployment. Deployment in a complex SCADA system typically spans several computers in a network, and may require different projects to be deployed on different computers for runtime. Minor and major project changes can be rolled out quickly and efficiently. For more information, refer to the Deployment section.

## Project Revisions

You can track changes to your projects through the revision fields in the [Edit a Project's Properties](#). A good practice would be to assign a major revision number for significant project changes, or a minor revision number for trivial updates. The **Date/Time** field can be used in conjunction with the revision fields to track the revision details of projects.

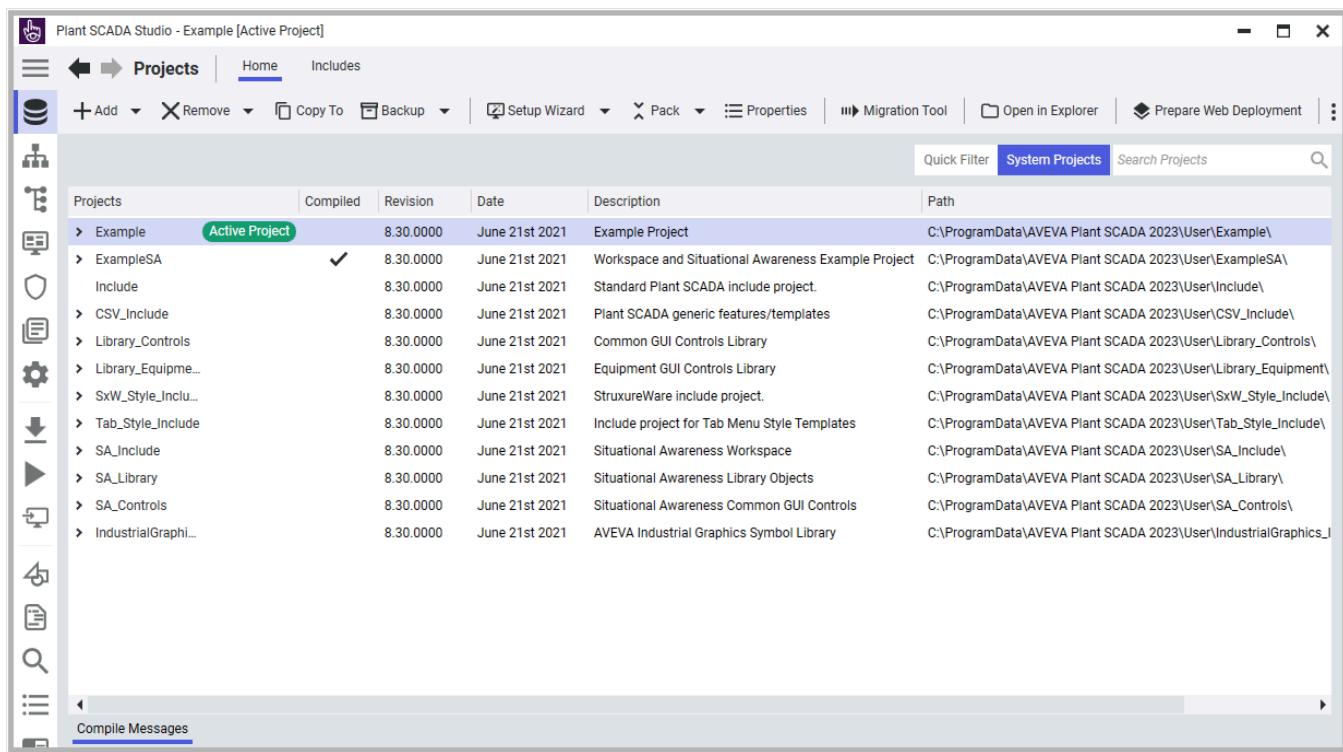

When you create a deployment version of your project, you can see the individual project revisions from any included projects that make up that deployment version.

## The Projects Activity

Projects can be created and managed in Plant SCADA Studio via the **Project** activity.

To access the **Project** activity, select **Project** on the Activity Bar.

**Note:** With the release of Plant SCADA 2023, unique IDs are applied to every Plant SCADA project. This provides consistent identification across the lifetime of a project. When you [Copy a Project](#) or [Restore a Project](#) a project, you may need to consider how you want the project IDs to be implemented.

## See Also

[Create a Project Using a Starter Project](#)

[Create a Standard Project](#)

[Make Active](#)

[Back Up a Project](#)

[Restore a Project](#)

[Edit a Project's Properties](#)

## Project Types

Plant SCADA projects can be one of the following types:

### User Projects

User projects are projects that you create to store customized content for a particular runtime system. They can include graphics components, tags and alarms, equipment definitions, Cicode files, and so on.

User projects are typically created using a template that provides the basic components required to compile and run the project. This allows you to create content that you can immediately test in a runtime environment.

To create a new project based on a template, you can use a Starter Project (see [Create a Project Using a Starter Project](#)).

You can also create a user project by taking a copy of an existing project (see [Copy a Project](#)).

---

**Note:** Due to the nature of their content, it is recommended that you regularly archive your user projects (see [Back Up a Project](#)).

### [Starter Projects](#)

When you create a new project, you have the option to base the project on a "starter project". This generates content that includes the basic components required to compile, run and navigate the project.

A project created using a starter project will also incorporate included projects that provide access to a page templates and library objects that you can use to create your own customized content.

You can choose from the following template styles when you create a project with a starter project:

- **Situational Awareness** — a workspace-based project that is designed to support abnormal situation management for operators.
- **SxW** — designed for use with systems that conform to Schneider Electric's StruxureWare specification.
- **Tab Style** — features navigation that uses a tabbed ribbon menu.

All styles are available in a variety of resolutions to suit the screen size of a client computer.

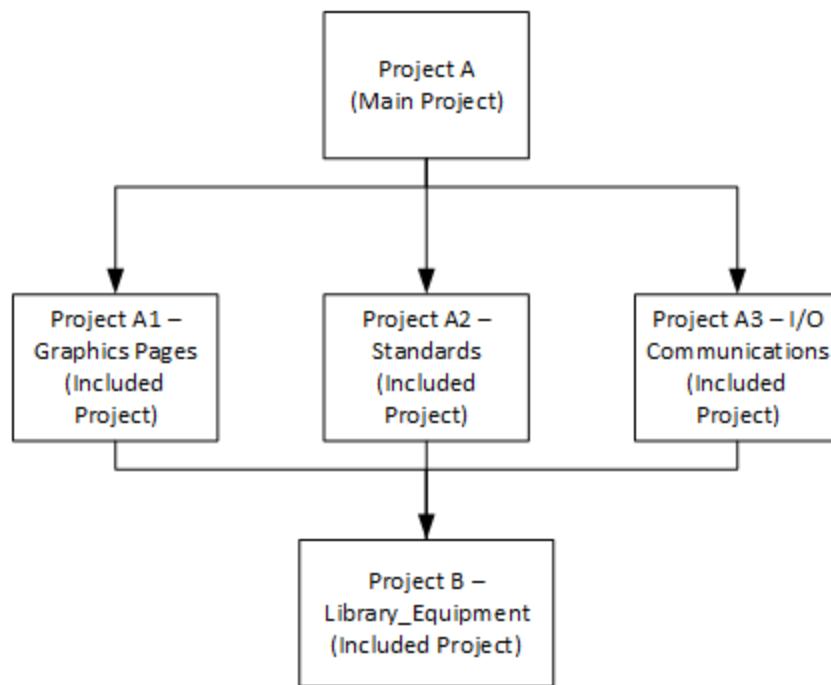

For more information about the contents of a starter project, see the following topics:

- [Situational Awareness Projects](#)
- [StruxureWare \(SxW\) Templates Project](#)
- [Tab Style Templates Project](#).

### [Included Projects](#)

Plant SCADA allows you to "include" a project within a project. This means you can separate configuration or share common configuration with multiple runtime systems.

Included projects are especially useful when you are configuring a large system as they allow you to work with a series of smaller projects that you can combine into a main project.

For example, you could use one project for common configuration for standardization and then a separate project for each section of a plant, or for each production process. This way, you can develop and test each of the smaller projects and system standards before including them in the main project. This also allows multiple users to work simultaneously in the configuration environment with each user working on a separate project.

To add a project within a project, see [Add an Included Project](#)

### System Projects

System projects are installed with Plant SCADA. They are intended for use as included projects or starter projects. They provide content that can assist with the configuration of a runtime system. This can include page templates, symbols, genies, and generic Cicode functions. The following system projects are installed with Plant SCADA.

Name	Type	Description
Include	Include	A template project with standard trending and alarm pages. This project cannot be compiled.
Library_Controls	Include	Contains a set of genies that are common interface controls, such as a tree-view, data table and scroll bars. This project cannot be compiled.
Library_Equipment	Include	Contains the "equip_motors" genie library, and a pop up template library called "equipment". Also contains diagnostic and status information pop up templates.

Name	Type	Description
		This project cannot be compiled.
IndustrialGraphics_Include	Include	Contains a default set of Industrial Graphics which includes charting and dashboard symbols, as well as ISA symbols. See <a href="#">AVEVA™ Industrial Graphics</a> .
SA_Include	Include	A Situational Awareness Include Project which contains public and Genie functions.
SA_Controls	Include	Contains a set of Genies for common user interface controls for Situational Awareness projects.
SA_Library	Include	Contains a set of Genies for common user interface controls for meter, drive and valve objects including output bar, numeric PV and tracker. This includes a set of Composite Genies that provide a template to easily create multiple objects with a consistent look and feel.
SA_Style_1_MultiRes	Starter	A Situational Awareness starter project with two screen resolutions of HD 1080 and UHD 4K.
SxW_Style_1_HD1080_titlebar	Starter	A SxW starter project with a screen resolution of 1080 HD (Full HD). Wide screen only. Includes the SxW_Include and Library_Equipment projects.
SxW_Style_1_HD768_titlebar	Starter	A SxW starter project with a screen resolution of 768 HD (Full HD). Wide screen only. Includes the SxW_Include and Library_Equipment projects.
SxW_Style_Include	Include	Includes a set of SxW templates styled for wide screen only.
Tab_Style_Include	Include	Includes a set of Tab Style templates that use a tabbed ribbon menu.

Name	Type	Description
		This project cannot be compiled.
Tab_Style_1_HD1080_titlebar	Starter	A Tab Style starter project with a screen resolution of 1080 HD (Full HD). Includes the Tab_Style_Include project.
Tab_Style_1_SXGA_titlebar	Starter	A Tab Style starter project with screen resolution for SXGA. Includes the Tab_Style_Include project.
Tab_Style_1_WUXGA_titlebar	Starter	A Tab Style starter project with screen resolution for WUXGA. Includes the Tab_Style_Include project.
Tab_Style_1_XGA_titlebar	Starter	A Tab Style starter project with screen resolution for XGA. Includes the Tab_Style_Include project.

You can view system include projects in the Project activity by clicking **System Projects**. Starter projects will not appear in the Project activity.

---

**Note:** You should avoid making configuration changes to a system project, as each time Plant SCADA is upgraded it installs new versions of the system projects. This means any changes you make to a system project will be lost.

See [System Projects](#).

### Example Projects

Example projects are installed with Plant SCADA to demonstrate some of the functionality that can be supported in an operational runtime system.

Two example projects are installed:

- **ExampleSA** – demonstrates a workspace-based [Situational Awareness Project](#).
- **Example** – demonstrates a project based on the [SxW Templates Project](#).

### The ExampleSA Project

A Situational Awareness project is designed to support abnormal situation management for operators. It provides accurate information to an operator in a way that can be perceived and acted upon quickly, without overwhelming their cognitive abilities. A consistent look and feel is applied to all graphical content, and standardized colors settings are used to emphasize important process data and alarms.

A Situational Awareness project differs to other Plant SCADA projects as it uses a master page on each client screen that is comprised of a set of "panes". Each pane displays a page that can be updated independently at runtime based on navigational or contextual changes. It creates a workspace that supports contextual updates that are managed via a project's equipment hierarchy, which creates an association between the location of a

detected change, and the type of content each pane is configured to display.

The ExampleSA project demonstrates the default layout applied to projects created using a Situational Awareness Starter project. This layout includes common elements such as a header bar, content area, and a dashboard that displays contextual information and navigational tools.

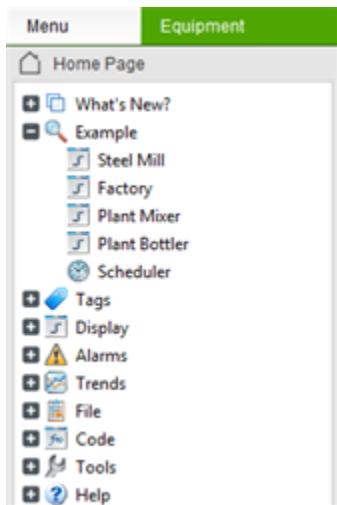

The project pages are built using objects that are available in an included library project (named "SA\_Library"). The included objects (and associated faceplates) support the autofill functionality of the workspace, and maintain a consistent look and feel across a project's display pages. See [Situational Awareness Library Project](#).

### The Example Project

This project comprises a set of pages based on the SxW templates (accessible via a starter project). These pages display tag and alarm values for a set of I/O devices that operate in memory. An equipment hierarchy is also included.

The graphical content included in the Example project pages demonstrates how Plant SCADA can be used to represent complex production processes such as a steel mill, a plant mixer, and a bottling process.

You can select and run the Example project from the **Project** activity in Plant SCADA Studio. To run this project, you need to make this the Active Project using the **Make Active** button. When runtime launches, you can access the project's pages via the **Menu** panel to the right.

The project is supported by its own help file that describes each of the included pages. This help file is available from the **Menu** panel.

---

**Note:** You should avoid making configuration changes to an Example project, as each time Plant SCADA is upgraded it installs a new version of the project. This means any changes you make to the Example project will be lost.

---

[Create a Project Using a Starter Project](#)

[Create a Standard Project](#)

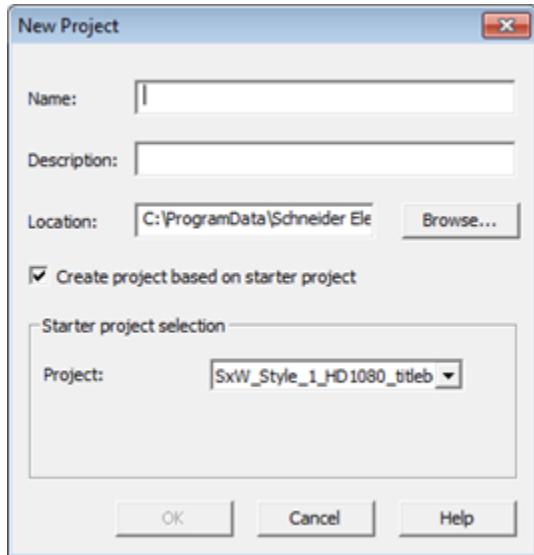

## Create a Project Using a Starter Project

A [Project Types](#) allows you to create a new project that includes the basic components required to compile, run and navigate the project.

**To create a project using a starter project:**

1. In the **Project** activity, select **Home**.
2. On the Command Bar, click **Add | New Project**.

The New Project dialog appears.

3. Complete the required fields (see below for a description of the fields).
4. Click **OK**.

The new project will appear in the **Project** activity.

## New Project Properties

Field	Description
<b>Name</b>	A unique name for the project. The project name is restricted to 64 characters. It can contain any characters other than characters in the Windows file naming rules "* \{}:<>?/'; Since the project name is a unique identifier, Plant SCADA does not permit you to create or restore a project with a duplicate name.
<b>Description</b>	A description of the project. This field is useful for giving an explanation of the role of the project. It is recommended that you complete this field.
<b>Location</b>	The directory path where the project files are stored. As the <b>Name</b> field is entered, the directory is automatically generated in the <b>Location</b> field. You can override this by manually

Field	Description
	entering the location or clicking <b>Browse</b> .
<b>Create project based on starter project</b>	<p>Select this option if you want to create a project based on the built-in starter projects. Choose the project style from the <b>Project</b> drop down list that is displayed when this option is selected.</p> <p>You can create custom starter projects by placing *.ctz backup files in the &lt;User&gt;/&lt;Data&gt;/Starter folder (where &lt;User&gt;/&lt;Data&gt; is the directory you chose during installation). The <a href="#">[CtEdit]Starter</a> parameter can be used to change this default path.</p>
<b>[Starter project selection] Project</b>	<p>Select the starter project you wish to use as a template for your project. You can change the style of existing pages and templates using the Page Properties, accessed through the Graphics Builder.</p>

## See Also

[Create a Standard Project](#)

[Make Active](#)

## Create a Standard Project

Use this procedure to create a new project that does not include the content generated by a starter project.

---

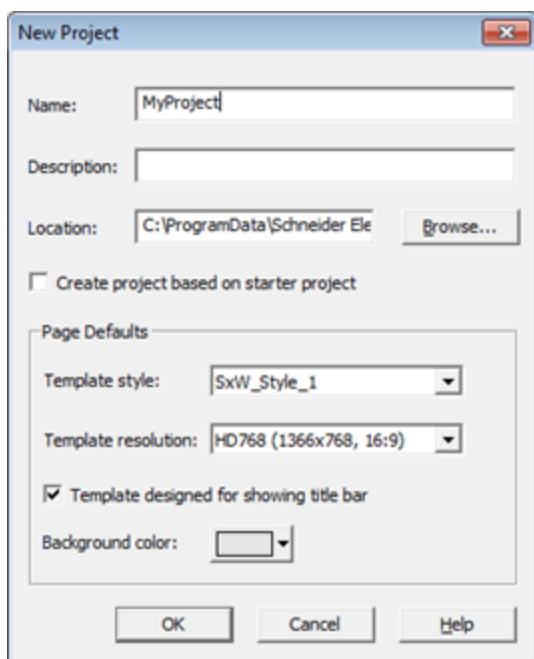

**Note:** If you use the steps described below to create a new project, you will not be able to compile the project until you have defined at least one cluster, one user and an I/O device.

---

### To create a standard project:

1. In the **Project** activity, select **Home**.
2. On the Command Bar, select **Add | New Project**.

The New Project dialog appears.

3. Complete the required fields (see below for a description of the fields).
4. Click **OK**.

The new project will appear in the **Project** activity.

### New Project Dialog Box

Field	Description
<b>Name</b>	A unique name for the project. The project name is restricted to 64 characters. It can contain any characters other than characters in the Windows file naming rules "*   \{}:<>?/;' Since the project name is a unique identifier, Plant SCADA does not permit you to create or restore a project with a duplicate name.
<b>Description</b>	A description of the project. This field is useful for giving an explanation of the role of the project. It is recommended that you complete this field.
<b>Location</b>	The directory path where the project files are stored. As the <b>Name</b> field is entered, the directory is automatically generated in the <b>Location</b> field. You can override this by manually entering the location or clicking <b>Browse</b> .
<b>Create project based on starter project</b>	To create a standard project, clear this check box.
<b>[Page defaults] Template style</b>	The style (appearance) of the graphics pages in the runtime system. The style you select is the default

Field	Description
	<p>style for any new pages you add to the project. You can change the style of existing pages and templates using the Page Properties, accessed through the Graphics Builder. You can choose from:</p> <ul style="list-style-type: none"> <li>• Top</li> <li>• Standard</li> <li>• Bottom</li> <li>• Tab_Style_1</li> <li>• Situational Awareness</li> <li>• SxW_Style_1</li> </ul>
<b>[Page defaults] Template resolution</b>	<p>The default screen resolution of the standard graphics pages (such as alarms pages and standard trend pages):</p> <ul style="list-style-type: none"> <li>• VGA (640 x 480, 4:3)</li> <li>• SVGA ( 800 x 600, 4:3)</li> <li>• XGA (1024 x 768, 4:3)</li> <li>• SXGA (1280 x 1024, 5:4)</li> <li>• HD768 (1366 x 768, 16:9)</li> <li>• HD1080 (1920 x 1080, 16:9)</li> <li>• WUXGA (1920 x 1200, 16:10)</li> <li>• 4K (3840 x 2160, 16:9)</li> <li>• User-defined</li> </ul>
<b>[Page defaults] Template designed for showing title bar</b>	<p>Determines whether to display the Windows title bar (at the top of each graphics page). To display a page in fullscreen (without a title bar), the size of the page needs to be the same size as the display (or larger). If the page is smaller than the display, the title bar still displays, even if fullscreen mode is enabled. Standard templates styles are available for both page sizes.</p>
<b>[Page defaults] Background color</b>	<p>The background color that will be displayed in newly created graphics pages.</p>

## See Also

[Create a Project Using a Starter Project](#)

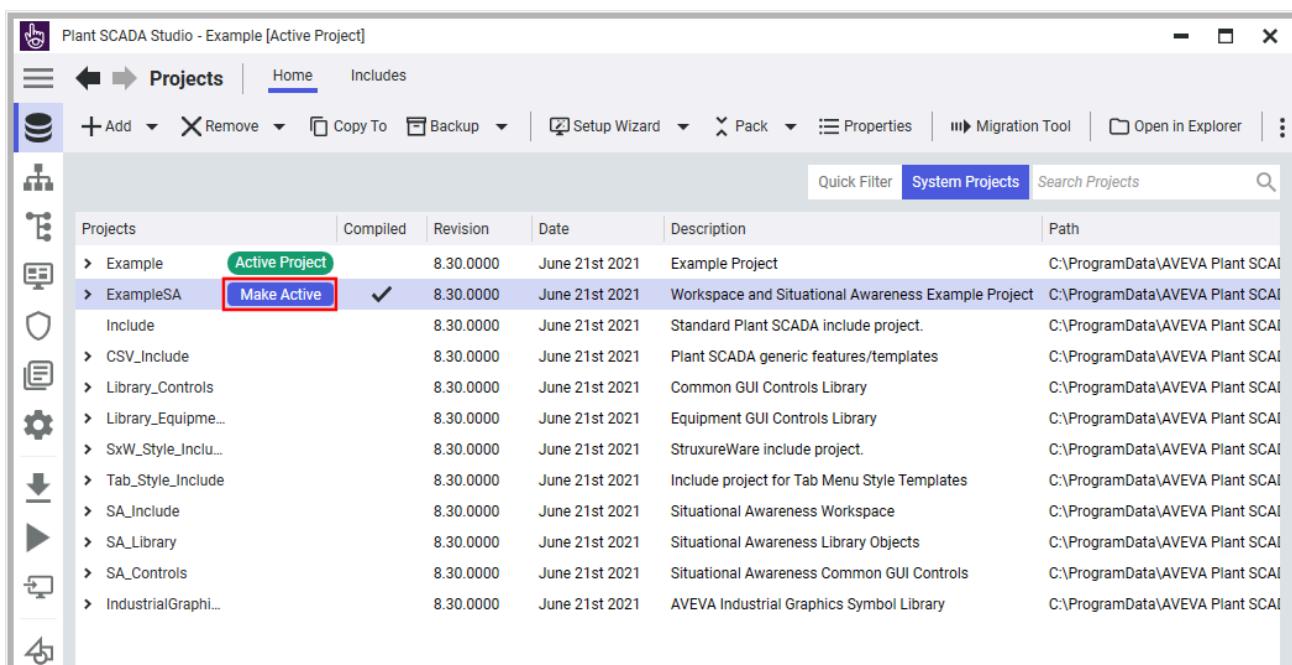

## Make Active

The Make Active functionality allows you to set the project you want to compile and run as "Active". Options on the Activity Bar, the Setup Wizard and the grid views (except the Includes view) work on the Active Project and its included projects rather than on the project selected in Projects view. You do not have to make included projects Active in order to view and edit their data; you can use the Project filter in the Grid Editor for individual projects. This eliminates the need to switch between individual projects to view the corresponding data. If there is only one project in your system, that will be the Active Project by default.

Most Command Bar operations such as **Backup** and **Copy To** in the **Project** view run on the selected project while others run on the Active Project. Tooltips on the Command Bar buttons indicate whether the associated operation will be run on the selected or the Active project.

### To make a project the Active Project:

1. In the **Project** activity, select **Home**.
2. Click to select the project you want to make active.
3. Click the **Make Active** button next to the project name. The Active Project indicator is displayed next to the project name and in the window title.

## Add an Included Project

When you "include" a project within another project, you can share content across both projects while maintaining each as a separate entity (see [Project Types](#)).

### To add an included project:

1. In the **Project** activity, select **Home**.
2. Click to select the project to which you would like to add an included project.

3. Select the **Includes** Tab.
4. Add a row to the Grid Editor.
5. Type the required information in each column, or in the Property Grid (see below for a description of the properties).
6. Click **Save**.

You can include up to 1024 projects. If the number of included projects is less than this and you receive an "out of file handles" compile error, you may need to adjust the parameter [\[CtEdit\]DbFiles](#).

## Included Project Properties

### Include Properties

Property	Description
<b>Included Project</b>	The name of the project to include in the selected project.  You can select the project you would like to include from a drop-down menu within the <b>Include Project</b> field.
<b>Comment</b>	Any useful comment.

### Project Properties

Property	Description
<b>Project</b>	The project in which the specified project is included.

## See Also

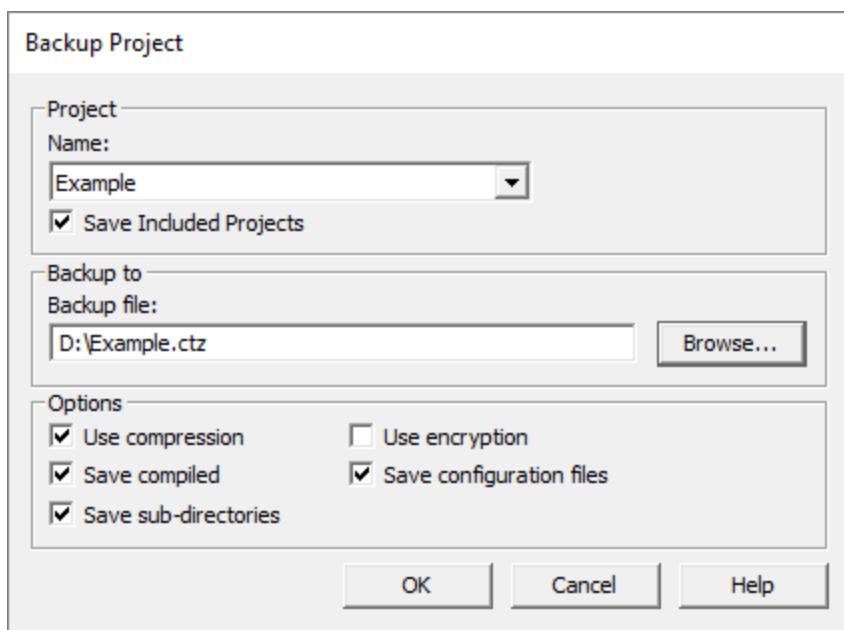

[Link to an Existing Project](#)

## Back Up a Project

Use the Plant SCADA backup functionality to archive project files using the industry standard ZIP compression algorithm. The default file extension for Plant SCADA backup files is .ctz, though any extension (including .zip) can be used. You can use any utility that supports .zip files to extract project files from a compressed Plant SCADA backup.

### To back up a project:

1. In the **Project** activity, select **Home**.
2. On the Command Bar, click **Backup**.  
The Backup Project dialog appears.

3. Complete the required fields (see below for a description of the fields).
4. Click **OK**.

### Backup Project Dialog Box

Field	Description
<b>Name</b>	Select the name of the project to back up.
<b>Save Included Projects</b>	Select to add any included projects to the backup file. The included projects are saved to a sub-directory named "_IncludeProjects".  <b>Note:</b> If you select the <b>Save Included Projects</b> option, any system projects that are installed with the product (such as "Library_Controls" and "SxW_Style_Include") will not be added to the backup file.
<b>Backup file</b>	Enter the path to the backup file location, including the file name. You can either type the path in directly or use the <b>Browse</b> button.  The backup file name defaults to <project>.ctz. If the extension is omitted then .ctz is used.
<b>Use compression</b>	Select to use data compression when you are backing up a project to save space.
<b>Save compiled</b>	By default, Plant SCADA backs up the project in

Field	Description
	<b>uncompiled</b> mode. If you select this option, Plant SCADA backs up both the <b>compiled</b> and <b>uncompiled</b> projects files, resulting in a larger backup file.
<b>Save sub-directories</b>	<p>If you select this option, Plant SCADA also backs up data in any sub-directories within the project directory. The directory structure is maintained in the backup, and you can choose to restore the sub-directories when restoring the project.</p> <p>For example, if you wish to back up your Process Analyst views, save them in a sub-directory of the project and select this option. When you restore the project, you will have the option to also restore the Process Analyst Views directory.</p>
<b>Use encryption</b>	<p>As an added security measure, you can back up your project in an encrypted format. If you select this option, a dialog box that requests a password is displayed when you click <b>OK</b> on the Backup Project dialog. It writes the project to disk in a format that encodes the password along with the protected project. The project can only be restored if the password is entered.</p>
<b>Save configuration files</b>	<p>Select this option to back up *.ini files from the Config folder. This will also backup the TimeSyncConfig.xml file used to store the time synchronization settings configured in the Time Synchronization utility.</p> <p>If you are using a custom INI file (for example 'abc.ini') and it is placed in the Config folder, it will also be backed up. If you are using a custom INI file that is stored in a sub-directory of the project, select the <b>Save sub-directories</b> option to back it up as well.</p> <p><b>Note:</b> You can define a non-default INI file for Plant SCADA by passing a parameter through to Plant SCADA Studio from the Properties dialog box that is accessible from the Shortcut tab. See <a href="#">Using an Alternative INI File</a> for further information on how to do this.</p>

---

**Note:** With the release of Plant SCADA 2023 R2, the **CSV\_Include** project is no longer supported as a system project. If you have any projects based on the CSV\_Include templates, you will need to create a separate backup of the CSV\_Include project and restore manually it in version 2023 R2 (or later). You can then include it as a user project.

---

## See Also

[Restore a Project](#)

## Run a Backup from the Command Line

You can execute the Plant SCADA backup program from the command line to back up and restore files other than Plant SCADA projects.

The backup program is called CtBack32.exe. By default, it is installed in the Plant SCADA project 'Bin' folder. The backup program archives files using a standard compression routine, producing Zip compatible files. The default extension for Plant SCADA backup files is .ctz, though any extension (including .zip) can be used. This means you can also use any Zip compatible program to extract files from a compressed Plant SCADA backup if you prefer.

---

**Note:** If you run the backup program from the command line, and you specify an INI file as a parameter, the specified INI file will be backed up instead of Citect.ini.

---

The backup program reads the citect.ini file for any parameters set using the [BACKUP] category. These settings (if any, and their defaults if not) are over-ridden by any values passed as command line options.

The table below describes the backup command line options.

Option	Description
-d<name>	Database name
-m<ext>	Include extension
-x<ext>	Exclude extension
-e (follow with a number e.g. -e1, -e0)	Encrypt with password
-p<password>	Encrypt/decrypt password
-s[+/-]	Recurse subdirectories
-u[+/-]	Save uncompiled, use -u- to save compiled
-g[+/-]	Show configure dialog
-c[+/-]	Compress files
-b<path>	Path to backup from
-r<path>	Path to restore to
-i<filename>	ini file name

Option	Description
-a	Run in auto mode <b>(Note:</b> Every necessary input needs to be in command line or INI file.)
-o	Overwrite target ctz

**Note:** If -d is not specified and the application is not running in 'auto' mode (-a), the project will be restored to the path of the project from the [CtEdit]LastDatabase ini parameter. If the ini parameter is not present then the project will be restored to the location the -r option specifies. If you restore a project with the -d option on a configuration workstation the application will look in the master.dbf for this project and restore to the path specified in the master.dbf, therefore the project must exist. If you restore a project with the -d option on a runtime only workstation the application overwrites the -d parameter with the [CtEdit]Run parameter from the ini file and restores to this path.

## Examples

- To back up "c:\data" use the following command:  
CTBACK32 -g- -bc:\data
- To restore the above data use:  
CTBACK32 -g -rc:\data
- To backup a Plant SCADA database, for example, to backup "demo" use:  
CTBACK32 -dDEMO -b -u- -c+ -d-

Ctback32 also uses the following parameters in the citect.ini file:

```
[BACKUP]
Database= ! database to backup or restore
BackupPath= ! file to backup to, for example c:\temp\example.ctz.
FilePath= ! file path, used in not a database
Password= ! encryption password
Encrypt=0/1 ! encrypt backup
Configure=0/1 ! display configure dialog
Compress=0/1 ! compress backup
Overwrite=0/1 ! overwrite
SaveCompiled=0/1 ! save compiled
Recurse=0/1 ! recurse sub directories
DeleteAll=0/1 ! delete all before restore
SaveInclude=0/1 ! add included projects to backup file
IncludedDBOn=0/1 ! display a notification after backup if include projects found
SaveIniFiles=0/1! determines whether save ini files is checked
Operation=0/1 ! 0=backup, 1=restore
RestoreInclude=0/1 ! restore included projects contained in backup file
Include= ! include list
Exclude= ! exclude list, default DBK,_CI
CompiledFiles= ! compiled files, default RDB
```

## Restore a Project

You can restore a project that has been backed up using the Restore Project functionality. This functionality allows you to:

- Overwrite a current project with a backed up version
- Restore a backed up project as a new project.

When restoring a project, you need to consider the impact it will have on the unique ID used to identify the project.

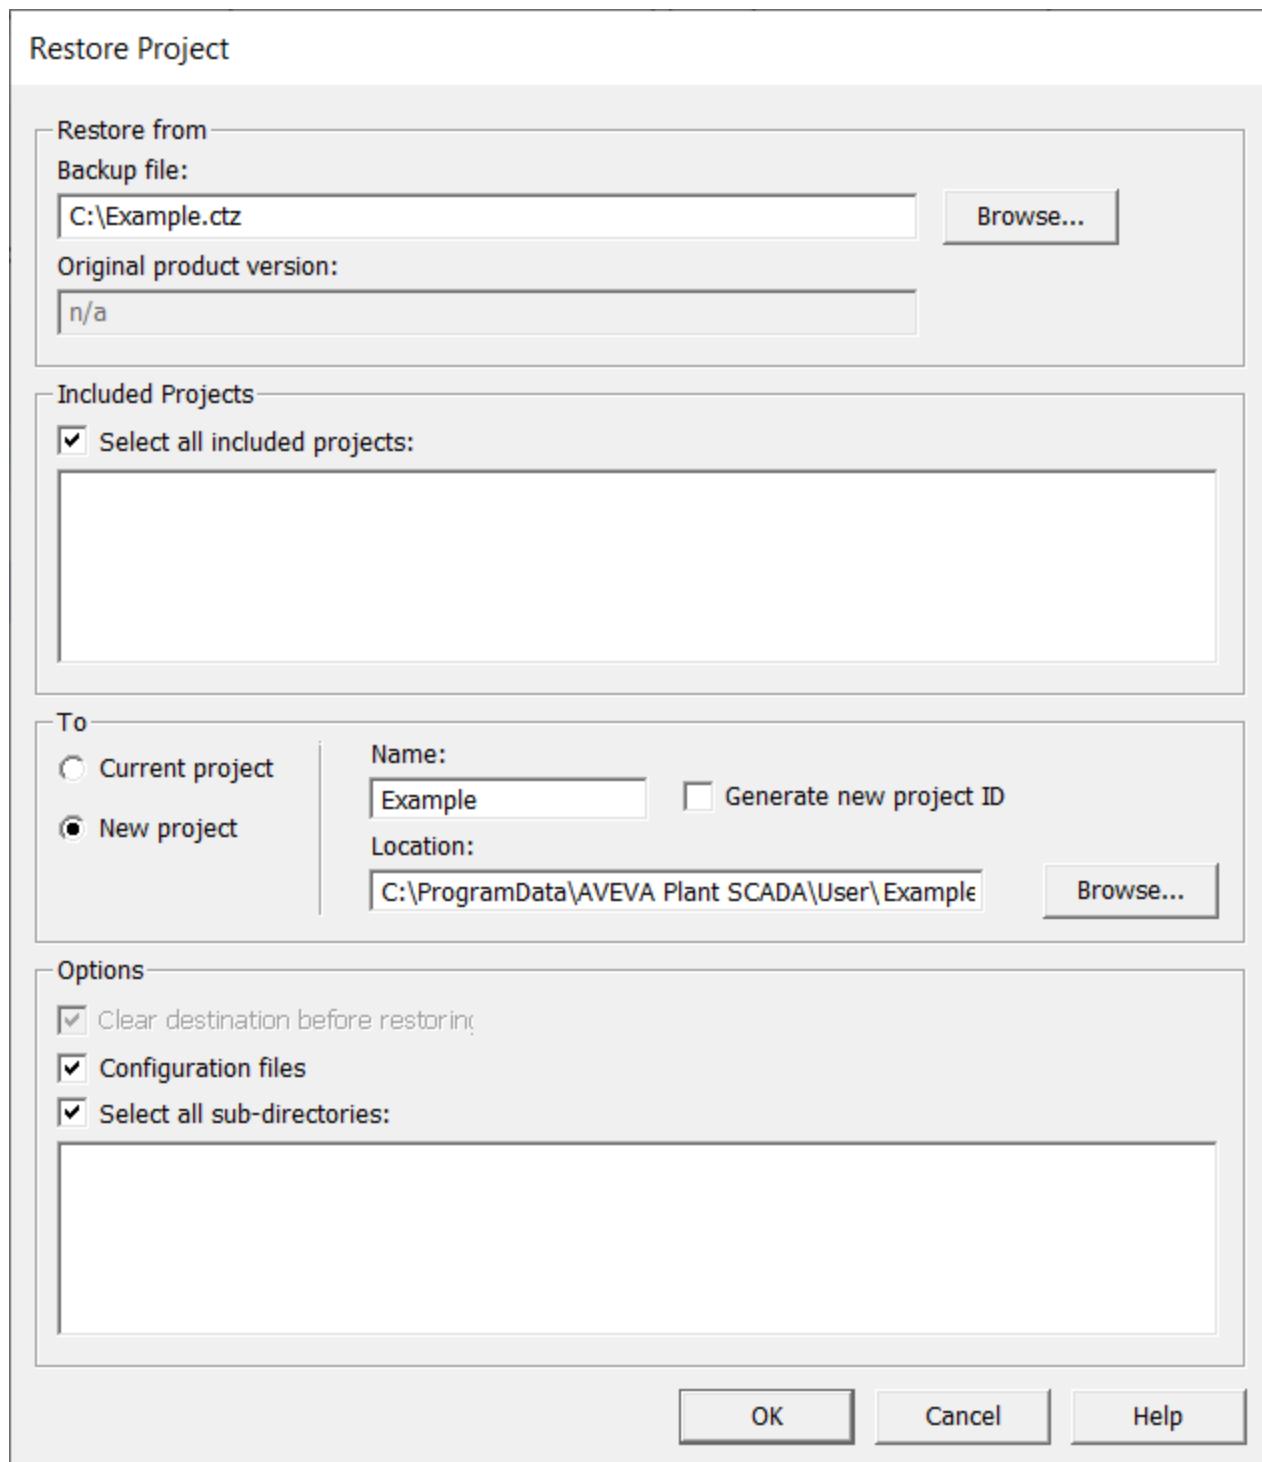

You can use the **Generate new project ID** option to create a new unique ID for the restored project. For example, you could select this option if you wanted to use the restored project as the basis for new project development.

If you want to use an archived backup to restore an earlier version of a project, you should not select this option. The unique ID of the backed up project will be preserved.

### To restore a project:

1. In the **Project** activity, select **Home**.
2. On the Command Bar, click **Backup | Restore**.

The Restore Project dialog appears.

3. Complete the required fields (see below for a description of the fields).
4. Click **OK** to initiate the restore process.

## Restore Project Dialog Box

Field	Description
<b>Backup File</b>	Name and location of the backup file for the project you would like to restore. You can use the <b>Browse</b> button to locate the file.
<b>Original product version</b>	Indicates which version of Plant SCADA was used to create the selected backup file.
<b>Select all included projects</b>	<p>Select to restore all of the included projects that were added to the backup file. This will place a check mark next to each of the included projects listed in the panel below. Clear the <b>Select all included projects</b> check box to restore the project without any of its included projects.</p> <p>Or:</p> <p>In the panel displaying the list of included projects, select the check box for each included project you would like to restore.</p> <p>If you restore an included project that already exists, the existing project will be overwritten. If you restore an included project that does not already exist, it will be added as a new project to the same parent directory as the main project.</p> <p><b>Note:</b> If the <b>Select all included projects</b> check box is disabled, it indicates that the backup file does not contain any included projects.</p>
<b>Current project</b>	Select to overwrite the project that is currently selected in the <b>Project</b> activity in Plant SCADA Studio.
<b>Generate new project ID</b>	<p>A unique ID is applied to each Plant SCADA project to provide consistent identification across a project's lifetime.</p> <p>Select this check box to generate a new unique ID for the restored project. This will not create new IDs for any included projects.</p> <p><b>Note:</b> If you use Plant SCADA 2023 to restore a project that was backed up in a previous version, a unique ID will be applied to the project even if the <b>Generate new project ID</b> option is not selected.</p>
<b>New project</b>	Select to restore a backed up project as a new project. If required, enter a new <b>Name</b> for the restored a project.
<b>Location</b>	Specify the destination for the restored project files. The path should end with a directory that reflects the

Field	Description
	project name. You can either type in the path directly, or use the <b>Browse</b> button to select a location.
<b>Clear destination before restoring</b>	<p>Select the check box to delete all existing content before the restore commences.</p> <p><b>Note:</b> Be careful when using the <b>Clear destination before restoring</b> feature, as every file and sub-directory in the destination location will be deleted before a restore commences. If you <i>accidentally</i> set the restore path to the root directory of your computer drive, the entire disk drive will be deleted.</p> <hr/> <p><b>NOTICE</b></p> <p><b>HARD DISK DRIVE ERASURE</b></p> <p>The <b>Clear destination before restoring</b> feature will delete all files and sub-directories in the restore location. Do not set the location path to the root directory of your drive (usually c:\). <b>Failure to follow these instructions can result in equipment damage.</b></p>
<b>Configuration files</b>	Select to restore backed up INI files, and the TimeSyncConfig.xml file used to store the time synchronization settings configured in the Time Synchronization utility. To make these files active, and to update the current Wizard or Time Synchronization settings with the restored settings, copy the restored files to the Config folder, replacing the currently used corresponding configuration files.
<b>Select all sub-directories</b>	<p>If the backup file includes a project's sub-directories, select this check box to restore all of the sub-directories that were added to the backup file. This will place a check mark next to each of the sub-directories listed in the panel below.</p> <p><b>Note:</b> If the <b>Select all sub-directories</b> check box is disabled, it indicates that the backup file does not contain any sub-directories.</p> <p>Or:</p> <p>In the panel displaying the list of included sub-directories, select the check box for each sub-directory you would like to restore.</p> <p>Or:</p> <p>Clear this check box to restore the project without any of its sub-directories.</p>

[Back Up a Project](#)

[Repair A Project's Unique IDs](#)

## Link to an Existing Project

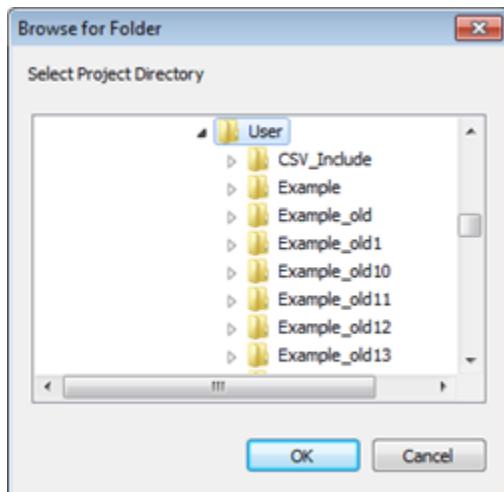

You can link to a project that already exists, even if it is located on a remote network computer. A remote project can be edited and compiled over the network. Only the selected project is linked; its includes are not linked (see [Link to Project Hierarchy](#) for more information).

**Note:** This feature is not designed to allow multiple users access to a common project from different computers. If you create a remote link to a project, you should externally manage the situation to avoid any scenario that would allow two people make changes to a project at the same time. Support for multiple users should be enabled using [Project Types](#).

### To link to an existing project:

1. In the **Project** activity, select **Home**.
2. On the Command Bar, select **Add | Add Project Link**.

The **Browse for Folder** dialog box appears. Select the required project.

3. Select the directory that contains the required project.
4. Click **OK**.

If your selection has the same name as an existing project in Plant SCADA Studio, you will be prompted to provide a new name. You will also be notified if the project has any links to an included project that cannot be located.

### To remove a project link:

1. Select the linked project in the Project activity.
2. Click **Remove | Remove Project Link**. A notification dialog will appear.
3. Select **OK** to proceed.

4. If one or more Industrial Graphics items in this project have unsaved changes, a notification dialog will appear with the list of all unsaved items.
5. Select any of the following option to proceed:

SAVE ALL	Save all the changes, close the Industrial Graphics items, and unlink the selected project from the Plant SCADA Studio.
DISCARD ALL	Discard all the changes, close the Industrial Graphics items, and unlink the selected project from the Plant SCADA Studio.
CANCEL	Cancel the procedure.

**Note:** Unlinking an existing project removes the project, but does not delete it. The project file continues to be available at its original location on the disk.

## Link to Project Hierarchy

You can link Plant SCADA Studio to a project and its includes from any location using the Link to Project Hierarchy functionality. After you have linked a project and its includes to Plant SCADA Studio, you can view these projects in the Projects activity. If one of the include projects is already linked, linking the project hierarchy will not change the existing link.

**Note:** The project to which you are linking and its includes need to be in the same folder.

### To link a project hierarchy:

1. In the **Project** activity, select **Home**.
2. On the Command Bar, select **Add | Link Project Hierarchy**. The Select Folder dialog appears.
3. Click to select the project folder for the project you want to link.
4. Click **Select Folder**. The selected project and its includes are linked.

### To unlink a project hierarchy:

1. Select the project that you want to unlink.
2. On the Command Bar, select **Remove | Unlink Project Hierarchy**. A message is displayed to confirm the action.
3. Click **OK** to proceed.
4. If one or more Industrial Graphics items in this project or its included projects have unsaved changes, a notification dialog will appear with the list of all unsaved items.
5. Select any of the following options to proceed:

SAVE ALL	Save all the changes, close the Industrial Graphics items, and unlink the selected project and its includes from the Plant SCADA Studio.
DISCARD ALL	Discard all the changes, close the Industrial Graphics

	items, and unlink the selected project and its includes from the Plant SCADA Studio.
CANCEL	Cancel the procedure.

**Note:** Unlinking a project hierarchy removes the project and its includes from the view, but does not delete them. The project files continue to be available at their original location on the disk.

## Pack a Project

When you delete project items such as equipment, alarm tags, variable tags and so on they are marked for deletion. Packing a project deletes all items marked for deletion from the various database files and re-indexes these files.

It is recommended to run the pack operation at regular intervals.

### To pack the current project:

1. In the Project activity, select **Home**.
2. On the Command Bar, click **Pack**.

To pack the current project and its included projects, on the Command Bar click **Pack | Pack with Included Projects**.

## See Also

[Repair A Project's Unique IDs](#)

## Repair a Project's Unique IDs

Unique IDs are applied to the following Plant SCADA components:

- Variable tags
- Equipment instances
- Equipment types.

This provides consistent identification across the lifetime of a project.

Each unique ID is a Globally Unique Identifier (GUID) generated by Plant SCADA using the following format:

XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX

In some cases, a project may be missing unique IDs for some components. This happens in the following circumstances:

- You have used an external editing tool to make changes to a project DBF.
- You have not run the Migration Tool for a project created in an earlier version.

If you need to generate missing IDs for a project, you can run a repair process.

**To repair a project's unique IDs:**

1. In Plant SCADA Studio, go to the **Projects** activity.
2. On the command bar, open the menu on the **Pack** button.
3. From the menu, select **Repair Unique IDs**.

When the repair process is complete, a dialog will provide a tally of the changes that were made. The dialog will also include the location of a log file that captures more detailed information.

**See Also**

[Unique IDs for Variable Tags and Equipment](#)

## Copy a Project

You can copy the contents of a project to an existing project or a new project.

When you create a copy of a project, you need to consider the impact it will have on the unique ID used to identify the project.

You can use the **Generate new project ID** option to create a new unique ID for the copy you are creating. For example, you could select this option if you wanted to use the copy as the basis for new project development.

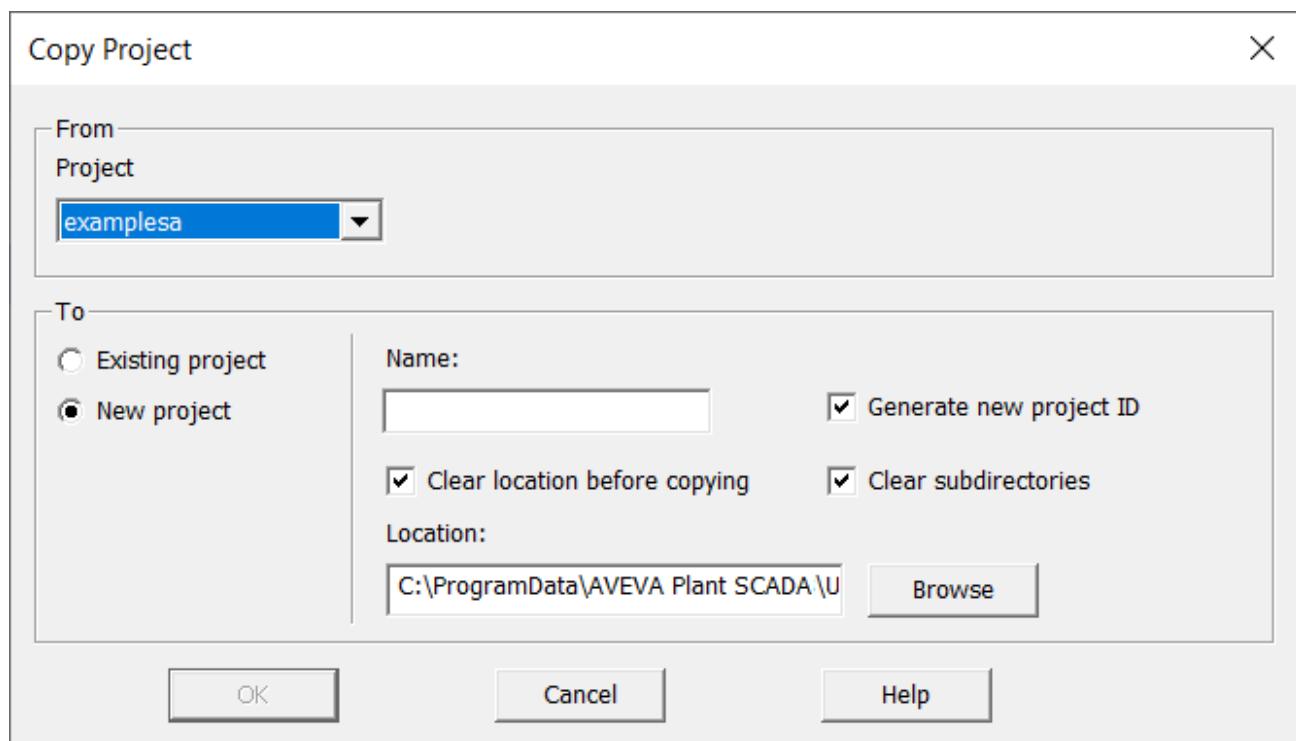

If you want to create an archived copy of a project that you eventually may use to replace the original, you should not select this option.

If you select the **[To] Existing project** option, the unique ID of the source project will replace the ID of the destination project.

**To copy the contents of a project to an existing or a new project:**

1. In the **Project** activity, select **Home**.
2. On the Command Bar, click **Copy To**.

The Copy Project dialog box appears.

3. Complete the following fields (see below for a description of the fields).
4. Click **OK**.

### Copy Project Dialog Box

Field	Description
[From] Project	The name of the project you would like to copy. The drop-down list includes all the projects that are currently available in Plant SCADA Studio. You can select a project name from this list.
[To] Existing Project	Select this option to copy the content of the source project to an existing project.
[To] New Project	Select this option to copy the content of the source project to a new a project.
[To] Name	<p>The name of the project to which the copied content will be added.</p> <p>If <b>Existing project</b> is selected, you can choose a project name from the drop-down list.</p> <p>If <b>New project</b> is selected, enter a unique name for the destination project. The name is restricted to 64 characters, and can contain any characters other than semi-colon (;) or single quote (').</p>

Field	Description
<b>[To]</b> <b>Generate new project ID</b>	<p>A unique ID is applied to each Plant SCADA project to provide consistent identification across a project's lifetime.</p> <p>Select this check box to generate a new unique ID for the copy of your project. This will not create new IDs for any included projects.</p> <p><b>Note:</b> If you are copying to an <b>Existing project</b> and you do not select this option, the unique ID of the copied project will be used to overwrite the ID of the destination project.</p>
<b>[To]</b> <b>Clear location before copying</b>	Select this check box to delete any existing content in the top level folder of the destination project directory.
<b>[To] Clear subdirectories</b>	Select this check box to delete any existing content in the destination folder's subdirectories.
<b>[To] Location</b>	<p>This field is only available if <b>New project</b> is selected. Use it to specify the directory where the copied project files will be stored.</p> <p>Use the <b>Browse</b> button to select a location.</p>

## See Also

[Repair A Project's Unique IDs](#)

## View Projects

The Project activity displays a list of all user and system projects. The name of the Active Project is displayed in the title bar of the application along with the text **[Active Project]**.

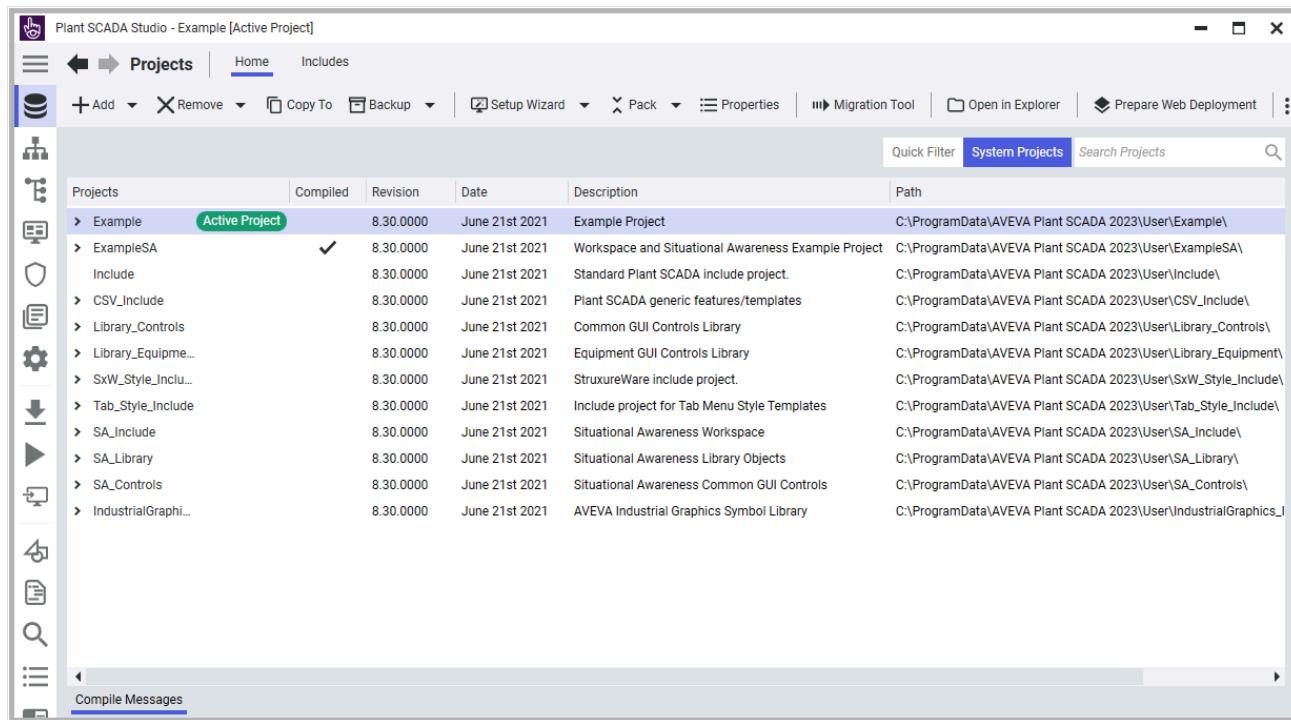

To make a different project the Active Project, click to select the project and then click the **Make Active** button on the Command Bar. Most Command Bar operations in the Project activity are run on the selected project. Only the Setup Wizard and Prepare Web Deployment operations run on the Active Project as do Activity Bar options like **Run** and **Compile**.

Use the expandable icon to the left of a project name to display any included projects.

The Project activity displays the following details for each project:

- **Project** — Name of the project.
- **Compiled** — Whether the project has been compiled. If the project has been compiled, this displays a green tick.
- **Revision** — Revision number of Plant SCADA project that you can manually assign to keep track of changes to your projects.

- **Date** — Date specified in the project Properties dialog box.
- **Description** — description specified in the project Properties dialog box.
- **Path** — Folder in which the project files are stored.

Click **Includes** to view the selected project's included projects.

Row	Project	Include Project	Comment
1	Example	SxW_Style_Include	
2	Example	Library_Equipment	

## Delete a Project

### To delete a project:

1. In the Project activity, select **Home**.
2. Click to select the project you want to delete.
3. On the Command Bar, select **Remove | Delete Project**.  
A confirmation dialog will appear.
4. Click **OK** to confirm that you would like to delete the project.

You cannot delete a [Project Types](#).

**Note:** You should consider creating a backup of a project before you delete it (see [Back Up a Project](#)).

## Filter Projects

By default, all user projects created in Plant SCADA are displayed in the **Project** activity. The name of the [Make Active](#) is displayed title bar and also next to the project name.

To view only the selected project and its included projects, click **Quick Filter**.

To view all [system projects](#), click **System Projects**.

You can also use Search to filter projects. To do so, type the search term in the **Search** box. Project names that contain the search term will be displayed. For example, if you search for "exam", the Example project and projects containing the term "exam" in their name will be displayed.

Projects	Compiled	Revision	Date	Description	Path
Example	8.30.0000	June 21st 2021	Example Project	C:\ProgramData\AVEVA Plant SCADA 2021	
SxW_Style_Include	8.30.0000	June 21st 2021	StruxureWare include project.	C:\ProgramData\AVEVA Plant SCADA 2021	
Library_Equipment	8.30.0000	June 21st 2021	Equipment GUI Controls Library	C:\ProgramData\AVEVA Plant SCADA 2021	

**Note:** Search can be used only by itself; it cannot be used in conjunction with the **Quick Filter** and **System Projects** filter buttons.

[Edit a Project's Properties](#)

[View a Project's Folders](#)

## Edit a Project's Properties

The Project Properties dialog box displays information about the current project across two tabs:

- **General**
- **Page Defaults**.

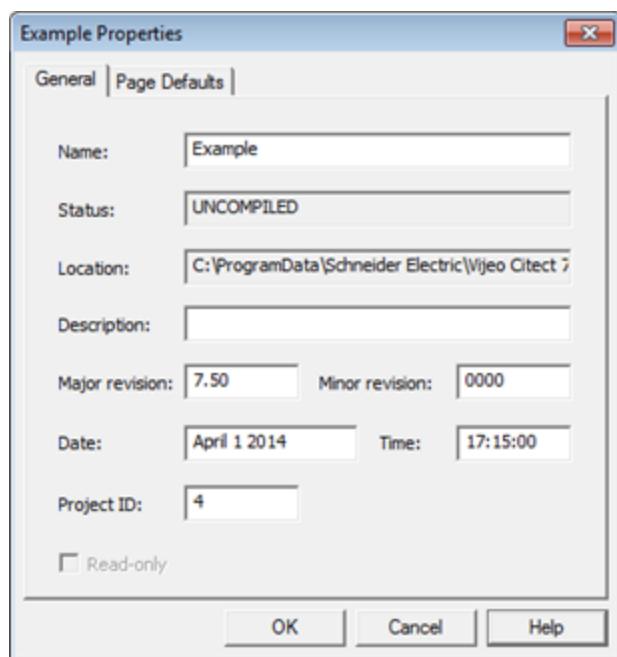

The **General** tab provides information about a project such as its name, location and current status. You can also use this tab to label revisions of a project.

The **Page Defaults** tab includes information about the appearance of the pages in a project, including the default template style and screen resolution. To edit these properties, you need to use Graphics Builder (see [Edit the Default Page Settings](#)).

**To view and edit a project's properties:**

1. In the **Project** activity, select **Home**.
2. On the Command Bar, click **Properties**.

The Project Properties dialog box appears.

3. Edit the General properties as required, or view the Page Defaults (see below for a description).
4. Click **OK**.

## General Properties

Property	Description
<b>Name</b>	The name of the project (restricted to 64 characters). It can contain any characters other than the semi-colon (;) or single quote (''). Since the project name is a unique identifier, Plant SCADA will not permit you to create, restore or rename a project with a duplicated name.
<b>Status</b>	The status of the project. This can be either <b>COMPILED</b> or <b>UNCOMPILED</b> .
<b>Location</b>	The directory path for the location of the project files (see <a href="#">View a Project's Folders</a> ). This field cannot be edited.
<b>Description</b>	A description of the project. This field is useful for providing an explanation of the project's purpose. Maximum length is 255 characters.
<b>Major Revision</b>	Plant SCADA sets this property to one (1) when the project is first created. You can use this field to track major changes to the project. You can use

Property	Description
	an incremental revision history (for example 1, 2, 3, . . . or A, B, C, . . .). Maximum length is 4 characters.
<b>Minor Revision</b>	Plant SCADA sets this property to zero (0) when the project is first created. You can use this field in conjunction with Major Revision to track your project's development. Maximum length is 4 characters.
<b>Date and Time</b>	Plant SCADA will initially set these fields to reflect when the project was created. These fields are useful when used in conjunction with the Revision fields. Maximum length is 20 characters each.
<b>Unique ID</b>	<p>A unique ID is applied to each Plant SCADA project. This provides consistent identification across the lifetime of a project.</p> <p>Each unique IDs is a Globally Unique Identifier (GUID) generated by Plant SCADA using the following format:</p> <p>XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX</p> <p>You cannot edit this field.</p> <p>If you <a href="#">Copy a Project</a> or <a href="#">Restore a Project</a> a project, you need to consider how a project's Unique ID will be impacted.</p>

## Page Defaults

**Note:** To edit these properties, you need to use Graphics Builder (see [Edit the Default Page Settings](#)).

Property	Description
<b>[Template] Style</b>	<p>The name of the project (restricted to 64 characters). It can contain any characters other than the semi-colon (;) or single quote (').</p> <p>Since the project name is a unique identifier, Plant SCADA will not permit you to create, restore or rename a project with a duplicated name.</p>
<b>[Template] Resolution</b>	The default screen resolution of the graphics pages (such as alarms pages and trend pages).

Property	Description
<b>[Template]</b> <b>Designed for showing title bar</b>	Determines whether the Windows™ title bar displays at the top of each graphics page. To display a page in full screen (without a title bar), the size of the page needs to be the same size as the display (or larger). If the page is smaller than the display, the title bar still displays, even if full screen mode is enabled.
<b>Background color</b>	The color that will display in the background of new graphics pages.

## See Also

[View a Project's Folders](#)

## View a Project's Folders

A project's configuration, data and log files are stored in different folders.

The configuration files for a project are stored in two locations:

- **Project folder** - contains the project files (database files, graphics files, and so on)
- **Config folder** - contains the configuration files for the local computer (such as citect.ini).

Project data that is associated with the runtime system is also stored in two locations:

- **Data folder** - contains runtime data
- **Logs folder** - contains runtime log files.

The following table shows the install path for each of these folders in the Windows™ Program Data directory.

Folder	Install Path
Project folder	%PROGRAMDATA%\AVEVA Plant SCADA <VersionNumber>\User\<current project name>
Config folder	%PROGRAMDATA%\AVEVA Plant SCADA <VersionNumber>\Config
Data folder	%PROGRAMDATA%\AVEVA Plant SCADA <VersionNumber>\Data
Log folder	%PROGRAMDATA%\AVEVA Plant SCADA <VersionNumber>\Logs

**To view a project folder:**

1. In the **Project List**, select the required project.
2. On the Command Bar, click **Open in Explorer**.

A new Windows Explorer window will open and display the content of selected project folder.

**To view the Data, Configs or Log folders:**

1. Go to the System menu by clicking on the following icon in Plant SCADA Studio's top left corner.

2. Select the required folder.

A new Windows Explorer window will open and display the contents of selected folder.

**See Also**

[Create a Project Using a Starter Project](#)

[Create a Standard Project](#)

## Analyze a Project

When you use the **Project Analysis** command, a file called "ProjectSummary.xml" is created and placed in the project folder. This file presents information about the selected project and any user-created include projects.

**To create a project summary file:**

1. In the **Project** activity, select **Home**.
2. Click to select the project you would like to analyze.
3. On the Command Bar, select **Project Analysis**.

After the XML file has been created, Windows Explorer will appear with the summary file selected in the project folder.

**Note:** Project Analysis runs in the background and may take a long time depending upon the size of your project.

**See Also**

[View a Project's Folders](#)

## Project Specifications

The table below defines the specifications that are supported by Plant SCADA projects.

**Note:** Values marked with an asterisk (\*) are not restricted, they are maximum recommended values only. However, exceeding these recommendations can impact the performance of your system. For example, it may

affect the trend server (CPU loading) and the CPU loading of a client displaying the Process Analyst.

Configuration Projects	1022 *
Number of Variable Tags defined in Plant SCADA	<p>4,194,303 (but no more than 500,000* is the recommended)</p> <p>This is a system wide limitation for a running system. Tags in every project included in the project you are currently compiling and running will contribute to this figure, regardless of clustering.</p> <p>Be aware that if you are using one or more tag based drivers in your project, the figure depends on the bit length of your variables defined for the driver(s). This is due to the need for these drivers to use OIDs to identify each tag. For example, a tag based driver that uses 32-bit digitals may reduce the number of possible variables by 32 (i.e. if your project contains only 32-bit digitals, you can have a maximum of 131,072). If no bit size is defined for digitals by for the driver, it defaults to 16.</p>
Number of Included projects	1024
Simultaneously logged-in users	250 *
Number of reports	1000 *
Number of I/O Device addresses monitored by alarms	150000 *
Number of historical trends	32000 *
Number of trends displayed on the same chart	16 *
Number of alarms	65,535 per alarm type *
Number of trends displayed on the same page	16000
Number of user functions	4500 *
Number of standard built-in functions provided	1165
Number of operator commands for the system	3000 *
Number of I/O Devices connected to Plant SCADA	16383
Number of simultaneous multiple protocols	4095
Number of areas	255
Number of alarm categories	16376
Maximum simultaneous multi-tasking threads	512

DBF File size	2 GB (2,097,512 KB)
---------------	---------------------

## Run a Project Using the Setup Wizard

Before you run your project you will need to configure each computer in your Plant SCADA system. Configuration information is stored on each machine in a Citect.ini file based on your installation, database configuration and compiled project. Configuration is done with the Setup Wizard.

**Note:** The Setup Wizard runs on the Active Project and its includes.

The Setup Wizard contains a series of pages allowing configuration of the computer specific settings including:

- The role the computer has in the system network
- The project being run
- The CPU Configuration
- The Plant SCADA Events enabled for each component
- The Cicode run for each component on startup
- The cluster configuration
- The security settings applied.

The wizard uses the configuration stored in the project databases to provide information to you. Selected options are written to the Citect.ini file.

The wizard needs to be run on each computer in your system to appropriately configure Plant SCADA for each particular machine. Run after compiling your project and as the last step before running the system.

### See Also

[Run the Setup Wizard](#)

## Run the Setup Wizard

The Setup Wizard runs on the active project and its includes as a default.

### To start the Setup Wizard:

1. In the **Project** activity, select **Home**.
2. If not previously compiled, compile the project.
3. On the Command Bar, click **Setup Wizard**. The Setup Wizard is displayed.
4. Select **Express Setup** or **Custom Setup**.

The pages that are displayed depend on the configuration of the machine. They can include the following:

- [Project Configuration](#)
- [Profile Setup](#)
- [Screen Setup](#)
- [Computer Role Configuration](#)

- Network Model
- Server Password Configuration
- Server User Configuration
- Reports Configuration
- Trends Configuration
- Alarm Server Configuration \*
- CPU Configuration
- Events Configuration
- Startup Functions Configuration
- Cluster Connections Configuration \*
- Control Menu Security Configuration
- Keyboard Security Configuration \*
- Miscellaneous Security Configuration \*
- General Options Setup \*

\* Only available in **Custom Setup** mode.

## Project Configuration

The Project Setup page will vary depending on whether you are configuring a project from Plant SCADA Studio, or from a [Runtime-only Environment](#).

Select the project source to run on this Plant SCADA computer. You will have the following options:

Option	Description
<b>Deployed</b>	This option should only be selected if <a href="#">deployed</a> projects exist. If no deployed project(s) exist and you select this option, the following alert message is displayed: "Cannot use Deployed as the project source, as no projects have been deployed". Projects that have been deployed will be listed in the "Select the project to run" field. Select a project and the version of the project to run. You can use this option to roll back to previous versions of the project.
<b>Local Plant SCADA Studio</b>	Compiled projects available in the Local Plant SCADA Studio will be listed. If there is only one compiled project present, it will be selected automatically. If there are no compiled projects present, an alert message is displayed and the wizard will terminate. If this occurs, return to the Project and confirm that the necessary project is saved locally and has compiled without errors.

Option	Description
Run/Copy	No additional options are available. Refer to <a href="#">Runtime-only Environment</a> for more information.

**Note:** If you change this setting from **Deployed to Local Plant SCADA Studio**, the project that runs on the computer will no longer be synchronized with deployment updates. You need to consider the implications of changing the runtime project on the local computer.

## See Also

[Profile Setup](#)

### Runtime-only Environment

Before configuring the runtime only environment, and running the Setup Wizard, it is assumed you have transferred a project from the configuration environment, including compiled projects to your local machine. If not refer to [Back Up a Project](#) for more information.

Using the .CTZ files from your backup included projects and target project, you can restore the project. It is recommended you restore the included project before the target project. The restore project tool is available from the start menu shortcut **Runtime Configuration | Project restore**

In the Project Restore dialog :

1. In the **Backup file** field, browse or enter the name of the project to restore.
2. Under To, the option **Current project**, may be unavailable. This is due to no project having been run on the local machine before. The option **New project** will be selected to restore a backed up project as a new one.
3. In the **Name** field, enter a name of the restored project.
4. In the **Location** field, enter or browse to the location of the project to restore (restore the project under the 'User' folder).
5. Leave the remaining settings as default and click **OK**.
6. The project will be restored.

You are now ready to run the Setup Wizard available from the start menu shortcut **Runtime Configuration | Plant SCADA Computer Setup**

In the RUN path edit box enter, or use the select button to browse for, the path to the local project that you wish to the client to run. If you enter the run path set the run folder under the 'User' Folder.

If you wish to maintain a synchronized local version of an external project select the Enable RUN/COPY deployment check box. Then in the COPY path edit box enter, or use the select button to browse for, the path to the external project that you wish maintain synchronization. This feature uses the [\[CtEdit\]Run](#) and [\[CtEdit\]Copy](#) commands to maintain synchronization between the two projects.

**Note:** The Run/Copy mechanism does not transfer custom files such as meta-data, icons, images or runtime DBF files. Therefore, it is recommended deploying a project before Run/Copy to help ensure that those files at least exist. You will still need to re-deploy a project, when you want to update the custom files.

## Profile Setup

Select the INI file to be loaded on this Plant SCADA computer at runtime.

- To load the Citect.ini file at runtime, select **Configure Local Settings**.
- To use a [Profiles](#) you have created, select **Use Profiles**.

You can create a <profile>.ini file with the [Profile Wizard](#). Once created, you can use the [Computer Setup Editor](#) to configure parameters specific to that profile. To do this, select one of the profiles configured in your project from the drop-down list in the **Use Profiles** field. The selected profile will be loaded at runtime.

**Note:** If you selected the **Deployed** option on the previous page of the Wizard ([Project Configuration](#)), the **Use Profiles** field will be disabled. The profile that is loaded at runtime will be determined by your deployment configuration.

## See Also

[Screen Setup](#)

## Screen Setup

Use the Screen Setup page to select the Screen Profile that will be used. To do this:

1. From the **Screen Profile** list, select the profile you wish to use for the current workstation. The monitors defined for the selected profile are displayed.
2. For each screen, select a **Startup Page**. A list of available pages can be accessed from a drop-down menu. To just see a list of master pages (pages with their Content Type set to "Master"), select the **Show master pages only** check box.  
You can also use the parameter [\[MultiMonitors\]StartupPage<n>](#) to specify a Startup Page.
3. If your project is a [Situational Awareness](#) project, you will need to select a **Context** for each screen. The context sets the entry point of display for the screen; it could be an area of the plant or the entire site or any graphics page in your project. This can also be done through the [\[MultiMonitors\]Context<n>](#) parameter.

**Note:** Context is only supported for Situational Awareness projects.

## See Also

[Computer Role Configuration](#)

[Run the Setup Wizard](#)

## Computer Role Configuration

Use the Computer Role Setup page to specify the role of the computer running Plant SCADA. Select one of the options described below.

**Note:** To use Plant SCADA's multi-process capabilities with a Server and Control Client, networking needs to be enabled.

Option	Description
Server and Control Client	<p>This computer will be a standalone or networked I/O server and Control Client. This option is disabled if this computer has no Server components assigned to it to run. Selecting this option enables the <b>Multi-Process</b> check box.</p> <p>Select the <b>Multi-Process</b> check box to separate your client and server components into individual processes. This option can be used for distributing the components across multiple CPUs.</p> <p>If the <b>Multi-Process</b> check box is selected the <a href="#">[General]Multiprocess</a> parameter in the Citect.ini file is saved with the value 1. If not selected, the parameter is saved with the value 0.</p> <p>If you leave the <b>Multi-Process</b> check box unselected, Plant SCADA will run the client and server components in one process.</p> <p><b>Note:</b> Running Plant SCADA as a service in single process mode is not recommended. If you run Plant SCADA in this condition, the following limitations will apply:</p> <ul style="list-style-type: none"><li>• Hardware alarms originating from the server process will not appear.</li><li>• The following Cicode functions will not be executed within the server process:<ul style="list-style-type: none"><li>• AlarmSumAppend</li><li>• AlarmSumCommit</li><li>• AlarmSumDelete</li><li>• AlarmSumFind</li><li>• AlarmSumFindExact</li><li>• AlarmSumFirst</li><li>• AlarmSumGet</li><li>• AlarmSumLast</li><li>• AlarmSumNext</li><li>• AlarmSumPrev</li><li>• AlarmSumSet</li><li>• AlarmSumSplit</li><li>• AlarmSumType</li><li>• DriverInfo</li><li>• IODeviceControl</li></ul></li></ul>

Option	Description
	<ul style="list-style-type: none"> <li>• IODeviceInfo</li> <li>• SPCAlarms</li> <li>• ServerInfoEx</li> <li>• TrnAddHistory</li> <li>• TrnDelHistory</li> </ul>
Control Client	<p>This computer will only be a Control Client. This option is disabled if the computer has been assigned a server component to run.</p> <p>Selecting this option enables the <b>Full License</b> check box.</p> <p><b>Note:</b> The Full License checkbox is only available when running the Setup Wizard in Custom Mode.</p> <p>Select the full server license check box if you want this Control Client to use a full (server) license, as opposed to a client license. This sets the <a href="#">[Client]FullLicense</a> parameter in the Citect.ini file to 1 (the default value is 0).</p> <p>Generally, you would not allocate a full server license to a client as there is no difference in functionality between the two licenses. Allocate a full server license if you have insufficient client licenses available, or for some other specific need.</p>
View-only Client	<p>This computer will be a view-only client. This read only option is disabled if this computer has been assigned a Server component to run.</p>
HMI (Standalone, no networking)	<p>This computer will run as a standalone HMI setup with networking disabled. Select this option for any computers that require a dedicated HMI license from an Enterprise License Server that hosts multiple license types.</p> <p>If you are using Sentinel licensing, you can use a key that has networking disabled. If a full Sentinel key is plugged in, runtime will start in standalone mode with networking disabled.</p> <p>Select the <b>Multi-Process</b> check box to separate your client and server components into individual processes. This option can be used for distributing the components across multiple CPUs.</p> <p>If the <b>Multi-Process</b> check box is selected the</p>

Option	Description
	[General]Multiprocess parameter in the Citect.ini file is saved with the value 1. If not selected, the parameter is saved with the value 0.

Some of these options may be disabled depending on what servers have been configured to run on this computer. The Setup Wizard cross-references your computer's network identification with the network addresses configured for each server in your project configuration.

The option you select will adjust the [Client]ComputerRole parameter in the Citect.ini file.

## See Also

[Network Model](#)

[Run the Setup Wizard](#)

### Network Model

Select the network model to be applied to this Plant SCADA computer. The options include:

- Stand alone (no other SCADA computers)
- Networked (connect to other SCADA computers)

**Note:** TCP/IP address information for servers is configured within the Plant SCADA project itself. See [Add a Network Address](#) for more information.

#### Stand alone

Select **stand alone** to run all server and client components of a Plant SCADA system on a single computer. This allows you to run Plant SCADA as a small and self-contained system.

#### Networked

Select **Networked** to connect to a system of multiple Plant SCADA computers configured with different server and client components. In a **Networked** setup where hostnames are used to resolve IP addresses, specify the following:

- Select network address type from the **Address Type** drop-down list (refer to [LAN]AddressType).
- For an IPv6 **Address Type**, select the **Address Scope** from the drop-down list (refer to [LAN]AddressScope).

Refer to the following table for information regarding the status of a server with respect to the computer network configuration, the **Address Type** and the **Address Scope** selection.

Computer Network Configuration	Address Type	Address Scope	Server Status
IPv4	IPv4	-	Starts with IPv4 address.
IPv4	IPv6	Link-Local	Starts with the Link-Local IPv6 address available in the machine.
IPv4	IPv6	Global	Does not start.
IPv4	IPv6	Global and Link-Local	Starts with the Link-Local IPv6 address available in the machine.  <b>Note:</b> When you start <b>Runtime Manager</b> , the <b>User Location</b> column on the <b>Alarm Summary</b> and <b>Sequence of Events</b> pages shows the server address as "::1." It is the IPv6 loop-back address.
IPv6	IPv4	-	Starts with the IPv4 loop back address 127.0.0.1.
IPv6	IPv6	Link-Local	Starts with the Link-Local IPv6 address.
IPv6	IPv6	Global	Starts with Global IPv6 address.
IPv6	IPv6	Global and Link-Local	Starts with Link-Local / Global IPv6 address (depends on first return address).
IPv6 and IPv4	IPv4	-	Starts with IPv4 address.
IPv6 and IPv4	IPv6	Link-Local	Starts with Link-Local IPv6 address.
IPv6 and IPv4	IPv6	Global	Starts with Global IPv6 address.
IPv6 and IPv4	IPv6	Global and Link-Local	Starts with Link-Local / Global IPv6 address (depends on first return address).

When you complete the Profile Setup Wizard, the selected network model is written to the [LAN] section in the

ini file; for example:

```
...
[LAN]
TCPIP=1
...
```

## See Also

[Reports Configuration](#)  
[Run the Setup Wizard](#)

### Reports Configuration

The Reports Configuration page will only be displayed if this machine is configured as a Reports Server in the [Topology](#) activity.

**Note:** For a networked computer to be a Reports Server it needs to also be the I/O Server or needs to be able to communicate with the I/O Server on the network.

Plant SCADA has several options available for report processing:

Option	Description
Startup report	Defines the name of the report to run when Plant SCADA starts up.
Inhibit triggered reports on startup	For example, you might have a report that is triggered off the rising edge of a bit on startup. The Reports Server detects the bit come on, and runs the report. If this option is checked, the Reports Server does not run this report until it has read the I/O Devices a second time.
Run reports concurrently with primary Reports Server	Enables or disables tandem processing of reports. If this server is the standby Reports Server, it can process every report in tandem with the primary server, or it can remain idle until called.

## See Also

[Trends Configuration](#)  
[Run the Setup Wizard](#)

### Trends Configuration

The Trends Configuration page will only be displayed if this machine is configured as a Trends Server in the [Topology](#) activity.

**Note:** For a networked computer to be a Trends Server it needs to also be the I/O Server or needs to be able to

---

communicate with the I/O Server on the network.

Plant SCADA has one option available for trend processing:

Option	Description
Inhibit triggered trends on startup	You might have a trend that is triggered off the rising edge of a bit on startup. If this option is enabled, the trends server does not display the trend until it has read the I/O Devices a second time.

## See Also

[Alarm Server Configuration](#)

### Alarm Server Configuration

The Alarm Server Properties Setup page is displayed if the computer has one or more alarm servers configured that are part of a redundant pair. Correctly setting the options on this page will improve outcomes for alarm server redundancy. Enter an IP address for **Device IP 1** and **Device IP 2**.

If the Plant SCADA system is using an IPv4 network, use a standard IPv4 address format. For example, 192.1.2.34.

If the Plant SCADA system is using an IPv6 network, use a standard IPv6 address format (or any acceptable abbreviation). For example, 2001:0db8:0000:0000:0000:8a2e:0123:1234 or 2001:db8::8a2e:123:1234 (abbreviated).

**Device IP 1** and **Device IP 2** correspond to the INI parameters [\[Alarm\]IsolationDetectIP1](#) and [\[Alarm\]IsolationDetectIP2](#).

## See Also

[CPU Configuration](#)

[Run the Setup Wizard](#)

### CPU Configuration

The CPU Setup page of the Setup Wizard is used to assign client and server components to specific processors on a multi-processor computer.

The page includes a table that identifies each **Component** (and the cluster to which it belongs), its **Priority** and its **CPU** assignment.

- If the **Multi-process** option was selected on the Computer Role Setup page, you can select specific CPUs for the Client, I/O Server, Alarm Server, Trends Server and Reports Server processes.
- If the **Multi-process** option was not selected, there will only be one entry listed. It will either be “Client” or “Client and Servers”.

**To assign a CPU to a component:**

1. Select one or more components from the list (hold the **Ctrl** key down to select multiple components).
2. Click the **Modify** button.
3. Select the CPUs you want to assign to the component (you can select more than one) or select **<All CPUs>**.
4. Click **OK**.

When you complete the Setup Wizard, the CPU assignations are written to each component section in the INI file; for example:

```
...
[Alarm.Cluster1.AlarmServer1]
CPU=1
Clusters=Cluster1
...
[Trend.Cluster1.TrendServer1]
CPU=2
Clusters=Cluster1
...
```

If ALL is selected, the component sections in the INI file will be left empty and the processes will run on all CPUs.

In situations where ALL is selected, be aware that performance issues may still occur when your CPU usage is less than 100%. You can detect these issues when your CPU usage for a process is fixed at 100 divided by the number of processors.

---

**Note:** If a computer has more than 32 CPUs, the CPU Setup page in Setup Wizard will be disabled. The component sections in the INI file will be left empty and the processes will run on all CPUs.

---

## See Also

[Events Configuration](#)

[Run the Setup Wizard](#)

## Events Configuration

Events are used to trigger actions, such as a command or set of commands. For example, an operator can be notified when a process is complete, or a series of instructions can be executed when a process reaches a certain stage. Select the **Enable Events on this computer** check box if events are to be enabled on this Plant SCADA computer.

The Events Setup page lists each component's full name, including the cluster to which it belongs, alongside a list of events that can be enabled for each component. If the **Multi-process** option was not selected on the Computer Role Configuration page there will only be one entry listed, either Client or Client and Servers. If the **Multi-process** option was selected, you have the option of enabling events for each component on this computer.

---

**Note:**

- The Setup Wizard only displays named events from the selected project. If you are using events in included projects you will need to edit your ini file to add these under the [Events] section header.
- Events named 'Global' or events with no title will not appear as these are global events. These events will run on computers that have events enabled. These events will run in the client process.

**To enable an event for a component:**

1. Select the component from the list.
2. Select the events you want to enable for that component, or click **Enable All** or **Disable All**.
3. Click **Next** when finished.

When you complete the Profile Setup Wizard, the events are written to each component section in the ini file; for example:

```
...
[Alarm.Cluster1.AlarmServer1]
CPU=1
Clusters=Cluster1
Events=CSV_AlarmClient...
[Trend.Cluster1.TrendServer1]
CPU=2
Clusters=Cluster1
Events=CSV_TrendXClient,CSV_TrendXServer...
```

**See Also**

[Startup Functions Configuration](#)

[Run the Setup Wizard](#)

**Startup Functions Configuration**

The Startup Functions Setup page is used to define the Startup Cicode that is executed by each Plant SCADA process.

The Startup Functions Setup page lists each component's full name, including the cluster to which it belongs, the priorities of the components and the startup function assigned to each component. If the **Multi-process** option was not selected on the **Computer Role Configuration** page there will only be one entry listed, either Client or Client and Servers. If the Multi-process option was selected, you have the option of assigning startup functions for each component on this computer.

If the StartupCode parameter value for a process is invalid, the Plant SCADA Runtime Manager will simply ignore it on start up.

**To assign a startup function to a component:**

1. Select the component from the list. To select multiple components, hold down the Ctrl key as you select each item.
2. Click **Modify**.
3. Type the name of the Cicode function you want to call on startup for that component.
4. Click **OK**.

When you complete the Setup Wizard, the events are written to each component section in the ini file; for example:

```
...
[Alarm.Cluster1.AlarmServer1]
CPU=1
```

```
StartupCode=alarmServerStartup
...
[Trend.Cluster1.TrendServer1]
CPU=2
StartupCode=trendServerStartup
...
```

[Cluster Connections Configuration](#)

[Run the Setup Wizard](#)

### Cluster Connections Configuration

The Cluster Connections Setup page is used to specify the clusters that each component connects to on startup. This controls what data streams a component can see in the system.

The Cluster Connections Setup page lists each component's full name, including the cluster to which it belongs, the priorities of the components and the clusters assigned to each component. If the **Multi-process** option was not selected on the Computer Role Configuration page there will only be one entry listed, either Client or Client and Servers. If the **Multi-process** option was selected, you have the option of assigning clusters for each component on this computer.

By default, every component will connect to every cluster unless otherwise modified.

If the Clusters parameter value for a process is invalid, then the Plant SCADA Runtime will simply ignore it on startup.

#### To assign a cluster to a component:

1. Select the component from the list. To select multiple components, hold down the Ctrl key as you select each item.
2. Click **Modify**.
3. Select the clusters you want the component to connect to on startup.
4. Click **OK**.

When you complete the Setup Wizard, the clusters are written to each component section in the Citect.ini file; for example:

```
...
[Alarm.Cluster1.AlarmServer1]
CPU=1
Clusters=Sydney
...
[Trend.Cluster1.TrendServer1]
CPU=2
Clusters=Sydney,Tokyo
...
```

[Server Password Configuration](#)

[Run the Setup Wizard](#)

## Server Password Configuration

If networking is enabled, use this page to configure the server password. This password is used by computers to authenticate each other and create a trusted network between servers and, optionally, clients.

You can create a new password, or enter the password that is already used by other server computers in your Plant SCADA system.

If server processes do not have matching server passwords, they will not communicate with each other. Only trusted tran channels can handle remote requests initiated by [MsgRPC](#) or [ServerRPC](#) Cicode functions and CTAPI connections.

Configuring the password automatically sets the [\[Client\]PartOfTrustedNetwork](#) INI parameter.

---

**Note:** To configure the server password, you need to be a member of the **Configuration Users** security role. To read the server password you need to be a member of either the **Configuration Users** or the **Server Users** security role. You can be a member of these roles either directly or via an associated domain group (see [Security Roles](#)).

---

- **If a server process exists and networking has been enabled:**

The **Configure Server Password** check box is selected and unavailable.

Enter and confirm the password in the fields provided, before clicking **Next**.

If the **Password** and **Confirm Password** fields already contain an entry, it means a server password has already been configured on the local computer. If required, you can enter a new password.

- **If a client process exists and networking is enabled:**

The **Configure Server Password** check box is unchecked. To use the client computer as a CTAPI server, you need to configure the server password. Setting this password allows servers to authenticate each other and creates a trusted network between server computers.

Select **Configure Server Password** check box to enable the password fields.

Enter and confirm the password in the fields provided, before clicking **Next**.

If you change the server password while the runtime system is active, it will not disrupt any established connections as the password is only retrieved when authentication needs to occur. However, it is recommended that you apply the new password as soon as possible. To do this, you need to restart the runtime system.

If you are extending an existing system by adding computers that will run additional clusters and servers, you should determine what the existing server password is before you proceed. This will allow you to set the same server password on all existing and new servers.

[Control Menu Security Configuration](#)

[Run the Setup Wizard](#)

## Control Menu Security Configuration

The Plant SCADA window property options allow you to control an operator's access to system features.

This allows for flexibility with system security at run time.

Option	Description
Plant SCADA configuration environment on menu	Allows the operator to use the control menu (top left-hand icon) to access Plant SCADA Studio, Graphics Builder, and Cicode Editor from Plant SCADA at run time. Disabling this provides better security.
FullScreen	Allows the operator to set whether pages will be displayed in fullscreen or restored state. When checked "FullScreen" will set the ini parameter [Animator]FullScreen to 1. If "FullScreen" is set.
Show title bar	Allows the operator to set whether pages will be displayed in fullscreen mode with the title bar. The <a href="#">[Animator]FullScreen</a> ini parameter is set as follows: 0 if "Fullscreen" is unchecked; 1 if "Fullscreen" is checked and "Show title bar" is unchecked; 2 if both "Fullscreen" and "Show title bar" are checked. "Show title bar" cannot be modified if the option "Fullscreen" is unselected.
Shutdown on menu	Allows the operator to use the control menu (top-left icon) to shut down Plant SCADA at runtime. The shutdown is not password- or privilege-protected. Disabling this provides better security.
Kernel on menu	Allows the operator to use the control menu (top left icon) to display the Plant SCADA Kernel at run time. Disabling this provides better security.

[General Options Setup](#)

[Run the Setup Wizard](#)

### General Options Setup

Use the General Options Setup page to specify general options.

Option	Description
Data Directory	The directory where the Plant SCADA data files are located. The data files are the files that are generated at run time: trend files, disk PLC etc.
Backup project path	The backup directory that is used if a runtime database cannot be located (due to inoperative hardware or a file that has been moved, corrupted, or deleted).
Startup page	The Page Name of the graphics page to display when Plant SCADA starts up.
Page scan time	<p>The delay (in milliseconds) between updating a graphics page and starting the next communications cycle. The Page Scan Time sets the default for how often your graphics pages are updated. When a page is updated, relevant data (variable tags etc. represented on the graphics page) is scanned to determine if field conditions have changed. This setting is overridden by the Scan Time value specified in Page Properties (if applied).</p> <p>A value of 250 (the default value) indicates that Plant SCADA will try to update the page every 250 ms. However, if Plant SCADA cannot read the entire data from the I/O Device within 250 ms, the page is processed at a slower rate. For example, if it takes 800 ms to read the data from the relevant I/O Device, Plant SCADA processes the page every 800 ms.</p> <p>Under some conditions, you might want to slow the update of your pages to reduce the load on the I/O Servers. By reducing the page scan time, you allow more communication bandwidth to other Plant SCADA tasks or Clients. For example, you might want fast response on your main operator computers, while slowing the response time on manager computers. You can enter any value from 0 to 60000 (milliseconds).</p>
OPC Alarms and Events	<p>Click the <b>Register</b> button to register an alarm server as a runtime OPC AE server that supports the OPC AE interface specification. This will allow the alarm data to be accessed by third-party OPC client applications.</p> <p>The registration process requires administrative privileges.</p> <p><b>Note:</b> The OPC AE Server does not support DCOM for remote communications. It is recommended that you</p>

Option	Description
	run any connecting OPC client applications on the computer that is registered as the OPC AE Server.

[Run the Setup Wizard](#)

# Topology

Topology comprises physical computers, clusters, server processes and I/O devices. SCADA functions such as an alarm-related event or an I/O operation run on the computers. In addition, these functions are combined into a logical entity known as a cluster and added as an alarm server or an I/O server process to computers for ease of administration.

Multiple functions from multiple clusters may run on a single machine; however, the resources available on the computer govern the feasibility of running these functions on that computer. Therefore, multiple clusters may be associated with a single computer or a single cluster may need to be configured across multiple computers.

You can configure the computers in your SCADA system and organize the processes in clusters in the Topology activity of Plant SCADA Studio. You can view, add and edit configuration information for computers, clusters, server processes and I/O devices.

The Topology activity can also be used to create and manage [Profiles](#) that can be used when deploying your project.

---

**Note:** If you created a project in a version of Plant SCADA prior to version 2016, you need to run the Migration Tool to view the project's system topology in Plant SCADA Studio.

---

## Configuring a Topology

Configuring a topology involves the following steps:

1. Add [Add a Computer](#) and [Add Network Addresses](#). Each physical computer in your system needs to be identified with a unique name and IP address.

2. Add [Add a Cluster](#) to create groups within your runtime components. Each cluster needs to be defined with a unique name.
3. Add the required **server processes**. Each process server needs to be named, and assigned to a cluster and network address.
  - [Add an Alarm Server Process](#)
  - [Add a Report Server Process](#)
  - [Add a Trend Server Process](#)
  - [Add an I/O Server Process](#)
  - [Configure an OPC DA Server](#)
4. Configure [redundancy](#) if it is required.
5. Add the [I/O Devices](#) in production your system.

## See Also

[Computers](#)

[Clusters](#)

[I/O Devices](#)

[Profiles](#)

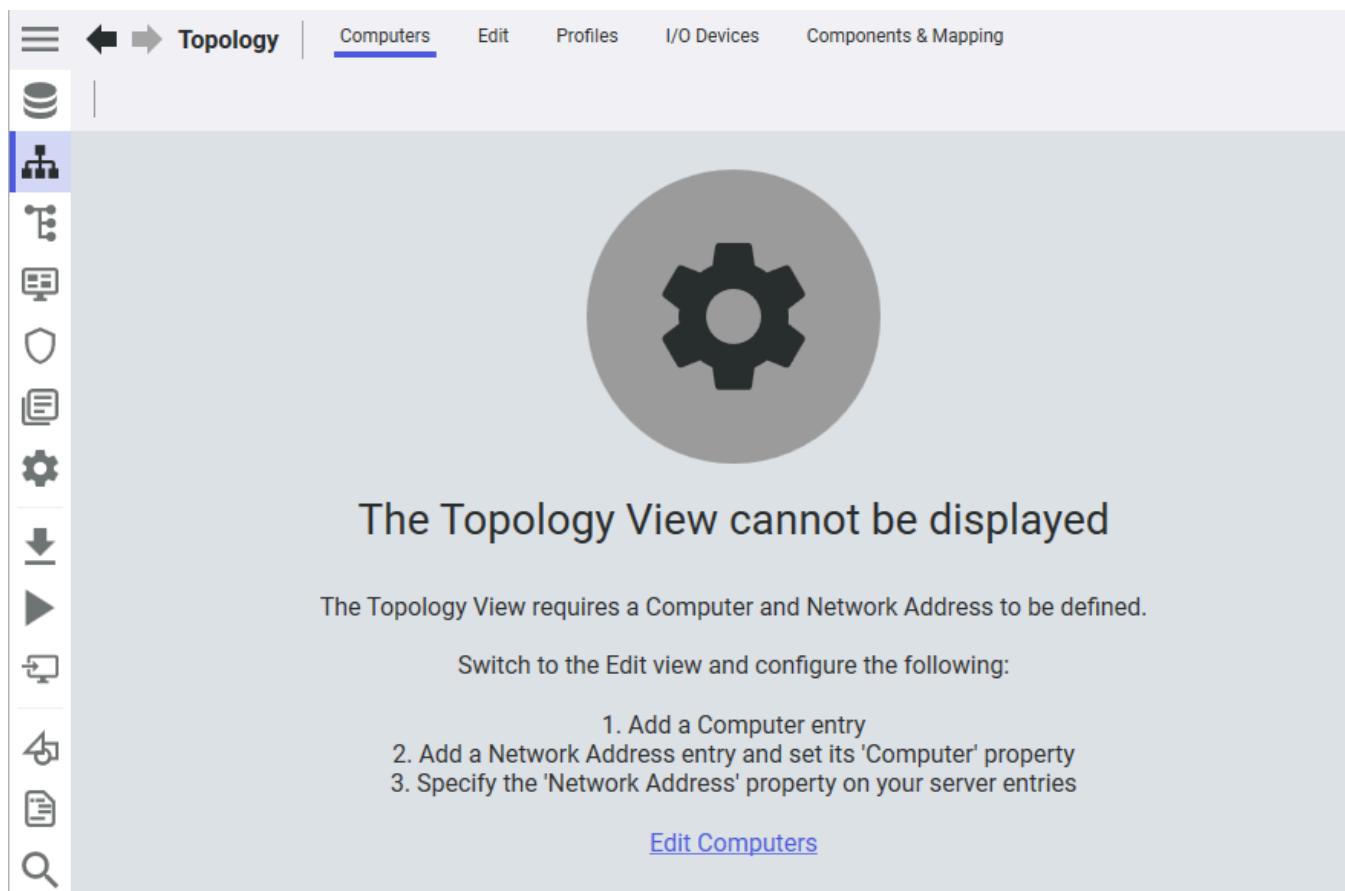

## Computers

The **Computers** view in the **Topology** activity presents the computers included in your Plant SCADA system and the server processes that run on them. Each server process need to be assigned to a computer and then run on that computer at runtime.

In the **Topology** activity you can:

- [Add a Computer](#) and configure computers
- Assign [Add Network Addresses](#) to computers
- Organize computers in [Clusters](#) for efficient management
- [View Computers](#) system topology organized by computers.

When you first launch Plant SCADA, the following information may appear in the **Computers** view.

This indicates that no computers have been configured in the current project. Follow the steps to [Add a Computer](#) (and the associated [Add Network Addresses](#)) to your topology.

When you create a project from a starter project, the computer on which the product is installed is added as the "LocalComputer" and shown in the Topology activity. It's assigned the IP address 127.0.0.1 by default.

## Add a Computer

### To add a computer:

1. In the **Topology** activity, select **Edit**.
2. On the menu below the Command Bar, select **Computers**.
3. Add a new row to the grid.
4. Type the required information in each column, or in the Property Grid (see below for a description of the properties).
5. Click **Save**.

## Computer Properties

### General Properties

Property	Description
Name	The name of the host computer on which SCADA components will be installed. The name needs to be unique.
Comment	This is a brief description of the computer.
DNS Name	<p>The Windows computer name (or localhost if you are running on a standalone computer), which is used for validating security certificates. If this is left blank, the system will use the value specified in the <b>Topology   Network Addresses   Address</b> property. If an IP address is specified for that property, a compiler error will be displayed.</p> <p>The DNS Name can only contain alphabetical characters (A-Z or a-z), numeric characters (0-9), the minus sign (-) or period (.). The name cannot start with a period.</p>

### Project Properties

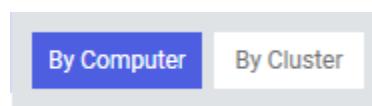

Property	Description
Project	Name of the project with which this computer is associated.

### See Also

[Add Network Addresses](#)

### View Computers

In the **Topology** activity, select **Computers**. Click **By Computer** to view your SCADA system's topology organized by the computers in the system. This view is used by default to display the topology of the selected project.

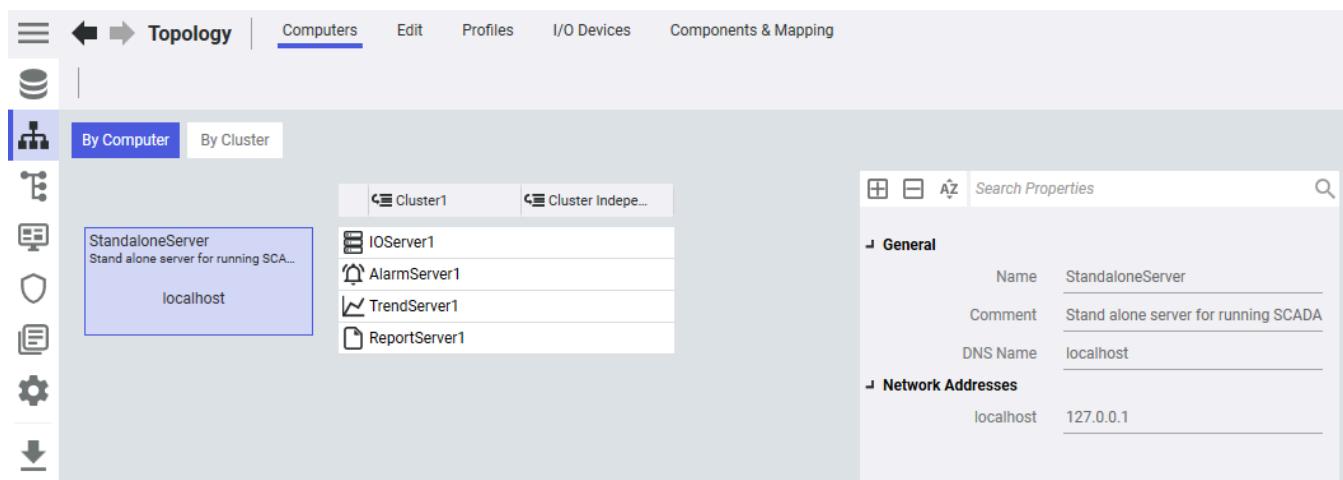

By Computer

By Cluster

---

**Note:** To access information describing the **By Cluster** view, see the topic [View Clusters](#).

In this view, computers configured in the selected project are listed with a description of each machine's clusters and the servers allocated to each cluster. The selected machine card is highlighted as shown below.

Within the machine card, the following information is displayed:

- The computer name
- A comment about the computer (if configured)
- The DNS name.

The Property Grid on the right displays the following properties for the selected computer:

- Name
- Comment
- DNS Name
- Network Addresses (assigned to this computer).

## See Also

[Add a Computer](#)

## Add Network Addresses

Network addresses are required for any computers in your Plant SCADA network that will run a server process.

**To configure a network address:**

1. In the **Topology** activity, select **Edit**.
2. On the menu below the Command Bar, select **Network Addresses**.
3. Add a new row to the grid.
4. Type the required information in each column, or in the Property Grid (see below for a description of the properties).
5. Click **Save**.

## Network Address Properties

### General Properties

Property	Description
<b>Name</b>	The name of the computer at the network address being configured. The name needs to be unique to the project and not contain spaces.
<b>Address</b>	<p>The IP address or name of the computer or network card being configured.</p> <p>In most cases, the IP address will use a standard IPv4 format. For example, 192.1.2.34.</p> <p>"Localhost" or a fully qualified domain name (the complete domain name for a computer) are not supported.</p> <p>If your Plant SCADA system is running on an IPv6 network, you will need to enter a 128 bit IPv6 address (or any acceptable abbreviation). For example, 2001:0db8:0000:0000:0000:8a2e:0123:1234 or 2001:db8::8a2e:123:1234 (abbreviated).</p> <p><b>Note:</b> A link-local IPv6 address should not have a zone index appended to the address. For example, from the IPv6 address "2001:db8::8a2e:123:1234%12" exclude the zone index "%12" and use "2001:db8::8a2e:123:1234" in the <b>Address</b> field.</p> <p>For computers with dual network cards, add a network address for each card in each computer with which you want to communicate. See <a href="#">Network Redundancy</a> for more information.</p> <p><b>Note:</b> If your computer has multiple network adapters configured in Windows that are connected to the same subnet, then we recommend you configure the address field with a computer name rather than an IP address.</p>
<b>Comment</b>	Any useful comment. This property is optional and is not used at runtime.
<b>Computer</b>	The computer with which the network address is associated.

### Project Properties

Property	Description
<b>Project</b>	Name of the project in which the network address is defined.

## Clusters

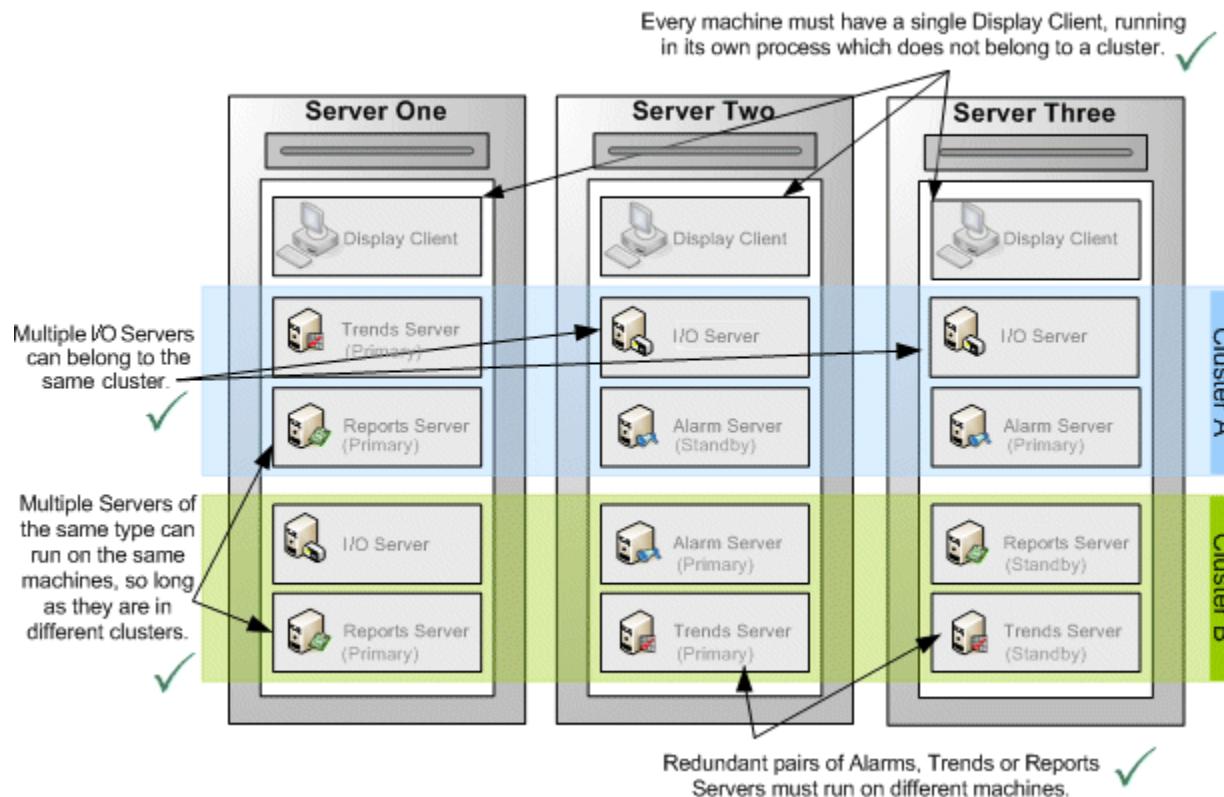

Clustering allows you to group different sets of the runtime components within a single project, allowing multiple independent systems to be monitored and controlled. Many Plant SCADA items require a cluster to be specified in order for them to work correctly.

There are countless variations in how a clustered system can be configured. An appropriate configuration will depend on the requirements for the solution to be deployed and the environment in which it is being deployed. For more information and examples, see [Typical System Scenarios](#).

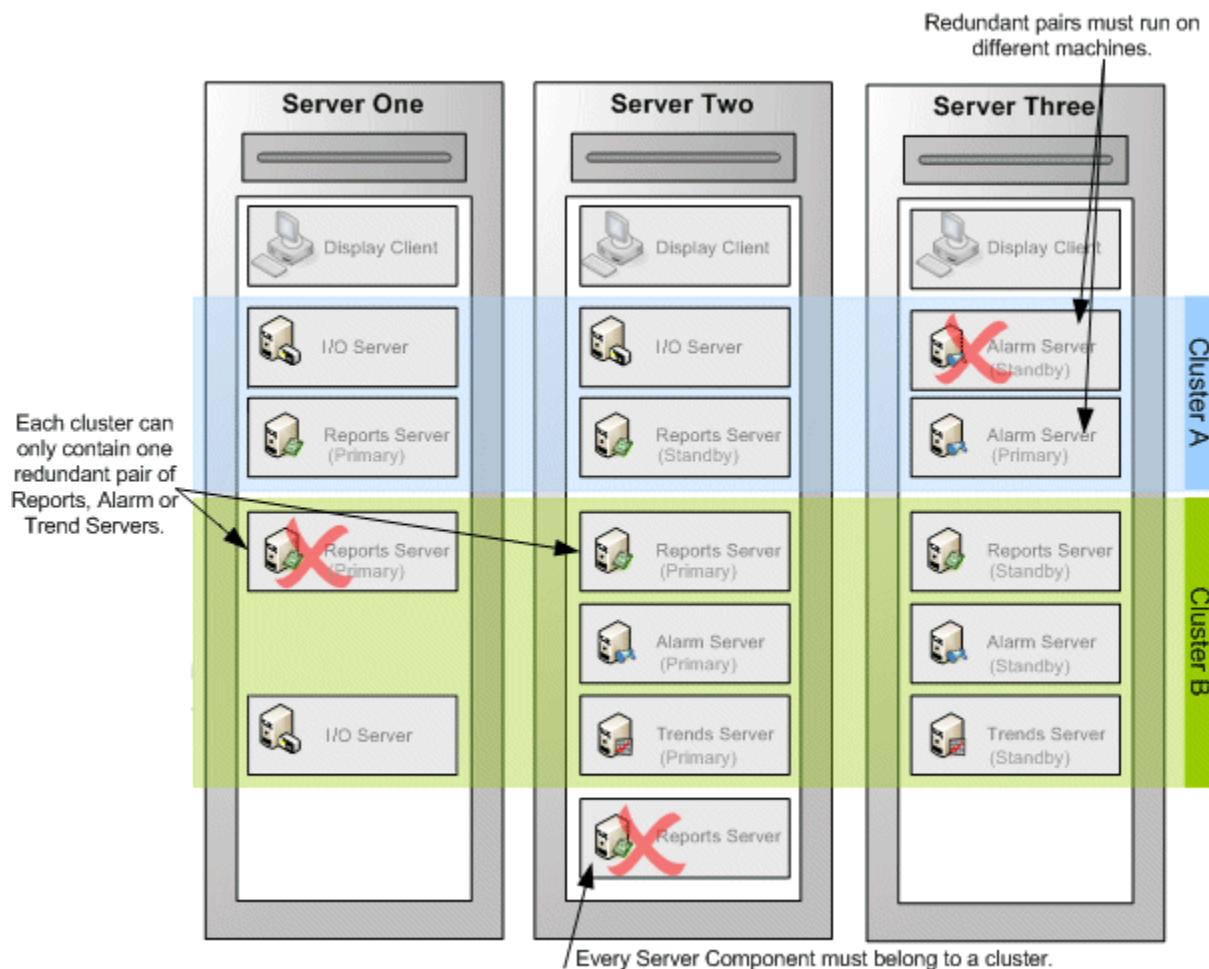

### Rules of Clustering

When configuring Plant SCADA the following clustering rules apply:

- Each cluster needs to have a unique name.
- Each server process needs to have a unique name.
- Each server process needs to belong to one cluster.
- Each cluster can contain only one pair of redundant alarm servers. They need to reside on different machines.
- Each cluster can contain only one pair of redundant reports servers. They need to reside on different machines.
- Each cluster can contain only one pair of redundant trends servers. They need to reside on different machines.
- Each cluster can contain an unlimited number of I/O servers.

The next diagram demonstrates circumstances where clustering is not configured correctly.

The Plant SCADA compiler or the [Runtime Manager](#) detects when the rules of clustering are not being observed and advises the user accordingly.

## Cluster Context

The Cluster Name can either be explicitly specified when the item is called or displayed, or an item can use the default cluster context of the calling process or page.

If your system has only one cluster, you do not need to specify a cluster. Plant SCADA will allow tags or tag references without a cluster context specified to be automatically resolved if every tag name in the project is unique.

This means if you use a unique naming convention for your tags, you will be able to configure a multi-clustered system without having to specify cluster context. For any tags that are not unique, #COM will be displayed if cluster context cannot be determined.

---

**Note:** This capability is enabled by default via the parameter [\[General\]TagDB](#).

---

## See Also

[Assigning Graphics Page Objects to a Cluster at Runtime](#)

## Add a Cluster

Clusters can be added in the Topology activity.

### To add a cluster:

1. In the **Topology** activity, select **Edit**.
2. From the drop down menu below the Command Bar, select **Clusters**.
3. Add a new row to the grid.
4. Type the required information in each column, or in the Property Grid (see below for a description of the properties).
5. Click **Save**.

## Cluster Properties

### General Properties

Property	Description
<b>Cluster Name</b>	The name of the cluster (maximum of 16 characters). The name needs to be unique to the project and not contain spaces. The fields are not case-sensitive and can contain 'A'..'Z', 'a'..'z', '0'..'9', and the underscore '_'. <b>Note:</b> When defining a cluster name, avoid using the <a href="#">Reserved Words</a> . If you use any of these, an error message will display when you compile your project.
<b>Comment</b>	Any useful comment. This property is optional and is not used at runtime.

### Project Properties

Property	Description
<b>Project</b>	The project in which the cluster is configured.

## See Also

[Clusters](#)

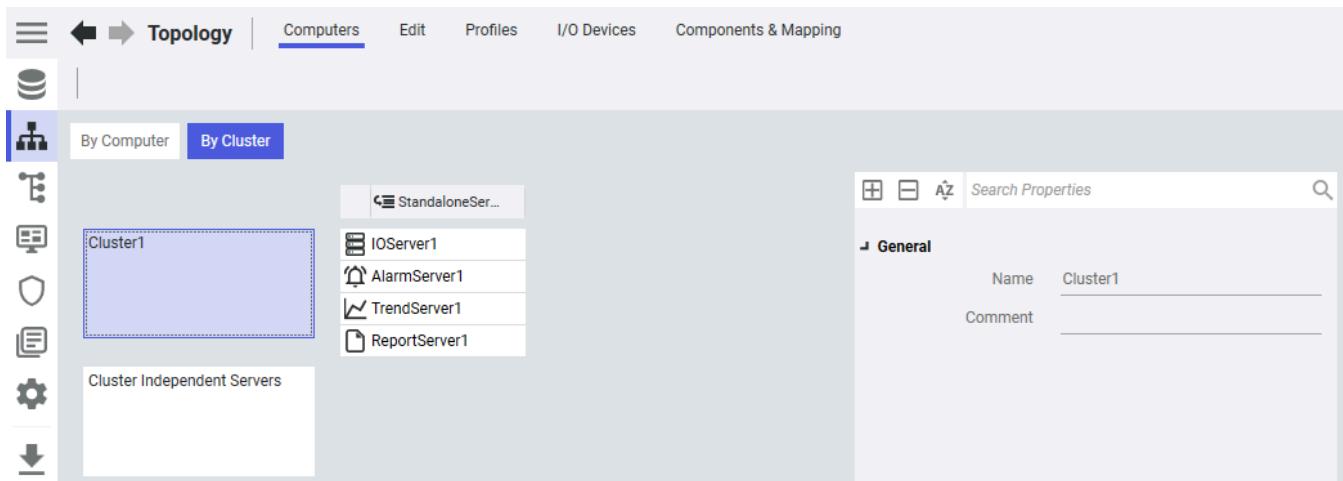

## View Clusters

In the **Topology** activity, select **Computers**. Click **By Cluster** to view your system's topology organized by clusters.

[By Computer](#)

[By Cluster](#)

The list of computers allocated to each cluster and the list of server processes (Alarm, Trend, Report, IO) installed on the computers in the cluster are displayed. The selected cluster card is displayed as shown below.

The selected cluster card displays the name of the cluster.

The Property Grid on the right displays the following information for the selected cluster:

- **Name**
- **Comment**

## See Also

[Add a Cluster](#)

## Assigning Graphics Page Objects to a Cluster at Runtime

Plant SCADA includes functionality that allows you to assign the objects on a graphics page to a specific cluster during Runtime.

If the tags on a page exist within a number of different clusters, you can use Cicode to pass a cluster name to the page as it opens. Any tags without a cluster explicitly defined will then be assigned to the specified cluster as the page is launched.

This provides a practical solution for a replicated system, where your project controls a number of identical sites or production lines. As the sites contain the same equipment, the tags representing the hardware architecture will potentially be the same for each. The ability to pass a cluster name to a page at runtime means just a single mimic page is necessary to represent multiple sites, reducing configuration time and simplifying project deployment.

**Note:** Plant SCADA will automatically resolve tags without a cluster context specified if every tag name in the project is unique. See [Clusters](#).

For example, a menu page could be created to launch the mimic page for three identical production lines, each based on the same page called "ProductionLine".

To achieve this, you would use the [PageDisplay](#) function to configure the following buttons on your menu page:

Button One	Text	<b>Production Line A</b>
	Command	PageDisplay("ProductionLine","Cluster_A")
	Comment	Display the mimic page in the context of production line A
Button Two	Text	<b>Production Line B</b>
	Command	PageDisplay("ProductionLine","Cluster_B")
	Comment	Display the mimic page in the context of production line B
Button Three	Text	<b>Production Line C</b>
	Command	PageDisplay("ProductionLine","Cluster_C")
	Comment	Display the mimic page in the context of production line C

In each case, PageDisplay would pass the name of the host cluster to the page, depending on which button is selected. As each production line shares a common architecture, any tags without a cluster explicitly defined will be assigned to the specified cluster as the page is opened.

This functionality is supported by the following Cicode functions:

- [PageDisplay](#)
- [PageGoto](#)
- [WinNew](#)
- [WinNewAt](#)
- [WinNewPinAt](#)

You can also use the [PageInfo](#) function to determine the cluster context that has been set for a page.

This functionality extends to any Cicode that may be called from a graphics page. You can write Cicode that only specifies variable tag names, allowing the cluster to be defined by the current context of the page from which it is launched.

If the Cicode is executed by the function [TaskNew](#), you have the option to specify a cluster by setting the *ClusterName* parameter.

---

**Note:** The cluster context for Cicode cannot be changed once the code is running.

---

## Server Processes

After you have configured computers, network addresses and clusters, you can add server processes and assign them to clusters and computers. Primary and standby alarms, reports, trends, and I/O server processes can be

added in Plant SCADA Studio's **Topology** activity.

## Default Ports

Each server process has a unique default port assigned to it. This default port may only be used with that type of server process. Attempting to use a default port on another type of server process will result in a compilation error message:

"Invalid port number (2080-2088,2073,3073,5482,20222 are reserved)."

The following table lists the default port numbers and their associated server process type.

Default Port	Server Process Type
2073	CtAPI  <b>Note:</b> Plant SCADA will open ports 2073 and 3073 when a CtAPI application is running. If the connection to a client is fully encrypted ("mixed mode" is not enabled), only port 3073 will be used. See <a href="#">Secure the Connection from a Remote CtAPI Application</a> .
2080	Alarm server.
2082	I/O server.
2084	Reports server.
2085	Trends server.
2087	System services process.
2088	Time synchronization port.
3073	CtAPI  <b>Note:</b> Plant SCADA will open ports 2073 and 3073 when a CtAPI application is running. If the connection to a client is fully encrypted ("mixed mode" is not enabled), only port 3073 will be used. See <a href="#">Secure the Connection from a Remote CtAPI Application</a> .
5482	Alarm server database port. This port is only used between the alarm server and its backend database on the same computer. It does not require external access.
20222	Required if Plant SCADA is configured to run as an ODBC server (see <a href="#">Using Plant SCADA as an ODBC Server</a> ).

**Note:** Ports 2074 - 2079 were reserved in earlier versions for legacy connections. These ports are no longer used.

For a list of the ports used by Plant SCADA runtime, see [Firewall Settings and Plant SCADA](#).

For details on adding and configuring server processes, refer to:

- [Add an Alarm Server Process](#)
- [Add a Report Server Process](#)
- [Add a Trend Server Process](#)
- [Add an I/O Server Process](#)
- [Configure an OPC DA Server](#)

## Add an Alarm Server Process

An alarm server process is responsible for evaluating the conditions that define an alarm (for more information, see [Alarm Server Process](#) in the section on Alarms).

Refer to the default server port numbers under [Server Processes](#).

---

**Note:** The Alarm server reuses the Alarm Properties port. As a result alarm properties are now published for configured alarm servers.

### To add an alarm server process:

1. In the **Topology** activity, select **Edit**.
2. From the drop down menu below the Command Bar, select **Alarm Server**.
3. Add a new row to the grid.
4. Type the required information in each column, or in the Property Grid (see below for a description of the properties).
5. Click **Save**.

## Alarm Server Properties

### General Properties

Property	Description
<b>Server Name</b>	The name of the server. The name needs to be unique to the project and any included projects, and not contain spaces.
<b>Mode</b>	The mode for this server, either Primary or Standby. If this property is left blank, the default value will be Primary.  The Primary and Standby servers need to run on different computers, and only one Primary and one Standby can be defined per cluster. Mode determines which server will be assigned the highest arbitration priority. The arbitration priority is used to work out which server will continue to be 'main' after a 'main-main' situation has occurred (see <a href="#">Alarm Server Side Synchronization</a> ).

Property	Description
<b>Cluster Name</b>	The name of the cluster to which this Alarm Server will belong. If there is only one cluster defined in the project, you can leave this field blank. The Alarm Server will default to the defined cluster
<b>Comment</b>	Any useful comment. This property is optional and is not used at runtime.

**Security Properties**

Property	Description
<b>Allow RPC</b>	Determines if the server process will execute remote <a href="#">MsgRPC</a> and <a href="#">ServerRPC</a> calls. Select <b>TRUE</b> or <b>FALSE</b> . If this field is left blank it will default to FALSE and the following compiler warning will be generated: "Allow RPC' permission is not defined for server (defaulting to FALSE) (W1038)".

**Communication Properties**

Property	Description
<b>Network Addresses</b>	The network address(es) of the server being configured. To specify dual network connections to the server, use a comma delimited list. See <a href="#">Network Redundancy</a> .
<b>Port</b>	The port this server will listen on. You can leave this field blank if you are running only one Alarm Server on the machine, in which case the default port number will be used.
<b>Database Port</b>	The port the server database will listen on. You can leave this field blank if you are running only one Alarm Server on the machine, in which case the default port number will be used.

**Other Properties**

Property	Description
<b>Extended Memory</b>	Determines whether the alarm server operates in Extended Memory mode (64-bit). Select TRUE to use Extended Memory Mode (see <a href="#">Alarm Server Process</a> ).
<b>Highest Priority Order</b>	Determines the order in which alarms are sorted. Select the required algorithm from the drop-down list.

Property	Description
	<p>If no algorithm is selected, the alarms will be listed according to "<b>Priority, Alarm State</b>" by default. For example:</p> <p>P1 Unacknowledged + Active  P1 Acknowledged + Active  P2 Unacknowledged + Active  P2 Unacknowledged + Inactive  P1 Shelved/disabled</p> <p>Select "<b>Alarm State, Priority</b>" to change the algorithm. The order of the example above would change to the following:</p> <p>P1 Unacknowledged + Active  P2 Unacknowledged + Active  P2 Unacknowledged + Inactive  P1 Acknowledged + Active  P1 Shelved/disabled</p> <p><b>Note:</b> Alarm servers across the system need to have the same algorithm selected. A compiler error will occur if they are different.</p> <p>If you want to create a customized sort order for alarms in a Situational Awareness project, you can use the parameter <a href="#">[Workspace]AlarmSortOrder</a>.</p>
<b>Archive Interval (Days)</b>	Schedules archiving to occur every ' number' of days. If set, archiving will occur automatically.
<b>Archive Path</b>	<p>Define where the archived data will be stored.</p> <p><b>Note:</b> The volume where data is to be saved should be labeled. This includes any removable storage devices. If this is not the case, archiving will not succeed and a message will display on the SOE page.</p>
<b>Archive Prefix</b>	Required prefix to the archive folder.

#### Project Properties

Property	Description
<b>Project</b>	The project in which the alarm server is configured.

## Add a Report Server Process

Note the default server port numbers under [Server Processes](#).

### To add a report server process:

1. In the **Topology** activity, select **Edit**.
2. On the menu below the Command Bar, select **Report Server**.
3. Add a new row to the grid.
4. Type the required information in each column, or in the Property Grid (see below for a description of the properties).
5. Click **Save**.

## Reports Server Properties

### General Properties

Property	Description
<b>Server Name</b>	The name of the server. The name needs to be unique to the project and not contain spaces.
<b>Mode</b>	The mode for this server, either Primary or Standby. If this property is left blank, the default value will be Primary. The Primary and Standby servers need to run on different computers, and only one Primary and one Standby can be defined per cluster.
<b>Cluster Name</b>	The name of the cluster to which this Reports Server will belong. If there is only one cluster defined in the project, you can leave this field blank. The Reports Server will default to the defined cluster
<b>Comment</b>	Any useful comment. This property is optional and is not used at runtime.

### Security Properties

Property	Description
<b>Allow RPC</b>	Determines if the server process will execute remote MsgRPC and <a href="#">ServerRPC</a> calls. Select <b>TRUE</b> or <b>FALSE</b> . If this field is left blank it will default to FALSE and the following compiler warning will be generated: "Allow RPC' permission is not defined for server (defaulting to FALSE) (W1038)".

### Communication Properties

Property	Description
<b>Network Addresses</b>	The network address(es) of the server being configured. To specify dual network connections to the server, use a comma delimited list. See <a href="#">Network Redundancy</a> .
<b>Port</b>	The port this server will listen on. You can leave this field blank if you are running only one Reports Server on the machine, in which case the default port number will be used.

**Project Properties**

Property	Description
<b>Project</b>	The project in which the report server is configured.

**See Also**[Add a Trend Server Process](#)

## Add a Trend Server Process

A Trend Server process controls the accumulation and logging of trend information. This information provides a current and historical view of the plant, and can be processed for display on a graphics page or printed in a report. Note the default server port numbers under [Server Processes](#).

**To add a trend server process:**

1. In the Topology activity, select **Edit**.
2. On the menu below the Command Bar, select **Trend Server**.
3. Add a new row to the grid.
4. Type the required information in each column, or in the Property Grid (see below for a description of the properties).
5. Click **Save**.

## Trend Server Properties

**General Properties**

Property	Description
<b>Server Name</b>	The name of the server. The name needs to be unique to the project and not contain spaces.
<b>Mode</b>	The mode for this server, either Primary or Standby. If this property is left blank, the default value will be

Property	Description
	Primary. The Primary and Standby servers need to run on different computers, and only one Primary and one Standby can be defined per cluster.
<b>Cluster Name</b>	The name of the cluster to which this Trends Server will belong. If there is only one cluster defined in the project, you can leave this field blank. The Trends Server will default to the defined cluster.
<b>Comment</b>	Any useful comment. This property is optional and is not used at runtime.

**Security Properties**

Property	Description
<b>Allow RPC</b>	Determines if the server process will execute remote <a href="#">MsgRPC</a> and <a href="#">ServerRPC</a> calls. Select <b>TRUE</b> or <b>FALSE</b> . If this field is left blank it will default to FALSE and the following compiler warning will be generated: "'Allow RPC' permission is not defined for server (defaulting to FALSE) (W1038)".

**Communication Properties**

Property	Description
<b>Network Addresses</b>	The network address(es) of the server being configured. To specify dual network connections to the server, use a comma delimited list. See <a href="#">Network Redundancy</a> .
<b>Port</b>	The port this server will listen on. You can leave this field blank if you are running only one Trends Server on the machine, in which case the default port number will be used.

**Project Properties**

Property	Description
<b>Project</b>	The project in which the trend server is configured.

**Add an I/O Server Process**

An I/O server process is a dedicated communications server that exchanges data between I/O devices and control clients. No data processing is performed by the I/O server (except for its local display) process.

Data is collected and passed to the control clients for display, or to another server for further processing. Data sent to an I/O device from any computer is also channeled through the I/O server. If data traffic is heavy, you can use several I/O servers to balance the load. The default server port numbers are listed in the topic [Server Processes](#).

**Note:** With the release of version 2020 R2, Plant SCADA now includes a Connectivity Service that manages tag subscriptions for the OPC UA Server and Industrial Graphics Server. This will place an additional load on your I/O servers, particularly if a subscribed tag also specifies a property or extension. The greater the number of I/O devices, the greater the processing load. If you have a large number of I/O servers on a single computer, it may impact CPU usage. To manage this, you should consider distributing your I/O servers across a number of computers.

### To add an I/O Server process:

1. In the **Topology** activity, select **Edit**.
2. On the menu below the Command Bar, select **I/O Server**.
3. Add a new row to the grid.
4. Type the required information in each column, or in the Property Grid (see below for a description of the properties).
5. Click **Save**.

## I/O Server Properties

### General Properties

Property	Description
<b>Server Name</b>	The name of the server. The name needs to be unique to the project and any included projects, and not contain spaces.
<b>Cluster Name</b>	The name of the cluster to which this I/O Server will belong. If there is only one cluster defined in the project, you can leave this field blank. The I/O Server will default to the defined cluster.
<b>Comment</b>	Any useful comment. This property is optional and is not used at runtime.

### Security Properties

Property	Description
<b>Allow RPC</b>	Determines if the server process will execute remote <a href="#">MsgRPC</a> and <a href="#">ServerRPC</a> calls. Select <b>TRUE</b> or <b>FALSE</b> . If this field is left blank it will default to FALSE and the following compiler warning will be generated: "'Allow RPC' permission is not defined for server"

Property	Description
	(defaulting to FALSE) (W1038)".

**Communication Properties**

Property	Description
<b>Network Addresses</b>	The network address(es) of the server being configured. To specify dual network connections to the server, use a comma delimited list. See <a href="#">Network Redundancy</a> .
<b>Port</b>	The port this server will listen on. You may leave this blank in which case the default port number will be used.

**Project Properties**

Property	Description
<b>Project</b>	The project in which the I/O server is configured.

[I/O Devices](#)

## I/O Devices

Plant SCADA can communicate with any control or monitoring I/O device that has a communication port or data exchange interface, including PLCs (programmable logic controllers), loop controllers, bar code readers, scientific analyzers, remote terminal units (RTUs), and distributed control systems (DCS).

In a Plant SCADA system, I/O device communications typically consists of four key parts:

### [Plant SCADA I/O Server](#)

The Plant SCADA computer that directly connects to an I/O device is an **I/O server**. I/O servers are responsible for servicing the read, write and subscription requests from clients. A project can have many I/O servers, with each cluster able to include multiple I/O servers.

An I/O server keeps up-to-date information on its connected I/O devices by regularly retrieving data from each and storing it in a cache (I/O device data cache). Whenever a Plant SCADA client requires data from an I/O

device, it will use the information stored in the I/O server cache. Clients will not retrieve data directly from an I/O device.

An I/O server will read the necessary data from the I/O device to execute a requested Cicode task or process. For example, when you schedule a report, Plant SCADA reads the I/O device data that the report might need before the first line of the report starts running.

Plant SCADA performs writes to the I/O device asynchronously, allowing other operations to continue while a write is taking place.

### I/O Device

Plant SCADA is predominantly a supervisory system. It is the I/O devices that directly monitor and control automation equipment. In most I/O devices (such as PLCs) a program stored in the I/O device controls the outputs. The logic (control strategy) of this stored program and the status of the inputs determine the value of each output.

The value of each input and output is stored in a separate memory register in the I/O device. Each memory register is referenced by its address. You usually don't need to read (or write) to every register in the I/O device: Plant SCADA lets you specify which inputs and outputs you want to monitor or control.

By reading and writing to memory registers in I/O devices, Plant SCADA collects data from your plant or factory for monitoring and analysis, and provides high-level (supervisory) control of your equipment and processes.

**Note:** I/O devices such as programmable logic controllers (PLCs) usually have an internal program that controls the low-level processes within your plant. A PLC program continually scans the input registers of the PLC, and sets the output registers to values determined by the PLC program logic. While Plant SCADA can replace any PLC program, this is not recommended. PLCs are designed for high-speed response (typically 1 to 100 ms) and replacing this functionality with Plant SCADA could negatively affect your control system's performance. Only use Plant SCADA to complement your PLC program (that is, for high level control and system monitoring).

### WARNING

#### UNINTENDED EQUIPMENT OPERATION

Do not use Plant SCADA or other SCADA software as a replacement for purchased control programs. SCADA software is not designed for direct, high-speed system control.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

### Transport Medium

The term 'transport' refers to both the physical communications medium and the low-level logic necessary to drive it. As far as Plant SCADA is concerned, it simply defines how to package a message, how to send it, and where to send it.

The available transport options are usually governed by the kind of ports available on the target I/O device. However, they are also influenced by the geography of the automation system, specific domain requirements (such as performance and redundancy), and the amount of money the owners are willing to invest.

The three main categories of available transport are:

- **Simple serial** – such as RS-232, RS-422, RS-485
- **Ethernet** – the dominant frame-based inter-network protocol
- **Proprietary** – using intermediary PC-communications hardware or software (such as OPC servers).

Of these, Ethernet is by far the transport technology of choice.

Fortunately, by using the concepts of packet encapsulation and intelligent gateway/routing devices, you are able to mix different transport layers and mediums, including high-speed wireless links or an FDDI network. For example, you could use a serial cable from Plant SCADA to a modem, a PSTN line from the modem to another modem, then a serial cable to an Ethernet gateway, and Ethernet to the I/O device.

---

**Note:** Modems are treated as a special case in Plant SCADA since they are recognized as logical devices by Windows. Refer to the specific online help on setting up modems.

---

Plant SCADA uses the ‘COMx’ driver to implement simple serial transports. Similarly, the ‘TCPIP’ driver implements the Ethernet transport. These are commonly used transport drivers, and both have a range of options and settings that can be tuned. Each proprietary board has its own specific transport driver – which is typically integrated with the protocol driver.

Similarly, the protocol-specific message could be a simple ASCII message or a complex object-based message such as DNP3. Engineers are free to assemble different combinations of I/O devices, transports, and protocols.

### Protocol

Protocol refers to the type of messages exchanged between the I/O server and I/O device.

I/O devices support at least one protocol – which governs the kind of commands and data you can exchange with the device. They vary significantly in functionality and in complexity. However, because Plant SCADA supplies the protocol drivers, the engineer does not need to know the details of the protocol.

Most modern devices support two or more protocols. This gives engineers flexibility in designing appropriate communications architectures. Occasionally the protocol is closely linked to the transport layer used – particularly in the case of proprietary protocols and communications hardware. In many cases, a specific card or module is necessary in the I/O device to support additional protocols.

### Industry Standard Protocols

The automation and associated industries have developed a number of standardized protocols for communicating with I/O devices:

- **ASCII** – for simple serial communications
- **Modbus** – a widely used simple serial protocol for automation
- **DNP 3.0** – a protocol for distributed networks such as RTUs
- **BACNet** – specifically for the building automation control industry
- **OPC** – a technology for sharing automation data at the PC level
- **IEC870-5** – communication profile for sending basic telecontrol messages
- **EIB** – European installation bus
- **Profibus** – field bus communications protocols for automation
- **SNMP** – widely used protocol for network devices.

As Plant SCADA allows you to choose whatever protocol you need for the situation, you can choose to use these protocols where supported by your I/O device. This is particularly useful when you have a mix of I/O device brands but you want to simplify and use one common protocol.

These components work in unison to expose the inputs and outputs of an I/O device to a Plant SCADA system.

- Inputs to the I/O device provide information about your plant, such as the speed of a machine, status of a conveyor, or the temperature of an oven.
- Outputs from the I/O device usually initiate tasks that control the operation of your plant, such as starting electric motors, varying their speed, or switching valves and indication lamps.

[Configure I/O Device Communications](#)

## Configure I/O Device Communications

Setting up communications between a device and a Plant SCADA I/O server typically involves the following steps:

### 1. Define an I/O server process.

This defines the name of the Plant SCADA server with which the I/O device will communicate. See [Add an I/O Server Process](#).

### 2. Define a board.

This defines which board on your I/O server computer to use (for example, the mother board, network card, serial board or a PLC communication card). See [Add a Board](#).

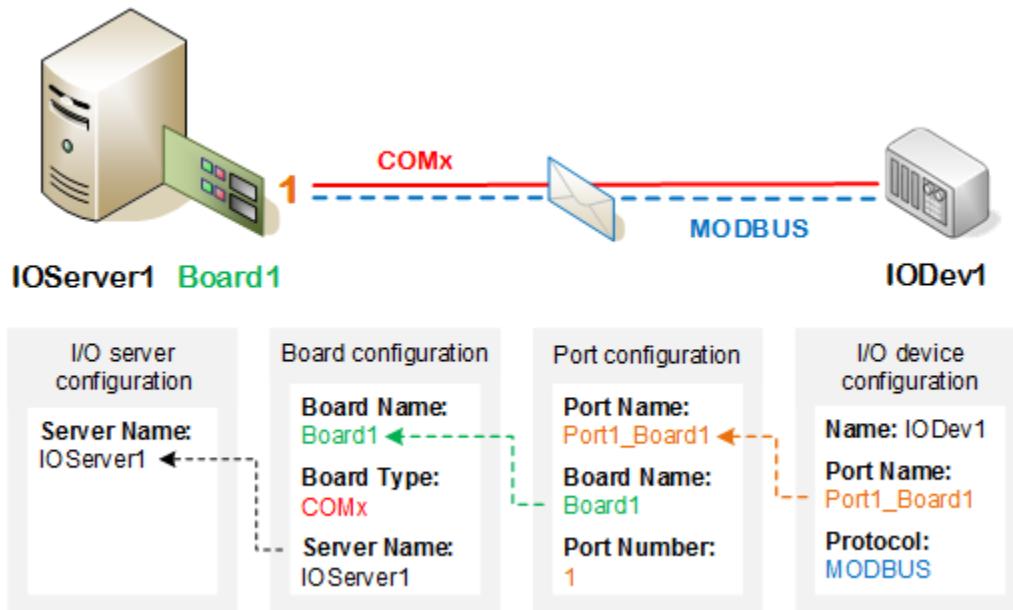

### 3. Define a port.

Often boards have multiple communication ports and you need to specify the port to use. Some equipment can have several logical (virtual) ports assigned to the one physical port. See [Add a Port](#).

### 4. Define the I/O device.

This defines the I/O device in Plant SCADA and specifies its address. The protocol is also defined at this level. See [Add an I/O Device](#).

The following diagram shows how the elements in the configuration environment map to the software components in the runtime system.

An I/O device driver is also required to implement the protocol and transport. Plant SCADA supports over 140 device drivers, enabling communication with a vast array of production devices across several communication types. These include generic drivers that support industry-standard protocols such as OPC and Modbus. Much of the functionality of the protocols and transports can be modified using the driver options and parameters. See [Working With Device Drivers](#).

A good place to start when setting up communications is with the [Using the Device Communications Wizard](#), a tool that automatically configures a default setup according to your specified requirements. Once you understand how the setup works, you can manually configure arrangements that are more complex.

**Note:** If there is no data to read or write, Plant SCADA will not communicate with an I/O device regardless of whether it is defined or not. You need to create a variable tag and use it before Plant SCADA will do a read request. For example, use an integer variable to display a number on a page.

## Add a Board

The properties of a board depend on the type of board installed in the I/O server computer. Common scenarios are:

- [Using a COM Port](#)
- [Using a Serial Board](#)
- [Using Ethernet](#)
- [Using a Proprietary Board](#).

You should confirm that the I/O server is enabled to support the necessary communications method. This may involve installing and configuring any communications hardware and/or software necessary for communications.

**Note:** The term "Board" is a legacy term from the time when ports on a computer were provided by additional boards. For example, an Ethernet card. The logical board concept is still useful even though a physical board may not exist (it may be software).

### To add a board:

- In the **Topology** activity, select **Components & Mapping**.
- On the menu below the Command Bar, select **Boards**.
- Add a row to the Grid Editor.
- Type the required information in each column, or in the Property Grid (see below for a description of the properties).  
For a description of the properties, see below.
- Click **Save**.

## Board Properties

### General Properties

Property	Description
<b>Server Name</b>	The name of the I/O server that hosts the board.
<b>Board Name</b>	A name for the board. 16 characters maximum. For example Server1_Board1. If you have more than one board in your I/O Server computer, the name of each board needs to be unique. If you have multiple I/O Servers, the board

Property	Description
	name need only be unique within each server. For example, Server1_Board2. The field is not case-sensitive.
<b>Board Type</b>	The type of board. 16 characters maximum. If you are using a serial board or your computer's COM port, enter COMx.
<b>Address</b>	The starting address of the Board. For example 0xCC00. 8 characters maximum. You need to specify the address to match the switch settings on the board when it was installed in your computer. If you are using a serial board or your computer's COM port, enter 0 as the address. <b>Note:</b> If more than one board is installed in the same computer, use a different memory address for each board.
<b>I/O Port</b>	The I/O port address of the Board. 8 characters maximum. You need to specify the address to match the switch settings on the board when it was installed in your computer. <b>Note:</b> If you are using your computer's COM port there is no need to enter the port address here. Specify the port number in the Ports form.
<b>Interrupt</b>	The interrupt number used by the Board. This is not necessary if using your computer's COM port.
<b>Special Opt</b>	Any special options supported by the board. 32 characters maximum. Please check the Hardware Arrangements Help Topic for your specific I/O Device to see if specific options are necessary.
<b>Comment</b>	Any useful comment. 48 characters maximum.

### Project Properties

Property	Description
<b>Project</b>	The project in which the board is configured.

### See Also

[Add a Port](#)

## Add a Port

The properties of a port depend on the type of board installed in the I/O server, and on the I/O device connected to the port.

### To add a port:

- In the **Topology** activity, select **Components & Mapping**.
- On the menu below the Command Bar, select **Ports**.
- Add a row to the Grid Editor.
- Type the required information in each column, or in the Property Grid (see below for a description of the properties).
- Click **Save**.

## Port Properties

### General Properties

Property	Description
<b>Server Name</b>	The name of the I/O server that hosts the board on which the port is located.
<b>Port Name</b>	A name for the port connected to your I/O Device(s). 31 characters maximum. Each port needs to have a unique name (i.e. you cannot assign the same Port Name to two ports in your system). You can use any name, for example, "Board1_Port1".  If you have more than one board in your computer, you can use the port name to identify the board, for example, "Board2_Port1".
<b>Port Number</b>	The port number that the I/O device is connected to. 4 characters maximum.  Avoid assigning the same Port Number to two ports on a board, unless connecting to a dial-up remote I/O device via a modem (see the note below). Ports on different boards can be assigned the same number.  If you are using your computer's COM port enter the port number here - the port number is defined in the Ports section of the Windows Control Panel.  <b>Note:</b> If you are connecting to a dial-up remote I/O Device (via a modem), you need to define a unique port name on the I/O server for each dial-up remote I/O device, and the port number needs to be -1 for each.

Property	Description
<b>Board Name</b>	The name you used for the board. 16 characters maximum. This is necessary to link the port to the board. For example "Server1_Board1".
<b>Baud Rate</b>	<p>The baud rate of the communication channel (between the Plant SCADA I/O Server and the I/O Device). 16 characters maximum.</p> <p><b>Note:</b> The I/O device hardware and serial board may support other baud rates. If you do choose an alternative baud rate, verify that both the I/O Device and serial board support the new baud rate.</p>
<b>Data Bits</b>	The number of data bits used in data transmission. You need to set your I/O Device to the same value or a communication link cannot be established.
<b>Stop Bits</b>	The number of stop bits used to signify the completion of the communication. You need to set your I/O Device to the same value.
<b>Parity</b>	The data parity used in data transmission.
<b>Special Opt</b>	Any special options supported by the port. 32 characters maximum. Please check the Hardware Setup Help Topic for your specific I/O Device to see if specific options are necessary.
<b>Comment</b>	Any useful comment. 48 characters maximum.

### Project Properties

Property	Description
Project	The project in which the port is configured.

## See Also

[Add a Board](#)

### Add an I/O Device

To manually add an I/O device to a project, you need to specify its properties using the **Topology** activity. The properties depend on both the I/O device and protocol.

You should verify your system meets the hardware and software requirements needed to establish communication between a device and Plant SCADA.

This may include a variety of possibilities, including:

- the installation of a proprietary communications card
- the establishment of a device server
- the installation of configuration software.

The **Driver Reference Help** provides the hardware and software requirements for each device, and includes any additional information you need to know about setting up specific devices.

**Note:** You can use the Device Communications Wizard to add an I/O device to your project. This will automatically configure many of the property settings described in this topic.

#### To add an I/O device:

- In the **Topology** activity, select **I/O Devices**.
- Add a row to the Grid Editor.
- Type the required information in each column, or in the Property Grid (see below for a description of the properties).
- Click **Save**.

## I/O Device Properties

### General Properties

Property	Description
<b>Server Name</b>	The name of the I/O server to which the I/O device is connected.
<b>Name</b>	The name for the I/O device (31 characters maximum).  The name needs to be unique in the Plant SCADA system, unless the I/O device is defined in other I/O servers (to provide redundancy). If redundancy is used, the I/O device needs to then have the same I/O device number and address for each I/O Server. use different I/O device names for your primary and standby I/O devices, otherwise I/O device Cicode functions cannot differentiate between them.
<b>Number</b>	A unique number for the I/O device (0-16383).  The number needs to be unique in the Plant SCADA system, unless the I/O device is defined in other I/O servers (to provide redundancy). If redundancy is used, the I/O device needs to then have the same I/O device number and address on each redundant I/O server. You may use the same device name, but if you want to use I/O device Cicode functions, it is easier to have different I/O device names.
<b>Address</b>	The address of the I/O device (64 characters)

Property	Description
	<p>maximum).</p> <p>The format of the address you enter in this field is determined by the type of I/O device (and protocol) used, as each has a different addressing strategy.</p>
<b>Protocol</b>	<p>The protocol used to communicate to the I/O device (16 characters maximum).</p> <p>Many I/O devices support multiple protocols, dependent on the communication method chosen.</p>
<b>Port Name</b>	<p>The port on the board to which the I/O device is connected (31 characters maximum).</p> <p>This is necessary to link the I/O device to the port. For example Board1_Port1.</p> <p><b>Note:</b> There is a limit of 255 COMx ports on a server. To avoid this limitation restricting the number of remote I/O devices you use, you can connect multiple remote I/O devices to the same port as long as communication details (telephone number, baud rate, data bits, stop bits and parity) are identical.</p>
<b>Startup Mode</b>	<p>The type of I/O device redundancy used. The options are:</p> <ul style="list-style-type: none"> <li>• Primary — Enable immediate use of this communications channel. This is the default mode if no mode is specified.</li> <li>• Standby — This channel will remain unused until the I/O device configured with the primary channel becomes inoperative.</li> <li>• StandbyWrite — This channel will remain unused until the I/O device configured with the primary channel becomes inoperative. Write requests sent to the primary channel are also sent to this channel.</li> </ul> <p>To use Standby or StandbyWrite modes, you need to also configure a primary I/O device with the same I/O device name, number and address.</p> <p><b>Note:</b> Avoid using StandbyWrite mode for scheduled I/O devices because there is the possibility that the Standby I/O device write queue will not be cleaned up. When writing to a scheduled I/O device which it is not communicating, write requests are queued up until communication resumes.</p>

Property	Description
	<p>In case of using I/O device redundancy and StandbyWrite mode, Primary and Standby I/O devices have their own queues of pending write requests. If I/O device communication is controlled automatically by the communication schedule, then both queues are flushed when the schedule dial-time occurs.</p> <p>Where manual communication is controlled by the <a href="#">IODeviceControl</a> Cicode function, only the Primary I/O device write queue is flushed and the Standby I/O device write queue will not be cleaned up.</p>
<b>Priority</b>	<p>Specifies the order standby devices are promoted in if a primary I/O device becomes inoperative during runtime (8 characters maximum).</p> <p>If there is more than one standby I/O device configured for a cluster, you can use this field to give precedence to a particular standby device. If this field is left blank, priority will be automatically allocated to the device during project compilation, based on the priority settings of other standby devices and/or the order in which the devices were configured.</p> <p>See <a href="#">I/O Device Promotion</a>.</p>
<b>Memory</b>	<p>Specifies whether the I/O device runs in Memory mode. The default value is FALSE.</p> <p>If you select TRUE, the I/O device will be created in memory and its values stored in memory at runtime. This may be useful if you are testing your system, before connecting physical I/O devices, as memory mode stops Plant SCADA from communicating with physical I/O devices. See <a href="#">Using Memory Mode</a>.</p> <p><b>Note:</b> If a device is configured with <b>Memory</b> set to TRUE, the <b>Port Name</b> and <b>Address</b> fields can be left blank as they will not be used by the compiler or the I/O server at runtime.</p>
<b>Read-Only</b>	<p>Specify whether the I/O device is read-only. The default value is FALSE.</p> <p>If you select TRUE, any attempt to write to a tag associated with the I/O device will be unsuccessful.</p>
<b>Exclusive</b>	<p>This setting controls the way in which redundant I/O device(s) configured with the same network number on different I/O servers activate communications to the physical device they represent.</p>

Property	Description
	<p>When Exclusive is set to TRUE, only one I/O device (on one I/O server) will activate communications to the physical device at a time. The best available I/O device (online with the lowest priority) at a particular time will be chosen to actively communicate. When this I/O device is no longer the best available, it will deactivate, which will in turn trigger the best available I/O device on another server to activate.</p> <p>When Exclusive is set to FALSE (default), the best available I/O device will typically be the only active I/O device; however this may not be enforced. When a different I/O device becomes the best it will activate immediately, without waiting for the other I/O device to deactivate. An I/O device that is not the best may also be forced into actively communicating with the physical device if a particular client can only communicate with the I/O server that I/O device is running on.</p> <p><b>Note:</b> The parameter <a href="#">[IOServer]PeerServerConnectTimeOut</a> has been implemented so that on startup of an I/O server, all I/O devices with Exclusive set to TRUE will not be allowed to activate before the I/O server has successfully connected to its peers. This parameter defines how long an I/O server will wait until it ceases trying to connect to peer I/O servers.</p>
Comment	Any useful comment. This field is optional and is not used at runtime.

**Note:** For the **Number**, **Protocol** and **Port** properties, the same network number is used for redundancy (as stated above), however this implies that the protocol is usually the same (though there maybe some special circumstances where devices support multiple protocols) and the Port modes are similar. i.e. a real world port reference, DISKDRV or MEMORY . If DISKDRV is being used, then redundant units (i.e. the same NUMBER) needs to be DISKDRV. This also applies for MEMORY mode.

#### External Properties

Property	Description
Linked	<p>Select TRUE or FALSE to specify whether or not the I/O device is linked to an external data source (see <a href="#">Link Tags to an External Data Source</a>).</p> <p>If you link to an external data source, Plant SCADA is updated with any changes made to the external data source when a refresh is performed (see <a href="#">Refresh the Tags for a Linked I/O Device</a>).</p>

Property	Description
	<p>If you disconnect an existing link, you can choose to make a local copy of the tags in the database or you can delete them from Plant SCADA's variable tags database altogether.</p> <p>If an I/O device is linked to an external data source the Database Type, External Database, Connection String, Tag Prefix and Live Update fields will be greyed out.</p>
<b>Database Type</b>	<p>The format of the data referenced by the external data source.</p>
<b>External Database</b>	<p>The path and file name of the external data source for the I/O device.</p> <p>If the <b>Linked</b> property is set to TRUE (and a <b>Database Type</b> has been specified), you can use the <b>Browse</b> button next to this field in the Property Grid to select and validate a database.</p> <p>Alternatively, you can enter the IP address/directory, computer name, or the URL of a data server. For example:</p> <ul style="list-style-type: none"> <li>• "C:\Work.CSV"</li> <li>• "127.0.0.1"</li> <li>• "139.2.4.41\HMI_SCADA"</li> <li>• "http://www.abicom.com.au/main/scada"</li> <li>• "\coms\data\scada".</li> </ul>
<b>Connection String</b>	<p>Enter a connection string to provide connection details for the data source. This is similar to an ODBC connection string. For example:</p> <p>UserID = XXX; Password = YYY</p> <p>or</p> <p>ServerNode=111.2.3.44; Branch=XXX</p> <p>Not every data source needs a connection string.</p>
<b>Tag Prefix</b>	<p>The prefix that will be inserted in front of the names of linked tags in Plant SCADA's variable tags database (for this I/O device only). To change the prefix, delete it first, perform a manual refresh, then add the new prefix.</p>
<b>Automatic Refresh</b>	<p>Determines whether the linked tags in Plant SCADA's variable tags database will be updated when the external data source is changed.</p>

Property	Description
	<p>This refresh will occur the first time you link to the data source, and then whenever you compile your project.</p> <p>Without an automatic refresh, you will need to perform a manual refresh to update the linked tags in Plant SCADA (see <a href="#">Refresh the Tags for a Linked I/O Device</a>).</p>
<b>Live Updating</b>	<p>Controls whether or not the linked tags in Plant SCADA and an external tag database will be synchronized if either database is changed. To enable live linking, choose Yes from the Live Update menu.</p> <p>When Live Update is enabled and the variable tag database is accessed (for example, during project compilation or when a drop-down list is populated), Plant SCADA queries the external tag database to determine if it has been modified. If so, Plant SCADA merges the changes into the local variable tag database. Conversely, any changes made to the local tag variable database will be incorporated automatically into the external tag database.</p>

### Logging Properties

Property	Description
<b>Log Write</b>	<p>Enables/disables the logging of writes to the I/O device. When enabled, writes are logged to the SYSLOG.DAT file in the <b>Logs</b> folder of the Plant SCADA <b>User and Data</b> folder selected during installation, also specified in the INI file as <a href="#">[CtEdit]Logs</a>.</p> <p>See <a href="#">Tag Functions</a> for information about <a href="#">TagWriteEventQue</a> and logging tag data.</p> <p><b>Note:</b> Logging writes to every I/O Device may slow communications as the Plant SCADA system will be writing large amounts of data to disk. However, logging of writes is useful when debugging a system.</p>
<b>Log Read</b>	<p>Enables/disables the logging of reads from the I/O device. When enabled, reads are logged in the Plant SCADA SYSLOG.DAT file.</p> <p><b>Note:</b> Logging reads to every I/O device may slow communications as the Plant SCADA system will be writing large amounts of data to disk. However, logging of reads is useful when debugging a system.</p>

### Cache Properties

Property	Description
<b>Cache</b>	<p>Enables/disables data caching. When enabled, a cache of the I/O device's memory is retained at the I/O server, thus improving communications turn-around time.</p> <p><b>Note:</b> Data caching has to be enabled for scheduled I/O devices, but disabled for memory or disk I/O devices.</p>
<b>Cache Time</b>	<p>The cache time specified in milliseconds. When caching is enabled, data that is read from a I/O device is stored temporarily in the memory of the I/O server. If another request is made (from the same or another client) for the same data within the cache time, the Plant SCADA I/O server returns the value in its memory - rather than read the I/O device a second time. Data caching results in faster overall response when the same data is needed by many clients.</p> <p>A cache time of 300 milliseconds is recommended.</p> <p>The Cache Time for a scheduled I/O device is automatically calculated. You can view a scheduled I/O device's cache time using the Kernel Page Unit command.</p>

#### Update Properties

Property	Description
<b>Background Poll</b>	<p>Specifies that tags for a particular device are continuously polled at a minimum background poll rate. The options are True or False. Set this field to True if you are operating on a slow network, with a slow device, or where tags may normally only be polled infrequently.</p> <p><b>Note:</b> This setting does not apply to drivers that use the Driver Runtime Interface (DRI), as a DRI driver controls updates to the I/O server. DRI-based devices should leave this set to FALSE.</p> <p>For a list of DRI drivers, see <a href="#">Retrieving Time-stamped Data from I/O Devices</a>.</p>
<b>Background Rate</b>	<p>When Background Poll is set to True, specifies the minimum rate by which the device will be polled. You may select any predefined value from the drop-down list, or enter your own in the format of HH:MM:SS.</p> <p>If a value is not entered, the default value of 30 seconds will be used.</p>

Property	Description
	<p><b>Note:</b> This setting does not apply to drivers that use the Driver Runtime Interface (DRI). If you are using a DRI-based device, you should not change this setting.</p> <p>For a list of DRI drivers, see <a href="#">Retrieving Time-stamped Data from I/O Devices</a>.</p>
<b>Min Update Rate</b>	<p>The DataSource will send tag update value notifications to subscription clients after a pre-defined period of time expires. You may select any predefined value from the drop-down list, or enter your own in the format of HH:MM:SS.</p> <p>If a value is not entered, the default value of 0 seconds will be used and no update value notifications will be sent.</p>
<b>Staleness Period</b>	<p>Staleness period represents total number of seconds that will elapse after the last update before extended quality of the tag element is set to "Stale". You may select any predefined value from the drop-down list, or enter your own in the format of HH:MM:SS. If a value is not entered, the default value of 0 seconds will be used and tag elements will not be set to "Stale".</p> <p><b>Note:</b> For further information on Minimum Update Rate and Staleness Period refer to <a href="#">Tag Data Persistence</a>.</p>

### Scheduling Properties

Property	Description
<b>Scheduled</b>	<p>Determines whether the I/O device is configured for scheduled communications. This is normally set using the Device Communications Wizard.</p> <p><b>Note:</b> If a schedule for a dial-up remote I/O device is not specified, the connection will be established at startup and will remain connected until shut-down.</p> <p>See <a href="#">Scheduled Communications</a>.</p>
<b>Time</b>	<p>The I/O server will attempt to communicate with the I/O device at this time, and then at intervals as defined below. This time is merely a marker for Plant SCADA. If you run up your project after this time, the I/O server will not wait until the next day to begin communicating. It will operate as if your project had been running since before the start time.</p>

Property	Description
<b>Period</b>	<p>The time between successive communication attempts. The period needs to be long relative to the driver's watchtime and the <a href="#">[Dial]WatchTime</a>. If necessary, decrease these watchtimes or increase Period to make Period more than double the watchtimes.</p> <p>Examples (based on a Synchronize at time of 10:00:00):</p> <ul style="list-style-type: none"> <li>• If you enter 12:00:00 in the Repeat every field, and start your project at 9 a.m., the I/O Server will communicate with the I/O Device at 10 a.m., then once every 12 hours after that, i.e. 10 p.m., then again at 10 a.m. of the following day, etc.</li> <li>• If you enter 12:00:00, and start your project at 4 p.m., the I/O Server will communicate with the I/O Server at 10 p.m., then again at 10 a.m. of the following day, and so on. The I/O Server will assume that communications were established at 10 a.m., so it continues as if they had been - communicating once every 12 hours after 10 a.m.</li> <li>• If you enter 3 days, and start your project at 9 a.m. on a Wednesday, the I/O Server will communicate with the I/O Device at 10 a.m., then once every 3 days after that, i.e. 10 a.m. on the following Saturday, then at 10 a.m. on the following Tuesday, etc.</li> <li>• If you enter the 6th of December in the Repeat every, and start your project during November, the I/O Server will communicate with the I/O Device at 10 a.m. on December 6, then again on December 6 of the following year, etc.</li> </ul> <p>Select On Startup for a persistent connection. To disconnect a persistent connection, you need to call the <a href="#">IODeviceControl()</a> function with type 8.</p>
<b>Connect Action</b>	Cicode to be executed once communication with the I/O device has been established (and before any read or write requests are processed).
<b>Disconnect Action</b>	Cicode to be executed once communication with the I/O device has been terminated (and after read and write requests are processed).
<b>Phone Number</b>	The telephone number that needs to be dialed to

Property	Description
	initiate contact with the I/O device. (i.e. for dial-up remote I/O Devices)

**Storage Properties**

Property	Description
<b>Persist</b>	Set to TRUE or FALSE to indicate if the persistence of the tag cache file is on or off. Default is TRUE and the data will be written to the XML file as described in "File Name" below. If one of the primary/standby I/O devices (identified by the same network number) has persistence set to FALSE, then every device has it turned off.
<b>Persist Period</b>	Indicates how often to persist the XML cache file to disk. Default is 10 minutes (00:10:00). Normally, the period used is the highest value specified for one of the primary/standby I/O devices (identified by the same network number).
<b>File Name</b>	Indicates the path to the file on disk where the XML cache will be stored. You can specify just the path or the path with the actual file name. The default is Data directory using the format:  <ClusterName>.<IOServerName><ClusterName>.<IODeviceName>.cache.  If the location cannot be created, then either the default path, default file name or both is used. Normally, the path used is the first non-empty path specified for one of the primary/standby I/O devices (identified by the same network number).  Be aware that you will need to manually configure the access control list for a new folder location so that it matches the permissions that were applied to the default location during installation. See <a href="#">Configure Directory Security for Modified Folder Locations</a> .

**Project Properties**

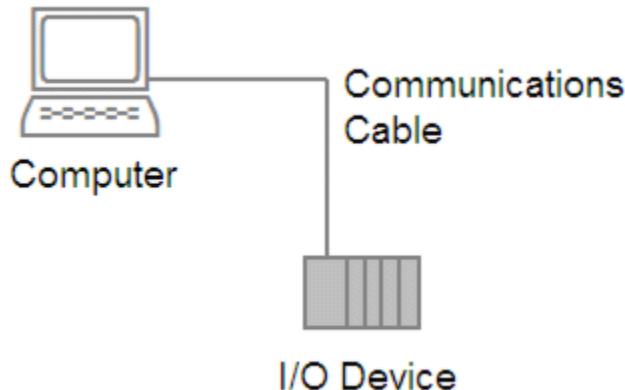

Property	Description
<b>Project</b>	The project in which the I/O device is configured.

**See Also**

[Add a Board](#)

## Using a COM Port

The simplest Plant SCADA systems use a single computer connected to the I/O device(s). You can connect an I/O device directly to a communications port with a standard RS-232 communications cable.

### To set up Plant SCADA to use your computer's COM port:

1. Verify that the **Boards** configuration has **COMx** as the **Type**, and the **Address** set to 0. The **I/O Port**, **Interrupt** and **Special Opt** can be left blank.
2. Enter the **Port Number** in the **Ports** configuration. The COM port number will usually be either 1 or 2, and is set in the Ports section of the Control Panel.

Use the **Special Opt** field to modify the behavior of the COMx driver (see [COMx Driver Special Options Reference](#) for more information).

**Note:** You only need to define the COMx board once. You can then add several ports that use the same Plant SCADA board. For example, a COM port and two serial boards could be defined as one COMx board in Plant SCADA, with multiple ports.

## See Also

[Debugging a COMx Driver](#)

[Using a Serial Board](#)

## COMx Driver Special Options Reference

**Special Options** (in the **Ports** grid) are space separated and start with the dash character (-) immediately followed by the option characters. Only a small percentage of users will need to use the following options:

Special Option Character	Description
<code>--cATS0=1</code>	Send the string 'ATS0=1<CR>' on startup to allow the modem to detect the baud rate the port is running at. Abandon transmit if DCD is low. Wait for incoming call to raise DCD.
<code>--d</code>	Data will be transmitted only when DSR is high.

Special Option Character	Description
—di	Received data is ignored when DSR is low.
—dMS	When transmitting a message the driver will wait up to 2000 ms for DSR to go high, then wait another MS milliseconds before transmitting.
—e	<p>Provides access to the output signal lines. The format is "~EIAWXYZ" where WXYZ represents one of the following options:</p> <ul style="list-style-type: none"> <li>S Simulate XOFF received</li> <li>S Simulate XON received</li> <li>RT Set RTS high</li> <li>RT Set RTS low</li> <li>D Set DTR high</li> <li>D Set DTR low</li> <li>B Set the device break line</li> <li>B Clear the device break line</li> </ul> <p>Example: "~EIADTR1" sets DTR high.</p>
—h	Data will be transmitted only when CTS is high.
—hMS	When transmitting a message the driver will wait up to 2000 ms for CTS to go high, then wait another MS milliseconds before transmitting.
—i	<p>The string sent whenever the port is initialized. The tilde (~) and '\M' characters represent special instructions:</p> <ul style="list-style-type: none"> <li>~: Delay for 500 milliseconds</li> <li>\M: Send carriage return</li> </ul> <p>Examples:</p> <ul style="list-style-type: none"> <li>~Fred: Wait 500 milliseconds and then send 'Fred'</li> <li>Fred\MMary: Send 'Fred', a carriage return, and then 'Mary'</li> </ul> <p><b>Note:</b> This option is not available for dialable devices (i.e. when the port number is -1).</p>
—nt	With some serial interfaces, line interruptions can cause the COMx read thread to shutdown. If this happens, the driver does not recover after the interruption. However, with the -nt (no terminate) option set, the thread is not shutdown, allowing the system to recover when the interruption is rectified.

Special Option Character	Description
—nts	If error messages occur when the COMx driver is starting up, it will not terminate, but will continue attempts to open the COMx port.
—r	Driver will raise DTR only when transmitting.
—ri	DTR is raised when there is enough room in the input buffer to receive incoming characters and drop DTR when there is not enough room in the input buffer.
—rPRE,POST	When transmitting a message the driver will raise DTR for PRE milliseconds, transmit message, wait for POST milliseconds then drop DTR.
—sc	Activates software flow control using XON and XOFF. XonLim: A number in bytes. This represents the level reached in the input buffer before the XON character is sent (30 bytes). XoffLim: The maximum number of bytes accepted in the input buffer before the XOFF character is sent. This is calculated by subtracting (in bytes) 100 from the size of the input buffer.
—t	Driver will raise RTS only when transmitting.
—ti	RTS is raised when there is enough room in the input buffer to receive incoming characters and drop RTS when there is not enough room in the input buffer.
—to	RTS is raised only when there are characters to transmit.
—tPRE,POST	When transmitting a message the driver will raise RTS for PRE milliseconds, transmit message, wait for POST milliseconds then drop RTS.

## Using a Serial Board

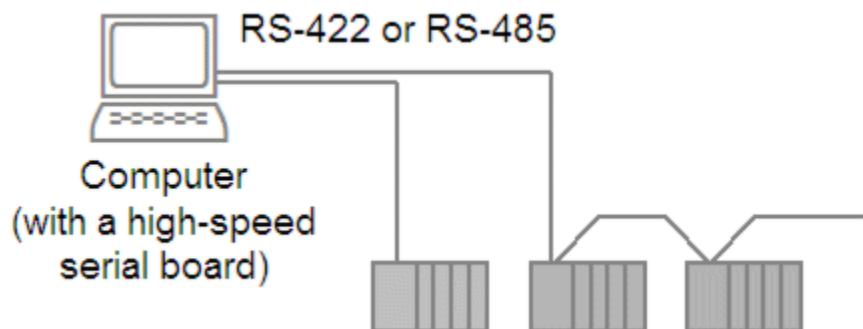

The communications port on the computer is not designed for high-speed communications and reduces system performance. Instead, install a high-speed serial board. High-speed serial boards have several ports (usually 4, 8,

or 16) to let you connect several I/O devices to your Plant SCADA system.

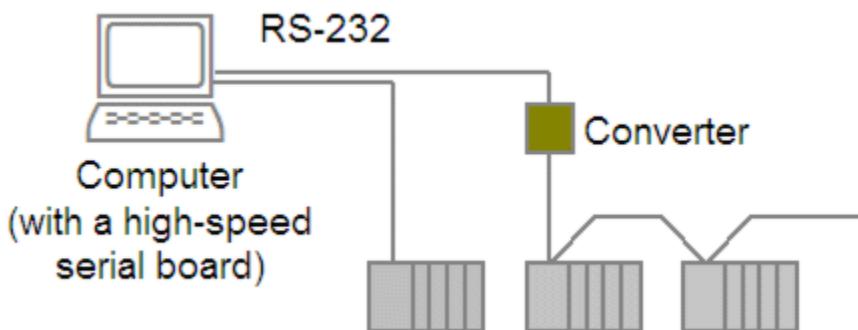

You can use identical I/O devices or I/O devices supplied by different manufacturers; Plant SCADA supports many popular I/O devices. You can connect any number of I/O devices; the only limitation is the size of your computer. High-speed serial boards are available for RS-232, RS-422, or RS-485 communication.

If you have several I/O devices from the same manufacturer and these I/O devices support multi-drop communication, you can connect them to an RS-422 or RS-485 high-speed serial board installed in your computer. (The RS-232 standard does not support multi-drop communication.)

Not every high-speed serial board supports RS-422. You can use an RS-232/RS-422 or RS-232/RS-485 converter to achieve the same arrangement.

**Note:** Using a converter can introduce handshaking/timing considerations.

#### To set up Plant SCADA to use a serial board:

1. Install the board in your computer and set it up under Windows as per the accompanying instructions. Use the latest driver from the board manufacturer.

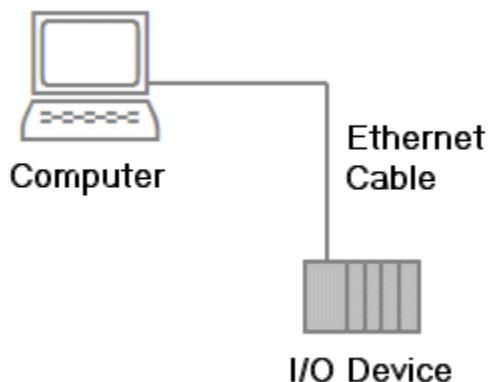

2. Check that the boards configuration has COMx as the Type, and the Address set to 0. The **I/O Port, Interrupt**, and **Special Opt** can be left blank.
3. Enter the **Port Number** in the Ports configuration. The COM port number is usually greater than 2 and set in the **Ports** section of the Control Panel. Use the **Special Options** field to modify the behavior of the COMx driver. (See [COMx Driver Special Options Reference](#) for more information).

**Note:**

- If using your computer's COM port, you don't need to install additional software.
- You only need to define the COMx board once. You can then add several ports that use the same Plant SCADA board. For example, a COM port and two serial boards could be defined as one COMx board in Plant SCADA, with multiple ports.

**See Also**[Add a Board](#)[Using a Proprietary Board](#)**Using Ethernet**

Ethernet is a popular method of communicating with a number of I/O Devices at high speed. It is certainly one of the easiest to configure. You can typically connect to Ethernet capable I/O Devices using a standard Ethernet card, or integrated Ethernet port.

**To set up Plant SCADA to use your computer's Ethernet card:**

1. Confirm that your Ethernet card is installed correctly and working under Windows.
2. Check that the **Boards** configuration has TCP/IP as the **Type**, and the **Address** set to 0. The **I/O Port, Interrupt** and **Special Opt** can be left blank.
3. In the **Ports** form, use the **Special Opt** field to enter the destination IP address using the following format:

**-la -Pn -T**

Where:

**a** = the destination IP address in standard Internet dot format. (For example 192.9.2.60)

**n** = the destination Port number. Often one physical port has several virtual ports, used for different purposes. Use this option only if you want to override the default of 2222.

**T** = forces the driver to use TCP (the default), rather than UDP (-U).

(See [TCP/IP Driver Special Options Reference](#) for more information)

Leave other fields blank. You can now define your I/O Device units.

**Note:** You only need to define the TCP/IP board once. You can then add several ports that use the same Plant SCADA board.

## See Also

[Using a Serial Board](#)

### TCP/IP Driver Special Options Reference

Special Options (in the properties for a port) are space separated and start with the dash character (—) immediately followed by the option characters. You can use the following special options for TCP/IP:

Special option character	Description
—A	Allows the TCPIP driver to be used from Cicode.
—la.b.c.d	Defines remote IP address to connect to.
—K	Sets socket SO_KEEPALIVE flag.
—Lla.b.c.d	Defines local IP address.
—LPn	Defines local PORT.
—Ma.b.c.d	Defines multicast IP address. IP address joins a multicast group listening for UDP multicast packets. For the parameter to work configure the -LP local port switch, so the driver selects the correct port on the multicast IP to listen on. This option can be set using the [TCPIP]PortName.MulticastAddress parameter. See <a href="#">Debugging a TCP/IP Driver</a> .
—Pn	Defines remote PORT to connect to.
—RC	Activates the reconnection retries on reception of FD_CLOSE event. FD_CLOSE is only received if the Keepalive option is activated. -RC can be useful where the TCP/IP driver is notified of the connection close. For a more comprehensive handling, the -k option is needed.
—T	Sets this port for TCP (stream) operation.
—U	Sets this port for UDP (datagram) operation.

Where:

**a.b.c.d** = standard IP address in dot notation using decimal numbers 0- 255. (Avoid using a leading 0 when adding an IP address).

**n** = decimal value for the port ID for the necessary service.

[Using a Serial Board](#)

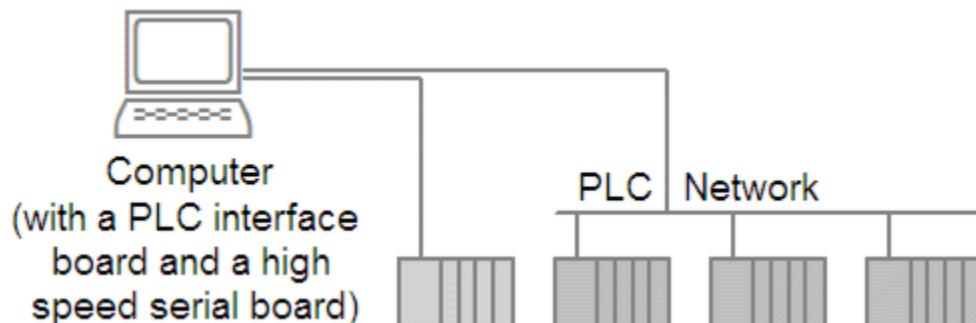

## Using a Proprietary Board

With some brands of I/O devices you can install a proprietary interface board in your computer, or intermediary software. This PLC interface board/software is supplied by the PLC manufacturer; you can connect it to a single PLC or a PLC network.

**Note:** With some PLCs, a high-speed serial board provides better performance than a PLC interface board when the system is connected to more than one PLC.

You can mix both PLC interface boards and high-speed serial boards in a single computer. You can, for example, connect a PLC network to a PLC interface board, and individual I/O Devices to a high-speed serial board.

There are many possible hardware arrangements for a Plant SCADA application. Plant SCADA is a flexible system and imposes few restraints on the type (or manufacturer) of I/O Devices that you can use, or on the way you connect them to the computer.

### To set up Plant SCADA to use a proprietary board/software:

If you are using a proprietary board/software (that is, supplied by the PLC manufacturer):

1. Install the board/software in your computer and set it up under Windows as per the accompanying

instructions. Use the latest driver from the manufacturer.

2. If possible, run diagnostics on the board before configuring Plant SCADA to check that the board works correctly.
3. Check that the **I/O Port** and **Interrupt** settings are correct.
4. Configure the **Boards** and **Ports** as instructed by the PLC-specific help.

## Working With Device Drivers

The word ‘driver’ is often used when referring to communications. A driver is a component piece of software that implements a protocol or transport (or both). Drivers are modular, such that new drivers can be easily ‘plugged-in’ to existing systems.

Drivers enable Plant SCADA to communicate with the devices in your system. Every communication setup in Plant SCADA needs drivers to implement the protocol and transport. Often this means two separate drivers, but in some cases both are combined into one driver – termed a ‘board’ driver.

Plant SCADA has over 140 device drivers available, enabling communication with a vast array of production devices across several communication types. These include generic drivers that support industry-standard protocols such as OPC and Modbus.

The driver you will need to communicate with a particular device is determined by:

- the device itself
- the communication protocol the device supports
- the communication channel used to connect the device to the Plant SCADA I/O server.

To add a particular device to your Plant SCADA project, you will need to determine the driver necessary to support it. If the particular driver is not installed with your current version of Plant SCADA, you will have to obtain a driver pack and install it separately.

---

**Note:** With the release of Plant SCADA 2020 R2, a classification system for the driver portfolio was introduced to indicate the level of ongoing maintenance that customers can reasonably expect for each driver. In line with these classifications, the number of drivers included by default with the Plant SCADA installation media has been reduced to a set of ‘core’ drivers that have undergone recent updates. All other drivers continue to be available for download from the [Communication Drivers](#) page at the [AVEVA Knowledge and Support Center](#).

## See Also

[Determining Which Driver to Use](#)

[Installing a Driver Pack](#)

## Determining Which Driver to Use

To connect a device to Plant SCADA, you will initially need to determine which driver is necessary to support

communication with the I/O Server. In most cases, you can use one of the following methods:

- a native driver, engineered specifically for the device
- a generic driver, available for devices that support industry-standard protocols such as Modbus or DNP
- an OPC Server, with communication taking place via a third-party application.

Initially check if a native driver is available. To do this, go to the **Supported Devices** page in the **Driver Reference Help** and locate the device you are trying to connect to. The list is sorted alphabetically by manufacturer name.

If the device is not included on the list, consider the communication capabilities of the device to determine if it supports any industry-standard protocols, such as Modbus, DNP, COMLI or SNMP. If this is the case, you may be able to use one of the generic Plant SCADA drivers that support these standards.

Similarly, you can use OPC to connect a device to Plant SCADA, however this will require the purchase of a third party application to establish an OPC Server. If you take this approach, use an OPC Server application recommended by the manufacturer of the device you are trying to connect.

If these options do not provide an appropriate solution, you can contact Technical Support for this product.

---

**Note:** Check the **Communication Drivers** page at the [AVEVA Knowledge and Support Center](#) for information about driver updates and new driver pack releases.

---

## See Also

[Installing a Driver Pack](#)

### Installing a Driver Pack

In some cases, a required driver may not be included among those available on the Plant SCADA installer. This may occur if a driver is new, has been recently updated, or is not included with the installer due to its ongoing maintenance classification. If this is the case, you will need to obtain a Driver Pack and install it separately.

---

**Note:** Check the **Communication Drivers** page at the [AVEVA Knowledge and Support Center](#) for information about driver updates and new driver pack releases.

---

You need to install a driver pack on the computer that will connect to the target device. This computer needs to be configured as a Plant SCADA I/O server. It needs to be also be installed on any machines where the Plant SCADA project is compiled.

Before installing the driver pack, close your Plant SCADA runtime environment and Plant SCADA Studio. You need administrator permissions for the I/O server PC.

#### To install a driver pack:

1. Save the driver pack to an appropriate location on the I/O Server PC.
2. Double-click the EXE file to launch the installation.
3. Follow the instructions provided by the installation Wizard.
4. You are prompted to select the Plant SCADA installation folder. If you installed Plant SCADA in a different folder to the default, browse to that location. An alert message will alert you if you have selected the wrong folder.
5. Click **Finish** to complete the installation.

After you have installed a Driver Pack, the associated help will be automatically merged into the Driver Reference Help.

---

**Note:** If you are installing a driver pack on an older version of Plant SCADA that precedes the initial release of the driver, the supporting help may not appear automatically in the Driver Reference Help. If this is the case, you can locate the driver help in the Plant SCADA bin directory. The help file will be named <drivername>.chm.

---

## See Also

[The Driver Reference Help](#)

### The Driver Reference Help

Each driver, whether it is installed with Plant SCADA or as part of a driver pack, is supported by the **Driver Reference Help**.

#### To open the Driver Reference Help:

1. In the **Topology** activity, select **I/O Devices**.
2. On the Command Bar, click **Driver Reference Help**.

This is where you will find the specific reference information related to each driver. This information includes:

- The device(s) each driver supports
- The address used to identify and locate a device
- Any necessary device setup information
- The information necessary to configure a device in your Plant SCADA project
- The data types each driver supports
- Parameters you can use to customize a driver
- Driver-specific error messages.

You will need much of this information to establish communication with a device; some of it is more suited to advanced engineering tasks and troubleshooting.

If you familiarize yourself with the processes explained in [Configure I/O Device Communications](#), you will be instructed on how to use this information to configure devices within a Plant SCADA project.

## Using the Device Communications Wizard

You use the Device Communications Wizard to set up communications for a new I/O Device.

Based on your selections, the Device Communications Wizard provides default values and a setup tailored to your I/O device communications requirements.

#### To access the Device Communications Wizard:

1. In the **Topology** activity, select **I/O Devices**.
2. On the Command Bar, click **New Device**. The Device Communications Wizard is displayed.
3. Complete each page of the Wizard as required.

---

**Note:** Each combination of I/O device and protocol requires a unique configuration of **Boards**, **Ports**, and **I/O Device** settings. See the [The Driver Reference Help](#) for the required settings.

---

[Device Communications Wizard - Introduction](#)

### Device Communications Wizard - Introduction

You will be asked to select an I/O Server, choose a name, and indicate the type of I/O Device(External, Memory, Disk).

From the list of available manufacturers you choose the manufacturer, model and communications method for the I/O device. If you are connecting external devices or using a proprietary board in your computer, you may be requested to nominate addresses and a communications port.

After completing your setup, the Summary Page summarizes the configuration of your I/O Device and/or internal boards. Click **Finish** to save the listed configuration, or click **Back** to change a previous selection.

## See Also

[Device Communications Wizard - Server Selection](#)

### Device Communications Wizard - Server Selection

Select **Use an existing I/O Server** (as defined in the current project), or **Create a new I/O Server**.

When you create a new I/O server, Plant SCADA automatically suggests the name **IOServer**. You can enter a different name if you want. The name you specify needs to be 16 characters or less. The fields are not case-sensitive and can contain alphanumeric characters (A-Z, a-z, 0-9). You can also use the underscore character ( \_ ).

---

**Note:** If you add a new I/O server, you will need to run the Setup Wizard on the designated computer before you attempt to run the project. This is necessary to enable the computer to function as an I/O server.

---

## See Also

[Device Communications Wizard - Device Selection](#)

### Device Communications Wizard - Device Selection

Enter the name of the new I/O device that you want to create, or accept the name **IODev** which Plant SCADA automatically suggests.

## See Also

## Device Communications Wizard - I/O Device Communications Selection

From the list of available manufacturers, select the manufacturer, model, and communications method specific to the I/O device.

If a memory or disk I/O device has been selected, the Plant SCADA Generic Protocol is included at the top of the tree.

## See Also

[Device Communications Wizard - TCP/IP Address](#)

## Device Communications Wizard - TCP/IP Address

This page allows you to enter the IP address for an I/O device that uses TCP/IP protocol. This address is set on (or specified by) the I/O device.

In most cases, you will use a standard IPv4 address. For example, 192.1.2.34.

If you have selected a device that uses IPv6, you will need to enter a 128 bit address (or any acceptable abbreviation). For example, 2001:0db8:0000:0000:8a2e:0123:1234 or 2001:db8::8a2e:123:1234 (abbreviated).

The **Port** and **Use Protocol** (TCP or UDP) fields will be set to the default values for the I/O device. Change these fields only if necessary.

For details about addressing your specific I/O device, browse the [The Driver Reference Help](#).

## See Also

[Device Communications Wizard - I/O Device Address](#)

## Device Communications Wizard - I/O Device Address

Enter the address for the I/O device. What you enter in this field is determined by the type of I/O device (and protocol) used, as each has a different addressing strategy.

For details about addressing your specific I/O device, refer to the information in the [The Driver Reference Help](#) for your I/O device.

## See Also

[Device Communications Wizard - I/O Device Connection Schedule](#)

## Device Communications Wizard - I/O Device Connection Schedule

The Device Communications Wizard allows you to define the details of the communications schedule for your I/O device and indicate that your I/O device is remote by checking the PSTN box.

Options	Description
<b>Connect I/O Device to PSTN</b>	<p>Check this box to indicate that the I/O device is a dial-up I/O device (connected to a PSTN - Public Switched Telephone Network).</p> <p><b>Note:</b> Even if your I/O device is not connected via a modem, you need to still check this box to schedule communications (but leave the Phone number to dial and Caller ID fields blank).</p> <p>Once you have completed your I/O device setup using this Wizard, you need to go to the Ports form and change the Port number to the actual number of the COM port.</p> <p>You can choose to define the communication period in terms of <b>months, weeks, days, or hours, minutes, and seconds</b>. Alternatively, you can choose to communicate only at <b>startup</b> (persistent connection). Click a radio button to make your selection, then enter the start time and period as described below.</p>
<b>Synchronize at</b>	<p>The I/O Server will attempt to communicate with the I/O device at this time, and then at intervals as defined below. This time is merely a marker for Plant SCADA. If you run up your project after this time, the I/O Server won't wait until the next day to begin communicating. It will operate as if your project had been running since before the start time.</p>
<b>Repeat Every</b>	<p>The time between successive communication attempts. (See Examples below.)</p>

Options	Description
<b>Phone number to dial</b>	The telephone number that needs to be dialed to initiate contact with the I/O device.

**Note:** These values can also be set using the I/O devices view in the Topology activity.

## Examples

Examples are based on a **Synchronize at** time of 10:00:00:

- If you enter 12:00:00 in the **Repeat every** field, and start your project at 9 a.m., the I/O Server will communicate with the I/O device at 10 a.m., then once every 12 hours after that, i.e. 10 p.m., then again at 10 a.m. of the following day, etc.
- If you enter 12:00:00 in the **Repeat every** field, and start your project at 4 p.m., the I/O Server will communicate with the I/O Server at 10 p.m., then again at 10 a.m. of the following day, etc. It will assume that communications were established at 10 a.m., so it continue as if they had been - communicating once every 12 hours after 10 a.m.
- If you enter 3 days in the **Repeat Every**, and start your project at 9 a.m. on a Wednesday, the I/O Server will communicate with the I/O device at 10 a.m., then once every 3 days after that, i.e. 10 a.m. on the following Saturday, then at 10 a.m. on the following Tuesday, etc.
- If you enter the 6th of December in the **Repeat every**, and start your project during November, the I/O Server will communicate with the I/O device at 10 a.m. on December 6, then again on December 6 of the following year, etc.
- Select **On Startup** for a persistent connection. To disconnect a persistent connection, you need to call the [IODeviceControl\(\)](#) function with type 8.

[Device Communications Wizard - Caller ID and Commands](#)

[Device Communications Wizard - Link to External Database](#)

### Device Communications Wizard - Caller ID and Commands

A **Caller ID** is a unique identifier which identifies a remote I/O device when it dials back to the I/O server. The caller ID can be any combination of alpha-numeric characters and/or the character '\_' (underscore).

This ID will only be used if the I/O device initiates the call to the I/O server. If the modem initiates the call, you need to set the caller ID on the modem.

**Note:** If you are multi-dropping off a single modem, use your I/O devices to issue the caller ID, not the modem. This is because using the modem to issue the ID will send the same ID no matter which I/O device the call is relevant to, which makes it difficult to identify the I/O device that triggered the call.

By using the I/O device to issue the ID, the I/O server will receive a unique caller ID for each I/O device. However, not every I/O device is capable of issuing caller IDs. If you are multi-dropping, use I/O devices that can issue caller IDs.

Option	Description
[Event Commands] On connect	Cicode to be executed once the modem is connected and the I/O Device has come online (that is, before any read or write requests are processed).
[Event Commands] On disconnect	Cicode to be executed before the connection to the I/O Device is terminated (and after read and write requests are processed).

[Device Communications Wizard - Link to External Database](#)

### Device Communications Wizard - Link to External Database

This screen allows you to link to an external data source (see [Link an I/O Device to an External Data Source](#)).

Option	Description
Link I/O Device to an external tag database	<p>Determines whether or not you want to link the I/O device to an external data source. If you link to an external data source, Plant SCADA is updated with any changes made to the external data source when a refresh is performed.</p> <p>If you disconnect an existing link, you can choose to make a local copy of the tags in the data source or you can delete them from Plant SCADA's variable tags data source altogether.</p>
Database type	<p>The format of the data referenced by the external data source.</p>
External tag database	<p>Specify the location of the external database. This could either be a path and filename of the external data source for the I/O device, or the IP address/directory, computer name, or URL of a data server, etc. (for example "Work.CSV" or "127.0.0.1", "139.2.4.41\HMI_SCADA" or "http://www.abicom.com.au/main/scada" or "\\coms\data\scada").</p> <p>Depending on the database type selected, the browse button could:</p> <ul style="list-style-type: none"> <li>• Display a standard Windows file browse dialog to browse for the external database.</li> <li>• Display a modal dialog to browse in a tree view of</li> </ul>

Option	Description
	<p>servers on the network connected to the computer.</p> <ul style="list-style-type: none"> <li>Display the <a href="#">Unity Link Tag Import</a> dialog.</li> </ul>
<b>Connection string</b>	<p>Enter a connection string to provide connection details for the data source. This is similar to an ODBC connection string. For example:</p> <p>UserID = XXX; Password = YYY</p> <p>or</p> <p>ServerNode=111.2.3.44; Branch=XXX</p> <p>Not every data source requires a connection string.</p>
<b>Add prefix to externally linked tags</b>	<p>Check this box if you want to insert a prefix in front of the names of linked tags in your Variable.DBF.</p>
<b>Tag prefix</b>	<p>The prefix that will be inserted in front of the names of linked tags in your Variable.DBF (for this I/O device only). To change the prefix, delete it first, perform a manual refresh, then add the new prefix.</p>
<b>Automatic refresh of tags</b>	<p>Determines whether the linked tags in Plant SCADA's variable tags database will be updated when the external data source is changed (i.e. you manually change a field, etc.). This refresh will occur the first time you link to the data source, and then whenever you attempt to read the changed variables (for example you compile your project, display the variable using the Variable Tags form, or paste the tag, etc.).</p> <p>Without an automatic refresh, you will need to perform a manual refresh to update the linked tags in Plant SCADA.</p>
<b>Live Update</b>	<p>This field controls whether or not the linked tags in Plant SCADA and an external tag database will be synchronized if either database is changed. To enable live linking, choose <b>Yes</b> from the <b>Live Update</b> menu, and verify that the <b>Automatic refresh</b> check box is not selected. (Live Update and Automatic Refresh are mutually exclusive.)</p> <p>When Live Update is enabled and the Plant SCADA variable tag database is accessed (for example, during project compilation or when a drop-down list is populated), Plant SCADA queries the external tag database to determine if it has been modified. If so,</p>

Option	Description
	Plant SCADA merges the changes into the local variable tag database. Conversely, any changes made to the local tag variable database will be incorporated seamlessly into the external tag database.

[Device Communications Wizard - Serial Device](#)

### Device Communications Wizard - Serial Device

Since your protocol is based on serial communications you need to select which port on your computer will be used for the I/O device.

The serial ports listed have been detected from your operating system registry. If you have correctly installed a proprietary serial board and the associated driver, the available port will be listed.

## See Also

[Device Communications Wizard - Summary](#)

### Device Communications Wizard - Summary

Summarizes the I/O device setup using the information you provided. The summary shows the Plant SCADA communications setup and the recommended configuration of your I/O device and/or internal boards.

## Retrieving Time-stamped Data from I/O Devices

Plant SCADA supports the retrieval of time-stamped data directly from field devices. This capability is enabled by the Driver Runtime Interface (DRI), a component that is used by some drivers, such as:

- BACNET
- DNPr
- IEC61850
- IEC870IP
- OPC
- OFSOPC
- OPCUA
- S7TCP.

**Note:** Check with Technical Support if new drivers are available that support the DRI.

The DRI allows a driver to push time-stamped data from field devices into a Plant SCADA system. This means the

following can be updated directly from devices:

- Time-stamped digital alarms (see [Add a Time Stamped Digital Alarm](#))
- Time-stamped analog alarms (see [Add a Time Stamped Analog Alarm](#))
- Double point status alarms (see [Add a Double Point Status Alarm](#))
- Event-based trends.

When these drivers start up they scan the system for time-stamped digital alarms, time-stamped analog alarms, double point status alarms and trend events. No configuration is necessary for alarms. For event-based trends, see [Configure Event Trends for a DRI Driver](#).

If the driver receives updated information for any detected tags, it will pass it directly on. Regular I/O server polling is no longer used.

---

**Note:** Non-timestamped alarms which are associated with a tag that uses the DRI mechanism will occasionally miss timestamped events. This will occur when multiple updates for the same tag occur within the period specified by [\[Alarm\]ScanTime](#).

This mechanism can work in tandem with the tag extension feature to enable access to field-generated timestamp and quality tag values (see [Tag Extensions](#)).

---

**Note:** Prior to version 7.20, time-stamped data was manually pushed into Plant SCADA using the Cicode functions `AlarmNotifyVarChange` and `TrnSetTable`. If you are upgrading a project to a version 7.20 system with a driver that uses the new DRI push mechanism, you will no longer need to use these functions.

## I/O Server Parameters

Events pushed from a DRI-supported driver can be buffered on an I/O server while an alarm or trend server is offline. The way this mechanism operates can be configured via the following parameters:

- `[IOServer]MaxEventsQueued`
- `[IOServer]MaxEventsDrop`
- `[IOServer]MaxTimeInQueueMs`

For more information, see [IOServer Parameters](#).

---

**Note:** Tags associated with devices using the DRI could be set to bad quality for reasons specific to an I/O point. You need to consider the implications this may have on your Cicode. See [Considering Tag Value Quality in Cicode](#).

[Configure I/O Device Communications](#)

[Working With Device Drivers](#)

## Configure a Disk I/O Device

In addition to connecting to actual I/O devices, Plant SCADA supports the configuration of disk I/O devices, which exist only within your computer. The value of each variable in the disk I/O device is stored on your computer's hard disk.

---

**Note:** With the release of version 7.20, a feature called persistence could be applied to I/O devices in memory mode. Using a Persisted Memory I/O device is recommended as an alternative to using a disk I/O device, as full synchronization is supported if a server becomes unavailable for a period of time. See [Using Persisted I/O Memory Mode](#) for more information.

A disk I/O device is configured using the Device Communications Wizard. When specifying an I/O device type, select the **Disk I/O Device** option.

You are not required to configure a board or a port for a disk I/O device.

Once configured, disk I/O devices appear exactly as any other I/O device in your system, but are not connected to any field equipment. Disk I/O devices can contain any type of variable supported by Plant SCADA, and you can configure them to emulate any supported I/O device. You can also specify a generic protocol for a disk I/O device.

A disk I/O device is useful when the status of your plant needs to be restored after a planned or unplanned system shutdown. You can configure your system to continually update a disk I/O device with the subset of variables that defines the status of your plant. When you restart your system after a shutdown, Plant SCADA can restore this status immediately.

You can also use disk I/O devices for storing predefined data that needs to be recalled immediately when a process is necessary (for example, in a simple recipe system).

---

**Note:** If you create a RAM disk in the computer for the disk I/O device, you are not required to create or copy the disk file to the RAM disk. Plant SCADA automatically creates a disk file on startup. Avoid setting up your disk I/O device on a RAM disk if you want the data written to it to survive a power cycle of the servers.

If you need to edit the settings for a disk I/O device, see [Disk I/O Device Setup](#).

## See Also

[Redundant Disk I/O Devices](#)

[Disk I/O Device Error Messages](#)

## Disk I/O Device Setup

To set up communications with a device, follow the basic steps given in the I/O Device setup procedure below.

Sometimes you might need to edit the communications forms directly. They require the following specific information.

- You are not required to complete a Boards dialog box.
- You are not required to complete a Ports dialog box.
- Complete the I/O Devices dialog box as follows.

Perform the setup by entering the following information:

Text Box	Required information
<b>I/O Device name</b>	A name or your Disk I/O Device, for example: DISK_PLC. Each I/O Device needs to have a unique name in the Plant SCADA system.
<b>I/O Device number</b>	A unique number for the disk I/O Device (1-4095). Each I/O Device needs to have a unique number in the Plant SCADA system.
<b>I/O Device address</b>	<p>The path and filename of the disk file, for example: [RUN]:DSKDRV.DSK</p> <p>If you are using redundant disk I/O Devices, specify the path to both the primary file and the Standby file in the configuration of both disk I/O Devices.</p> <p>For example, if this is the primary disk I/O Device, enter:</p> <p><b>Primary_File, Standby_File</b></p> <p>If this is the Standby Disk I/O Device enter:</p> <p><b>Standby_File, Primary File</b></p> <p><b>Primary_File</b> is the name (and path) of the primary disk I/O Device file. You may use path substitution in this part of the field.</p> <p><b>Standby_File</b> is the name (and path) of the Standby Disk I/O Device file. You may use path substitution in this part of the field.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>• If the specified disk I/O device file is not found, Plant SCADA creates a new (empty) file with the specified filename.</li> <li>• To use redundant disk I/O devices, you need to use a network that supports peer-to-peer communication.</li> <li>• Disk files need to have write permission (on both primary and standby servers).</li> <li>• The frequency with which Plant SCADA writes data to the disk I/O device(s) is determined by the [DiskDrv]UpDateTime parameter.</li> </ul>
<b>I/O Device protocol</b>	<p>To use the Plant SCADA generic protocol, enter: <b>GENERIC</b></p> <p>- or -</p> <p>To select a specific protocol supported by Plant SCADA, see the I/O Devices online Help.</p>

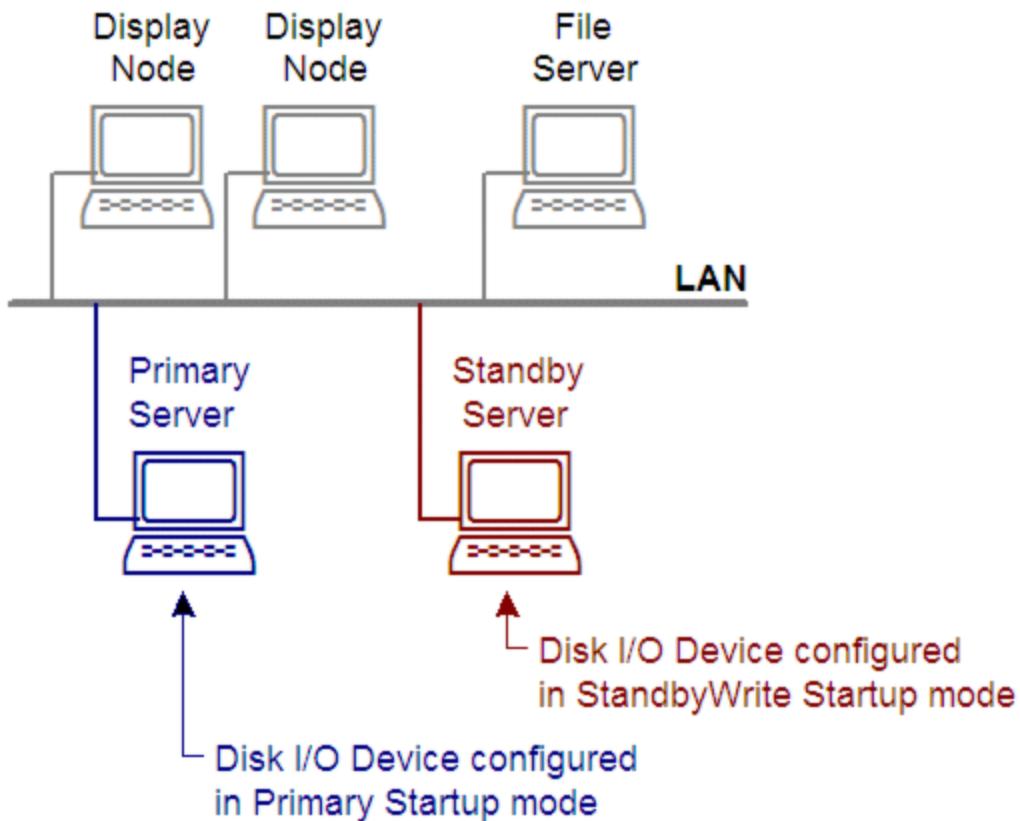

Text Box	Required information
I/O Device port name	You need to use: <b>DISKDRV</b>
I/O Device comment	Any useful comment.
I/O Device startup mode	<p>If not using redundant disk I/O Devices, leave this property blank.</p> <p>If you are using redundant disk I/O Devices, use either:</p> <p><b>Primary:</b> Enable immediate use of this disk I/O Device</p> <p><b>StandbyWrite:</b> This disk I/O Device will remain unused until the computer with the primary disk I/O device configured becomes inoperative. Every write request sent to the primary disk I/O Device is also sent to this disk I/O Device.</p> <p>To use StandbyWrite mode, you need to also configure an I/O disk device in the primary server. Both I/O Devices need to have the same I/O Device name and number.</p>
I/O Device Log Write, Log Read, Cache and Cache Time	Leave these properties blank.

- [Redundant Disk I/O Devices](#)
- [Disk I/O Device Error Messages](#)

## Redundant Disk I/O Devices

If using a network, you can configure a redundant disk I/O device to minimize the potential for data loss (in the event the server becomes inoperative). This diagram illustrates the use of redundant disk I/O devices:

When the system is operating, Plant SCADA reads and writes runtime data to the disk I/O device configured in the primary server. It also writes runtime data to the disk I/O device configured in the standby server. (Plant SCADA maintains both disk I/O devices identically.)

If the primary server becomes inoperative, the Disk I/O device in the standby server is activated without interrupting the system. When the primary server becomes active, Plant SCADA automatically returns control to the primary server, and copies the Disk I/O Device from the standby server to the primary server. The disk I/O device in the standby server reverts to its standby role.

#### To define a redundant disk I/O device:

- Configure a new disk I/O device
- Select **StandbyWrite** for the Startup Mode.

For redundant disk I/O devices, you need to use Microsoft Networking (or another peer-to-peer network), and the hard disk of the standby server (the directory where the disk I/O device file is stored) needs to be shared. Use Windows Explorer to set the directory to shareable.

[Communication Performance Considerations](#)

[Disk I/O Device Error Messages](#)

## Disk I/O Device Error Messages

The following error messages, listed in order, are specific to the Plant SCADA DISKDRV driver.

Error Codes	Message
48	Error Opening DiskFile
49	Error in DiskFile Header
50	DiskFile Header contains invalid variable
51	DiskFile out of memory error
52	Read Error in DiskFile
53	Write Error in DiskFile
54	Seek Error in DiskFile
55	Error creating queue
56	Error creating thread
57	Error creating event

## See Also

[Disk I/O Device Setup](#)

[Redundant Disk I/O Devices](#)

## Using Memory Mode

When configuring an I/O device, you have the option to set it to memory mode. This means that the I/O device will be created in memory and its values stored in memory at runtime.

Devices using memory mode are not connected to any hardware and write their values to a cache. The I/O device values can be read by many processes. The difference between a local variable and a device in Memory Mode is that an I/O device in Memory Mode will reside in the I/O Server's memory and will observe standard networking and redundancy rules of a standard I/O device.

Memory mode is useful when you are configuring a system for the first time, as you can design and test your system before connecting a physical I/O Device.

An I/O device with Memory set to TRUE or FALSE will behave differently in instances where Variable Tags share the same address.

For example:

Define a MODNET IODevice:

- 1 - INT1 (INT Tag)
- 2 - DIG1 (DIG Tag for bit0 of INT1)
- 3 - DIG2 (DIG Tag for bit1 of INT1)

At runtime the Display Client will show:

- IODevice Memory mode = FALSE, at runtime setting DIG1 = 1, DIG2 = 1, INT1 = 3, modifying DIG1 and/or DIG2 affects INT1.
- IODevice Memory mode= TRUE, at runtime setting DIG1 = 1, DIG2 = 1, INT = 0 or cached value, modifying DIG1 and/or DIG2 does not affect INT1.

In both instances the Override and Control Mode settings for each tag (INT1, DIG1, DIG2) did not affect the other tag. Setting INT1 in Override or Control Inhibit mode did not set DIG1 or DIG2 in Override or Control Inhibit mode.

As with local variables, values in an I/O device using only memory mode are not retained when you shut down. However, if you set the Persist field to TRUE in the I/O devices properties, their values will be retained. For more information on local variables, refer to Local Variables.

## See Also

[Using Persisted I/O Memory Mode](#)

### Using Persisted I/O Memory Mode

Since the release of version 7.20, a feature called persistence can be applied to I/O devices. When implemented, the tag cache for an I/O device is written to an XML file at a set period, allowing the last available data to be reloaded following a shutdown.

Persistence is enabled using the **Persist** property for an I/O devices.

You can also create a persisted memory I/O device using the Device Communications Wizard. When this type of device is selected, the wizard creates a new I/O device with the **Address** and **Port Name** properties left blank, **Memory** set to "TRUE", and **Persist** set to "TRUE". The **File Name** field is left empty to allow runtime to generate a default cache file name. This file will be located in the [DATA] directory.

### Migrating Disk I/O Devices

When applied to I/O Devices in memory mode, persistence provides an improved alternative to a disk I/O device, as synchronization is supported in scenarios where a server becomes unavailable for a period of time.

Many customers use disk I/O devices to provide system-wide global variable tags that are managed by I/O servers and are persisted to disk to maintain their latest values. Disk I/O devices take advantage of the standard I/O system redundancy features, such that, if one I/O server is unavailable, another can provide client(s) with tag values. They also perform a level of synchronization by using features such as standby write and by providing redundant paths to the persisted binary data files, so that, at startup of an I/O server, the latest value can be read into the system from the latest modified data file.

---

**Note:** Persisted memory PLCs have the ability to synchronize values between redundant devices after network connections are inoperative and regained. For this reason, it is recommended that data assigned to disk I/O devices be migrated to the new persisted memory I/O mode.

---

#### To migrate disk PLC devices to persisted I/O memory mode:

1. Perform the procedures listed in Upgrading to Plant SCADA 7.20, as is appropriate. Refer to the v7.20 documentation for more information.

2. For disk I/O devices, set the **Background Poll** property to TRUE and the **Persist** property to TRUE (the default setting). See [Add an I/O Device](#)) for more information.
3. Start the I/O server up and wait for a few minutes so that the background poll updates every tag.
4. Shutdown the I/O server.
5. On the I/O Device dialog, for disk I/O devices set Background Poll back to FALSE, set Memory to TRUE and clear out the Port Name field as it is not necessary for Memory Mode.
6. Restart the I/O server to finish the migration to persisted memory I/O mode, with your devices now containing your original values from the disk I/O device.

[Using Memory Mode](#)

## Link an I/O Device to an External Data Source

When you add an I/O device to Plant SCADA, you can choose to link it to an external data source. This provides a link to the tag data that was saved when the I/O device was programmed.

**To link an I/O device to an external data source:**

1. In the **Topology** activity, select **I/O Devices**.
2. Scroll to the relevant I/O device.
3. Set the **Linked** property to **True** in the Grid Editor or the Property Grid.
4. Complete the remaining fields as required.
5. Click **Save**.

**To link an I/O device to an external data source using the Device Communications Wizard:**

1. In the **Topology** activity, select **I/O Devices**.
2. On the Command Bar, select **New Device**. The Device Communications Wizard is displayed.
3. Complete the wizard screens one by one, selecting the relevant I/O device, and so on.

When the **Link to External Database** screen appears, select the **Link I/O Device to an external tag database** check box and complete the remaining details.

## See Also

[Refresh the Tags for a Linked I/O Device](#)

[Import Variable Tags from an External Data Source](#)

## Refresh the Tags for a Linked I/O Device

You can manually refresh the tags for an I/O device that is linked to an external data source. This will load any changes that have occurred in the external data source into Plant SCADA Studio.

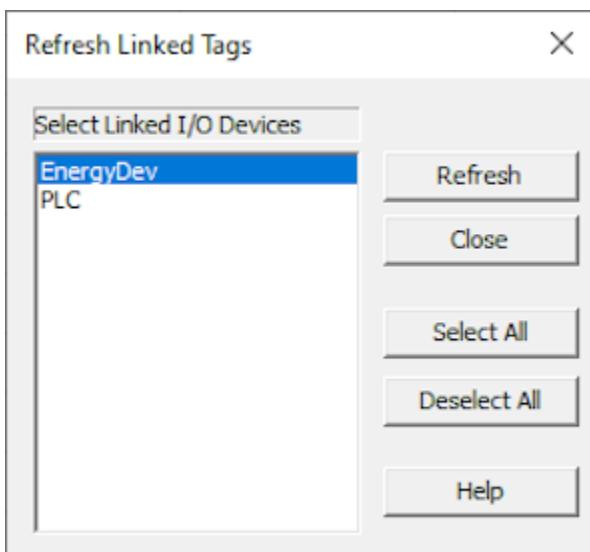

**Note:** If the **Automatic Refresh** property is set to True for a linked I/O device, a tag refresh will occur

---

automatically when you compile your project.

**To manually refresh linked tags:**

1. In the **Topology** activity, select **I/O Devices**.
2. Select **Refresh Tags** from the Command Bar. The **Refresh Linked Tags** dialog box will appear.

The **Select Linked I/O Devices** section lists every linked I/O device in your project (and included projects).

3. To refresh the tags for a device, select it and click **Refresh**.

This updates your project with the latest tag values for the selected I/O device. If you use Plant SCADA to modify any I/O device tags, your modifications will not be overwritten on refresh.

4. When you are finished, click **Close**.

## See Also

[Link an I/O Device to an External Data Source](#)

[Import Variable Tags from an External Data Source](#)

## Breaking the Link to the External Data Source

You can break the link to the external data source from the I/O Devices form or through the Device Communications Wizard.

If you break the link, you can choose to make a local copy of the tags or you can simply delete them altogether.

## See Also

[Link Tags to an External Data Source](#)

## Import Variable Tags from an External Data Source

Importing tags from an external data source allows you to program an I/O device and then import the tags

straight into Plant SCADA, where they are treated as regular tags. Plant SCADA will automatically create a variable tag records for every tag in the I/O device.

**Note:** Plant SCADA only supports the use of alphanumeric characters, the backslash and underscore characters (see Tag name syntax). Any other characters will be converted to underscores on import. This may result in Duplicate Tag error messages on compilation.

## About Importing Variable Tags

Like linking, importing tags is an I/O device specific operation: you import the tags for a particular I/O device. Unlike linking, however, imported tag records are not linked in any way to the tags in the external data source. Therefore, importing is typically a one-time operation. To update imported tags, you need to import them again.

**Note:** Tags will be imported into the project in which the selected I/O device is defined. This could be either the selected project or one of its included projects.

For most external data sources, the import process involves two steps. First you export the data from the I/O device to a format that Plant SCADA can read, then you import the database into Plant SCADA. However, tag data saved using Unity Pro can be read directly by Plant SCADA. This means that no export is necessary.

Some characteristics of the import are defined in the format files in the Config directory (with the extension .fmt). There is one format file for each database type, and each file specifies how external data is converted to Plant SCADA variable data. In general, imported tags are either added to the Plant SCADA variable database if the tag does not already exist, or updated if the tag exists. However, if a field is listed in the [EditableFields] section of the format file corresponding to the import database type:

- If the tag already exists, the Plant SCADA field for the tag will not be updated with the external value.
- If the tag does not yet exist, the Plant SCADA field for the tag will be updated with the external value.

For example, if a tag has 10 fields to be imported and five of them are listed in the [EditableFields] section of the format file, then if the tag already exists in Plant SCADA the tag will be updated with the external values for the five fields that are listed in [EditableFields]. If the tag does not already exist then the tag will be created with the external values for every 10 fields.

Fields marked as editable in this way can be changed by Plant SCADA. To avoid internal changes being lost, changes to these fields in the external database are ignored.

**Note:** If the external database supports to LiveUpdate and the **LiveUpdate Link** has been selected for the I/O device, existing Plant SCADA tags will be synchronized with the external database and the tags will be updated for the imported fields regardless of whether it is marked as an editable field. An I/O device configured as **Linked** or **Auto-refreshed Linked** will behave as in a normal import and will not update fields marked as editable.

When you import tags into Plant SCADA, you have two options for dealing with existing tags:

- Delete tags associated with that I/O device prior to the import.
- Update existing tags on import. Tags found in Plant SCADA and in the external data source are updated in Plant SCADA. Tags found in Plant SCADA but not in the external data source will remain untouched. New tags are appended.

If you import a data source that is already linked, every tag in the data source are duplicated. That is, you will have two copies of each tag: one local and one linked.

See Imported Tags for information about levels of support between Unity and Plant SCADA.

Some properties defined for the external tags will not be relevant to Plant SCADA. Also, some will not be in a

format that Plant SCADA can read. To define what information is copied to Plant SCADA's variable tags database and how this information is to be converted, you need to edit the I/O device's format file.

#### To import variable tags from an external database:

1. In the **Topology** activity, select **I/O Devices**.
2. On the Command Bar, select **Import Tags**.
3. Complete the **Import Variable Tags** dialog box.

See Import Variable Tags Properties below for a description of the information required in each field.

### Import Variable Tags Properties

Property	Description
<b>I/O Device</b>	<p><b>Note:</b> If an I/O device is linked to an external data source the Database Type, External Database, Connection String, and Tag Prefix fields will be greyed out.</p> <p>The Import Variable Tags dialog has the following fields:</p> <p>The I/O Device for which you are importing tags. Use the menu to select an I/O Device that has been defined using Plant SCADA.</p> <p><b>Note:</b> Tags will be imported into the project in which the selected I/O Device is defined. This could be either the project selected in the Explorer, or in one of its included projects.</p>
<b>Database type</b>	The format of the data referenced by the external data source.
<b>External database (128 Chars.)</b>	<p>References the source for the external database. Click the Browse button to either navigate to the file or to specify configuration options. The external database can be:</p> <ul style="list-style-type: none"><li>• An explicit path and file (for example, "C:\Data\Tags.csv")</li><li>• An IP address and node (for example, "127.0.0.1\HMI_Scada")</li><li>• A URL (for example "http://www.abicom.com.au/main/scada")</li><li>• A computer name (for example "\\\coms\data\scada").</li></ul> <p>Tag data can be read directly from a Unity SpeedLink or OPC Factory Server data sources.</p>

Property	Description
	Click the browse button to specify configuration options. See <a href="#">OPC Factory Server (OFS) Tag Import</a> or <a href="#">Unity Link Tag Import</a> .
<b>Connection string (128 Chars.)</b>	<p>Connection details for the data source. This is similar to an ODBC connection string. For example:</p> <p>UserID = XXX; Password = YYY or      ServerNode=111.2.3.44; Branch=XXX</p> <p>Only certain drivers require a connection string:</p> <ul style="list-style-type: none"> <li>• Unity SpeedLink (Static/Dynamic)</li> <li>• OPC</li> </ul> <p>Selecting one of these drivers and then browsing for the external database will automatically populate the Connection String field where necessary.</p>
<b>Add prefix to imported tags</b>	Select this box to insert a prefix in front of the names of imported tags in your <i>Variable.DBF</i> .
<b>Tag prefix</b>	The prefix (8 characters max.) that is inserted in front of the names of imported tags in the variable tags database.
<b>Delete I/O Device tags prior to import</b>	<p>Select this box to delete every one of the I/O Device's tags (from the variable tags database) before importing.</p> <p>If this check box is not selected, tags found in Plant SCADA and in the external data source are updated in Plant SCADA. Tags found in Plant SCADA but not in the external data source remain untouched. New tags are appended.</p>
<b>Purge deleted tags not found in data source</b>	Select this box to delete tags which have been removed from the external database. In other words, if a tag is still part of the I/O Device in your project, but not in the external database, it is deleted from your project.

## See Also

[OPC Factory Server \(OFS\) Tag Import Limitations](#)

## Unity Link Tag Import

The Unity Link Configuration dialog specifies the parameters used to generate alarm and trend tags. It has the following fields:

### I/O Device & Protocol Driver

The name of the destination I/O Device and its corresponding protocol. Unity SpeedLink will only import tags to an I/O Device using either the MODBUS, MODNET, MBPLUS, or UNITE.

### Unity Database Type

The import/export database driver type selected from the Import Variable Tags dialog.

### PLC Family

The family name of the PLC you are importing from. It can be either Premium or Quantum. This option is only valid for the Unity SpeedLink Static protocol.

### Unity File

Path of the Unity project file from which you want to import the tags. If the database type is Unity SpeedLink Dynamic, this is a \*.stu file. If the database type is Unity SpeedLink Static, this is a \*.xsy file.

### Unity Profile Enable

Enable this if the Unity database is restricted by user profile and a user name and password combination are needed to gain access. See the Access Security Management section of the Unity Pro online help for further information.

### Unity Username and Password

The username and password, if it is necessary, for the Unity database from which you are importing.

### DCOM Enable

Enable this if the database host is a DCOM server.

### DCOM Server Name

If enabled, the DCOM server that the client uses to hosts the database from which you are extracting tags.

### DCOM Username and Password

If enabled, the username and password for the DCOM server.

### Tag Gen Configuration Enable

Enable this to automatically generate tags from the variable Tags database. Tags are created using rules specified in the XML template file.

### Configured template is saved as

Filename of the [TagGen XML Template](#) file that specifies the rules for generating tags. Click **Configure** to select and configure the XML file. See [Additional Tag Generation Configuration](#).

### Log File Path

The path name for log files generated during the import or export process.

### Logging Level

The level of detail necessary in the import or export logs.

### Log Pool Size

Specifies the maximum number of log files for the given device.

### Validate

Click the validate button to check the Unity Link settings are correct. This button enables the OK button on the page.

### Additional Tag Generation Configuration

This dialog specifies the path of the XML template, the parameters specified in the template, and displays the template description (extracted from the desc attributes used in the template).

1. Click **Browse** to select the XML file to use.
2. Double click on a parameter in the parameters list to change its value.
3. Click **OK** to save this template into your project. The template will be copied into the project and, when validated, saved with a taggen\_import\_ioDeviceName.xml or taggen\_link\_ioDeviceName.xml filename.

**Note:** When you return to this dialog, the path name will point to the location of the template in the project, rather than the path of the original template file.

### OPC Data Access Server Tag Browser

The OPC Data Access Server Tag Browser dialog generates the strings that the OPC Data Access Server database driver requires in Plant SCADA.

The OPC Data Access Server Tag Browser dialog has the following fields:

#### Machine Name

The location of the OPC Server which can be an IP address or the network path server. Leave blank to select the local machine.

#### Database Tree Display

Displays the Servers on the network that are running the OPC Server application, and the hierarchical database node structure for each.

Select a group of tags to import from an available database. OPC data can be either a tree (hierarchical) or a flat structure. The Plant SCADA OPC driver supports access to both types of storage. If the data is in a tree structure, it can be accessed to the first branch level down from the root node. Deeper levels of branching may be supported in the future.

**Note:** The authentication values needs to be valid for read/write access, as assigned by the appropriate database administrator.

### OPC Factory Server (OFS) Tag Import

Plant SCADA can now import tags from the OPC Factory Server. For Database Type, choose the "Unity SpeedLink via OFS" option and then click the Browse button to specify the location of the database. In the OPC Data Access Server Parameters dialog that is displayed, you can browse the OFS servers installed on the PC and select tags to be imported into Plant SCADA.

There are some limitations and things to be aware of when importing tags from OFS. See [OPC Factory Server \(OFS\) Tag Import Limitations](#) for more information.

**Note:** There are two modes that can be used on the OPC Factory Server when importing tags; device mode and OFS simulator mode. If device mode is used, the time taken to import tags is increased significantly. This is because for each tag requested by Plant SCADA the OPC Factory Server needs to verify the item from the device.

---

OFS simulator mode is recommended.

**Machine Name**

The location of the OPC Factory Server which can be an IP address or a UNC path. Leave blank to select the local machine.

**Select Server and Branch to Import**

Displays the OPC Factory Servers on the network that are running the OPC Factory Server application, and the hierarchical database node structure for each.

Select a group of tags to import from an available database. OPC data can be either a tree (hierarchical) or a flat structure. The Plant SCADA OPC driver supports access to both types of storage. If the data is in a tree structure, it can be accessed to the first branch level down from the root node. Deeper levels of branching may be supported in the future.

---

**Note:** The authentication values needs to be valid for read/write access, as assigned by the appropriate database administrator.

**Tag Gen Configuration Enable**

Enable this to automatically generate tags from the variable Tags database. Tags are created using rules specified in the XML template file.

**Configured Template is Saved as**

Filename of the Tag Gen XML Template file that specifies the rules for generating tags. Click **Configure** to select and configure the XML file. See [Additional Tag Generation Configuration](#).

**Log File Path**

The path name for log files generated during the import or export process.

**Log Level**

The level of detail necessary in the import or export logs.

**Log Pool Size**

Specifies the maximum number of log files for the given device.

## OPC Factory Server (OFS) Tag Import Limitations

Please be aware of the following limitations when importing tags from an OFS database.

- For each imported tag, the Plant SCADA tag name will be the same as the name of the tag defined on the OFS except "." characters will be replaced by "\_" characters.
- Using OFS tag import to import tags from an OFS database may not succeed if Windows User Account Control (UAC) is enabled. UAC stops access to the external database. Either turn off UAC, or right click on the OFS and Unity Pro Windows shortcuts and select "Run as Administrator".
- To generate Alarm and Trend tags, a unique identifier can be set in the Custom and Comment field for Elementary Data Type (EDT) tags. For example, the string "VJA" is used to identify a tag that the user wants to use to generate a corresponding Digital Alarm Tag. Only the Comment field can be used for this feature on Derived Data Types (DDT) and Derived Function Block (DFB) tags.
- OFS built-in tags are not imported. They can be added in Plant SCADA manually.
- The length of the comment field in the Plant SCADA tag form is limited to 48 characters.
- Plant SCADA does not support DDT or DFB structure types. The OFS import will enumerate each element of this type of tag and import them as elementary tags.

- OFS tag import is only supported when the OFS links to the .STU and .XVM files.
- DFB components of type "ANY\_ARRAY\_xxxx" are not imported when the OFS links to a \*.xvm file. When a data dictionary is used, the data dictionary ignores comment and custom fields and therefore taggen cannot generate alarm and trend tags. If there are DFB components of type "ANY\_ARRAY\_xxxx", the whole DFB is not imported.

The following table shows data types supported by the tag import and TagGen when the OFS links to \*.stu or \*.xvm file.

	OFS links to *.stu file	OFS links to *.xvm file			
	<b>Tag Import</b>	<b>Tag Gen</b>		<b>Tag Import</b>	<b>Tag Gen</b>
		<b>Comment Field</b>	<b>Custom Field</b>		<b>Comment Field Only</b>
<b>Data Types</b>					
<b>Elementary Data Types (EDT)</b>					
BOOL	Yes	Yes	Yes	Yes	Yes
EBOOL	Yes	Yes	Yes	Yes	Yes
BYTE	Yes	Yes	Yes	Yes	Yes
INT	Yes	Yes	Yes	Yes	Yes
DINT	Yes	Yes	Yes	Yes	Yes
WORD	Yes	Yes	Yes	Yes	Yes
DWORD	Yes	Yes	Yes	Yes	Yes
UINT	Yes	Yes	Yes	Yes	Yes
UDINT	Yes	Yes	Yes	Yes	Yes
REAL	Yes	Yes	Yes	Yes	Yes
STRING	Yes	Yes	Yes	Yes	Yes
DATE	Yes	Yes	Yes	Yes	Yes

DT	Yes	Yes	Yes	Yes	Yes
TIME	Yes	Yes	Yes	Yes	Yes
TOD	Yes	Yes	Yes	Yes	Yes
<b>Derived Data Types (DDT)</b>					
EDT in DDT	Yes	Yes <sup>2</sup>	No	Yes	Yes <sup>3</sup>
Array in DDT	Yes	Yes <sup>2</sup>	No	Yes	No
<b>Arrays</b>					
Array of EDT 4	Yes	Yes	No	Yes	No
Array of DDT 4	No	No	No	Yes	Yes <sup>1</sup>
<b>Function Block Types (FBT)</b>					
Elementary Function Block (EFB)	Yes	Yes <sup>2</sup>	No	Yes	Yes <sup>3</sup>
Derived Function Block (DFB)	Yes	Yes <sup>2</sup>	No	Yes	Yes <sup>3</sup>
<b>Synchronization</b>					
Live Update	No	No	No	No	No
Automatic Refresh of tags	No	No	No	No	No

1. Only the BOOL type tags in the DDT can be used to generate Alarm and Trend tags when the OFS links to the \*.xvm file.
2. When OFS links to the stu file, the comment string defined in the tag instance will be taken, the comment string defined in the DDT/DFB definition will be ignored.
3. When OFS links to the xvm file, the comment string defined in the DDT/DFB definition will be taken and the comment defined in the tag instance will be ignored.
4. Array with negative index is not supported.

## TagGen XML Template

The TagGen template is an XML file that uses proprietary tags and attributes to specify the fields of input and output databases, and define filters and transformation rules that create tags from existing database fields.

The basic structure of the XML file is as follows:

```
<?xml version="1.0"?>
<template>
<param name="parameter">
</param>
<input name="variable" file="variable.dbf">
</input>
<output name="trend" file="trend.dbf" filter="">
</output>
</template>
```

This outline template specifies no parameters, takes input from the variable.dbf database and outputs the results to the trend.dbf database. The `<template>` tag is the root tag of the template document and need to be present.

Within the `<template>` tag are three sections:

- `<param>`

This is an optional section you can use to specify string constants that can be referred to in other sections of the template. For example:

```
<param name="parameters">
<string name="MyIODevice">DISK_PLCC</string>
</param>
```

In this example the variable **MyIODevice** is given the value DISK\_PLCC.

The `<param>` tag has a **name** attribute. You can use any name provided that it uniquely identifies the section within the XML file. This section name is used when referring to variables from other sections of the file. See [Referencing Variables](#).

Strings defined here are displayed in the [Additional Tag Generation Configuration](#) dialog when templates are selected. It is possible to define strings that are otherwise not used in the template to specify version or revision information in order to track template modifications.

- `<input>`

The `<input>` section specifies the name of the database and the fields that are used for processing into tags. There needs to be only one input section in the XML file. For example:

```
<input name="variable" file="variable.dbf">
<field name="name"></field>
<field name="type"></field>
<field name="unit" load="true">{parameter.IODevice}</field>
```

```
<field name="custom"></field>
<array name="taginfo">{ToProperty('{custom}', '=', ';')}</array>
<string name="alarminfo">{variable.taginfo[VJA]}</string>
<string name="trendinfo">{variable.taginfo[VJT]}</string>
</input>
```

This example identifies four fields from the variable.dbf database: **name**, **type**, **unit** and **custom**. These fields are used later in the file. The input section loads only rows where the **unit** field matches the value of the IODevice variable in the parameter section. This helps improve performance by avoiding the processing of irrelevant rows.

An array is created called taginfo that contains key value pairs based on the value of the custom field. If the custom field value was "VJA=Alarm;VJT=Trend", then an array is created containing the values taginfo[VJA] = "Alarm" and taginfo[VJT] = "Trend".

Two string variables are created based on the values of the taginfo array.

- <output>

The <output> section defines the output database, the processing to be done on the input fields and the respective output fields to be generated. There can be many output sections in the XML file. The output section can specify the same database file as the input section if necessary. For example:

```
<output name="digalm" file="digalm.dbf"
filter="'{variable.alarminfo}=VJA' AND
'{variable.type}=DIGITAL'"
<field name="tag">{variable.name}_ALARM</field>
<field name="name">{variable.name}_ALARM</field>
<field name="var_a" key="true">{variable.name}</field>
<field name="taggenlink" load="true">{parameter.IODevice}</field>
</output>
```

In this example, fields are written to the digalm.dbf database. Output processing only occurs for the current row if the input row relates to a digital alarm. That is, if the **alarminfo** variable from the input section has the value of "VJA" and the type field from the input database is "DIGITAL. The **tag** and **name** fields are given the value **name\_ALARM**.

Curly braces are usually used for substitutions to replace pre-defined texts with tag properties. To use curly brace characters as normal characters, use double curly braces which will be exceptionally converted to singular ones to express curly braces. Round brackets are not regarded as special characters when used in tags other than <calculator> tag.

### Example

```
<output name="digalm" file="digalm.dbf" filter=" ( '{variable.alarminfo1}=VJA' OR
'{variable.alarminfo2}=VJA' ) AND '{variable.type}=DIGITAL'" desc="Generate digital alarm
tags from input digital variable tags">
<field name="tag">{variable.name}_ALARM</field>
<field name="name">{variable.name}_ALARM</field>
<field name="var_a" key="true">{variable.name}</field>
<field name="taggenlink" load="true">{parameter.IODevice}</field>
<field name="comment">{{Testing1}}</field>
</output>
```

Proprietary tags used in the template are described in [XML Template Tags](#). See [Sample XML Templates](#) for more comprehensive examples.

## Referencing Variables

Variables can be used to temporarily store information. Variables can be defined either globally in the `<param>` section of the XML file or locally in an `<input>` or `<output>` section.

Variables are defined using the `<string>` tag as shown in . For example:

```
<string name="MyIODevice">DISK_PLC</string>
```

To refer to a variable, use the following syntax:

```
{SectionName.VariableName}
```

For this example:

```
{parameters.MyIODevice}
```

The **SectionName** can be omitted if you are referencing a variable defined in the same section.

Variables are evaluated sequentially in the XML file. Variables in the `<param>` section are assigned first, followed by those in the `<input>` section, followed by variables in each `<output>` section in sequence. This means that:

- Variables in the `<param>` section can be referenced by the `<input>` section and every `<output>` section in the same template.
- Variables in the `<input>` section can be referenced by every `<output>` section.
- Variables in each `<output>` section can only be referenced by subsequent `<output>` sections.

## Referencing Arrays

To reference a member of an array by member name use:

```
{SectionName.ArrayName[MemberName]}
```

To reference a member of an array by matching a pattern use:

```
{SectionName.ArrayName(PatternString)}
```

See [Pattern Matching](#) for information on pattern matching wildcards.

## XML Template Tags

The proprietary tags used in TagGen XML files are listed below.

### `<template>`

This is the root tag in the XML file. Only have one `<template>` tag in each XML file.

Can contain:

`<param>`, `<input>`, `<output>`

Attributes:

#### `desc`

Description of the template section.

### `<param>`

This optional tag defines global parameters for the XML file. Here you can specify string constants to be used in

the rest of the file.

Can contain:

<string>

Attributes:

**name**

Name of the parameter section.

**desc**

Description of the parameter section.

### <input>

This defines the source database of the XML file, the fields to be imported and any input filtering that might be necessary. There needs to be only one input section defined.

Can contain:

<field>, <string>, <array>, <calculator>

Attributes:

**name**

Name of the input section.

**file**

Input database file name.

**desc**

Description of the input section.

### <output>

This defines the output database of the XML file, the tags to be generated and any transformations necessary to generate tag data from input variable data. A template needs to have at least one output section defined.

Can contain:

<field>, <string>, <array>, <calculator>

Attributes:

**name**

Name of an output section

**file**

Output database file name

**filter**

Output section filter, syntax:

**filter="variable=FilterString"**

<FilterString> is a string expression that can combine wildcards or wildcard strings with boolean operators (AND, OR and NOT), as well as grouped boolean terms using parentheses. For example, "L\*" will match if string beginning with the letter "L"; "L\* OR H\*" will match if string beginning with "L" or "H". See [Pattern Matching](#) for a list of wildcard operators.

**desc**

Description of the output section.

**<field>**

This tag specifies the database fields that will be processed in <input> and <output> sections.

When used in the input section it specifies the named fields for each record loaded from the input database. It is read only.

When used in an output section it specifies the named fields to write to for each generated tag record in the output database.

Attributes:

**name**

Case insensitive name of a database field.

**key**

Valid for output sections only, this boolean flag indicates whether this is a key field. This is useful for special handling in the output section. For example, you can synchronize between a new record set and an old record set by matching the key fields.

**load**

Valid for both input and output sections, this boolean flag indicates whether this is a load filter field. Load filter fields are used to filter records when loading data from the input database and output database.

**desc**

Description of the field element.

---

**Note:** Key and Load string expressions can contain a regular string, a variable reference, wild card operators, or a mixture of these. See [Pattern Matching](#) for a list of wildcard operators.

---

**<string>**

This tag defines a string constant that can be used in <param>, <input> and <output> sections.

Attributes:

**name**

Name of a variable string.

**desc**

Description of the string element.

---

**Note:** For Unity SpeedLink, the string "IODevice", when defined in the <param> section, refers to the project's IO Device. Do not assign it another value.

---

**<array>**

This tag defines a dynamic array of strings in <input> and <output> sections.

The set of strings depends on the fields of the record being processed and those strings that are generated by the ToProperty() and Split() commands. See [Built-In Functions](#) for more information.

Attributes:

**name**

Name of a variable string array.

**desc**

Description of the array element.

## <calculator>

This tag defines an expression variable in <input> and <output> sections.

The content of this tag is a mathematical expression used to specify a simple operation for data transformation.

The operands in the expression can be only numbers or variables with numeric values. The expression can use parentheses to change the precedence of the evaluation.

For example, the following calculator in an <input> section counts input records by incrementing its current value.

```
<calculator name="c1" initial="0">{c1} + 1</calculator>
```

Attributes:

**name**

Name of a calculator.

**initial**

Initial value of the calculator, zero by default.

**desc**

Description of the calculator element.

## Pattern Matching

The following wildcards can be used in strings.

Character	Description
%	Matches any string in the input data stream
?	Matches any single character in the data stream
%d	Matches any decimal integer (nnn... where n is 0-9) in the data stream
%e	Matches any octal number (0onnn... where n is 0-7) in the data stream
%h	Matches any hexadecimal number (0xnnn... where n is 0-9, A-F or a-f) in the data stream
%s	Matches any string in the data stream (same as *)
{	Begin a token string. The characters between { and } in the Input Pattern (including regular and special characters) represent a "token string". The characters in the data stream that match this token string are a token, and can be referenced by the Output Data String, and written directly to the output database as a group
}	End of a token string

Character	Description
\	Treat the following character as a literal. For example, if a literal '*' character was expected in the input data stream, you would use \* to denote this. If a literal backslash \ is expected, use \\.

## Built-In Functions

There are three built-in functions that can be used to manipulate strings in the XML template. The syntax to call a built-in function as follows:

```
{<FunctionName>(<arg1>, <arg2>,...)}
```

The three built-in functions are:

**SubString(string, 'start', 'count')**

This function extracts a substring from the given source string starting at character **start** and ending after **count** characters.

```
<string name="AddrWord">{SubString('{'tagprefix'}','3','2')}</string>
```

**Split(string, delimiter)**

This function splits the source string into parts separated by the delimiter and stores them in a zero based string array. For example:

```
<array name="tagid">
{split('VJA;VJT', ';')}
</array>
```

produces tagid[0] = VJA, tagid[1] = VJT.

**ToProperty(string, separator, delimiter)**

This function splits the source string parts separated by the delimiter, and then further into key value pairs separated by the separator. For example:

```
<array name="taginfo">
{ToProperty('VJA=Alarm;VJT=Trend', '=', ';')}
</array>
```

This produces taginfo[VJA] = Alarm, taginfo[VJT] = Trend.

## Sample XML Templates

A sample template is provided to create analog or digital alarm tags and trend tags. The template shown below specifies the rules for generating Plant SCADA Alarm and Trend tags from a Unity SpeedLink device/database, for the import and/or synchronization of variable tags.

---

**Note:** You will need to modify this template to suit your particular requirements. Refer to [TagGen XML Template](#) for more information.

For each Unity Database variable tag with the text "VJA" in the custom field imported in to Plant SCADA of type "DIGITAL", this file will generate a linked Digital Alarm Tag within Plant SCADA (digalm.dbf) with the name <variablename>\_ALARM.

For each Unity Database variable tag with the text "VJA" in the custom field imported in to Plant SCADA not of

type "DIGITAL" and not of type "STRING", this file will generate a linked Analogue Alarm Tag within Plant SCADA (anaalm.dbf) with the name <variablename>\_ALARM.

For each Unity Database variable tag with the text "VJT" in the custom field imported in to Plant SCADA, this file will generate a linked Trend Tag within Plant SCADA (trend.dbf) with the name <variablename>\_TREND. This example file does not enter values for any of the other Trend tag properties.

```
<?xml version="1.0"?>
<template desc="Default SpeedLink Unity Pro TagGen template">

<param name="parameter">
<string name="IODevice" desc="SpeedLink necessary parameter, it will be set to the given I/O Device name by the system."></string>
</param>

<input name="variable" file="variable.dbf" desc="Load variable tags for the specified I/O Device">
<field name="name"></field>
<field name="type"></field>
<field name="unit" load="true">{parameter.IODriver}</field>
<field name="custom"></field>

<array name="taginfo">{ToProperty('{custom}', '=', ';')}</array>

<string name="alarminfo">{variable.taginfo[VJA]}</string>
<string name="trendinfo">{variable.taginfo[VJT]}</string>
</input>

<output name="digalm" file="digalm.dbf" filter="'{variable.alarminfo}=VJA' AND '{variable.type}=DIGITAL'" desc="Generate digital alarm tags from input digital variable tags">
<field name="tag">{variable.name}_ALARM</field>
<field name="name">{variable.name}_ALARM</field>
<field name="var_a" key="true">{variable.name}</field>
<field name="taggenlink" load="true">{parameter.IODriver}</field>
</output>

<output name="anaalm" file="anaalm.dbf" filter="'{variable.alarminfo}=VJA' AND '{variable.type}=NOT DIGITAL' AND '{variable.type}=NOT STRING'" desc="Generate analog alarms from input analog variable tags">
<field name="tag">{variable.name}_ALARM</field>
<field name="name">{variable.name}_ALARM</field>
<field name="var" key="true">{variable.name}</field>
<field name="taggenlink" load="true">{parameter.IODriver}</field>
</output>

<output name="trend" file="trend.dbf" filter="'{variable.trendinfo}=VJT'" desc="Generate trend tags from input variable tags">
<field name="name">{variable.name}_TREND</field>
<field name="expr" key="true">{variable.name}</field>
<field name="taggenlink" load="true">{parameter.IODriver}</field>
</output>

</template>
```

### Simple Wildcard Example

The following example shows how an empty string variable called "wildcard" can be used as a wildcard pattern

to load a set of data from a variable database. The string variable is substituted for a "%" wildcard character when the xml file is processed. The example below loads data where the names of variable tags contain the word "Tank".

```
<input name="variable" file="variable.dbf">
<string name="wildcard"></string>

<output name="anaalm" file="anaalm.dbf" filter="'{variable.alarminfo}=VJA' AND
'{variable.type}=INT'>
<field name="tag">{variable.name}_ALARM</field>
<field name="name">{variable.name}_ALARM</field>
<field name="var" key="true">{variable.name}</field>
<field name="taggenlink" load="true">{parameter.IODevice}</field>
<calculator name="highhh" >({variable.eng_full}-{variable.eng_zero})/
{parameter.Divisor} </calculator>
<field name="highhigh">{highhh}</field>
</output>
```

```
</template>
```

## Export Variable Tags to an External Data Source

The export feature allows you to export I/O device data to an external data source, specifying the destination and format of your choice (for example RSLOGIX driver). This file might then be imported into a third-party I/O device programming package database. Alternatively, you might use it as a backup.

**Note:** Exporting using the OPC driver is not supported.

The file to which you are exporting needs to already exist; otherwise the export will not work. You can choose to delete its contents before exporting, or you can leave it and create duplicate tags.

**Note:** The export tags feature is not yet supported by every database type. If you have existing links to any external data source, the linked tags will also be exported. As the structure of each type of external data source differs, some tag data might not be exported. This is determined by the format file for the I/O Device.

See [Exported Tags](#) for information about levels of support between Unity and Plant SCADA.

**Note:** Tag names greater than 32 Chars cannot be exported to Unity.

### To export variable tags to an external database:

1. In the **Topology** activity, select **I/O Devices**.
2. On the Command Bar, select **Export Tags**.
3. Complete the **Export Variable Tags** dialog box.

See the Export Variable Tags Properties below for a description of the information required in each field.

## Export Variable Tags Properties

Property	Description
<b>I/O Device</b>	The I/O device for which you are exporting tags. Use the menu to select an I/O device that has been defined using Plant SCADA.
<b>Database type</b>	The format of the data referenced by the external data source.
<b>External database</b> (128 Chars.)	A reference (128 characters) to the external data source to which your variable tags will be exported. This can be: <ul style="list-style-type: none"><li>• An explicit path and file (for example, "C:\Data\Tags.csv")</li><li>• An IP address and node (for example, "127.0.0.1\HMI_Scada")</li><li>• A URL (for example "http://www.abicom.com.au/main/scada")</li><li>• A computer name (for example "\coms\data\"</li></ul>

Property	Description
	<p>scada").</p> <p><b>Note:</b> This data source needs to exist before the export can be performed.</p>
<b>Connection string (128 Chars.)</b>	<p>Enter a connection string to provide connection details for the data source. This is similar to an ODBC connection string. For example:</p> <p>UserID = XXX; Password = YYY</p> <p>Not every data source requires a connection string.</p>
<b>Remove prefix from tags</b>	<p>Select this box to remove a known prefix from the front of the exported tag names.</p>
<b>Tag prefix</b>	<p>The prefix (8 characters max.) to be removed from exported tag names.</p>
<b>Delete existing tags</b>	<p>Select this box to delete any tags in the external database before exporting.</p> <p><b>Note:</b> For the Unity driver, existing tags are not deleted, even if you select this check box.</p>

[Format File](#)

## External Data Source

When setting up an import, export, or link, you need to provide a data source and the format of the data.

Your data source can be entered as:

- An explicit path and file (for example, "C:\Data\Tags.csv")
- An IP address and node (for example, "127.0.0.1\HMI\_Scada")
- A URL (for example, "http://www.abicom.com.au/main/scada")
- A computer name (for example, "\coms\data\scada").

The database type field specifies the format of the external data source. When Plant SCADA attempts to read from this data source, it will use the mechanism specified by the database type. The supported database types are:

- OPC (OPC1 is not supported)
- CSV (comma-separated values)

- Concept Ver 2.1 ASCII file.

### To configure the external data source as a file

The example uses a CSV file, in this case an RSLOGIX database driver

In the Import/Export or Links dialog box, enter details as follows:

- **External database** C:\Data\Tags.csv
- **Database type** RSLOGIX Driver
- **Connection string** (leave blank)

### To configure the external data source using a specialized driver

---

**Note:** This example uses the supplied OPC driver.

---

In the Import/Export or Links dialog, enter details as follows:

- **External database:** The name of the OPC server process, for example, FactorySoft.InProc
- **Database type:** OPC
- **Connection string:** The parameters are **ServerNode** or **Branch**, though both are optional. Their use depends on the location of the OPC server and the scope of the necessary data. **ServerNode** can be an IP address or the network path to the server. For example:
  - ServerNode=127.0.0.1
  - ServerNode=\Server
  - ServerNode=www.server.comFor **Branch**, OPC data can be either a tree (hierarchical) or a flat structure. The OPC driver supports access to both types of storage. If the data is in a tree structure, it can be accessed to the first branch level down from the root node, by entering the name of the branch. For example:
  - Branch=device1Deeper levels of branching might be supported in the future.

[Format File](#)

### Format File

The format file defines the import/export/linking rules. The file maps columns from the external data source format to the internal Plant SCADA database format. In other words, it determines what information is imported/exported/linked and how this information is modified during the operation.

The format file also provides the information to allow Plant SCADA to use the correct driver for accessing the external data source.

Some format files are provided with Plant SCADA; however, sometimes you might need to write or modify a format file using an editor such as Microsoft Notepad.

Following is an example of how format file rules work. (For more information, see [Format File Layout](#).)

1. Column 3 in the external data source needs to be copied into the "Name" column in the Plant SCADA's tag

database. (Plant SCADA names are restricted to alphanumeric characters (a to z, A to Z, and 0 to 9) and the underscore character "\_", but this is not typically a consideration in the format file; Plant SCADA does the conversion automatically). However, if Column 3 in the external data source happens to be blank, there is no need to copy this record across (it needs to be rejected).

2. Column 1 in the external data source needs to be copied straight into the "Addr" column in Plant SCADA's tag database, because they both mean exactly the same thing.
3. Columns 4, 5, 6, and 7 in the external data source need to be copied into the "Comment" column in Variable.DBF. (It is not uncommon for external data sources to split the comments across several fields). The fields need to be copied in that order, so that if the data in Column 4 in the external data source is "**Loop**", Column 5 is "**1**", Column 6 is "**Process**", and Column 7 is "**variable**", these fields are copied across in order, so that the "Comment" column in Variable.DBF reads "**Loop 1 Process variable**". This process is called 'concatenation'. (For the "Comment" column, Plant SCADA automatically adds a space between each field from the external data source.)
4. The data in Column 1 in the external data source determines what Plant SCADA needs to write in the "Type" column. However the data cannot be copied across directly, because it would not make sense to Plant SCADA. Instead, it needs to go through a conversion (or filtering) process. This conversion needs its own set of rules, such as:
  5. If Column 1 in the external data source is "BT%d:%d.%d" (where %d means "any decimal number"), Plant SCADA needs to write the string "DIGITAL" in the "Type" column.
  6. If Column 1 in the external data source is "F%d:%d/%d" (where %d means "any decimal number"), Plant SCADA needs to write the string "DIGITAL" in the "Type" column.
  7. If Column 1 in the external data source is "O:%e" (where %e means "any octal number"; that is, every digit from 0 to 7), Plant SCADA needs to leave the "Type" column blank. It still accepts the record (provided other columns pass any filtering tests) but it does not write anything in the "Type" column. The assumption is that Plant SCADA currently does not have (or does not need) a suitable corresponding type.
  8. If Column 1 in the external data source is "PD%d:%d.%d", Plant SCADA needs to write the string "REAL" in the "Type" column.
  9. If Column 1 in the external data source is "ST%d:%d", Plant SCADA needs to write the string "STRING" in the "Type" column.
  10. If there are no rules covering the contents of Column 1 in the external data source, Plant SCADA needs to reject the whole record and not copy it into the Plant SCADA database.

[Format File Layout](#)

## Format File Layout

The format file is divided into sections:

- [\[General\] Section](#)
- [\[Columns\] Section](#)
- [\[ImportFilterMap\] and \[ExportFilterMap\] Sections](#).

Each section consists of a section header (the section name enclosed in square brackets (for example

"[my\_section]")) on a line by itself. This is followed by the body of the section, typically single line statements of the form:

```
"something = something_else -> something_else_again"
```

Any white space (or none at all) is acceptable around the "=" and the "->", but the whole statement needs to be on one line. Most statements within a format file follow this pattern, but in many cases there might be no "->" (the converter), or there might just be a converter without anything following it.

The following sections are necessary in every format file:

```
[General]  
[Columns]  
[ImportFilterMap]  
[ExportFilterMap]
```

Other sections might be necessary depending on the complexity of the conversion between Plant SCADA and the external data source. This is determined by the contents of [ImportFilterMap] and [ExportFilterMap].

Comments can also be added within or between sections. To do this, place a semicolon ";" as the first character on the line. The rest of the line is then considered a comment, and is ignored by Plant SCADA. For example:

```
; I am putting the [General] section here  
[General]
```

## [General] Section

The General section consists of 4 lines:

```
[General]  
Name=name  
Description= description  
DriverName= driver name  
DriverInst="a special string"
```

The **name** and the **description** are not currently used by Plant SCADA. Plant SCADA uses the **driver name** to load the correct driver for accessing the external data source. This driver might be one that is part of the Plant SCADA installation, or it might be a customized driver (including a driver that you have written yourself), for accessing a particular data source (which could be a protocol, type of hardware, server or file type). The driver needs to be an OLE DB-compliant driver.

The **special string** allows extra information to be passed to the driver. It is added to the connection string (in Plant SCADA Studio). So the connection string can be used for information that is likely to change often, and this **special string** can be used for more persistent information (such as the comma "," delimiter for a .CSV file). The main use of this string is as a delimiter for an input file. To specify that a comma "," is used by an input file as the delimiter, the following syntax would be used:

```
DriverInst="delimiter=,"
```

## [Columns] Section

The Columns section defines the format of the columns in the external data source. It is structured as follows:

```
[Columns]  
External column name 1 = column width -> data type  
External column name 2 = column width -> data type..  
External column name n = column width -> data type
```

The only restriction that Plant SCADA places on the data for **External Column name n** is that it needs to be unique within the section. For convenience, you can use the names that the external data source uses (such as "Description", "PLC\_id", "Iotype") or you can just make up names like "Column1", "Column2", etc. The order in which these entries appear needs to be the same as the order of the fields in the external data source. The names used for the External Data Source columns in the [ImportFilterMap] and [ExportFilterMap] sections needs to come from this list.

**Column width** is the number of characters in the field, and **data type** is the type of data for that column. Currently the only acceptable data type is "STRING".

### [ImportFilterMap] and [ExportFilterMap] Sections

The [ImportFilterMap] and [ExportFilterMap] sections have identical syntax and functionality, except that the [ImportFilterMap] describes how to convert data from the External data source on import, while the [ExportFilterMap] describes the opposite conversion.

These are the most complex sections in the format file. (The rest of the text will just focus on the [ImportFilterMap], as the [ExportFilterMap] follows basically the same logic.)

The [ImportFilterMap] is structured as follows:

```
[ImportFilterMap]
Import Rule 1 = External column name 1 -> Citect Column i
Import Rule 2 = External column name m -> Citect Column j..
Import Rule nn = External column name n -> Citect Column k
```

The values in **Import Rule nn** can be any name strings, but they needs to be unique within the section.

Therefore, for convenience, you might want to use names like "ImportRule1", "ImportRule2", "Mapping1", "Filter1" etc., or you might want something that is descriptive of the conversion involved, such as "Description\_to\_comment".

The name used for **External column name n** needs to be identical to a name that appears in **External column name n** in the [Columns] section above.

The name used for **Citect Column k** needs to be the same as one of the columns in the Plant SCADA internal tags database, such as "Name", "Type", "Addr", "Comment" etc.

Thus the values for the external column and the Plant SCADA column provide information on how to transfer data from the external column to the Plant SCADA column during import.

For example:

```
ImportRule1 = Description -> Comment
```

This indicates that there is a relationship between the data in the "Description" field in the external data source and the data that needs to go into the "Comment" field in the Plant SCADA database.

The name that you use for **Import Rule nn** might be the same as the name of another optional section in the format file: here, the extra section provides Plant SCADA with more information. In the simplest case, if there is no section with that name in the format file, the rule simply states that the data in **External column name n** is to be copied directly into **Citect Column k** without modification or filtering.

So if the "Description" column in the external database contains "Truck Position 1" and the above entry appears in the [ImportFilterMap] section, and there is no section called [ImportRule1], then after the import, the "Comment" column in the Plant SCADA database will contain the string "Truck Position 1".

## Concatenation

To concatenate fields from the external database into one field in the Plant SCADA database, add separate entries to the [ImportFilterMap] section. Each section needs to contain the name of a relevant external column and the name of the destination column in Plant SCADA. The entries need to appear in the order in which the fields are to be concatenated.

So, if the external data source has a field called "IOdev" containing the value "M", and another field called "IOaddr" containing the value "61", and you want to join them together so that the value "M61" is imported into the Plant SCADA "Addr" field, this is how it would be done:

```
[ImportFilterMap]  
Addr1= IOdev -> Addr  
Addr2= IOaddr -> Addr
```

Here, you need to verify that there are no sections in the format file called [Addr1] or [Addr2], unless you need some filtering or conversion.

## See Also

[Field Conversion](#)

## Field Conversion

To modify mapped data or to apply filtering (to reject certain records), create a new section using the name of the relevant line from the mapping section. For example, if you have the following mapping section:

```
[ImportFilterMap]  
Test1_to_type = Test1 -> Type
```

and you want to convert the data from the Test1 column before importing it, somewhere in the file you need to have a section called [Test1\_to\_type] followed by the necessary conversion rule.

---

**Note:** The name needs to be from the import mapping section, not from the export mapping section. If you use a name from the export mapping section, the conversion applies to the export, not the import.

The basic format of this conversion/filtering section is as follows:

```
[Relevant mapping name]  
Filtering Rule 1 = External Pattern 1 -> Citect String 1  
..  
Filtering Rule m = External Pattern m  
..  
Filtering Rule n = External Pattern n -> Citect String n
```

The name used for **Filtering Rule n** has no intrinsic significance to Plant SCADA (except that it uses it as a key to locate the entry). The only restriction is that it needs to be unique within the section, so you can use whatever is convenient.

The value in **External Pattern n** is a combination of characters which Plant SCADA will look for in the external data source column. This pattern can be any combination of the following:

Character in format file	Matches what string in external data source
<specific text>	<specific text>
*	Any string.
?	Any single character.
%d	Any decimal integer (nnn. . . where n is 0-9).
%e	Any octal number (0nnnn. . . where n is 0-7).
%h	Any hexadecimal number (0xnnnn. . . where n is 0-9, A-F or a-f).
%s	Any string.
{	Begin a "token string". Any characters enclosed by { } in the Input Pattern (including regular and special characters) represent a token string. The characters in the data stream that match a token string are referenced by the Output Data String and written directly to the output database as a group.
}	End of a token string.
\	Treat the following character as a literal. For example, if a literal * character was expected in the input data stream, you would use \* to denote this. If a literal backslash \ is expected, use \\.

Any other characters need to literally match the same character.

If External Pattern n is found in the external column, Citect String n is written to the relevant column in Plant SCADA (as per the mapping).

In addition, two special characters can appear in the output data string:

Character in output string	Meaning
\$	The pattern \$n (where n is any integer) is replaced in the output data stream by the nth "token"; a token is a matching sequence of characters enclosed by { } in the input pattern. (An alert message will result if \$ not followed by a token number.)
!REJECT!	This sequence needs to appear by itself in the output data pattern. The whole record is rejected. As the record had already been matched to the input pattern, no further rules are checked.
\	Treat the following character as a literal. This would be used if a literal \$ sign was necessary (use \\$) or if

Character in output string	Meaning
	another digit immediately follows. For example, if the string "3August2001" needs to immediately follow the token, use "\$1\3August2001".
\ (at end of line)	Insert a literal space ' ' character at the end of the output line. Without this provision, the system could not distinguish between the end of the input line (which is likely to be followed by characters, such as spaces, that Windows will ignore) and a space being necessary at the end of the output line.

Other characters are written literally to the output database.

Plant SCADA works through each filtering rule in the section, looking for a match. If a rule does not match, the next one is tried, then the next, and so on, until a match is found. If no match is found, the whole record is rejected; none of the data from any field is copied to Plant SCADA.

For example, to convert the string "FLOAT" in the external data source to "DIGITAL" in Plant SCADA, you could use the following entry:

```
[ImportFilterMap]
Test1_to_type = Test1 -> Type
..
[Test1_to_type]
Rule1 = FLOAT -> DIGITAL
..
```

For a more complex example, let us assume that the external data source has a column called "Tag" which is equivalent to the "Name" field in Plant SCADA. Let us also assume that the external database has no direct equivalent of Plant SCADA's "Type" field, yet Plant SCADA needs this field to be filled in. We need to use the "Tag" field to decide what goes into the "Type" field of the Plant SCADA database.

If the "Tag" column in the external data source has the value "I:060/07", we have determined that we write the string "DIGITAL" into Plant SCADA's "Type" field. In fact, if that field has "I:" followed by any octal value, followed by a slash "/", followed by any octal value, we want the string "DIGITAL" to appear in our "Type" field. How do we express this in the format file?

Firstly, there are two sets of relationships to consider, one connecting the "Tag" field in the external data source to the "Name" field in Plant SCADA, and the other connecting it to the "Type" field in Plant SCADA. So we need two "mappings" (entries) in the [ImportFilterMap] section:

```
[ImportFilterMap]
Tag_to_Name = Tag -> Name
Tag_to_Type = Tag -> Type
..
```

As we want the data in the "Tag" field to be copied directly into the "Name" field, we do this by not having a [Tag\_to\_Name] section anywhere in the format file.

But because we are not copying directly from the "Tag" field to the "Type" field, but are just using the data to decide what goes into the "Type" field, we need a [Tag\_to\_Type] section.

Recall the desired outcome: If the "tag" field has "I:" followed by any octal value, followed by a slash "/", followed by any octal value, we want the string "DIGITAL" to appear in our "Type" field.

We express this in the format file as follows:

```
[Tag_to_Type]
Rule1 = I:%e/%e -> DIGITAL
..
```

This will match "I:060/07" or "I:0453/02343445602" (and cause the string "DIGITAL" to be written to Plant SCADA's Type field), but will not match "I:060/98" or "I:054".

To give a few examples of how the wild-card characters (%s, \* and ?) might be used, the pattern "HE%sLD" or "HE\*LD" in the format file would match "HELLO WORLD" or "HE IS VERY BOLD" in the external data source. The pattern "HE??????LD" would match "HELLO WORLD" but not "HE IS BALD", as each question mark "?" needs to match exactly one character.

Plant SCADA will also handle multiple wildcard patterns, such as "%s/%s:%s".

For an example more useful than "Hello World", imagine that we need to copy the data straight across without modification, but we want to verify that no blank fields are copied across. The pattern "?%s" or "?\*" will match any string that has at least one character, but will not match a blank.

Sometimes only part of the input stream is necessary in the output, or the input might need to be split up into different output columns. In these situations "tokens" are useful.

In this example of an export situation, the "Addr" field in the Plant SCADA database needs to be split among two fields in the external database: the "IOdev" (whose value is always "D" or "M"); and "IOaddr" (whose value is a decimal integer of no more than 3 digits). Values in the "Addr" field of the Plant SCADA database are strings such as "D62", "M546", etc.

This situation could be solved by concatenation, i.e. using one mapping to write to the IOdev field, and three other separate mappings to copy each digit separately into the IOaddr field of the external database. But this would be complex and in some situations would not work.

It is better to use a token to address the situation:

```
[ExportFilterMap]
..
Addr2IOdev = Addr -> IOdev
Addr2IOaddr = Addr -> IOaddr
..
[Addr2IOdev]
D = D* -> D
M = M* -> M
AnythingElse = * ->
..
[Addr2IOaddr]
Rule = ?{%-d} -> $1
```

In the [Addr2IOaddr] section, the {%-d} is the token string, and as it is the first (and only) token appearing in the rule, \$1 is used to reference it on the output stream side. So if the "Addr" field of the Plant SCADA database contains "D483", "D" is written to the "IOdev" field of the external data sink, and "483" (the token) to the "IOaddr" field.

Here is another example illustrating the use of multiple tokens. Suppose we need to: convert period characters (.) to colons (:); remove the first two characters (which are blank); and remove any unnecessary characters from the data we are expecting; that is, convert "..BJ6452.78....." to "BJ6542:78". This can be achieved by using the following rule:

```
Rule = ??{*%-d}.{%-d}* -> $1:$2
```

At this point, we introduce another feature of the format file. If you use the following rule:

```
[Relevant mapping name]  
Filtering Rule = External pattern
```

i.e., without "-> Citect String" included, Plant SCADA interprets this as "check that the string matches the External Pattern, if it does, copy it across unchanged".

If this rule is used:

```
Filtering Rule = External pattern ->
```

i.e., without "Citect String", it would mean: "If the string pattern matches then accept the record but copy a NULL string to the Plant SCADA database."

Using the above example again, we can add the restriction that any records with no data (i.e. a blank or NULL string) in the Tag field of the external data source will not be imported into Plant SCADA. We would add a [Tag\_to\_Name] section, and would have just one rule: that we accept everything except for a blank.

```
[Tag_to_Name]  
RejectBlanks = ?*  
..
```

Recall that Plant SCADA checks the pattern in each filter rule sequentially until a pattern that matches the string is found in the external data source. With this in mind, a huge range of conversions and filterings are possible by ordering the rules correctly and, in some cases, by making use of concatenation.

For instance, if certain string types need to be converted but others need to be copied unmodified to Plant SCADA, you could have a section with a set of rules at the top, followed by a final rule to let everything else through unmodified.

```
[Tag_to_Name]  
Rule n = ..... -> .....,  
..  
LetEverythingElseThru = %s
```

A single %s or \*, without anything else, matches anything and everything, including blanks.

For an example of how to reject a particular string or pattern, let's suppose we want to reject any tags starting with "DFILE"(another real-life example). We would simply use the following:

```
[Tag_to_Name]  
Rule1 = DFILE* -> !REJECT!  
..  
LetEverythingElseThru = %s
```

Clearly, it is pointless having the !REJECT! rule not followed by other rules concerning patterns that you do want to accept, as anything that does not match an input pattern is rejected. The logic behind the order that the rules appear can become particularly important when using a !REJECT! rule. You would typically have any reject rule(s) as the first rule(s) in the mapping. There would not be any point in putting a !REJECT! rule as the last rule in the mapping.

!REJECT! rules can also be useful where some text file generated by another system contains some sort of header lines that are not wanted, but the rest of the data is necessary.

[Recognizing Format Files](#)

## Recognizing Format Files

Your format file needs to be saved to the config folder of the Plant SCADA User and Data folder selected during installation.

For Plant SCADA to import, export, or link, it needs to know the name of the format file and the name of the driver that will access the external data source. It also needs the text of the string that will appear in the **Database type** field of the Import or Export dialog box. This information is stored in another file, called tagdrv.ini, in the same directory.

The format of tagdrv.ini is simple and based on the odbc.ini format. When it is installed it already has the necessary information for the format files and drivers that come shipped with Plant SCADA. You just need to copy the same layout for your new format file, and the driver that you are using.

The tagdrv.ini file has several sections. The first section is the [External data sources] section, with the following general layout:

```
[External data sources]
```

Section name 1 = the name you want to appear in the import/export/ link menu for entry 1

Section name 2 = the name you want to appear in the import/export/ link menu for entry 2..

Section name nn = the name you want to appear in the import/export menu for entry nn

Each entry in this section refers to a combination of format file and driver necessary for a particular import, export, or link operation.

The text on the left of the "=" sign needs to refer to the name of another section which needs to appear in tagdrv.ini.

The text on the right of the "=" sign is exactly what will appear in the menu under "**Database type**" for importing, exporting or refreshing variable tags.

The other sections each refer to a type of import or export described in the [External data sources] section, and give details about the format file and driver pair. The general layout of these sections is as follows:

```
[Section name matching an entry in [External data sources] ]
```

driverid = Driver ID

datastring = The name of the format file

Currently the Driver ID is always CiTrans.

So if we assume that the version of Plant SCADA you are installing contains five format files, there would be five sections in tagdrv.ini, as shown in the following example:

```
; This file contains the driver name, driver prog id, and format file mappings
; The format file needs to reside in the BIN directory
```

```
[External data sources]
```

CSV = CSV Driver

Concept ver 2.1 Ascii = Concept Ver 2.1 ASCII file

OPC = OPC

UnityProDynamic = Unity SpeedLink Dynamic

UnityProStatic = Unity SpeedLink Static

```
[CSV]
```

driverid = CiTrans

datastring = csv.fmt

```
[Concept ver 2.1 Ascii]
```

```
driverid = CiTrans
datastring = concept ver 2_1(fmt

[OPC]
driverid = CiTrans
datastring = OPC(fmt

[UnityProDynamic]
driverid = CiTrans
datastring = UnityProDynamic(fmt
LiveUpdate = TRUE

[UnityProStatic]
driverid = CiTrans
datastring = UnityProStatic(fmt
LiveUpdate = FALSE
```

This adds 5 entries to the database type drop down menu: CSV, ASCII, OPC, Unity Pro Dynamic and Unity Pro Static.

The 5 entries in the menu match the strings on the right of the "=" sign in the [External data sources] section.

If you add another format file, you will also need to add a matching entry to tagdriv.ini. For example, if you add a new format file for a Simatic data source, you need to add a line similar to this to the [External data sources] section:

```
SIMATIC = Siemens SIMATIC Driver
```

You need to also add the following section to the bottom of the file:

```
[SIMATIC]
driverid = CiTrans
datastring = SIMATIC(fmt
```

Save the file, restart Plant SCADA Studio, and "Siemens SIMATIC Driver" appears in the menu.

Selecting this entry causes the format file in the datastring entry under the [SIMATIC] section to be used for the import, export, or link; that is, simatic(fmt.

## Communicating with Remote Devices via Modems

A dial-up remote I/O device is one which is connected to Plant SCADA through a PSTN (Public Switched Telephone Network), and is accessible through pre-selected and pre-configured modems. Once connected, Plant SCADA can write to, and read from, dial-up remote I/O devices just as it does with any other local or remote I/O device.

Communications can be:

- **On request:** initiated by Plant SCADA using IODeviceControl() or by the remote I/O device (for instance, to report an alarm condition).
- **Periodic:** for instance, to transfer the logged events for a period.
- **Persistent:** for instance, to monitor and control the water level at a remote dam.

The only limiting factor would be an inability to connect a modem to an I/O device due to incompatible communications capabilities. Many I/O devices have fixed settings and can only communicate at a pre-set rate determined by the manufacturer. If a modem cannot match these settings, communication cannot be established.

To make communications setup easier, you can connect dial-up remote I/O devices with identical communications to the same modem and port. Where I/O devices are connected to the same modem, Plant SCADA can communicate with each I/O device one after the other using the same phone connection, rather than hanging up and re-dialing. This reduces the number of necessary telephone calls and increases the speed and efficiency of communications.

## Modems at the I/O Server

To decide how many modems to use at the I/O server end, decide what function each modem will perform. A single modem can do any one of the following functions:

<b>Dial-out</b>	Makes calls to remote I/O devices in response to a Plant SCADA request; for example, scheduled, event-based, operator request, and so on. Also returns calls from remote I/O devices.
<b>Dial-in</b>	Only receives calls from remote I/O devices, identifies the caller, then hangs up immediately so it can receive other calls. Plant SCADA then returns the call using a dial-back or dial-out modem.
<b>Dial-back</b>	Only returns calls from remote I/O devices.
<b>Dial-in and dial-out</b>	Receives calls from remote I/O devices and makes scheduled calls to remote I/O devices.
<b>Dial-in and dial-back</b>	Receives and returns calls from remote I/O devices.

Your modem setup depends on your system requirements. When making your decision, consider the following guidelines:

- If you need to communicate with multiple remote I/O devices at once, you will need a separate modem for each I/O device. Otherwise you'll have to wait as I/O devices are contacted one after the other, and incoming calls may be held up.

- If you have scheduled requests to I/O devices and you also need to urgently return calls from remote I/O devices that dial in, you will need at least one modem for each of these functions. For example, if you have a large number of remote I/O devices and you require fast responses by Plant SCADA, provide an additional modem at the I/O server. This would reduce the chances of it being engaged when an I/O device dials in (say, with an urgent alarm).
- In a big system with many remote I/O devices or a system where calls from remote I/O devices can be time sensitive, it's a good idea to dedicate at least one modem to dial-back. This will give you quick responses to dial-In calls (from remote I/O devices). It also means your dial-out schedules won't be disrupted (if you use the same modem for returning calls and scheduled calls, the scheduled calls are forced to wait until the dial-back call is complete).

[Example Configurations for Modems at the I/O Server](#)

### Modems at the I/O Device

You can have multiple I/O Devices connected to a single modem if they have the same communication requirements (phone number, baud rate, data bits, stop bits, and parity). A separate port and modem needs to be used for each remote I/O Device with different communication requirements.

When deciding how many modems to use, consider the following:

- Once an I/O Device has been contacted, the connection can be retained for other I/O Devices in the group. If the I/O Server needs to request data from another I/O Device with the same communication details, it will wait until the current request has been completed, then it will use the same connection to make the second request. You can configure your modem to initiate telephone calls (call Plant SCADA), and/or receive telephone calls. This is done independently of Plant SCADA.

---

**Note:** Wherever your modem is, you need to verify that its **Data bits**, **Parity**, **Stop bits**, and **Serial Port Speed** settings are compatible with the remote I/O Device as defined by the device's manufacturer or your communications link will not work.

---

## See Also

[Modems at the I/O Server](#)

### Configure a Modem

Each modem connected to a Plant SCADA I/O server computer needs to be configured within Windows™ and then in Plant SCADA.

#### To set up a modem in Windows:

1. Open Windows **Control Panel | Phone and Modem**.
2. Select the **Modems** tab, and click **Add** to launch the Install New Modem wizard.
3. Check the box labeled **Don't detect my modem; I will select it from a list**, then click **Next**.

4. Select **Standard Modem Types** in the list of manufacturers.

**Note:** Do not select a brand name modem from the Manufacturers list, even if the name of the modem you're installing is included in the list. Do not click **Have Disk**.

5. Select the **Standard xxxx bps modem** rate from the list of models to exactly match the bit per second rate of the I/O device that is going to be communicating via this modem. Check the device to determine the device communication rate. If you are still unsure, select the 9600 bps model. This can be changed later if necessary.
6. Do not click **Have Disk**. Click **Next**.
7. Select the **COMx Port** that the modem is connected to. Click **Next**.
8. Click **Finish**. Windows displays the modem in the list of modems on the Modems Properties form.
9. No option was given for the selection and setting of the Data bits, Parity, or Stop bits information. The Modems wizard automatically defaults to 8-none-1 for Standard Modem types. To change these settings to match the Data bits, Parity, Stop bits requirements of the remote I/O device, select a modem in the list, then click the **Properties** button.
10. Click the **Advanced** tab and click **Change Default Preferences**.
11. Click the **Advanced** tab at the next dialog to gain access to the Data bits, Parity, Stop bits settings for the modem.
12. Change the Data bits, Parity, and Stop bits settings using the drop-down options, so that they exactly match those being used by the remote I/O device and its remote modem. Don't change any advanced settings. (The default is Hardware flow control.)
13. Click **OK**. If a modem of the same rate is installed to the same port as an existing modem, Windows asks for confirmation that you want to install the same thing more than once. Click **Yes** to install a duplicate copy of the modem.
14. Preconfigure the modem(s) to be used at the remote dial-up I/O device(s). These will be used to test modem configuration settings in the next step.
15. With Plant SCADA not running, confirm that the local and remote modems will properly communicate with each other by using a terminal communications program such HyperTerminal or PhoneDialer (both supplied with Windows).

Once the modem(s) are set up and tested with proven communications in Windows, they can then be set up in Plant SCADA.

#### To add a modem to Plant SCADA:

1. In the **Topology** activity, select **Components & Mappings**.
  2. On the menu below the Command Bar, select **Modems**.
  3. Add a row to the Grid Editor.
  4. Type the required information in each column, or in the fields in the Property Grid (see below for a description of the fields).
- For a description of the properties, see below.
5. Click **Save**.

**Note:** Plant SCADA allows you to set up a maximum of 256 modems on the I/O server for communication with remote dial-up I/O Devices. Before it can successfully establish communication, any targeted remote I/O devices need to also be properly configured within Plant SCADA on the I/O server.

## Modem Properties

### General Properties

Property	Description
<b>Server Name</b>	The name of the I/O server to which the modem is attached (maximum 16 characters)
<b>Modem Name</b>	The name of the modem you are configuring (as it appears in the Windows™ Control Panel   Phone and Modems). 64 characters maximum.
<b>Use this modem to make outgoing calls</b>	Determines whether this modem will be used to initiate calls from the I/O server to a dial-up remote I/O device. (Dial-Out)  This may include calls that are scheduled, event driven, or in response to I/O devices that dial in.
<b>Use this modem to answer incoming calls</b>	Determines whether this modem will be used to receive calls from a dial-up remote I/O device. (Dial-In)
<b>Use this modem to call back I/O devices</b>	Determines whether this modem will be used to initiate calls from the I/O server to a dial-up remote I/O device in response to a call received from the I/O device. (Dial-Back)
<b>Comment</b>	Any useful comment.

### Project Properties

Property	Description
<b>Project</b>	The project in which the modem is configured.

## I/O Device Constraints for Multi-dropping

If you are multi-dropping off a single modem, use your I/O Devices to issue the caller ID, not the modem. This is because using the modem to issue the ID will send the same ID no matter which I/O Device the call is relevant to. This makes it difficult to identify the I/O Device that triggered the call.

By using the I/O Device to issue the ID, the I/O Server will receive a unique caller ID for each I/O Device. However, not every I/O Device is capable of issuing caller IDs. If multi-dropping, use I/O Devices that can issue caller IDs.

### To configure dial-up remote I/O Devices for communication with Plant SCADA:

1. Run the Device Communications Wizard.
2. Complete the wizard, selecting the relevant I/O Server, then the I/O Device, creating each new instance when necessary.
3. On the Scheduling page of the wizard, select the **Connect I/O Device to PSTN** check box.

4. Select an appropriate schedule for Plant SCADA to communicate with the remote I/O Device. (For a persistent connection - whenever Plant SCADA is running - select **On Startup**.) For example (all based on a **Synchronize at** time of 10:00:00):
  - If you enter **12:00:00** in the **Repeat every** field, and start your project at 9 a.m., the I/O Server will communicate with the I/O Device at 10 a.m., then once every 12 hours after that; that is, 10 p.m., then again at 10 a.m. of the following day, and so on.
  - If you enter 12:00:00 and start your project at 4 p.m., the I/O Server will communicate with the I/O Server at 10 p.m., then again at 10 a.m., of the following day, and so on. Plant SCADA will assume that communications were established at 10 a.m., so will continue as if they had been, communicating once every 12 hours after 10 a.m.
  - If you enter 3 days and start your project at 9 a.m. on a Wednesday, the I/O Server will communicate with the I/O Device at 10 a.m., then once every 3 days after that; that is, 10 a.m. on the following Saturday, then at 10 a.m. on the following Tuesday, and so on.
  - If you enter the 6<sup>th</sup> of December in the **Repeat every** field and start your project during November, the I/O Server will communicate with the I/O Device at 10 a.m. on December 6, then again on December 6 of the following year, and so on.
5. Select **On Startup** for a persistent connection. To disconnect a persistent connection, call the [IODeviceControl](#) function with type 8.
6. Type in the phone number necessary for Plant SCADA to dial the remote modem attached to the remote I/O Device. Include any pre-dial numbers necessary to obtain a connection to an outside PSTN line (dial tone) before dialing (for example, **0** (zero)) - if appropriate.
7. On the next wizard page, if the device is configured to dial-in to Plant SCADA, create a unique identifying caller name for the remote I/O Device so that it can be identified by Plant SCADA.
8. Follow the instructions on the next page of the wizard and click **Finish**.

[Configuring Multidrop Remote I/O Devices](#)

## Configuring Multidrop Remote I/O Devices

Multidropping remote I/O devices from the same remote modem enables Plant SCADA to communicate with each I/O device one after the other, using the same phone connection, rather than hanging up and re-dialing. Although you can configure multidrop remote I/O devices using the Device Communications Wizard, we recommend that you do it manually. The wizard would create a new port for each I/O device. This would mean you couldn't have any more than 255 I/O devices.

1. Run the Device Communications Wizard to configure the first device.
2. Configure every other I/O device manually in the Topology activity (see "Add an I/O Device" on page ).
3. To increase the efficiency and capacity of your system you can allocate the same port name to I/O devices with the same communication settings.

**Note:** If you are multi-dropping and you want to be able to dial in to the I/O server, use your I/O devices to issue the caller ID, not the modem. This is because using the modem to issue the ID will send the same ID no matter which I/O device the call is relevant to. This makes it difficult to identify the I/O device that triggered the call.

By using the I/O device to issue the ID, the I/O server will receive a unique caller ID for each I/O device. However, not every I/O device is capable of issuing caller IDs. If multi-dropping, use I/O devices that can issue caller IDs.

### To set up a modem connected to your dial-up remote I/O devices:

You can connect multiple I/O devices to the same modem. This means Plant SCADA can communicate with these I/O Devices one after the other using the same phone connection, rather than hanging up and re-dialing. This will reduce the number of telephone calls and increase the speed and efficiency of communications.

1. Connect the modem to a PC with a telephony program installed (for example HyperTerminal or PhoneDialer). This is where you will configure the modem to answer calls from Plant SCADA and/or initiate calls.
2. If the modem is necessary to make calls to Plant SCADA, configure it to initiate the phone call to a pre-determined Plant SCADA I/O server dial-In type modem (following manufacturer instructions).

Depending on your hardware, either the modem or an intelligent PLC can be responsible for initiating calls to Plant SCADA and identifying the caller. Whichever is responsible needs to have a caller ID set. The caller ID can be any combination of alpha-numeric characters and/or the character '\_' (underscore).

Some modems have dip-switch settings, and some have initiation strings which can include auto-dial-up numbers that are stored within the modem's non-volatile memory. Consult the manual provided with the modem for exact details.

You can use either the Device Communications Wizard or the I/O devices form to set the caller ID for an I/O device.

If multi-dropping off a single modem, use your I/O devices to issue the caller ID, not the modem. This is because using the modem to issue the ID will send the same ID no matter which I/O device the call is relevant to, making it difficult to identify which I/O device triggered the call.

By using the I/O device to issue the ID, the I/O server will receive a unique caller ID for each I/O device. However, not every I/O device is capable of issuing caller IDs. If you are multi-dropping, use I/O devices that can issue caller IDs.

3. Set the modem's **Data bits**, **Parity**, **Stop bits**, and **Serial-Rate** to match manufacturer specifications for communication with the I/O devices.

Some modems do not allow you to manipulate their communications settings via methods such as extended AT commands or dip switches. If this is the case, the only way of setting the necessary values is to communicate with the modem using the values (for example, via HyperTerminal). Once this is done, the modem remembers the last values used to communicate with its serial port.

4. Connect the modem to the I/O devices.

To configure a modem at the I/O server you need to set it up in Windows and then set it up in Plant SCADA. See [Configure a Modem](#).

If every one of your I/O devices are the same, you only have to do this once for each modem. However, if your I/O devices talk using different communication specifications (data bits, parity, stop bits, and serial-rate), your modem has to be able to talk using each of these details as well. To set this up, you have to create a modem in Windows and Plant SCADA for each specification. See [Example Configurations for Modems at the I/O Server](#).

### Example Configurations for Modems at the I/O Server

The examples below demonstrate how to set up the modems at your I/O Server to accommodate different combinations of I/O Devices.

#### Example 1

All your remote I/O Devices have the same communication requirements (data bits, stop bits, parity, and baud rate) - 19200 8 E 1.

You don't expect any important calls from your I/O Devices, or you only have a few remote I/O Devices. This means you can use a single modem at the I/O Server end. This modem would be set up to answer and return incoming calls and make scheduled and other Plant SCADA initiated calls.

To configure your modem, define it in Windows. Assuming that the logical modem is called 'Standard Modem', configure it as follows:

Port	Modem Name	Max. Speed	Data Bits	Parity	Stop Bits
COM1	Standard Modem	19200	8	E	1

You would then configure it in Plant SCADA as a dial-out modem and dial-in modem:

Modem Name	Dial-out	Dial-in	Dial-back
Standard Modem	TRUE	TRUE	FALSE

### Example 2

In this example, your I/O Devices use a total of two different communication specifications - 9600 7 O 1 and 19200 8 E 1.

You don't expect important calls from I/O Devices or you have only a few I/O Devices. This means you can get by with a single modem at the I/O Server end. This modem has to receive and return calls from I/O Devices as well as initiate calls (dial out) to I/O Devices.

To configure your modem, you need to first define it in Windows (through the Windows Control Panel).

Remember, you're not just defining the physical modem here. You have to define a separate Windows (virtual) modem for each communication specification.

So far, this gives you two virtual modems - one for 9600 7 O 1 and one for 19200 8 E 1. However, Windows won't let you define both of these modems as dial-in. It only lets you define one dial-in modem per port. If you choose the first, it won't be able to receive calls with the second, and vice versa.

This means you have to set up a separate virtual modem that can answer calls no matter which communication specification is used. This modem would be set with a generic communication specification of 9600 8 N 1.

So in Windows, you'll end up with three logical modems (two for Dial-Out and one for Dial-In). Assuming that the logical modems are called 'Standard Modem' to 'Standard Modem #3', you would configure them as follows:

Port	Modem Name	Max. Speed	Data Bits	Parity	Stop Bits
COM1	Standard Modem	9600	7	O	1
COM1	Standard Modem #2	19200	8	E	1
COM1	Standard Modem #3	9600	8	N	1

You would then configure the modems in Plant SCADA as follows.

Modem Name	Dial-out	Dial-in	Dial-back
Standard Modem	TRUE	FALSE	FALSE
Standard Modem #2	TRUE	FALSE	FALSE
Standard Modem #3	FALSE	TRUE	FALSE

**Example 3**

In this example, there are five different communications frameworks - 9600 7 O 1, 19200 8 E 1, 4800 8 N 1, 9600 8 N 1, and 19200 8 N 1.

If you expect important calls from I/O Devices or you have many I/O Devices, you would set up three modems at the I/O Server end:

- One on COM3 dedicated to receiving calls from **9600 7 O 1** I/O Devices.
- One on COM2 for dialing out to **4800 8 N 1**, **9600 8 N 1**, and **19200 8 N 1** I/O Devices.
- One on COM1 for dialing out to **9600 7 O 1** and **19200 8 E 1** I/O Devices.

The two dial-out modems would return calls as well as initiate calls in response to scheduled requests, and so on.

To configure your modems, you need to first define them in Windows (through the Windows Control Panel).

Remember, you're not just defining the physical modem here. You have to define a separate Windows (virtual) modem for each communication framework.

Assuming that the logical modems are called 'Standard Modem' to 'Standard Modem #6', you would configure them as follows:

Port	Modem Name	Max. Speed	Data Bits	Parity	Stop Bits
COM1	Standard Modem	9600	7	O	1
COM1	Standard Modem #2	19200	8	E	1
COM2	Standard Modem #3	4800	8	N	1
COM2	Standard Modem #4	9600	8	N	1
COM2	Standard Modem #5	19200	8	N	1
COM3	Standard Modem #6	9600	7	O	1

You would then configure the modems in Plant SCADA as follows:

Modem Name	Dial-out	Dial-in	Dial-back
Standard Modem	TRUE	FALSE	FALSE
Standard Modem #2	TRUE	FALSE	FALSE
Standard Modem #3	TRUE	FALSE	FALSE
Standard Modem #4	TRUE	FALSE	FALSE
Standard Modem #5	TRUE	FALSE	FALSE
Standard Modem #6	FALSE	TRUE	FALSE

**Example 4**

In this example, your I/O Devices use three different communication frameworks: 9600 7 O 1, 19200 8 E 1, and 9600 8 N 1. However, in this example, you are expecting important calls from I/O Devices, so you need a modem dedicated to returning calls.

Here you need to configure your modems like this:

- One modem on COM1 to dial remote I/O Devices (for scheduled calls, and so on).
- One modem on COM2 to receive calls from remote I/O Devices.
- One dedicated modem on COM3 to return these calls.

To configure your modems, first define them in Windows (through the Windows Control Panel). Remember, you're not just defining the physical modem here: you need to define a separate Windows (virtual) modem for each communication framework. This means you have to configure:

- Three logical modems on the port to which the physical dial-out modem is attached.
- One logical modem on the port to which the physical dial-in modem is attached.
- Three logical modems on the port to which the physical dial-back modem is attached.

Assuming that the necessary total of seven logical modems are called 'Standard Modem' through to 'Standard Modem #7', configure these modems as follows:

Port	Modem Name	Max. Speed	Data Bits	Parity	Stop Bits
COM1	Standard Modem	9600	7	O	1
COM1	Standard Modem #2	19200	8	E	1
COM1	Standard Modem #3	9600	8	N	1
COM2	Standard Modem #4	9600	8	N	1
COM3	Standard	9600	7	O	1

Port	Modem Name	Max. Speed	Data Bits	Parity	Stop Bits
	Modem #5				
COM3	Standard Modem #6	19200	8	E	1
COM3	Standard Modem #7	9600	8	N	1

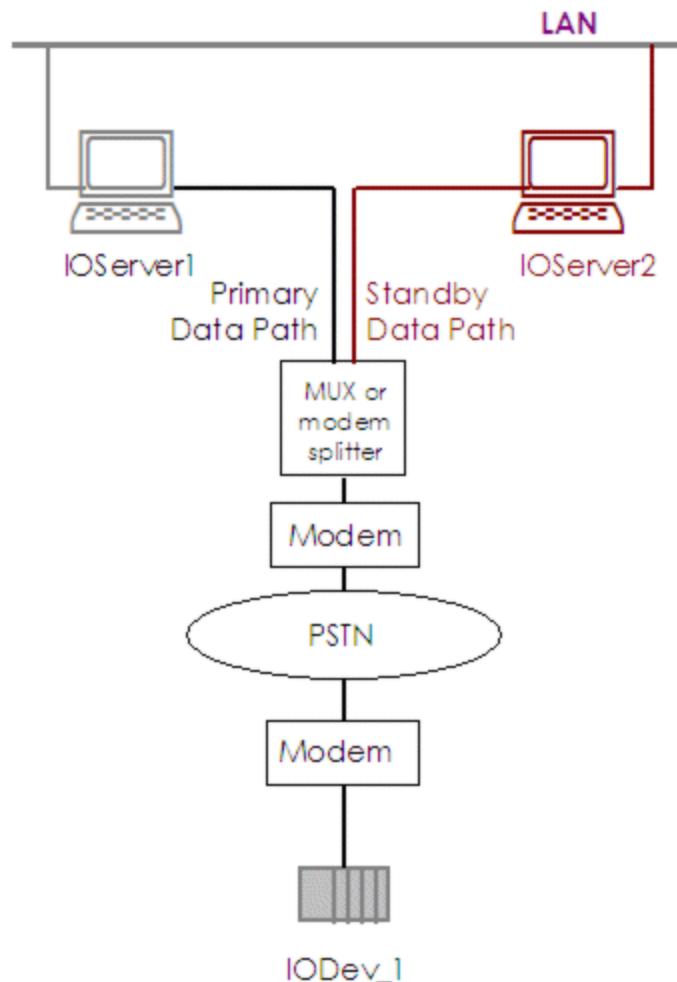

You would then configure the modems in Plant SCADA as follows:

Modem Name	Dial-out	Dial-in	Dial-back
Standard Modem	TRUE	FALSE	FALSE
Standard Modem #2	TRUE	FALSE	FALSE
Standard Modem #3	TRUE	FALSE	FALSE
Standard Modem #4	FALSE	TRUE	FALSE
Standard Modem #5	FALSE	FALSE	TRUE
Standard Modem #6	FALSE	FALSE	TRUE
Standard Modem #7	FALSE	FALSE	TRUE

## I/O Server Redundancy for Dial-up Remote I/O Devices

You can change the number of rings the I/O Server will wait before answering the call (using the **[Dial]RingCount** parameter). If you are using redundant I/O Servers, the primary I/O Server will be called by default. However, by setting **[Dial]RingCount** to a different value on each of the I/O Servers, you can make the standby I/O Server answer the call if the primary does not.

Consider the following setup:

If you set the ring count to 3 on IOServer1 and 4 on IOServer2, IODev\_1 will attempt to call IOServer1. If IOServer1 has not answered the call after 3 rings, IOServer2 will answer it.

## See Also

[Troubleshooting Dial-up Remote I/O Device Communications](#)

### Troubleshooting Dial-up Remote I/O Device Communications

The challenges most often encountered when using a dial-up remote I/O Device involve communications speed, parity, and control signals from the connected equipment. If changing the speed and parity does not resolve a communications interruption, evaluate the modem's answering codes and command echoing.

Following is a list of settings that might be helpful in resolving dial-up communications interruptions. (Since not every modem supports the same commands in the same way, this is only a guide. Consult the modem manual for exact details.)

#### On the modem at the PC end

```
ATV1 //Enables long-form (verbose) result codes
ATQ0 //Result codes are sent on the RS-232 connection
ATE0 //Commands sent from the computer are not echoed back to the RS-232 connection
```

```
AT&C1 //DCD will follow carrier on the line
AT&K0 //Handshaking OFF
ATW0 //Upon connection, only DTE speed is reported
AT%C0 //Compression OFF
AT&D0 //DTR always on
```

If the modem at the PC end is configured so that calls are automatically answered even when your Plant SCADA project is off, data being reported from the I/O devices may be lost. Therefore, it is recommended that you turn off the PC modem's auto-answer feature before taking your project offline. To do this, set the following parameter to zero:

```
ATS0 = 0 // Auto answer OFF
```

Be aware, however, this will also impact applications that might use the modem other than Plant SCADA, as the modem cannot answer a call while Plant SCADA is not driving its functionality.

#### On the modem at the I/O Device end

```
ATV0 //Enables short-form result codes
ATQ1 //No result codes are sent on the RS-232 connection
ATE0 //Commands that are sent from the computer are not echoed
back to the RS-232 connection
AT&C1 //DCD will follow carrier on the line
AT&K0 //Handshaking OFF
ATW0 //Upon connection, only DTE speed is reported
AT%C0 //Compression OFF
AT&D0 //DTR always on
ATS0 //Set to greater than 0 (sets the number of rings necessary before the modem answers
an incoming call).
```

### Alternative (backward compatibility) Method of Persistent Connection

If you are setting up your modem to dial a dial-up remote I/O Device, follow the procedures described in [Communicating with Remote Devices via Modems](#). This method is available for backward compatibility.

## Scheduled Communications

Plant SCADA allows you to schedule communications with your I/O Devices (regardless of the type of connection: modem, radio link, etc.). For example, if you have multiple I/O Devices on a single network or line, you can schedule reads so that the important I/O Devices are read more often than less important I/O Devices. Alternatively, a water supplier with radio link connections to dam level monitors might schedule hourly level reads from Plant SCADA in order to conserve band-width.

### See Also

- [Specifying a Schedule](#)
- [Writing to the Scheduled I/O Device](#)
- [Reading from the scheduled I/O Device](#)

### Specifying a Schedule

To configure scheduled communications with an I/O Device, you need to flag it as a "Scheduled" device. This is

done using the **Device Communications Wizard**. If your I/O Device is not capable of scheduled communications, the scheduling options will not be presented by the wizard.

---

**Note:** Scheduled communications will not work for drivers that are designed to handle Report-By-Exception protocols. For communicating with your I/O Device outside of schedule use the IODeviceControl function.

---

### To schedule communications with an I/O Device:

1. Navigate to the Topology activity | I/O Devices.
2. Click **New Device** on the Command Bar. The
3. Double-click the **Express I/O Device Setup** icon in the Communications folder of the current project.
4. Follow the instructions to work through the screens, selecting the relevant I/O Device, and so on. When the scheduling screen displays, check the **Connect I/O Device to PSTN** box, even if your I/O Device is not connected via a modem (but leave the Phone number to dial and Caller ID fields blank).
5. Fill out the schedule fields to achieve the desired schedule. For example (all based on a **Synchronize at time** of 10:00:00).

If you enter 12:00:00 in the **Repeat every** field, and start your project at 9 a.m., the I/O Server will communicate with the I/O Device at 10 a.m., then once every 12 hours after that, i.e. 10 p.m., then again at 10 a.m. of the following day, etc.

- If you enter 12:00:00, and start your project at 4 p.m., the I/O Server will communicate with the I/O Server at 10 p.m., then again at 10 a.m. of the following day, etc. i.e. it will assume that communications were established at 10 a.m., so it continues as if they had been, communicating once every 12 hours after 10 a.m.
  - If you enter 3 days, and start your project at 9 a.m. on a Wednesday, the I/O Server will communicate with the I/O Device at 10 a.m., then once every 3 days after that, i.e. 10 a.m. on the following Saturday, then at 10 a.m. on the following Tuesday, etc.
  - If you enter the 6th of December in the **Repeat every**, and start your project during November, the I/O Server will communicate with the I/O Device at 10 a.m. on December 6, then again on December 6 of the following year, and so on.
6. Select **On Startup** for a persistent connection. To disconnect a persistent connection, you need to call the IODeviceControl() function with type 8.
  7. If your I/O Device is not connected via a modem, you need to go to the Ports settings and change the Port number to the actual number of the COM port.

### See Also

[Writing to the Scheduled I/O Device](#)

### Writing to the Scheduled I/O Device

Whenever an I/O Device is actively communicating (as per its schedule), you can write to it directly. However, if you try to write to it when it is not communicating, your write request will be queued until it is. For example, you might decide to schedule one write per hour. If someone at a Control Client changes a tag's value during that hour, that change will not be written to the I/O Device until the hour has expired.

As write requests are not written to the I/O Device until it is communicating, confirm that pending writes have been completed in full before shutting down.

**Note:** Don't control hardware using a scheduled I/O Device, as the exact state of the hardware may not be known. Although you can read the state from the cache, it may have changed since the cache was created.

## ⚠️ WARNING

### UNINTENDED EQUIPMENT OPERATION

Do not use a scheduled I/O device to control hardware in a system managed by Plant SCADA.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

## See Also

[Reading from the scheduled I/O Device](#)

### Reading from the scheduled I/O Device

When the I/O Server initiates communication with the I/O Device, it immediately writes any queued write requests, then reads the I/O Device's tags. These values are then stored in a cache so that you can still access them between communications.

**Note:** Because the I/O Server reads tags on initiation of communication, the license point count is increased, even though some of the tags read may not actually be used.

### Keeping Data Up-to-Date during Prolonged connections

Normally, communication is terminated as soon as every read and write request is complete. Sometimes, however, you may want to prolong the communication (for example by calling the IODeviceControl() function with Type 7).

In this situation (if Read-Through Caching is disabled), when client computers request device data from the I/O Server, it retrieves the data from its cache, not from the I/O Device. This occurs even though the I/O Server maintains a connection to the device.

To retrieve fresh data from the I/O Device, you can force a periodic read using Cicode, or change the cache timeout by setting the IODeviceControl() function to Type 11.

For example:

```
INT hTask;
// Initiate communications and read tags.
// Sleep time will depend on how fast your
// modems connect.
FUNCTION
DialDevice(STRING sDevice)
    INT bConnected = 0;
    INT nRetry = 5;
    hTask = TaskHnd("");
    IODeviceControl(sDevice, 7, 0);
    Sleep(20);
    WHILE bConnected <> 1 AND nRetry > 0 DO
        bConnected = IODeviceInfo(sDevice, 18);
        nRetry = nRetry - 1;
        Sleep(10);
```

```
END
IF bConnected = 1 THEN
    WHILE TRUE DO
        Sleep(2);
        IODeviceControl(sDevice, 16, 0);
    END
END
// Kill the read task and terminate the connection.
FUNCTION
HangupDevice(STRING sDevice)
    TaskKill(hTask);
    IODeviceControl(sDevice, 8, 0);
END
```

You can also force the I/O Server to read data directly from an I/O Device by enabling Read-Through Caching. With [\[Dial\]ReadThroughCache](#) set, while the I/O Server is connected to a device it will supply data to requesting clients directly from the device. The cache is not updated during this time, but is refreshed with the most recent device data just before the server disconnects.

**Note:** If using modems, you might need to adjust or deactivate the inactivity timer in your modems to stop them from disconnecting while no data is being read. The inactivity timer is controlled by the S30 register. If your modem doesn't support this register, please consult your modem's manual.

### Avoiding Unnecessary Multiple Reads of I/O Device Data

To avoid unnecessary reads of an I/O Device, you can use data caching to temporarily store data read from the device in the memory of the I/O Server. This means that if the I/O Server receives more than one request for device data in a short time period, instead of contacting the I/O Device a second time and reading identical data, it can retrieve the data from the cache.

## Communication Performance Considerations

Many external factors influence the performance of control and monitoring systems. The capabilities of the computer, the I/O Device(s), and the communication pathway between them are obvious factors. The faster they can transfer data, the faster your system operates. (Plant SCADA always attempts to maintain a data transfer rate as fast as the I/O Device hardware can support.) The data transfer rate is hardware dependent: once you have installed the hardware, your ability to influence this characteristic is limited.

However, there is one area where you can directly affect the performance of your runtime system: the arrangement of data registers in the I/O Device(s).

## See Also

- [Caching Data](#)

- [Remapping Variables in an I/O Device](#)

## Caching Data

On large networked systems with many clients, you can improve communications turn-around time by using memory caching.

When caching is enabled, data that is read from an I/O Device is stored temporarily in the memory of the I/O Server. If another request is made (from the same or another client) for the same data within the cache time, the Plant SCADA I/O Server returns the value in its memory, rather than rereading the I/O Device. Data caching results in faster overall response when the same data is necessary by many clients.

A cache time of 300 milliseconds is recommended. Avoid using long cache times (in excess of 1000 milliseconds), as this may negatively impact the timely delivery of information to the system.

**Note:** Do not use data caching for [Configure a Disk I/O Device](#) as they implement a cache themselves.

---

## Grouping Registers

When you configure a Plant SCADA system, you need to define each variable (register address) that Plant SCADA will read when your system is running. When your runtime system is operating, Plant SCADA calculates the most efficient method of reading registers. Plant SCADA optimizes communication based on the type of I/O Device and the register addresses.

When Plant SCADA requests data from an I/O Device, the value of the register is not returned immediately; an overhead is incurred. This overhead (associated with protocol headers, checksum, device latency, and so on) depends on the brand of I/O Device, and is usually several times greater than the time necessary to read a single register. It is therefore inefficient to read registers individually, and Plant SCADA usually reads a contiguous block of registers. Because the overhead is only incurred once (when the initial request is made), the overhead is shared across every register in the block, increasing the overall efficiency of the data transfer.

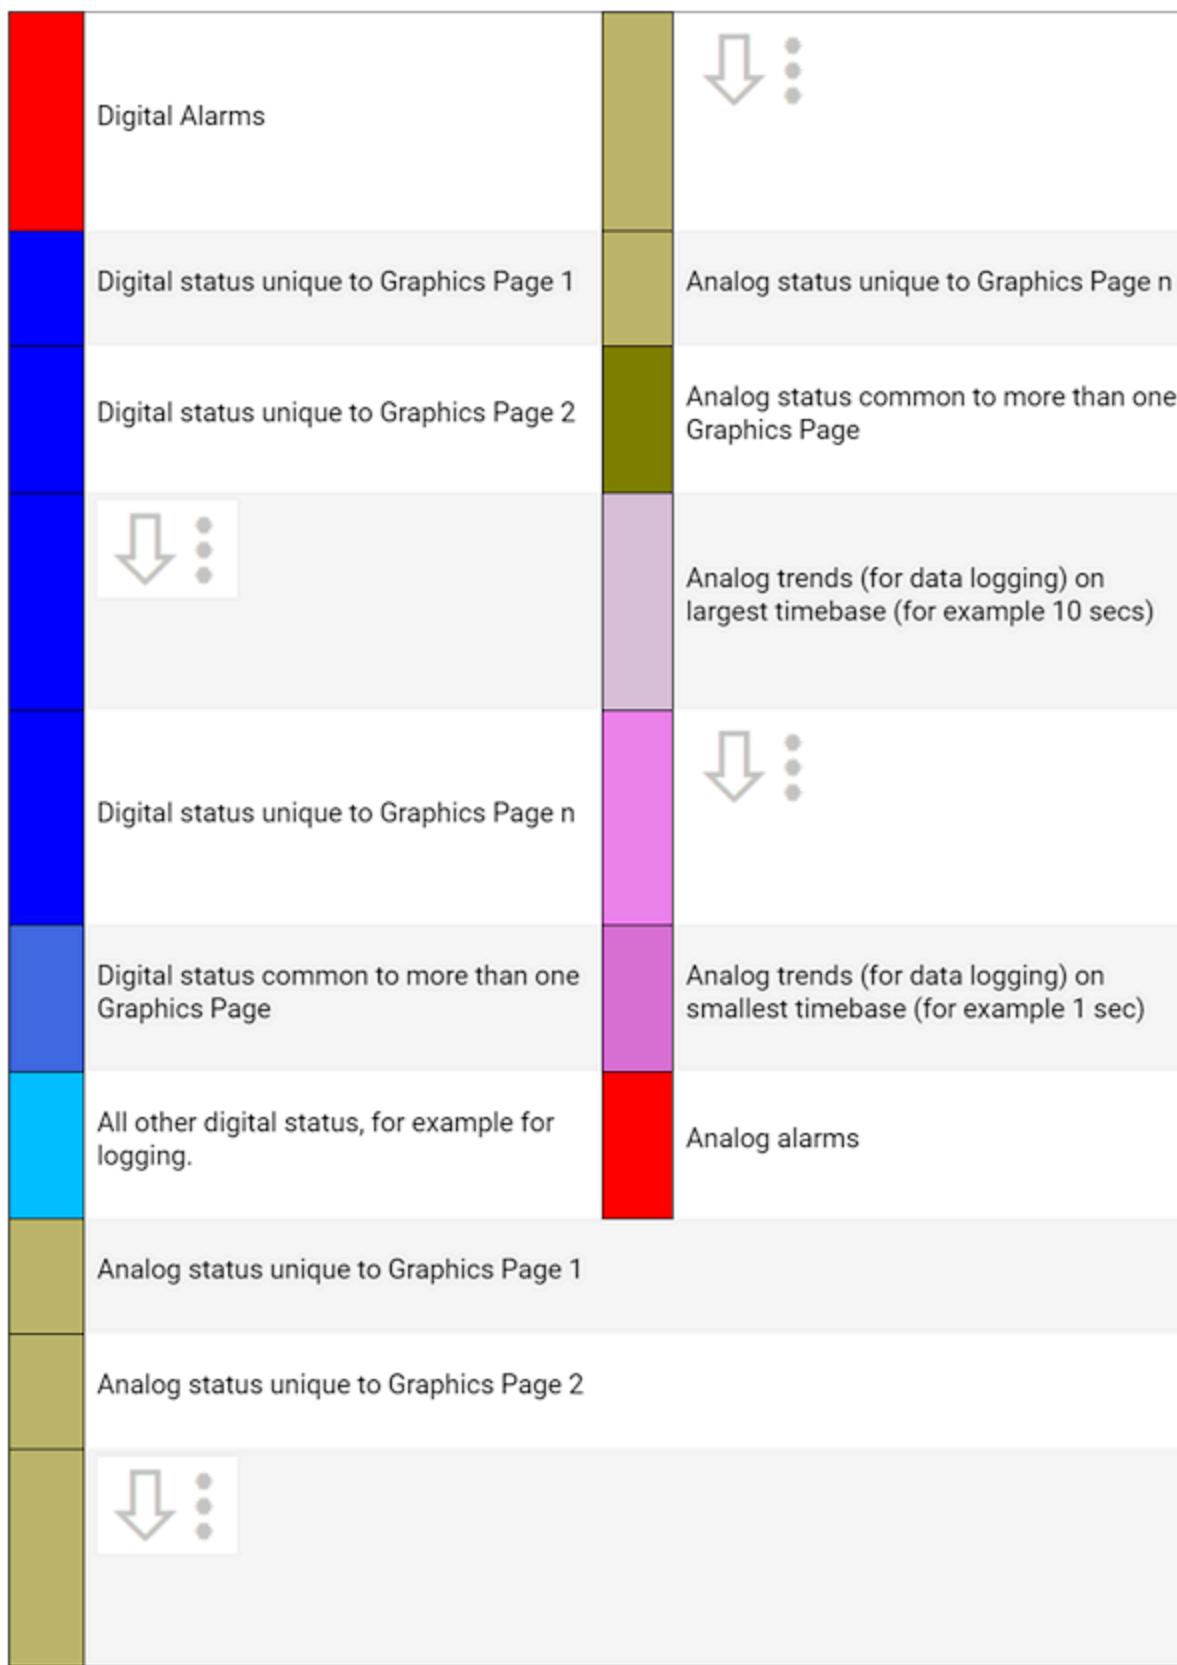

However, reading a block of registers where only a small percentage of the block is actually used is also inefficient. If the registers that your Plant SCADA system will read are scattered throughout the memory of your I/O Device, excessive communication will be necessary. Plant SCADA needs to either read many contiguous blocks (and discard the unused registers), or read registers individually, degrading system performance. You can avoid this by grouping the registers that Plant SCADA will read.

Plant SCADA continually reads registers associated with alarms. (If an alarm condition occurs, Plant SCADA can display the alarm immediately.) therefore group registers that indicate alarm conditions.

Registers associated with status displays (objects, trends, and so on) are only read as they are necessary (that is, when the associated graphics page is displayed) and are appropriately grouped according to the pages on which they are displayed.

Registers used for data logging are read at a frequency that you define. They are grouped according to the frequency at which they are read.

The following table shows an ideal register grouping for a Plant SCADA system:

While memory constraints and the existing PLC program might impose limitations, grouping registers into discrete blocks, even if they are not consecutive blocks, will improve system performance.

When designing your system, allow several spare registers at the end of each block for future enhancements.

[Remapping Variables in an I/O Device](#)

### Remapping Variables in an I/O Device

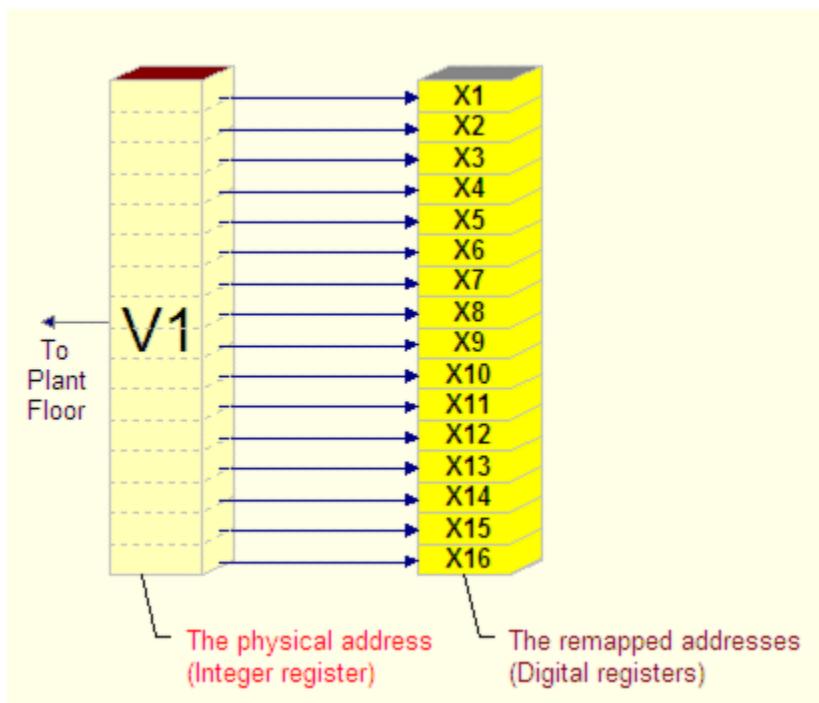

Some PLCs allow you to remap (or copy) an I/O device variable to another register address. Plant SCADA allows you to remap to:

- Group registers more efficiently to increase performance.
- Allow Plant SCADA to interpret a variable type (for example, an analog variable) as a different variable type (for example, a digital variable). For example, you can create additional digital addresses if an I/O device has run out of digital addresses.

To remap a variable in your PLC, you need to design (or modify) the logic in the PLC to associate both addresses. Plant SCADA can then read or write the variable to and from the remapped address instead of the physical address.

You can also reassign one type of variable (for example, an integer) to another type of variable (for example, a digital variable).

To remap in Plant SCADA, first create the variables in your project as you would normally. Then you can set up the remapping, specifying that any variable with an address in the desired range will be remapped. The I/O server will redirect the addresses at runtime as per the remapping instruction.

---

**Note:** Not every PLC and/or Plant SCADA driver supports remapping. It is not recommended unless necessary. Contact Technical Support if you need to evaluate whether the PLC and/or driver support remapping.

---

#### To remap a variable in Plant SCADA:

1. In the **Topology** activity, select **Components & Mappings**.
2. On the menu below the Command Bar, select **Remapping**.
3. Add a row to the Grid Editor.
4. Type the required information in each column, or in the fields in the Property Grid.
5. For a description of the properties, see below.
6. Click **Save**.

---

**Note:** To determine if the device supports remapped reads or writes, see the I/O Device Data Type help.

---

## Remapping Properties

### General Properties

Property	Description
<b>Plant SCADA variable</b>	The first remapped (Plant SCADA) variable defined in the variable tags database (using the Tags dialog box); for example: Motor_1_Run.

Property	Description
	(79 characters maximum). Alternatively, use the direct <Unit Name> <Address>  format (using values specific to your I/O device); for example: IODev X1 . The address entered here is remapped. At runtime the I/O server will read/write data through the physical address instead.
<b>Length</b>	The number of remapped variables. Plant SCADA reads enough physical variables to remap this number of variables (10 characters maximum). The length needs to be less than the maximum request length of the protocol. The protocol overview displays the maximum request length of the protocol.
<b>Physical Variable</b>	The first physical variable in the PLC, for example: ReMapIntV7. (79 characters maximum). This variable does not need to be defined in the variable tags database. You can use the <Unit Name> <Address>  format (using values specific to your I/O Device). For example, IODev V7 .
<b>Remap Read</b>	Determines whether to perform the remapping for reads. Set to TRUE or FALSE.  FALSE - Read normal (not remapped) variables. The actual address of the Plant SCADA variables will be read directly from the I/O Device, instead of through the Physical Variable. (Use this mode if your I/O Device does not support remap reads.)  TRUE - Read remapped variables (through the physical variable).
<b>Remap Write</b>	Determines whether to perform the remapping for writes. Set to TRUE or FALSE.  FALSE - Write to normal (not remapped) variables. The actual address of the Plant SCADA variables will be written directly in the I/O Device, instead of through the physical variable. (You need to use this mode if your I/O Device does not support remap writes.)  TRUE - Write to remapped variables (through the physical variable).
<b>Comment</b>	Any useful comment.

## Project Properties

Property	Description
Project	The project in which the remapping is configured.

## Advanced Driver Information

This section provides advanced information about drivers.

- [Variable \(Digital\) Limitations](#)
- [Validating Distributed Project Data for Tag-based Drivers](#)
- [Write Delay Effects](#)

### Variable (Digital) Limitations

Devices often have memory areas that are of a designated data type, like Byte, Integer, or Word. Some protocols do not support the reading and writing of data in these memory areas using a different data type. This situation is most common in the case of reading and writing of individual bits within the data types like Bytes, Integers, and Words.

In this case, reading individual bits within these larger data types is done by reading the designated data type and getting the Plant SCADA driver to sub-divide it into individual bits. Writing to bits within the larger data types is more complicated, as writing to one bit within the larger data type will at the same time overwrite the other bits within that same data type. To prevent overwriting existing bits when writing a new bit value, a 'read-modify-write' scenario can be used to write to a bit within the larger data type. Using this approach, the Plant SCADA driver will read the larger data type, modify the appropriate bit within the larger data type, and then write the larger data type back to the device.

While the 'read-modify-write' approach is necessary to avoid overwriting existing bits in the registers of larger data types, it can create an issue if the device being written to is also configured or programmed to modify these same registers. For example, if a PLC device modifies the registers of one of its larger data types after the Plant SCADA driver has read these same registers, but before Plant SCADA has written the modified value, the changes made by the PLC will be overwritten. This outcome can be avoided if Plant SCADA and any devices using these data types are configured so that only one or the other has write access at any given time.

This 'read-modify-write' method has a serious operational concern: if the device modifies the larger data type after the Plant SCADA driver has read it, but before Plant SCADA has written the new value, any changes made by the device are overwritten. This issue could be serious in a control system, and it is recommended that the device and Plant SCADA be configured so that only one of these systems writes to the data types of this kind.

### UNINTENDED EQUIPMENT OPERATION

When the read-modify-write method will be used to alter a data type's bit values, configure your system so that Plant SCADA and the host device do not have simultaneous write access to the affected memory ranges.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

Consider the following example:

- The initial state of a PLC register is 0x02h.
- The Plant SCADA driver reads the value of this register (effectively making a copy) in preparation for a change to bit 3.
- However, before the driver writes its change back to the PLC, the PLC code changes the value of bits 0 and 4 of this register to 0x13h.
- The Plant SCADA driver then changes bit 3 of its copy of the register to 0x0Ah. When it writes to the PLC, it overwrites the PLC's copy of the whole register (not just the changed bit). Because the PLC code modified bits 0 and 4 in the interval between Plant SCADA's read and write, these changes are overwritten.

## Validating Distributed Project Data for Tag-based Drivers

Plant SCADA uses numeric index values to uniquely identify the variable tags in a project. They are used as a reference point when requesting data from the I/O Server for a tag-based driver.

These index values are automatically generated when a project is compiled. Circumstances may arise where a distributed project has index values that represent different tag addresses on different computers. For this reason, Plant SCADA has a number of automatic checks in place that validate a project's tag index values and flag any discrepancies.

An initial security check takes place on client machines at a unit level, allowing a tag index mismatch to be isolated to a particular client before any requests are sent to the I/O Server. This confirms that the unit address, the unit type, the raw data type and the tag address match for index values across the client and server machines. Any discrepancies found are flagged by a hardware alarm on the client machine.

Each page is also checked to confirm that it was compiled against the current version of the variables database. There is also a check performed whenever a tag-based driver loads the variable database to test whether it matches the current tag addresses. The parameter TagAddressNoCase allows you to adjust the case-sensitivity of these checks.

In addition, Plant SCADA will also check if a project is currently running on the local machine when a compile is attempted, as this is one of the circumstances that may lead to mismatched index values.

If the project uses a tag-based driver and is currently in runtime, Plant SCADA will stop the compiler and generate an error in the error database noting that Citect32.exe was still running. The .ini parameter [General]CitectRunningCheck allows you to override this feature, however it is recommended that you leave it enabled so that your tag index values are assigned as intended.

## Write Delay Effects

Plant SCADA performs writes to the I/O Device asynchronously (that is, when you write to the I/O Device, the write takes time to get to the I/O Device, during which Plant SCADA continues to perform other operations). If the other Cicode assumes that the write has completed immediately, you might encounter some side effects such as inconsistencies in the value of a variable tag across two Cicode threads.

If you have the following Cicode:

```
PLC_VAR = 1234;  
Prompt("Variable is " + PLC_VAR : #####);
```

the first line is a write to the PLC.

When Plant SCADA executes the first line, it generates a request to the I/O Server to write the value 1234 into the PLC variable PLC\_VAR. Plant SCADA then executes the next line of Cicode before the PLC write is completed. Plant SCADA does this so that the Cicode is not stopped while waiting for a slow I/O Device. As the write to the

PLC has not completed, you might think that the next line of Cicode will display the last value of PLC\_VAR and not the value 1234. However, this Cicode will display the correct value (1234) because whenever Plant SCADA writes to the PLC, it first updates its local copy of the variable: any following Cicode will get the correct value.

Sometimes this solution will not work as Plant SCADA might keep multiple copies of an I/O Device variable, and only update the one associated with the current Cicode. The other variables will contain the old value of the I/O Device variable until they are refreshed (with a read from the I/O Device). There is a separate data area for each display page, Cicode file, for alarms, trends and reports. If you write to an I/O Device variable from a page keyboard command, the copy of the I/O Device variable associated with that page will be updated; however, the copy associated with other pages and the Cicode functions is not updated until the next read (as determined by the [\[Page\]ScanTime](#) parameter). If you call a Cicode function that assumes the write has completed, it will get the last value.

The workaround is to write to the I/O Device variable in the Cicode function. Every Cicode function shares the same I/O Device variables, so the writes will operate as expected.

#### FUNCTION

```
TestFunc(INT nValue)
PLC_VAR = nValue;
END
```

Another side effect of the delays inherent in asynchronous writes to I/O devices is that you might assume that Plant SCADA has successfully written to the I/O Device, when in fact the write operation might not yet have been completed or even attempted. In such cases, it is still possible that a hardware- or configuration-based error will prevent the success of the write operation. While such an unsuccessful write operation will generate an error, your Cicode cannot be notified or use the IsError() function because the Cicode has continued to execute past the initial I/O device write command. Therefore, when it is important to check the success of a write operation before allowing code execution to continue, you might insert the function TagRead() after the write and then verify the value of the variable. TagRead() forces Cicode to re-read the I/O Device variable so that you can check the new value. TagRead() is a blocking function. It blocks the calling Cicode task until the operation is complete.

```
PLC_VAR = 1234;
sTestStr = TagRead("PLC_VAR");
IF sTestStr <> 1234 THEN
Prompt("Write not completed");
END
```

Here the data will be read from the physical PLC, not from the I/O Server cache, as the I/O Server will invalidate any cached data associated with a PLC write. This will allow you to test for a completed write. Please be aware that other Cicode tasks running at the same time will not be waiting on the TagRead, so they might see the old or new value, depending on if they are using the same copy of the PLC variable. You can also stop Plant SCADA from writing to the local copy of the variable by using the function CodeSetMode(0, 0).

## Troubleshooting Device Communications

Debugging device communications involves the following processes:

- Gathering system information about current communication status
- Analyzing the available information to identify problems

The information needed to facilitate this is available from the following resources:

- Hardware alarms

- Driver errors
- Log files (system, trace, debug and driver logs)

This information can be analyzed directly to identify problems, or you can use the Plant SCADA Kernel to perform low-level diagnostic and debugging operations.

There are also procedures you can follow to debug low-level communications protocols, such as COMx and TCP/IP.

## See Also

[Gathering Communications Information](#)

[Debugging a COMx Driver](#)

[Debugging a TCP/IP Driver](#)

[Debugging a Protocol Driver Using Serial Communications](#)

## Gathering Communications Information

If you cannot establish communication with a device, check the following resources for evidence of a problem:

- Hardware alarms
- Plant SCADA log files
- Driver errors
- Runtime Kernel.

## Hardware Alarms

When an error occurs in a Plant SCADA operation, a hardware alarm is generated. Hardware alarms are typically displayed on a dedicated page within a project, allowing an operator to monitor the status of a system's infrastructure.

Hardware alarms will indicate if break in communications has occurred, if Cicode can't execute, if a server becomes inoperative, and so on. If you are having problems communicating with a device, initially check the hardware alarms page for evidence of an error.

See *Hardware Alarms* in the topic [Alarms](#).

## Plant SCADA log files

Plant SCADA supports a number of log files that track operational status during runtime.

The primary log file, syslog.dat, contains a log of system information; from low-level driver traffic and Kernel messages, to user-defined messages.

The **Log Read** and **Log Write** fields in the I/O Devices Properties dialog determine if logging is enabled for each I/O device.

Driver logs are also available. These relate to the operation of a particular driver and are named accordingly. For example, the ABCLX driver is logged in 'ABCLX.dat'. However some driver logs may be in differing locations, refer to the help for a particular driver to confirm the location.

For a description of the available log files and where they are stored, see [Log Files](#).

## Driver errors

There are two types of driver errors that are logged to syslog.dat:

- Generic
- Driver-specific

Generic errors are common to many drivers, and are mapped to general hardware errors.

Driver-specific errors are unique to a particular driver. A driver will convert a specific error into a generic error so that it can be recognized by the hardware alarm system. However, if further investigation is necessary, you can refer to a description of the original error in the [The Driver Reference Help](#). This includes a description of the errors associated with each driver.

See [Error Messages](#).

## Runtime Kernel

The Runtime Kernel is a gateway into the internal workings of Plant SCADA at runtime, and is provided for diagnostics and debugging purposes.

The Kernel can display several different diagnostic windows each providing an active view of the Plant SCADA runtime system.

The Runtime Kernel Driver window, launched via the Page Driver Kernel command, displays information about each driver in the Plant SCADA system. The statistics it presents include read requests, physical reads, digital reads per second, register reads, cache reads, error count, timeouts, and so on.

See [The Kernel](#).

## See Also

[Troubleshooting Device Communications](#)

## Debugging a COMx Driver

A COMx driver is the board driver typically used for serial communications. COMx driver events are logged in the following file:

`syslog.IOServer.<Cluster name>.<IO Server name>.dat`

This file is located in the directory specified by the [\[CtEdit\]Logs](#) parameter in the citect.ini file.

The COMx driver can log different combinations of trace levels. This is achieved by setting the following Citect.ini parameters:

[COMx] Parameter	Description	Allowable Values	Default Value
DebugLevel	The trace level used for the log file.	Any combination of the following, separated by a pipe character ( ):	-

		ERROR WARN TRACE DEBUG ALL  For example, ERROR   TRACE.	
DebugCategory	The categories used for the log.	The COMx driver supports one category: PROT = protocol level debug	-

The log file size and log file rollover process is controlled by the [\[Debug\]SysLogSize](#) and [\[Debug\]SysLogArchive](#) ini parameters.

When the log file reaches a specified size (100000 kilobytes by default), it may be rolled over into a timestamped file when [\[Debug\]SysLogArchive](#) is set to 1, otherwise it will be overwritten.

**Note:** The more detailed the logging, the larger the amount of log data that will be generated. This could create a large, cumbersome log file, or cause multiple wraparounds that write over data. Also when the number of pending messages to process exceeds the value set by the [\[Kernel\]ErrorBuffers](#) parameter, these messages are no longer logged. Messages not logged can be monitored in the General Kernel Window under the item "Lost Errors". It is recommended to use the following DebugLevel and DebugCategory settings:

`[COMx]DebugLevel=ERROR|WARN|TRACE`  
`[COMx]DebugCategory=PROT`

## Debugging a TCP/IP Driver

A TCPIP driver is the board driver typically used for serial communications. It might be over Ethernet, Token Ring or Arcnet. This driver communicates between Plant SCADA and Winsock, so it uses the normal networking functionality of Windows.

TCP/IP driver events are logged in the following file:

`syslog.IOServer.<Cluster name>.<IO Server name>.dat`

This file is located in the directory specified by the [\[CtEdit\]Logs](#) parameter in the `citect.ini` file.

The TCPIP driver can log different combinations of trace levels. This is achieved by setting the following `Citect.ini` parameters:

[TCPIP] Parameter	Description	Allowable Values	Default Value
DebugLevel	The trace level used for the log file.	Any combination of the following, separated by a pipe character ( ):  ERROR WARN TRACE DEBUG ALL	-

		For example, ERROR   TRACE.	
DebugCategory	The categories used for the log.	The TCPIP driver supports one category: PROT = protocol level debug	-
PortName. MulticastAddress	This parameter allows you to implement the TCPIP driver option "-Maa.bb.cc.dd" in the Citect.ini file.  This may be necessary if you have run out of characters in the Special Options field of the Ports settings, which is limited to 16 characters.	You need to specify the following in the Citect.ini file:  [TCPIP] PortName. MulticastAdress = aaa.bbb.ccc.ddd  Where:  PortName = the name of the port as entered in the Ports settings aaa.bbb.ccc.ddd = the multicast Class D IP address  See <a href="#">TCP/IP Driver Special Options Reference</a> .	
NoBufferSleepTime	Sleep time in milliseconds (ms) to wait AFTER getting a WSAENOBUFS (no system buffers message) before reading another buffer. There is no need to adjust this.	-	0
Timeout	Defines the timeout period between connection retries.		1000 (ms)

The log file size and log file rollover process is controlled by the [\[Debug\]SysLogSize](#) and [\[Debug\]SysLogArchive](#) ini parameters.

When the log file reaches a specified size (100000 kilobytes by default), it may be rolled over into a timestamped file when [\[Debug\]SysLogArchive](#) is set to 1, otherwise it will be overwritten.

**Note:** The more detailed the logging, the larger the amount of log data that will be generated. This could create a large, cumbersome log file, or cause multiple wraparounds that write over data. Also when the number of pending messages to process exceeds the value set by the [\[Kernel\]ErrorBuffers](#) parameter, these messages are no longer logged. Messages not logged can be monitored in the General Kernel Window under the item "Lost Errors". It is recommended to use the following DebugLevel and DebugCategory settings:

[\[TCPIP\]DebugLevel=ERROR|WARN|TRACE](#)

---

[TCPIP]DebugCategory=PROT

---

## Debugging a Protocol Driver Using Serial Communications

To debug a protocol driver that uses serial communications, do the following:

- Keep using your Simple As Possible Project (SAPP).
- Set the "DebugStr=\* all" for your protocol.
- Backup and delete both the syslog.dat and syslog.bak files. The system will recreate a fresh version of this file the next time Plant SCADA is started.
- Start the project. From the information you can see in the maximized Main window of the kernel be able to see if Plant SCADA is sending requests to your I/O device to initialize communications with it.

If there are no requests being sent then your software is improperly configured, and check that there were no errors on Startup of Plant SCADA. If there were errors on startup look them up in the Online Help. Also check that your computer is an I/O Server (and that it matches the one in your project). To do this run the **Setup Wizard**, and configure the computer for a standalone configuration.

If there are requests being sent but no reply, then Plant SCADA is trying to communicate. When Plant SCADA is sending requests but getting no reply, these are the most common causes:

- **The request Plant SCADA is sending is not getting to the I/O device** - Check the Address field in the I/O Devices form, and verify that it is correct. If the I/O device is one that needs a unique identifier (such as a node address), or you need some type of routing path, then verify that it is correct.

Check that you have the same parameters in the Ports form that the I/O device is using. If you have 8 data bits and the I/O device uses 7 data bits, communications will not work.

Check that your cable is OK. The easiest way to do this is to create a new project and use the Loopback protocol. You can use this to verify the **Tx** and **Rx** lines' integrity by placing a jumper on these lines. Initially test this with a jumper between pins 2 and 3 on your PC. Then plug in your cable and test again with the jumper between the **Tx** and **Rx** lines. Keep moving the jumper until it is at the end of your communications bus. You can find more information about the Loopback protocol via the AVEVA Knowledge and Support Center. Search for "Loopback".

Even if the Loopback protocol shows no errors, your cable might still be responsible for the loss of communications. Plant SCADA usually places a far higher constant load on serial communications than programming software does, this usually means that Plant SCADA will require much more stringent handshaking than the programming software. So it is possible that the cable you use to program your I/O device works fine for programming, but not for Plant SCADA.

Another major cause of improper cable connections is 9-pin to 25-pin converters. Many of these converters are made specifically for serial mice. These typically only use the **Tx**, **Rx** and **Ground** signals. If you use one of these converters they do not support any handshaking and will most likely not work for your Protocol.

If the above checks OK, use the parameters for COMx (as mentioned above) to create log files. Examine these log files and verify that what Plant SCADA thinks it is sending is actually what it is sending. The log files produced by using these parameters get their information from a lower level than Plant SCADA and show you exactly what is going through the COMx driver.

- **The Response from the I/O device is not getting to Plant SCADA** - This is unlikely and usually caused by cabling that is damaged, has insufficient bandwidth, or is connected improperly.. Check your cabling as above. Also, check that you are specifying everything you need within Plant SCADA. Many protocols require

Plant SCADA to send a unique identifier in its request packet. If this identifier is incorrect then the response cannot get back to Plant SCADA.

- **The I/O device does not understand the Request** - Every Plant SCADA protocol can check if an I/O device is running. Typically the protocol attempts to read data from the I/O device, usually a status register or other register that is there. However, many pseudo-standard protocols, such as Modbus, do not conform to the exact specification for that protocol. Many protocols supplied with Plant SCADA have some extra parameters to allow you to choose the specific initialization request from Plant SCADA. These can be found in either the Online Help or the AVEVA Knowledge and Support Center. Check with the manufacturer of your I/O device to confirm that it will respond to the request that Plant SCADA sends. If you are unsure of the request being sent for initialization, use DebugStr=\* to get the actual variable address that Plant SCADA is asking for in its initialization.

Check the protocol you are using. Plant SCADA may have many different protocols for communicating to an I/O device. PLCs such as the AB PLC5 can use different serial protocols, depending on the method you are trying to use. Make sure you are using the correct one. If you are unsure, try the other possible protocols.

- **The I/O device is not functioning properly** - There is usually some sort of software from the I/O device manufacturer that can be used to diagnose any problems with the I/O device.

## See Also

[Debugging Proprietary Board Drivers](#)

## Debugging Proprietary Board Drivers

Proprietary board drivers (such as the Allen Bradley KTX card, Modicon SA85 card, Siemens TIWAY card, and so on) have their own low-level drivers. Each driver has debugging parameters to make it easier to debug device behavior. See the driver documentation for details.

The debugging process is exactly the same as with a serial connection:

- Keep using your Simple As Possible Project (SAPP).
- Set any debugging parameters for the protocol and board drivers.
- Start Plant SCADA with clean log files.
- Find any errors and then look them up in the manufacturer's documentation.

## File Formats

The **Write** file will adopt the following format:

LINE 1	WRITE Debug file Started PORTNAME Debug Level 1 DOW MONTH DOM HH:MM:SS.sss
LINE 2	HH:MM:SS.sss
LINE 3	Out W In X nBytes Y Status Z
LINES 4...	AA BB CC ..

Where:

W & X =	Values of buffer pointers
Y =	Number of bytes written
Z =	Return status of the WriteFile
AA BB CC =	Values in hex of each byte written

**Example:**

```
WRITE Debug file Started PORT1_BOARD1 Mon Dec 15 16:07:.998
16:07:09.810
Out 0 In 8 nBytes 8 iStatus 997
0e 02 00 00 10 00 00
16:07:10.802
Out 8 In 16 nBytes 8 iStatus 997
0e 02 00 00 00 10 00 00
..
..
```

The **Read** file will adopt the following format:

LINE 1	READ Debug file Started PORTNAME Debug Level 1 DOW MONTH DOM HH:MM:SS.sss
LINE 2	HH:MM:SS.sss
LINE 3	Out W InRx X nBytes Y Status Z
LINES 4...	AA BB CC ..

Where:

W & X =	Values of buffer pointers
Y =	Number of bytes read
Z =	Number of characters remaining in the buffer
AA BB CC =	Values in hex of each byte written

**Example**

```
READ Debug file Started PORT1_BOARD1 Mon Dec 15 16:07:07.998
16:07:09.830
Out 0 In 0 nBytes 8 iStatus 0
0e 02 00 00 00 10 00 00
16:07:10.822
Out 0 In 8 nBytes 8 iStatus 0
0e 02 00 00 00 10 00 00
```

The **Status** file will adopt the following format:

LINE 1	STATUS Debug file Started PORTNAME Debug Level 1 DOW MONTH DOM HH:MM:SS.sss
LINE 2	HH:MM:SS.sss

LINE 3	modemStatus X
--------	---------------

**Example**

```
STATUS Debug file Started PORT_1 Debug Level 1 Wed Nov 05
15:28:55.310
15:29:55.950
modemStatus 34
..
```

More parameters might be added later, so check the COMx information and the AVEVA Knowledge and Support Center regularly.

**Serial Port Loop-Back Test**

You can use the serial port loop-back test to test your serial hardware configuration. This test can be used with any COM port, whether it is local, or on a multi-port serial board (such as a Digiboard). The test can be performed internally or externally with loop-back cable attached.

**See Also**

[Test Setup](#)

[Serial Port Loop-back Cable](#)

**Test Setup**

1. Do not configure any other protocols. Temporarily delete other boards and units while performing this test.
2. Configure a unit for each port to be tested. Make the I/O Devices form look as follows:
  - **Name:** <unique name for the I/O Device>
  - **Number:** <unique network number for the I/O Device>
  - **Address:** NA
  - **Protocol:** LOOPBACK
  - **Port Name:** <the "Port Name" in the Ports form>

3. The following Citect.ini options are supported:

- [LOOPBACK]

LoopBack - Set this to 1 if internal loop-back is to be performed (make sure this is deleted after running the test). When set to 0, a loop-back connector which ties pins 2 and 3 together is necessary at each port.

**Note:** The COMx driver does not support internal loop-back. The external loop-back is the default mode.

**Size** - Sets the maximum frame size. The length of each frame transmitted is random between 1 to 'Size'-1. The default size is 512.

4. Start up Plant SCADA. Each port will transmit a frame of random length. This process is repeated when the

entire frame is received.

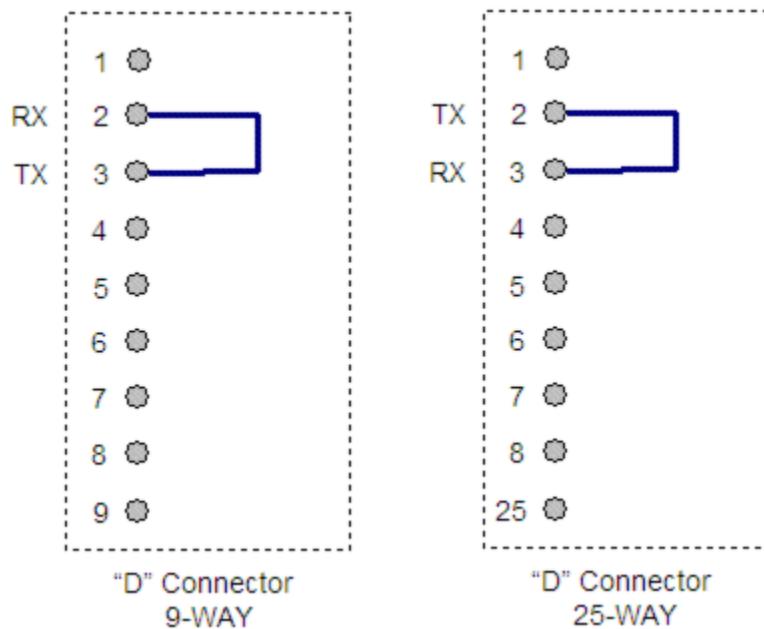

5. Open the kernel, type "page driver" and press **Enter**. Type **V** to set the display mode to 'verbose'. The following statistics appear:

- Number of characters transmitted.
- Number of frames transmitted.
- Number of characters received.
- Elapsed time in milliseconds.
- Characters received per second.
- Start time in milliseconds.
- Total number of errors.
- Error code of last detected error.

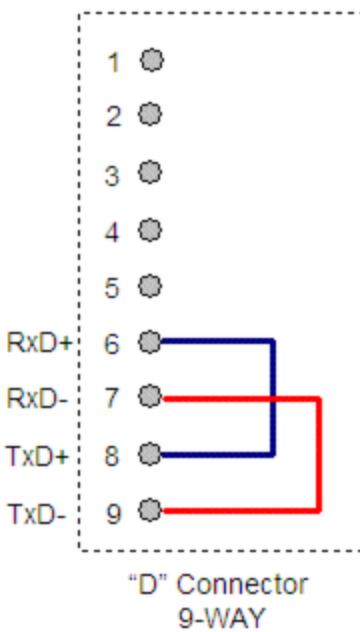

**Note:** The total number of errors should be 0. If the number of errors reported is not zero, your serial hardware is not operating properly.

### Serial Port Loop-back Cable

The diagram below shows the loop-back connections to use with RS-232.

The diagram below shows the loop-back connections to use with RS-422 or RS-485.

## Error Messages

Plant SCADA has two kinds of protocol driver errors:

- generic
- driver-specific

Generic errors are hardware errors 0-31, and are common to every protocol.

Drivers have their own specific errors, which can be unique and therefore cannot be recognized by the hardware alarm system. The drivers convert their specific errors into generic errors that can be identified by the I/O Server.

For example, when a driver becomes inoperative, there is often both a driver-specific error and a corresponding generic error.

---

**Note:** For reference information related to the implementation of device drivers, including driver alert messages, please refer to the [The Driver Reference Help](#).

---

- [Standard Driver Errors](#)

### Protocol Generic Errors

Plant SCADA has two kinds of protocol driver errors: generic and [Protocol-Specific Errors](#). Generic errors are hardware errors 0-31, and are common to every protocol.

Protocol drivers also have their own specific errors, which can be unique and therefore cannot be recognized by

the hardware alarm system. The drivers convert their specific errors into generic errors that can be identified by the I/O Server. For example, when a driver has a fault, there is often both a protocol-specific error and a corresponding generic error.

## Generic Errors

The table below describes the generic protocol errors.

Error number	Error title	Description
1	Address is out of range	A request was made to a device address that does not exist. For example, you tried to read register number 4000 when there are only 200 registers in the I/O device. Check the Variable Tags database to find the variable in error.
2	Command canceled	The server canceled the command while it was being processed by the driver. The driver may have taken too long to process the command. If a driver does not respond during the specified time limit, Plant SCADA cancels the command. The time limit is the product of the timeout period and the number of times to retry a command after each timeout. You can increase these values in the Timeout and Retry parameters for the protocol. also check the WatchTime parameter for the frequency with which the driver checks the link to the I/O device. Check also for communication errors.
3	Unknown data type	A request was made that specified a data type not supported by the protocol. This error will not occur during normal operation. Restart the computer to reset every driver and hardware. If the problem persists, contact Technical Support for this product. If you have written your own protocol driver, this error is caused by a mismatch in the compiler specification and the driver's database.

Error number	Error title	Description
4	Unknown data format	A write request contains invalid data, for example you tried to write to a floating-point address with an invalid floating-point number. Check the Plant SCADA database.
5	Command is unknown	The server sent a command that the driver did not recognize. This error will not occur during normal operation. Try re-booting the computer to reset drivers and hardware. If the problem persists, contact Technical Support of this product.
6	Response bad or garbled	A problem exists with the communication channel, causing errors in the transmitted data. Inspect the setup for the communication channel hardware. For example, there may be a mismatch in parity, baud rate, stop bits, or data bits between the transmitter and receiver. Check that the setup of the I/O device and the field data in the Plant SCADA Ports and Boards forms are the same.
7	I/O device not responding	An I/O device is not responding to read or write requests. The driver sent a command to the I/O device and the I/O device did not respond within the timeout period. This is usually the first indication of loss of communications. Check that the I/O device is correctly connected to the server and is switched on. This error can also occur if the timeout period is too short. Try increasing the timeout period in the Timeout parameter for the protocol. You could also increase the delay time between receiving a response and sending the next command, by increasing the Delay parameter.
8	General error	Plant SCADA has established

Error number	Error title	Description
		<p>communications with the I/O device; however, the I/O device has detected an error in the protocol. This error could be caused by a fault in the communications link, or an error in the ladder logic (in the I/O device).</p> <p>Solution:</p> <ol style="list-style-type: none"> <li>1. Check that the I/O device is operating correctly.</li> <li>2. Check the communication cable is connected correctly (at both ends).</li> <li>3. Use the Device Communications Wizard to check that the configuration of the I/O device (in particular, the Address and Special Options fields) matches the recommended settings and the settings on the I/O device.</li> <li>4. If you are using serial communications, use the Device Communications Wizard to check that the configuration of the Port (in particular the Baud Rate, Data Bits, Stop Bits, and Parity) matches the recommended settings and the settings on the I/O device.</li> <li>5. Display the hardware alarm page, and note the protocol error that is displayed.</li> <li>6. Use the documentation that was supplied with your I/O device, network, and communication board to locate the error.</li> <li>7. Check the ladder logic in the I/O device for errors.</li> <li>8. Run the Setup Wizard.</li> <li>9. Re-compile the project and start the Plant SCADA runtime.</li> </ol>
9	Write location is protected	A write operation was attempted to a location that is protected against unauthorized modification. Change

Error number	Error title	Description
		the access rights to this location to permit a write operation.
10	Hardware error	A problem exists with either the communication channel, server, or I/O device hardware. Examine hardware components. The command or data request has not been processed. The server's operation may no longer operate normally.
11	I/O device warning	The communication link between the server and the I/O device is functioning correctly, however the I/O device has some alert condition active, for example the I/O device is in program mode. Check that the I/O device is in the correct mode.
12	I/O device off-line, cannot talk	<p>The I/O device is in off-line mode, preventing any external communication.</p> <p><b>Solution:</b></p> <ol style="list-style-type: none"> <li>1. Check that the I/O device is operating correctly.</li> <li>2. Check the communication cable for breakage.</li> <li>3. Check the communication cable is connected correctly (at both ends).</li> <li>4. If you are using serial communications, check that the communication cable matches the diagram in the help system.</li> <li>5. Use the Device Communications Wizard to check that the configuration of the I/O device (in particular, the Address and Special Options fields) matches the recommended settings and the settings on the I/O device.</li> <li>6. If you are using serial communications, use the Device Communications Wizard to check</li> </ol>

Error number	Error title	Description
		<p>that the configuration of the port (in particular the baud rate, data bits, stop bits, and parity) matches the recommended settings and the settings on the I/O device.</p> <p>7. Run the Setup Wizard.</p> <p>8. Check the Citect.ini file for the following:</p> <p>[IOSERVER]</p> <p>Server=1</p> <p>Name=&lt;name&gt;</p> <p>where:</p> <p>&lt;name&gt; is the name of the server configured in the Plant SCADA project. (Use Custom Setup to check the server name.)</p> <p>9. Re-compile the project and start the Plant SCADA runtime system.</p> <p><b>Note :</b> If you have standby I/O devices configured, this error will cause any standby I/O devices to become active. The command or data request current when the I/O device went off-line has not finished.</p>
13	Driver software error	An internal software error has occurred in the driver. This error should not occur during normal operation. Try re-booting the computer to reset drivers and hardware. If the problem persists, contact Technical Support of this product.
14	User access violation	An attempt has been made by an unauthorized user to access information. Check the user's access rights.
15	Out of memory - FATAL	The server is out of memory and cannot continue execution. Minimize buffer and queue allocation or expand memory in the

Error number	Error title	Description
		server computer. The command or data request has not been processed.
16	No buffers, cannot continue	There are no communication buffers available to be allocated, or the computer is out of memory. The performance of the server may be reduced, however it can continue to run. Increase the memory.
17	Low buffer warning	This error may occasionally occur in periods of high transient loading, with no ill effects. If this error occurs frequently, increase the number of communication buffers.
18	Too many commands to driver	Too many commands have been sent to the driver.
19	Driver is not responding	The server is not receiving any response from the driver. This error should not occur during normal operation. Try re-booting the computer to reset the drivers and hardware. If the problem persists, contact Technical Support of this product.
20	Too many channels opened	Each driver can only support several communication channels. You have exceeded the limit. This error may occur if you abnormally terminate from the server and then restart it. Try re-booting the computer to reset drivers and hardware. If the problem persists, contact Technical Support of this product. The command or data request has not finished.
21	Channel off-line, cannot talk	A communication channel is currently off-line, disabling communication. Either the server cannot initialize the communication channel or the channel went off-line while running. Check the

Error number	Error title	Description
		channel hardware for errors. When this error occurs, I/O devices connected to this channel are considered off-line, and standby I/O devices become active. The command or data request has not finished.
22	Channel not yet opened	The server has attempted to communicate with a channel that is not open. Try re-booting the computer to reset drivers and hardware. If the problem persists, contact Technical Support for this product.. The command or data request has not finished.
23	Channel not yet initialized	The server is attempting to communicate with a channel that has not been initialized. This error should not occur during normal operation. Try re-booting the computer to reset drivers and hardware. If the problem persists, contact Technical support for this product. The command or data request has not finished.
24	Too many I/O devices per channel	A channel has too many I/O devices attached to it. This error should not occur during normal operation. The command or data request has not finished. Try re-booting the computer to reset drivers and hardware. If the problem persists, contact Contact Technical Support for this product..
25	Data not yet valid	The data requested is still being processed and will be returned in due course. This error only occurs with drivers that need to establish complex communication to retrieve data from the I/O device. Ignore this alert.
26	Could not cancel command	The server tried to cancel a

Error number	Error title	Description
		command, but the driver could not find the command. This error should not occur during normal operation. Try re-booting the computer to reset drivers and hardware. If the problem persists, contact Contact Technical Support for this product..
27	Stand-by I/O device activated	Communication has been switched from the primary to the standby I/O device(s). The server returns this message when a "hot" changeover has occurred. Rectify the error in the primary I/O device(s).
28	Message overrun	A response was longer than the response buffer. If this error occurs on serial communication drivers, garbled characters may be received. Check the communication link and the baud rate of the driver.
29	Bad user parameters	There is a configuration error, for example invalid special options have been set.
30	Stand-by I/O device error	There is an error in a standby I/O device. Rectify error in the standby I/O device.
31	Request Timeout from I/O Server	One or more requests sent to the I/O Server have not finished in the timeout period. Either the I/O Server is off line or the I/O Server is taking too long to finish the requests. Check the PLC communication link, PLC timeouts, PLC retries, and network communication. This error can occur even if you have no network, i.e. if the I/O Server is the same computer as the Control Client. If the error persists, increase the [LAN] TimeOut parameter. The default timeout is 8000

Error number	Error title	Description
		milliseconds.
32	Cannot talk to remote unit	The remote I/O device is not connected.
274	Invalid argument passed	An invalid argument has been passed to a Cicode function. This is a general error message and is generated when arguments passed to a function are out of range or are invalid. Check the value of arguments being passed to the function. If arguments are input directly from the operator, check that the correct arguments are being passed to the function.
281	No server could be found	The specified Plant SCADA server cannot be found. Either the server is not running or there is some communication problem with the network. Check that the network is set up correctly, and you are using the same Server Name on both the client and server.
418	No server of type on cluster	There is no server of the necessary type configured on the server.
448	Record size mismatch	An RDB file contains records with the wrong size.
451	Server previous reload busy	Unable to start a reload using the ServerReload Cicode function as a reload is already in progress for the specified server.
452	Invalid RDB version	An RDB file was compiled using an incompatible version of the software.
454	Cicode library timestamp differs	The timestamp of the Cicode library in memory is different from the timestamp of the Cicode library on disk. The Cicode libraries are potentially different.
519	Remote Cicode call Interrupted	Cicode call that triggers an RPC

Error number	Error title	Description
		remote call is interrupted before the expected result is returned.
520	Alarm category out of range	A category number is out of its valid range (from 0 to 16376 inclusively).
521	Data browse record is deleted	A record was deleted during a reload of ART server.
522	Trend archive property mismatch	A trend record's archive properties have changed during start-up or reload.
523	Alarm priority out of range	A category priority is out of its valid range (from 0 to 256 inclusively).

## Generic Driver Errors

The following errors are generic to every Plant SCADA driver. A driver error needs to be mapped to a generic error before Plant SCADA can interpret it.

Error	Description
GENERIC_ADDRESS_RANGE_ERROR (0x0001   SEVERITY_ERROR)	A request was made to a device address that does not exist. For example, an attempt was made to read register number 4000 when there are only 200 registers in the device.
GENERIC_CMD_CANCELED (0x0002   SEVERITY_ERROR)	The server canceled the command while the driver was processing it. This can happen if the driver takes too long to process the command. Check the timeout and retries for the driver.
GENERIC_INVALID_DATA_TYPE (0x0003   SEVERITY_ERROR)	A request was made specifying a data type not supported by the protocol. This error will not occur during normal operation.
GENERIC_INVALID_DATA_FORMAT (0x0004   SEVERITY_ERROR)	A request contains invalid data; for example, writing to a floating-point address with an invalid floating-point number. Check the Plant SCADA database.
GENERIC_INVALID_COMMAND (0x0005   SEVERITY_ERROR)	The server sent a command to the driver that it did not recognize. This error will not occur during normal operation.
GENERIC_INVALID_RESPONSE	The communication channel is not performing normally, and is causing errors in the transmitted data.

<b>Error</b>	<b>Description</b>
(0x0006   SEVERITY_ERROR)	
GENERIC_UNIT_TIMEOUT (0x0007   SEVERITY_ERROR)	A device is not responding to read or write requests. The driver sent a command to the device and the device did not respond within the timeout period.
GENERIC_GENERAL_ERROR (0x0008   SEVERITY_ERROR)	Unmapped driver specific errors are normally reported as a general error. Refer to the protocol-specific errors listed with the protocol you are using.
GENERIC_WRITE_PROTECT (0x0009   SEVERITY_ERROR)	A write operation was attempted to a location that is protected against unauthorized modification. Change the access rights to this location to permit a write operation.
GENERIC_HARDWARE_ERROR (0x000A   SEVERITY_UNRECOVERABLE)	The communication channel, server, or device hardware is not performing normally. Examine hardware components. The server's operation needs to also be examined for proper operation.
GENERIC_UNIT_WARNING (0x000B   SEVERITY_WARNING)	The communication link between the server and the device is functioning correctly; however, the device is experiencing an error or is in a non-operational state, for example, the device is in program mode.
GENERIC_UNIT_OFFLINE (0x000C   SEVERITY_SEVERE)	The device is in offline mode, preventing any external communication. This error will cause any stand-by units to become active. Plant SCADA will attempt to re-initialize the unit.
GENERIC_SOFTWARE_ERROR (0x000D   SEVERITY_SEVERE)	An internal software error has occurred in the driver. This error should not occur during normal operation.
GENERIC_ACCESS_VIOLATION (0x000E   SEVERITY_ERROR)	An attempt has been made by an unauthorized user to access information. Check the user's access rights.
GENERIC_NO_MEMORY (0x000F   SEVERITY_UNRECOVERABLE)	The server or driver has run out of memory and cannot continue execution. Minimize buffer and queue allocation or expand the server computer's memory (physical or virtual memory).
GENERIC_NO_BUFFERS (0x0010   SEVERITY_ERROR)	There are no communication buffers left to allocate. The performance of the server may be reduced; however, it can still continue to run. Increase the number of communication buffers.
GENERIC_LOW_BUFFERS (0x0011   SEVERITY_WARNING)	This error may occur in periods of high transient loading with no ill effects. If this error occurs

Error	Description
	frequently, increase the number of communication buffers.
GENERIC_TOO_MANY_COMMANDS (0x0012   SEVERITY_WARNING)	Too many commands have been sent to the driver.
GENERIC_DRIVER_TIMEOUT (0x0013   SEVERITY_ERROR)	The server is not receiving any response from the driver. This error should not occur during normal operation.
GENERIC_NO_MORE_CHANNELS (0x0014   SEVERITY_SEVERE)	Each driver can only support a fixed number of communication channels. You have exceeded the limit. The command or data request has not been completed.
GENERIC_CHANNEL_OFFLINE (0x0015   SEVERITY_SEVERE)	A communication channel is currently offline, disabling communication. The server cannot initialize the communication channel or the channel went offline while running. Every device (units)connected using this channel will be considered to be offline so this will cause any stand-by devices to become active. Plant SCADA will attempt to re-initialize the channel.
GENERIC_BAD_CHANNEL (0x0016   SEVERITY_SEVERE)	The server has attempted to communicate using a channel that is not open.
GENERIC_CHANNEL_NOT_INIT (0x0017   SEVERITY_SEVERE)	The server is attempting to communicate with a channel that has not been initialized. This error should not occur during normal operation. The command or data request has not been completed. If the condition persists, contact support.
GENERIC_TOO_MANY_UNITS (0x0018   SEVERITY_SEVERE)	A channel has too many devices attached to it. This error should not occur during normal operation.
GENERIC_INVALID_DATA (0x0019   SEVERITY_ERROR)	The data requested is not in a valid format or expected type.
GENERIC_CANNOT_CANCEL (0x001A   SEVERITY_WARNING)	The server tried to cancel a command, but the driver could not find the command. This error should not occur during normal operation.
GENERIC_STANDBY_ACTIVE (0x001B   SEVERITY_WARNING)	Communication has been switched from the primary to the stand-by unit(s). The server returns this message when a hot changeover has occurred.
GENERIC_MSG_OVERRUN	A response was longer than the response buffer. If this

Error	Description
(0x001C   SEVERITY_ERROR)	error occurs on serial communication drivers, garbled characters may be received. Check the communication link and the baud rate of the driver.
GENERIC_BAD_PARAMETER (0x001D   SEVERITY_ERROR)	There is a configuration error, for example invalid special options have been set.
GENERIC_STANDBY_ERROR (0x001E   SEVERITY_WARNING)	There is an error in a stand-by unit.
GENERIC_NO_RESPONSE (0x001F   SEVERITY_ERROR)	There is no response from the communications server.
GENERIC_UNIT_REMOTE (0x0020   SEVERITY_ERROR)	Cannot talk with remote unit (for example dial-up I/O Devices). Only used for scheduled I/O Devices.
GENERIC_GENERAL_WARNING (0x0024   SEVERITY_WARNING)	The driver is performing the action requested, but needs to notify of a potential issue. For example, some drivers may use this to alert you to stale data.

### Protocol-Specific Errors

Though each protocol may have multiple unique errors, the first 34 protocol-specific errors are standard for every protocol. Every protocol-specific error is also reported under error numbers 1 to 31 above. Although these errors have their own error number (also given in hexadecimal), it is only used as a notation.

**Note:** Errors that are protocol-specific are listed in the Protocol-Specific Errors help topic for each driver. Refer to the documentation that was supplied with your I/O Device if you cannot locate an error description.

Error Number	Error Title	Description
1 (0x01)	Cannot process received characters fast enough	Cannot process received characters fast enough. Lower the baud rate or use a faster computer. If the error persists, contact Technical Support for this product.
2 (0x02)	Parity error	The received message has a parity error. Check that the correct baud rate, parity, stop bits, and data bits are specified in the Plant SCADA Ports form. This error may be caused by a disconnected cable to the I/O Device or by excessive noise on the communication link.
3 (0x03)	Break detected in receive line	A break has been detected in the

Error Number	Error Title	Description
		receive line. This error may be caused by a disconnected cable to an I/O Device or by excessive noise on the communication link.
4 (0x04)	Framing error	The wrong baud rate may have been specified. Check that the correct baud rate is specified in the Plant SCADA Ports form.
5 (0x05)	Message too long	The message received from the I/O Device is too long. This error may be caused by a disconnected cable to an I/O Device or by excessive noise on the communication link. Contact Technical Support for this product. if the error continues.
6 (0x06)	Invalid checksum	The checksum in the received message does not match the calculated value. Check that the correct baud rate, parity, stop bits, and data bits are specified in the Plant SCADA Ports form. This error may be caused by a disconnected cable to the I/O Device or by excessive noise on the communication link. You can also try increasing the number of retries in the Retry parameter for the protocol.
7 (0x07)	Start of text missing	A start of text (STX) character is not present in the received message. Check that the correct baud rate, parity, stop bits, and data bits are specified in the Plant SCADA Ports form. This error may be caused by a disconnected cable to the I/O Device or by excessive noise on the communication link.
8 (0x08)	End of text missing	An end of text (ETX) character is not present in the received message. Check that the correct baud rate, parity, stop bits, and data bits are specified in the Plant

Error Number	Error Title	Description
		SCADA Ports form. This error may be caused by a disconnected cable to the I/O Device or by excessive noise on the communication link.
10 (0x0A)	Cannot transmit message	Plant SCADA cannot transmit the message. This error may be caused by a disconnected cable to an I/O Device or by excessive noise on the communication link.
11 (0x0B)	Cannot reset serial driver	An error has occurred with the serial (COMXI, PCXI, or COMx) driver. Try re-booting the computer to reset drivers and hardware.
12 (0x0C)	Length of request inconsistent	The length of a request is not consistent with the driver's requirements.
15 (0x0F)	Command from server invalid	The command from the server is invalid. Contact Technical Support for this product.
16 (0x10)	Cannot allocate timer resource for driver	Driver timer resources cannot be allocated. Contact Technical Support for this product.
17 (0x11)	Too many channels specified for driver	Too many channels have been specified for the device. Contact Technical Support for this product.
18 (0x12)	Channel number from server not opened	The channel number from the server is not open. Contact Technical Support for this product.
19 (0x13)	Command cannot be cancelled	A driver command cannot be cancelled. Contact Technical Support for this product.
20 (0x14)	Channel not on-line	The channel is not on-line. This error can occur if timeouts are occurring, and may be caused by a disconnected cable to an I/O Device or by excessive noise on the communication link.
21 (0x15)	Timeout error	No response was received from the

Error Number	Error Title	Description
		I/O Device within the specified timeout period. This error may be caused by a disconnected cable to the I/O Device or by excessive noise on the communication link. You can try increasing the number of retries in the Retry parameter for the protocol.
22 (0x16)	I/O Device number from server not active or out of range	The I/O Device number from the server is not active or is out of range. Contact Technical Support for this product.
23 (0x17)	I/O Device not on-line	Check that the I/O Device Address specified in the Plant SCADA I/O Devices form is the same as that configured on the I/O Device.
24 (0x18)	Data type from server unknown to driver	The data type from the server is unknown to the driver. Contact Technical Support for this product.
25 (0x19)	I/O Device type from server unknown to driver	The I/O Device type from the server is unknown to the driver. Contact Technical Support for this product.
26 (0x1A)	Too many I/O Devices specified for channel	Too many I/O Devices have been specified for the channel. Contact Technical Support for this product.
27 (0x1B)	Too many commands issued to driver	Too many commands have been issued to the driver. Contact Technical Support for this product.
28 (0x1C)	Data read invalid	The data read is not valid. Contact Technical Support for this product.
29 (0x1D)	Command is cancelled	A driver command has been cancelled. Contact Technical Support for this product.
30 (0x1E)	Address invalid or out of range	The address you tried to access has an invalid data type or is out of range. Check that you are using data types and ranges of addresses that are valid for the I/O Device.

Error Number	Error Title	Description
31 (0x1F)	Data length from server incorrect	The data length from the server is wrong. Contact Technical Support for this product.
32 (0x20)	Cannot read data from device	Plant SCADA cannot read the data from the I/O Device. Contact Technical Support for this product.
33 (0x21)	Device specified does not exist	The device specified does not exist. Contact Technical Support for this product.
34 (0x22)	Device specified does not support interrupt	The I/O Device specified does not support interrupt handling. You have specified an interrupt, either on the Boards form or by setting the PollTime parameter to 0, for a hardware device that does not support interrupts. Check the interrupt set for the board and set the PollTime parameter for the protocol.

### Standard Driver Errors

The following errors are low-level errors which are generic to every driver. These errors are mapped to Generic errors so that Plant SCADA can recognize them. Most drivers also have a set of driver specific errors in addition to these errors.

Error	Description
0 (0x00000000) NO_ERROR	No error condition exists.
1 (0x00000001) DRIVER_CHAR_OVERRUN	Transmitted characters could not be received fast enough. This error mapped to Generic Error GENERIC_INVALID_RESPONSE.
2 (0x00000002) DRIVER_CHAR_PARITY	Parity error in received characters. This error mapped to Generic Error GENERIC_INVALID_RESPONSE.
3 (0x00000003) DRIVER_CHAR_BREAK	A break was detected in the receive line. This error mapped to Generic Error GENERIC_INVALID_RESPONSE.
4 (0x00000004) DRIVER_CHAR_FRAMING	Framing error. Check the baud rate. This error mapped to Generic Error GENERIC_INVALID_RESPONSE.

Error	Description
5 (0x00000005) DRIVER_MSG_OVERRUN	The message received from the device was too long. This error mapped to Generic Error GENERIC_INVALID_RESPONSE.
6 (0x00000006) DRIVER_BAD_CRC	Checksum in received message does not match the calculated value. Error mapped to Generic Error GENERIC_INVALID_RESPONSE.
7 (0x00000007) DRIVER_NO_STX	Start of text character not present. Error is mapped to Generic Error GENERIC_INVALID_RESPONSE.
8 (0x00000008) DRIVER_NO_ETX	End of text character not present. Error is mapped to Generic Error GENERIC_INVALID_RESPONSE.
9 (0x00000009) DRIVER_NOT_INIT	Driver has not been initialized. This error is mapped to Generic Error GENERIC_UNIT_OFFLINE.
10 (0x0000000A) DRIVER_BAD_TRANSMIT	Cannot transmit message. This error is mapped to Generic Error GENERIC_UNIT_OFFLINE.
11 (0X0000000B) DRIVER_CANNOT_RESET	Cannot reset serial driver. This error is mapped to Generic Error GENERIC_CHANNEL_OFFLINE.
12 (0X0000000C) DRIVER_BAD_LENGTH	Response length is incorrect. This error is mapped to Generic Error GENERIC_GENERAL_ERROR.
13 (0X0000000D) DRIVER_MSG_UNDERRUN	Message length too short. This error is mapped to Generic Error GENERIC_INVALID_RESPONSE.
15 (0X0000000F) DRIVER_INVALID_COMMAND	The command from the server is invalid. This error is mapped to Generic Error GENERIC_INVALID_COMMAND.
16 (0X00000010) DRIVER_NO_TIMER	Cannot allocate timer resource for the driver. This error is mapped to Generic Error GENERIC_HARDWARE_ERROR.
17 (0x00000011) DRIVER_NO_MORE_CHANNELS	Too many channels specified for device. This error is mapped to Generic Error GENERIC_NO_MORE_CHANNELS.
18 (0x00000012) DRIVER_BAD_CHANNEL	The channel number from the server is not opened. This error is mapped to Generic Error GENERIC_BAD_CHANNEL.
19 (0x00000013) DRIVER_CANNOT_CANCEL	Command cannot be cancelled. This error is mapped to Generic Error GENERIC_CANNOT_CANCEL.

Error	Description
20 (0x00000014) DRIVER_CHANNEL_OFFLINE	The channel is not online. This error is mapped to Generic Error GENERIC_CHANNEL_OFFLINE.
21 (0x00000015) DRIVER_TIMEOUT	No response have been received within the user configure time. This error is mapped to Generic Error GENERIC_UNIT_TIMEOUT.
22 (0x00000016) DRIVER_BAD_UNIT	The unit number from the server is not active or is out of range. This error is mapped to Generic Error GENERIC_UNIT_OFFLINE.
23 (0x00000017) DRIVER_UNIT_OFFLINE	The unit is not online. This error is mapped to Generic Error GENERIC_UNIT_OFFLINE.
24 (0x00000018) DRIVER_BAD_DATA_TYPE	The data type from the server is unknown to the driver. This error is mapped to Generic Error GENERIC_INVALID_DATA_TYPE.
25 (0x00000019) DRIVER_BAD_UNIT_TYPE	The unit type from the server is unknown to the driver. This error is mapped to Generic Error GENERIC_INVALID_DATA_TYPE.
26 (0x0000001A) DRIVER_TOO_MANY_UNITS	Too many units specified for channel. This error is mapped to Generic Error GENERIC_TOO_MANY_UNITS.
27 (0x0000001B) DRIVER_TOO_MANY_COMMANDS	Too many commands have been issued to the driver. This error code can also occur if you are running a restricted version of a driver (i.e. one that will run for a limited time) for every issued read and write. This error is mapped to Generic Error GENERIC_TOO_MANY_COMMANDS.
29 (0x0000001D) DRIVER_CMD_CANCELED	Command is cancelled. This error is mapped to Generic Error GENERIC_COMMAND_CANCELLED.
30 (0x0000001E) DRIVER_ADDRESS_RANGE_ERROR	The address/length is out of range. This error is mapped to Generic Error GENERIC_ADDRESS_RANGE_ERROR.
31 (0x0000001F) DRIVER_DATA_LENGTH_ERROR	The data length from the server is wrong. This error is mapped to Generic Error GENERIC_INVALID_RESPONSE.
32 (0x00000020) DRIVER_BAD_DATA	Cannot read the data from the device. This error is mapped to Generic Error GENERIC_INVALID_DATA.
33 (0x00000021)	Device specified does not exists. This error is mapped

Error	Description
DRIVER_DEVICE_NOT_EXIST	to Generic Error GENERIC_HARDWARE_ERROR.
34 (0x00000022) DRIVER_DEVICE_NO_INTERRUPT	Device specified does not support interrupt. This error is mapped to Generic Error GENERIC_HARDWARE_ERROR.
35 (0x00000023) DRIVER_BAD_SPECIAL	Invalid special options in port database. This error is mapped to Generic Error GENERIC_BAD_PARAMETER.
36 (0x00000024) DRIVER_CANNOT_WRITE	Cannot write to variable. This error is mapped to Generic Error GENERIC_GENERAL_ERROR.
37 (0x00000025) DRIVER_NO_MEMORY	The driver has run out of memory and cannot continue execution. Minimize buffer and queue allocation or expand the computer's memory (physical or virtual memory). This error is mapped to Generic Error GENERIC_NO_MEMORY.

## Profiles

### UNINTENDED EQUIPMENT OPERATION

- Do not under any circumstances change or remove any of the undocumented <profile\_name>.ini parameters.
- Before deleting sections of the <profile\_name>.ini file, confirm that no undocumented parameters will be deleted.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

A profile stores runtime parameter settings that are specific to a particular type of computer within a Plant SCADA system (for example, a client or server). These settings are stored in a "<profile\_name>.ini" file that can be distributed to any computer where a project is deployed.

Profiles are created in the **Topology** activity using the [Profile Wizard](#).

The Plant SCADA Example Project includes three profiles that you can select from the [Profile Setup](#) page in the Setup Wizard. Once you have selected the profile you would like, you can compile and run the Example project.

You can use the **Deployment** activity to distribute Profile.ini files to the computers in a Plant SCADA system (see [Deployment Computers](#)).

To use an INI file you create with the Profile Wizard, either select it locally on a computer using the Computer Setup Wizard, or use the deployment feature.

### See Also

[Add a Profile](#)

## Add a Profile

### To add a Profiles:

1. In the **Topology** activity, select **Profiles**
2. On the Command Bar, click the **Add/Edit Profile** button. This launches the [Profile Wizard](#).

## See Also

[Run the Profile Wizard](#)

## Profile Wizard

The Profile Wizard is similar to the [Setup Wizard](#) in that it allows you to configure parameters for a specific computer. Configuration information is stored in an INI file which can be deployed to the for the specific computer for which it was configured.

The Profile Wizard contains a series of pages allowing configuration of computer-specific settings including:

- The role the computer has in the system network
- The project being run
- The CPU Configuration
- The Plant SCADA Events enabled for each component
- The Cicode run for each component on startup
- The cluster configuration
- The security settings applied.

Parameter values collected from the user through the Wizard interface are written to the <ProfileName>.ini file.

---

**Note:** To use a profile, either select it locally on a computer using the Computer Setup Wizard, or use the deployment feature (see Deployment Computers). The values in the profile.ini will take precedence over the values set in the local Citect.ini. However, values that are set for the parameters [\[CtEdit\]Run](#), [\[CtEdit\]Bin](#), [\[CtEdit\]Data](#), [\[CtEdit\]Logs](#), [\[CtEdit\]Config](#) will be taken from the local citect.ini and not from the profile.ini.

---

See [Run the Profile Wizard](#) for more information.

## Run the Profile Wizard

### To run the Profile Wizard:

1. Select a project in the Project activity. If not previously compiled, compile the project.
2. In the **Topology** activity, select **Profiles**.
3. On the Command Bar, click **Add/Edit Profile**. The Profile Setup Wizard is displayed.
4. Select **Express Setup** or **Custom Setup**.

The pages that are displayed depend on the configuration of the computer. They can include:

- [Profile Setup](#)
- [Add a New Profile](#)
- [Select a Profile](#)
- [Select a Node](#)
- [Select a Screen Profile](#)
- [Configure the Computer Role](#)
- [Configure the Network Model](#)
- [Configure Reports](#)
- [Configure Trends](#)
- [Configure Alarms](#)
- [Configure CPU](#)
- [Configure Events](#)
- [Configure Startup Functions](#)
- [Configure Cluster Connections \\*](#)
- [Configure the Server Password](#)
- [Configure Server User](#)
- [Configure Control Menu Security](#)
- [Configure Keyboard Security \\*](#)
- [Configure Miscellaneous Security \\*](#)
- [Configure General Options \\*](#)

\* Only available in Custom Setup mode.

Each screen of the wizard is described in the sections that follow.

## See Also

[Profile Wizard](#)

### Profile Setup

In the Profile Setup screen you can select the name of an existing profile to edit from the drop-down list, or choose the option to add a new profile.

- [Select a Profile](#)
- [Add a New Profile](#)

### Add a New Profile

#### To Add a New Profile:

1. Select the project that will host the Profile ini.
2. Select the **Add a New Profile** option.

3. Click **Next**.
4. In the **Profile Name** field enter the name of the profile.

---

**Note:** Profile names with spaces and the following characters <>:\\"/\?\*. are invalid and will generate a compile error message.

---

5. In the Comment field, add a description for the profile.
6. Click Next.

## See Also

[Select a Node](#)

### Select a Profile

Use this option to edit an existing Profile ini file belonging to the selected project.

The **Project Name** will display the name of the currently selected project.

1. In the **Profile Name** field, select the <profile>.ini file you want to edit.
2. Click **Next**.

## See Also

[Select a Node](#)

### Select a Node

Select whether the machine (the profile.ini belongs to) will be a client or server.

1. If Client , select the option **Configure Client Profile** before clicking **Next**.
2. If Server, select the option **Configure Server Profile**.
  - Enter the IP address of the machine you are configuring.
3. Click **Next**.

## See Also

[Select a Screen Profile](#)

### Select a Screen Profile

Use the Screen Setup page to select the Screen Profile that will be used. To do this:

1. From the **Screen Profile** list, select the profile you wish to use for the current workstation. The monitors defined for the selected profile are displayed.
2. For each screen, select a **Startup Page**. A list of available pages can be accessed from a drop-down menu. To just see a list of master pages (pages with their Content Type set to "Master"), select the **Show master pages**

only check box.

You can also use the parameter [\[MultiMonitors\]StartupPage<n>](#) to specify a Startup Page.

3. If your project is a [Situational Awareness](#) project, you will need to select a **Context** for each screen. The context sets the entry point of display for the screen; it could be an area of the plant or the entire site or any graphics page in your project. This can also be done through the [\[MultiMonitors\]Context<n>](#) parameter.

**Note:** Context is only supported for Situational Awareness projects.

## See Also

[Configure the Computer Role](#)

### Configure the Computer Role

Use the Computer Role Setup page to specify the role of the computer running Plant SCADA. Select one of the options described below.

**Note:** To use Plant SCADA's multi-process capabilities with a Server and Control Client, networking needs to be enabled.

Option	Description
Server and Control Client	<p>This computer will be a standalone or networked I/O server and Control Client. This option is disabled if this computer has no Server components assigned to it to run. Selecting this option enables the <b>Multi-Process</b> check box.</p> <p>Select the <b>Multi-Process</b> check box to separate your client and server components into individual processes. This option can be used for distributing the components across multiple CPUs.</p> <p>If the <b>Multi-Process</b> check box is selected the <a href="#">[General]Multiprocess</a> parameter in the Citect.ini file is saved with the value 1. If not selected, the parameter is saved with the value 0.</p> <p>If you leave the <b>Multi-Process</b> check box unselected, Plant SCADA will run the client and server components in one process.</p> <p><b>Note:</b> Running Plant SCADA as a service in single process mode is not recommended. If you run Plant SCADA in this condition, the following limitations will apply:</p> <ul style="list-style-type: none"><li>• Hardware alarms originating from the server process will not appear.</li><li>• The following Cicode functions will not be</li></ul>

Option	Description
	<p>executed within the server process:</p> <ul style="list-style-type: none"><li>• AlarmSumAppend</li><li>• AlarmSumCommit</li><li>• AlarmSumDelete</li><li>• AlarmSumFind</li><li>• AlarmSumFindExact</li><li>• AlarmSumFirst</li><li>• AlarmSumGet</li><li>• AlarmSumLast</li><li>• AlarmSumNext</li><li>• AlarmSumPrev</li><li>• AlarmSumSet</li><li>• AlarmSumSplit</li><li>• AlarmSumType</li><li>• DriverInfo</li><li>• IODeviceControl</li><li>• IODeviceInfo</li><li>• SPCAlarms</li><li>• ServerInfoEx</li><li>• TrnAddHistory</li><li>• TrnDelHistory</li></ul>
Control Client	<p>This computer will only be a Control Client. This option is disabled if the computer has been assigned a server component to run.</p> <p>Selecting this option enables the <b>Full License</b> check box.</p> <p><b>Note:</b> The Full License checkbox is only available when running the Setup Wizard in Custom Mode.</p> <p>Select the full server license check box if you want this Control Client to use a full (server) license, as opposed to a client license. This sets the <a href="#">[Client]FullLicense</a> parameter in the Citect.ini file to 1 (the default value is 0).</p> <p>Generally, you would not allocate a full server license to a client as there is no difference in functionality between the two licenses. Allocate a full server license if you have insufficient client licenses available, or for</p>

Option	Description
	some other specific need.
View-only Client	This computer will be a view-only client. This read only option is disabled if this computer has been assigned a Server component to run.
HMI (Standalone, no networking)	<p>This computer will run as a standalone HMI setup with networking disabled. Select this option for any computers that require a dedicated HMI license from an Enterprise License Server that hosts multiple license types.</p> <p>If you are using Sentinel licensing, you can use a key that has networking disabled. If a full Sentinel key is plugged in, runtime will start in standalone mode with networking disabled.</p> <p>Select the <b>Multi-Process</b> check box to separate your client and server components into individual processes. This option can be used for distributing the components across multiple CPUs.</p> <p>If the <b>Multi-Process</b> check box is selected the <a href="#">[General]Multiprocess</a> parameter in the Citect.ini file is saved with the value 1. If not selected, the parameter is saved with the value 0.</p>

Some of these options may be disabled depending on what servers have been configured to run on this computer. The Setup Wizard cross-references your computer's network identification with the network addresses configured for each server in your project configuration.

The option you select will adjust the [\[Client\]ComputerRole](#) parameter in the Citect.ini file.

## See Also

[Configure the Network Model](#)

### Configure the Network Model

Select the network model to be applied to this Plant SCADA computer. The options include:

- Stand alone (no other SCADA computers)
- Networked (connect to other SCADA computers)

---

**Note:** TCP/IP address information for servers is configured within the Plant SCADA project itself. See [Add a Network Address](#) for more information.

---

## Stand alone

Select **stand alone** to run all server and client components of a Plant SCADA system on a single computer. This allows you to run Plant SCADA as a small and self-contained system.

## Networked

Select **Networked** to connect to a system of multiple Plant SCADA computers configured with different server and client components. In a **Networked** setup where hostnames are used to resolve IP addresses, specify the following:

- Select network address type from the **Address Type** drop-down list (refer to [LAN]AddressType).
- For an IPv6 **Address Type**, select the **Address Scope** from the drop-down list (refer to [LAN]AddressScope).

Refer to the following table for information regarding the status of a server with respect to the computer network configuration, the **Address Type** and the **Address Scope** selection.

Computer Network Configuration	Address Type	Address Scope	Server Status
IPv4	IPv4	-	Starts with IPv4 address.
IPv4	IPv6	Link-Local	Starts with the Link-Local IPv6 address available in the machine.
IPv4	IPv6	Global	Does not start.
IPv4	IPv6	Global and Link-Local	Starts with the Link-Local IPv6 address available in the machine. <b>Note:</b> When you start <b>Runtime Manager</b> , the <b>User Location</b> column on the <b>Alarm Summary</b> and <b>Sequence of Events</b> pages shows the server address as "::1." It is the IPv6 loop-back address.
IPv6	IPv4	-	Starts with the IPv4 loop back address 127.0.0.1.
IPv6	IPv6	Link-Local	Starts with the Link-Local IPv6 address.
IPv6	IPv6	Global	Starts with Global IPv6 address.

Computer Network Configuration	Address Type	Address Scope	Server Status
IPv6	IPv6	Global and Link-Local	Starts with Link-Local / Global IPv6 address (depends on first return address).
IPv6 and IPv4	IPv4	-	Starts with IPv4 address.
IPv6 and IPv4	IPv6	Link-Local	Starts with Link-Local IPv6 address.
IPv6 and IPv4	IPv6	Global	Starts with Global IPv6 address.
IPv6 and IPv4	IPv6	Global and Link-Local	Starts with Link-Local / Global IPv6 address (depends on first return address).

When you complete the Profile Setup Wizard, the selected network model is written to the [LAN] section in the ini file; for example:

```
...
[LAN]
TCPIP=1
...
```

## See Also

[Configure Reports](#)

### Configure Reports

The Reports Configuration page will only be displayed if this machine is configured as a Reports Server in the [Topology](#) activity.

---

**Note:** For a networked computer to be a Reports Server it needs to also be the I/O Server or needs to be able to communicate with the I/O Server on the network.

Plant SCADA has several options available for report processing:

Option	Description
Startup report	Defines the name of the report to run when Plant SCADA starts up.
Inhibit triggered reports on startup	For example, you might have a report that is triggered off the rising edge of a bit on startup. The Reports Server detects the bit come on, and runs the report. If this option is checked, the Reports Server does not

Option	Description
	run this report until it has read the I/O Devices a second time.
Run reports concurrently with primary Reports Server	Enables or disables tandem processing of reports. If this server is the standby Reports Server, it can process every report in tandem with the primary server, or it can remain idle until called.

## See Also

[Configure Trends](#)

### Configure Trends

The Trends Configuration page will only be displayed if this machine is configured as a Trends Server in the [Topology](#) activity.

---

**Note:** For a networked computer to be a Trends Server it needs to also be the I/O Server or needs to be able to communicate with the I/O Server on the network.

Plant SCADA has one option available for trend processing:

Option	Description
Inhibit triggered trends on startup	You might have a trend that is triggered off the rising edge of a bit on startup. If this option is enabled, the trends server does not display the trend until it has read the I/O Devices a second time.

## See Also

[Configure Alarms](#)

### Configure Alarms

The Alarm Server Properties Setup page is displayed if the computer has one or more alarm servers configured that are part of a redundant pair. Correctly setting the options on this page will improve outcomes for alarm server redundancy. Enter an IP address for **Device IP 1** and **Device IP 2**.

If the Plant SCADA system is using an IPv4 network, use a standard IPv4 address format. For example, 192.1.2.34.

If the Plant SCADA system is using an IPv6 network, use a standard IPv6 address format (or any acceptable abbreviation). For example, 2001:0db8:0000:0000:8a2e:0123:1234 or 2001:db8::8a2e:123:1234 (abbreviated).

**Device IP 1** and **Device IP 2** correspond to the INI parameters [\[Alarm\]IsolationDetectIP1](#) and [\[Alarm\]IsolationDetectIP2](#).

## See Also

[Alarms Server Redundancy](#)

[Configure CPU](#)

### Configure CPU

The CPU Setup page of the Setup Wizard is used to assign client and server components to specific processors on a multi-processor computer.

The page includes a table that identifies each **Component** (and the cluster to which it belongs), its **Priority** and its **CPU** assignment.

- If the **Multi-process** option was selected on the Computer Role Setup page, you can select specific CPUs for the Client, I/O Server, Alarm Server, Trends Server and Reports Server processes.
- If the **Multi-process** option was not selected, there will only be one entry listed. It will either be “Client” or “Client and Servers”.

#### To assign a CPU to a component:

1. Select one or more components from the list (hold the **Ctrl** key down to select multiple components).
2. Click the **Modify** button.
3. Select the CPUs you want to assign to the component (you can select more than one) or select **<All CPUs>**.
4. Click **OK**.

When you complete the Setup Wizard, the CPU assignments are written to each component section in the INI file; for example:

```
...
[Alarm.Cluster1.AlarmServer1]
CPU=1
Clusters=Cluster1
...
[Trend.Cluster1.TrendServer1]
CPU=2
Clusters=Cluster1
...
```

If ALL is selected, the component sections in the INI file will be left empty and the processes will run on all CPUs.

In situations where ALL is selected, be aware that performance issues may still occur when your CPU usage is less than 100%. You can detect these issues when your CPU usage for a process is fixed at 100 divided by the number of processors.

---

**Note:** If a computer has more than 32 CPUs, the CPU Setup page in Setup Wizard will be disabled. The component sections in the INI file will be left empty and the processes will run on all CPUs.

---

## See Also

[Configure Events](#)

## Configure Events

Events are used to trigger actions, such as a command or set of commands. For example, an operator can be notified when a process is complete, or a series of instructions can be executed when a process reaches a certain stage. Select the **Enable Events on this computer** check box if events are to be enabled on this Plant SCADA computer.

The Events Setup page lists each component's full name, including the cluster to which it belongs, alongside a list of events that can be enabled for each component. If the **Multi-process** option was not selected on the Computer Role Configuration page there will only be one entry listed, either Client or Client and Servers. If the **Multi-process** option was selected, you have the option of enabling events for each component on this computer.

---

### Note:

- The Setup Wizard only displays named events from the selected project. If you are using events in included projects you will need to edit your ini file to add these under the [Events] section header.
  - Events named 'Global' or events with no title will not appear as these are global events. These events will run on computers that have events enabled. These events will run in the client process.
- 

### To enable an event for a component:

1. Select the component from the list.
2. Select the events you want to enable for that component, or click **Enable All** or **Disable All**.
3. Click **Next** when finished.

When you complete the Profile Setup Wizard, the events are written to each component section in the ini file; for example:

```
...
[Alarm.Cluster1.AlarmServer1]
CPU=1
Clusters=Cluster1
Events=CSV_AlarmClient...
[Trend.Cluster1.TrendServer1]
CPU=2
Clusters=Cluster1
Events=CSV_TrendXClient,CSV_TrendXServer...
```

## See Also

[Configure Startup Functions](#)

## Configure Startup Functions

The Startup Functions Setup page is used to define the Startup Cicode that is executed by each Plant SCADA process.

The Startup Functions Setup page lists each component's full name, including the cluster to which it belongs, the priorities of the components and the startup function assigned to each component. If the **Multi-process** option was not selected on the **Computer Role Configuration** page there will only be one entry listed, either Client or Client and Servers. If the Multi-process option was selected, you have the option of assigning startup functions for each component on this computer.

If the StartupCode parameter value for a process is invalid, the Plant SCADA Runtime Manager will simply ignore it on start up.

#### To assign a startup function to a component:

1. Select the component from the list. To select multiple components, hold down the Ctrl key as you select each item.
2. Click **Modify**.
3. Type the name of the Cicode function you want to call on startup for that component.
4. Click **OK**.

When you complete the Setup Wizard, the events are written to each component section in the ini file; for example:

```
...
[Alarm.Cluster1.AlarmServer1]
CPU=1
StartupCode=alarmServerStartup
...
[Trend.Cluster1.TrendServer1]
CPU=2
StartupCode=trendServerStartup
...
```

#### See Also

[Configure Cluster Connections](#)

#### Configure Cluster Connections

The Cluster Connections Setup page is used to specify the clusters that each component connects to on startup. This controls what data streams a component can see in the system.

The Cluster Connections Setup page lists each component's full name, including the cluster to which it belongs, the priorities of the components and the clusters assigned to each component. If the **Multi-process** option was not selected on the Computer Role Configuration page there will only be one entry listed, either Client or Client and Servers. If the **Multi-process** option was selected, you have the option of assigning clusters for each component on this computer.

By default, every component will connect to every cluster unless otherwise modified.

If the Clusters parameter value for a process is invalid, then the Plant SCADA Runtime will simply ignore it on startup.

#### To assign a cluster to a component:

1. Select the component from the list. To select multiple components, hold down the Ctrl key as you select each item.
2. Click **Modify**.
3. Select the clusters you want the component to connect to on startup.
4. Click **OK**.

When you complete the Setup Wizard, the clusters are written to each component section in the Citect.ini file; for example:

```
...
[Alarm.Cluster1.AlarmServer1]
CPU=1
Clusters=Sydney
...
[Trend.Cluster1.TrendServer1]
CPU=2
Clusters=Sydney,Tokyo
...
```

## See Also

[Clusters](#)

[Configure the Server Password](#)

### Configure the Server Password

If networking is enabled, use this page to configure the server password. This password is used by computers to authenticate each other and create a trusted network between servers and, optionally, clients.

You can create a new password, or enter the password that is already used by other server computers in your Plant SCADA system.

If server processes do not have matching server passwords, they will not communicate with each other. Only trusted tran channels can handle remote requests initiated by [MsgRPC](#) or [ServerRPC](#) Cicode functions and CTAPI connections.

Configuring the password automatically sets the [\[Client\]PartOfTrustedNetwork](#) INI parameter.

---

**Note:** To configure the server password, you need to be a member of the **Configuration Users** security role. To read the server password you need to be a member of either the **Configuration Users** or the **Server Users** security role. You can be a member of these roles either directly or via an associated domain group (see [Security Roles](#)).

---

- **If a server process exists and networking has been enabled:**

The **Configure Server Password** check box is selected and unavailable.

Enter and confirm the password in the fields provided, before clicking **Next**.

If the **Password** and **Confirm Password** fields already contain an entry, it means a server password has already been configured on the local computer. If required, you can enter a new password.

- **If a client process exists and networking is enabled:**

The **Configure Server Password** check box is unchecked. To use the client computer as a CTAPI server, you need to configure the server password. Setting this password allows servers to authenticate each other and creates a trusted network between server computers.

Select **Configure Server Password** check box to enable the password fields.

Enter and confirm the password in the fields provided, before clicking **Next**.

If you change the server password while the runtime system is active, it will not disrupt any established connections as the password is only retrieved when authentication needs to occur. However, it is recommended

that you apply the new password as soon as possible. To do this, you need to restart the runtime system.

If you are extending an existing system by adding computers that will run additional clusters and servers, you should determine what the existing server password is before you proceed. This will allow you to set the same server password on all existing and new servers.

## See Also

[Configure Server User](#)

### Configure Server User

Use this page to define the user to log in for the server processes running on the machine. The user can be the default server user, none (view-only), or a specified user. The Setup wizard will automatically configure the [\[Server\]AutoLoginMode](#) INI parameter in line with the user's settings.

Select **Specific User** to enable the Configure Server User fields. The fields will remain disabled if either the **Default Server User** option or **None** option are selected.

[Configure Control Menu Security](#)

### Configure Control Menu Security

The Plant SCADA window property options allow you to control an operator's access to system features. This allows for flexibility with system security at run time.

Option	Description
Plant SCADA configuration environment on menu	Allows the operator to use the control menu (top left-hand icon) to access Plant SCADA Studio, Graphics Builder, and Cicode Editor from Plant SCADA at run time. Disabling this provides better security.
FullScreen	Allows the operator to set whether pages will be displayed in fullscreen or restored state. When checked "FullScreen" will set the ini parameter <a href="#">[Animator]FullScreen</a> to 1. If "FullScreen" is set.
Show title bar	Allows the operator to set whether pages will be displayed in fullscreen mode with the title bar. The <a href="#">[Animator]FullScreen</a> ini parameter is set as follows: 0 if "Fullscreen" is unchecked; 1 if "Fullscreen" is checked and "Show title bar" is unchecked; 2 if both "Fullscreen" and "Show title bar" are

Option	Description
	checked. "Show title bar" cannot be modified if the option "Fullscreen" is unselected.
Shutdown on menu	Allows the operator to use the control menu (top-left icon) to shut down Plant SCADA at runtime. The shutdown is not password- or privilege-protected. Disabling this provides better security.
Kernel on menu	Allows the operator to use the control menu (top left icon) to display the Plant SCADA Kernel at run time. Disabling this provides better security.

[Configure Keyboard Security](#)

### Configure Keyboard Security

Windows has a set of standard task-swapping shortcut commands that are (optionally) supported by Plant SCADA at run time. This option allows the Alt-Space Windows command to be enabled or disabled at run time. Alt-Space provides access to the Windows control menu (even if the title bar has been disabled).

**Note:** The ability to disable Alt-Escape, Ctrl-Escape and Alt-Tab is not currently available.

## See Also

[Configure Miscellaneous Security](#)

### Configure Miscellaneous Security

Some standard Windows features may interfere with the secure operation of your system. Use the Miscellaneous Security page to disable these features.

Option	Description
Inhibit screen saver while Plant SCADA is running	Stops the screen saver from blanking out screens that need to be visible at all times. Alternatively the screen saver password can add additional security features.
Display Cancel button at startup	Provides the ability to stop Plant SCADA from starting up automatically. Automatic startup is a potential security concern.

## See Also

[Configure General Options](#)

### Configure General Options

Use the General Options Setup page to specify general options.

Option	Description
Data Directory	The directory where the Plant SCADA data files are located. The data files are the files that are generated at run time: trend files, disk PLC etc.
Backup project path	The backup directory that is used if a runtime database cannot be located (due to inoperative hardware or a file that has been moved, corrupted, or deleted).
Startup page	The Page Name of the graphics page to display when Plant SCADA starts up.
Page scan time	<p>The delay (in milliseconds) between updating a graphics page and starting the next communications cycle. The Page Scan Time sets the default for how often your graphics pages are updated. When a page is updated, relevant data (variable tags etc. represented on the graphics page) is scanned to determine if field conditions have changed. This setting is overridden by the Scan Time value specified in Page Properties (if applied).</p> <p>A value of 250 (the default value) indicates that Plant SCADA will try to update the page every 250 ms. However, if Plant SCADA cannot read the entire data from the I/O Device within 250 ms, the page is processed at a slower rate. For example, if it takes 800 ms to read the data from the relevant I/O Device, Plant SCADA processes the page every 800 ms.</p> <p>Under some conditions, you might want to slow the update of your pages to reduce the load on the I/O Servers. By reducing the page scan time, you allow more communication bandwidth to other Plant SCADA tasks or Clients. For example, you might want fast response on your main operator computers, while slowing the response time on manager computers. You can enter any value from 0 to 60000 (milliseconds).</p>
OPC Alarms and Events	Click the <b>Register</b> button to register an alarm server as

Option	Description
	<p>a runtime OPC AE server that supports the OPC AE interface specification. This will allow the alarm data to be accessed by third-party OPC client applications. The registration process requires administrative privileges.</p> <p><b>Note:</b> The OPC AE Server does not support DCOM for remote communications. It is recommended that you run any connecting OPC client applications on the computer that is registered as the OPC AE Server.</p>

## Finish

Select one of the following:

- **Finish** saves the setup to the INI file.
- **Cancel** quits the wizard without saving.
- **Back** navigates back to a page that requires adjusting.

## Redundancy

Redundancy in Plant SCADA can be defined at many different levels. When building redundancy for your system, you need to consider the degree of protection necessary to meet your requirements. This will involve the following:

- Deciding how important each processes is
- Determining the overall likelihood of system downtime, and the processes and equipment that will take the longest to restore to service
- Deciding which components require redundant operation
- Considering design and maintenance requirements.

The section covers the following redundancy concepts:

- [I/O Server Redundancy](#)
- [I/O Device Promotion](#)
- [Redundancy and Persistence](#)
- [Data Path Redundancy](#)
- [Network Redundancy](#)
- [Reports and Trends Server Redundancy](#)
- [Alarms Server Redundancy](#)

**Note:** Using the Setup Wizard will allow you to define the level of redundancy you require by defining the function of each computer (See [Run a Project using the Setup Wizard](#)).

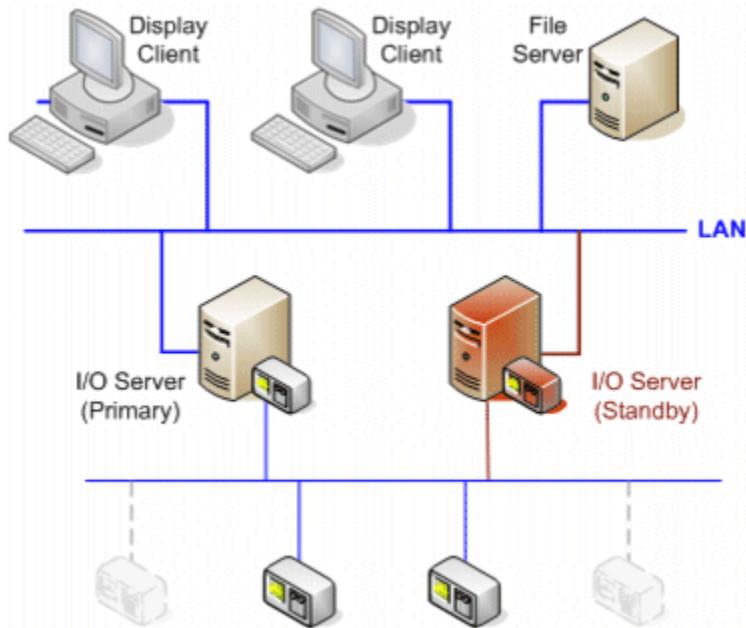

## See Also

- [Reports and Trends Server Redundancy](#)
- [File Server Redundancy](#)
- [Redundancy of Standalone Systems](#)

## I/O Server Redundancy

Systems with a single I/O Server can be interrupted by the inoperability of a single device or process. If the primary server isn't operating normally, control and monitoring of the system is lost. By introducing a second I/O Server and dedicating it to communicating with the same I/O Devices, the ability of a single device to influence the system as a whole is minimized. You now have a **primary** and **standby** I/O Server in your system where the standby I/O Server will assume operations in case the primary I/O Server becomes inoperative.

The diagram below illustrates the introduction of a standby I/O Server into the existing system. When the system is in operation, both I/O Servers are identically maintained.

---

**Note:** Although both I/O servers are identical, recognize that the standby server is not duplicating the primary server's functions. If it were, the load on the PLC portion of the network would be double and would significantly reduce performance. Therefore, only the primary server communicates with the PLCs at any given time.

Redundancy is provided as follows:

- When the system is in operation and the primary I/O Server becomes inoperative, or if you wish to perform some maintenance and take it offline, every client will be reverted to the standby server with minimal or no interruption to the system.
- When the primary server is brought back online, the system returns control of the I/O Devices back to the primary server. This is done by copying the disk image from the standby server to the primary, allowing the clients to reconnect to it, and thereby resuming control of the system.

When the system is running, you can also use redundant I/O Servers to split the processing load. This would

result in higher performance as every I/O Server would be running in parallel when servicing the I/O Devices.

## See Also

[I/O Device Promotion](#)

### I/O Device Promotion

I/O device promotion refers to when a system event forces a standby I/O device to assume a primary role during Runtime.

If there is more than one standby device available within a cluster, the order in which they are promoted will depend on how your project has been configured.

If necessary, you can manually set the order your standby devices are promoted in via the I/O device's **Priority** property (see [Add an I/O Device](#)). If priorities are not set, the compiler automatically allocates a priority value to each standby device based on the following rules:

- User-configured priority settings take precedence
- Any standby devices without a priority setting will follow those that do, their priority being allocated in the order they were configured
- If no standby devices have a priority setting, they will be assigned priority according to the order they were configured.

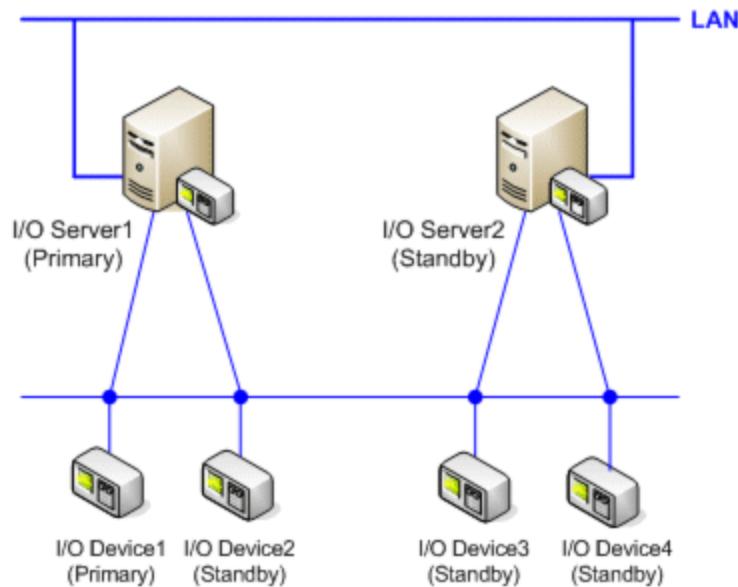

These rules apply regardless of the connections between the I/O devices and I/O Servers configured in a cluster.

The standby device priorities are confirmed and/or allocated during project compilation. Notification is provided for each allocation issued by the compiler. Compile error messages will result from the following circumstances:

- If a primary device has a priority setting other than the default value of 1
- If standby devices have duplicated priority values.

## Example

The following diagram shows four I/O devices connected to two I/O Servers, with just one primary device configured.

If no priorities were set for the standby devices, the compiler would allocate the following:

- I/O Device1 is allocated **Priority 1** by default (no compiler alert)
- I/O Device2 is allocated **Priority 2** (compiler alert generated)
- I/O Device3 is allocated **Priority 3** (compiler alert generated)
- I/O Device4 is allocated **Priority 4** (compiler alert generated)

This presumes the devices were configured in numerical order.

If I/O Device3 has been manually set to priority 2, the compiler would allocate the following:

- I/O Device1 is allocated **Priority 1** by default (no compiler alert)
- I/O Device2 is allocated **Priority 3** (compiler alert generated)
- I/O Device3 is allocated **Priority 2** (no compiler alert)
- I/O Device4 is allocated **Priority 4** (compiler alert generated)

In this case, the setting for I/O Device3 has taken precedence. The remaining standby devices are set for promotion based on the order they were configured.

**Note:** The automated priorities work on an n+1 equation; if I/O Device3 has been set to Priority 5, the remaining devices would have been allocated priority 6 and 7.

## See Also

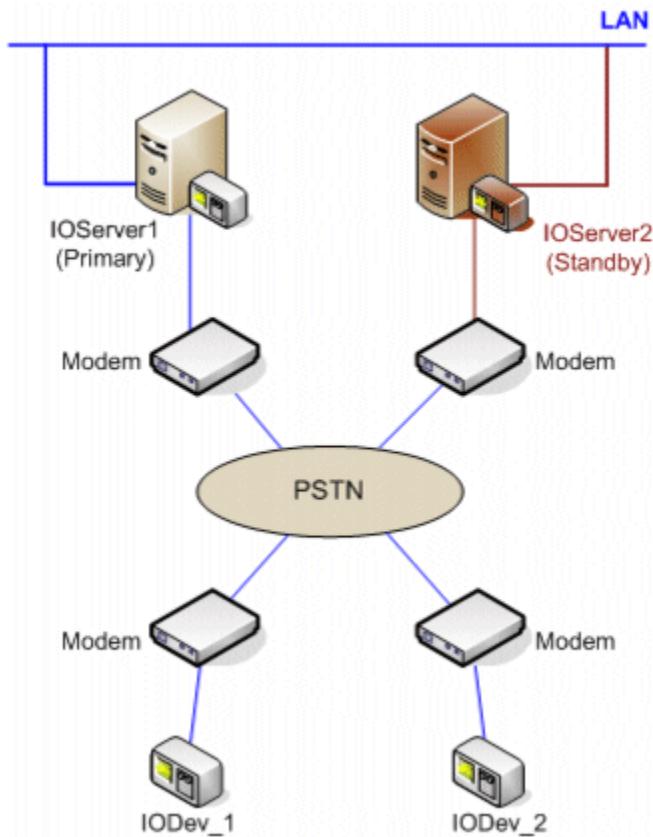

[Redundancy and Persistence](#)

[Data Path Redundancy](#)

## Redundancy and Persistence

If you are using server redundancy, persistence caches (I/O server cache) keep standby servers updated with the most recently read device data. A persistence cache, or I/O server cache, is created for each cached I/O device.

The following diagram introduces the concept of a persistence cache.

The diagram shows that there are two I/O servers, namely IOServer1 (primary) and IOServer2 (standby). Each connects to the public switched telephone network (PSTN) via a modem, which is in turn connects to the I/O devices, also over a modem. Persistence caches work as follows:

1. Every IODevices->Cache Time period, data from an I/O Device is stored temporarily in the memory of the I/O server (I/O server cache).
2. For every [IOServer]SavePeriod, IOServer1 stores its in-memory cache to disk.
3. The cache is saved in persistence caches -one for each cached device.
4. IOServer1 broadcasts to other I/O servers the UNC path of the persistence caches (set with [IOServer]SaveNetwork).
5. From these persistence caches, IOServer2 updates its in-memory cache for its I/O devices.
6. Depending on the value of the I/O server parameter of '[IOServer]SavePeriod' (determines how often the persistence cache is saved to the hard disk in seconds), IOServer1 stores its in-memory cache to the hard disk every x amount of seconds.

---

**Note:** You can define an I/O Device on an I/O server using the Device Communications Wizard, or by adding a device in the Topology activity.

You are not limited to just one Standby Server, since the UNC path name set in [IOServer]SaveNetwork is broadcast to I/O servers. Each I/O server updates its cache from the persistence caches only for the I/O devices defined on that server. It is then possible, therefore, set up several I/O servers which update their in-memory caches with the most recently read data.

For example, we set the [IOServer]SaveFile and [IOServer]SaveNetwork parameters as follows:

On IOServer1	On IOServer2
[IOServer]	[IOServer]
SaveFile=C:\Data\IOServer1.dat	SaveFile=C:\Data\IOServer2.dat
SaveNetwork=\\IOServer1\Data\IOServer1.dat	SaveNetwork=\\IOServer2\Data\IOServer2.dat

IOServer1 would broadcast the following UNC path of the persistence cache to other I/O servers: '\\IOServer1\ Data\IOServer1.dat'.

IOServer2 would then use the persistence caches to update its in-memory cache with the device data most recently read by IOServer1.

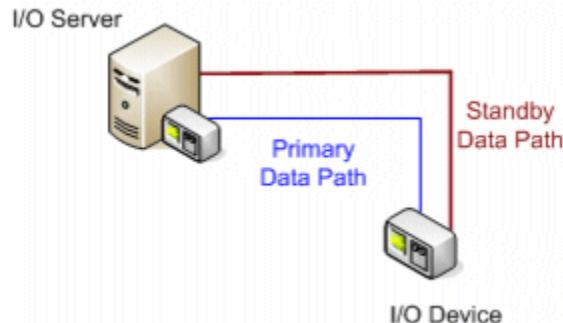

## See Also

[Data Path Redundancy](#)

## Data Path Redundancy

Data path redundancy is another form of redundancy involving defining data paths between the I/O server and the connected I/O devices. By providing a second (parallel) data path, you improve the chances that if one data path to the I/O device is disconnected, the other can be used.

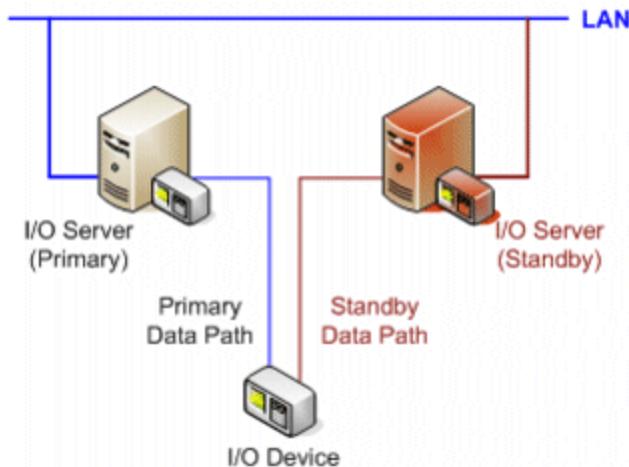

Many PLCs have the facility to allow you to install a parallel data path from the I/O server to the I/O device.

The diagram above shows that an additional data path (running in parallel) has been defined. The redundancy is provided as follows:

- When you start your runtime system, Plant SCADA connects to the I/O device using the **primary data path**.
- If communications with the I/O device is lost at any time (for example if the communications cable is disconnected), Plant SCADA will **switch to the standby data path** with minimal or no interruption to the system.
- Plant SCADA reconnects through the primary data path when it is returned in to service.

On a larger system (such as one running on a network), you can also use data path redundancy to maintain device communications with multiple I/O server redundancy, as shown in the following diagram.

The redundancy is provided as follows:

- By using a redundant data path from the I/O device (one path to each I/O server), you can maintain I/O device communication.
- If communications with either the primary I/O server or standby I/O server be disconnected, the I/O device is still accessible.

## See Also

[Multiple Device Redundancy \(Standby Data Paths\)](#)

### Multiple Device Redundancy (Standby Data Paths)

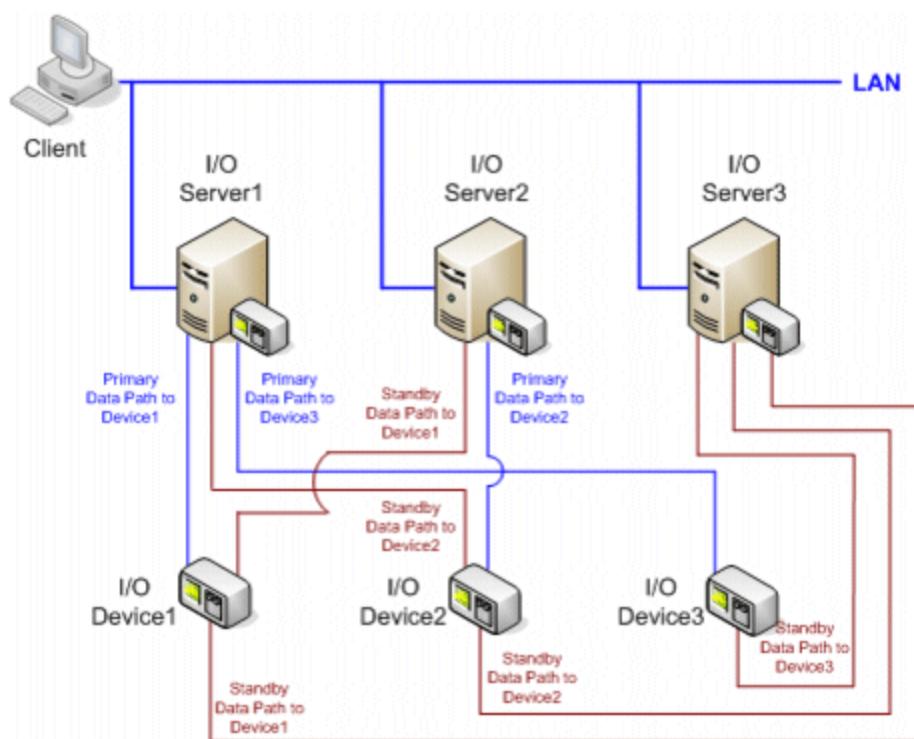

If your I/O devices support peer-to-peer communication, you can add another level of redundancy to your system by duplicating the I/O devices.

---

**Note:** Although I/O servers are not assigned the Primary or Standby role based on the I/O devices to which they are connected, it is common practice in redundant I/O systems to connect the Primary I/O devices to the Primary I/O server and the Standby I/O devices to the Standby I/O server. One I/O server can connect to a mixture of Primary and Standby I/O devices. The I/O server can support any number of Standby Data Paths.

---

The following diagram demonstrates multiple device redundancy and Standby Data Paths:

In this scenario, we have three I/O servers connected to three I/O devices in the following manner:

I/O Server	I/O Devices Connected
IOServer1	I/O Device1 (Primary) I/O Device2 (Standby) I/O Device3 (Primary)
IOServer2	I/O Device1 (Standby) I/O Device2 (Primary)
IOServer3	I/O Device1 (Standby) I/O Device2 (Standby) I/O Device3 (Standby)

The following is known:

- Plant SCADA clients communicate with every configured I/O server at the same time (on startup, the clients try to connect to each configured I/O server. If they cannot establish communications with an I/O server, a hardware error message is generated).
- When every device is running, Plant SCADA processes the I/O on the primary I/O devices as this reduces the I/O load on the I/O device (and PLC network), which can help improve performance.
- The client creates network sessions to the three I/O servers.
- The client then sends requests for I/O Device1 and I/O Device3 to I/O Server1, and requests for I/O Device 2 to I/O Server2.

Redundancy is provided as follows:

- If I/O Device1 become inoperative on I/O Server1, the client will send requests for I/O Device1 to I/O Server2

through the standby data path. It continues to send requests for I/O Device3 to I/O Server1.

- If I/O Device also becomes inoperative on I/O Server2, the client sends requests to I/O Server3.
- If the connection between I/O Device1 and I/O Server1 be re-established, the client resumes sending requests for I/O Device1 to I/O Server1.

The Standby I/O devices will be activated strictly in the order in which they are first created in the project. This can be viewed by looking in the Units.dbf file in the project directory.

When you connect primary and standby I/O devices to your I/O servers, share the primary I/O devices between your I/O servers to balance the loading. Be aware, however, that this might not apply for every protocol because the loading could be dependent on the PLC network and not the I/O server CPU. In this case, more than one active I/O server on the same PLC network can impact the PLC network and therefore, slow the total response.

[Alarms Server Redundancy](#)

[Reports and Trends Server Redundancy](#)

## Network Redundancy

You can use the dual NIC (or multiple network interface) capabilities of each client or server, enabling you to specify a complete and unique network connection from a client to a server.

Consider the following diagram:

The above example shows two levels of redundancy:

- network redundancy
- server redundancy

## Network Redundancy

**Note:** Currently Plant SCADA does not support dynamic port binding.

Each of the system components in the cluster are connected to two networks (LAN 1 and LAN 2). This is achieved by using the dual end points of each server. This provides LAN redundancy as follows:

- If LAN 1 is suddenly inoperative, each component in the cluster can easily maintain connection by using LAN 2.
- In turn, if LAN 2 becomes inoperative, LAN 1 remains in operation.

**Note:** For this type of redundancy to work, each system component needs to have two NICs to support two parallel LANs. On every computer, each NIC needs to use a separate IP network or subnet.

## Server Redundancy

For information about server redundancy, see [Reports and Trends Server Redundancy](#) and [Alarms Server Redundancy](#).

## See Also

[Configuring Network Redundancy](#)

### Configuring Network Redundancy

To connect to machines using dual network connections for redundancy you need to first define network addresses for each network interface and then specify which network addresses to use for each server.

#### To configure network redundancy:

1. In the **Topology** activity, choose **Edit | Network Addresses**.
2. Using the Grid Editor or the Property Grid, define the network address for each network interface card. See [Add Network Addresses](#).
3. In the **Topology** activity, choose **Edit** and then the server type you want to connect to the network.
4. In Network Addresses field, type the dual addresses for the server separated by a comma. For example, "AlarmPrimaryLAN1,AlarmPrimaryLAN2".

**Note:** If you are using address forwarding to enable server redirection, you need to consider how this may be impacted by network redundancy. For more information see [Server Redirection Using Address Forwarding](#).

## Using hostnames with dual network interface cards

Plant SCADA allows you to use a hostname when defining network addresses. This can simplify the configuration of a redundant network, as static IP addresses are not required. It also enables network redundancy for an OPC UA Server or an Industrial Graphics Server.

However, if you have used hostnames to define the network addresses for dual network interface cards in a computer, you will need to confirm some additional network configuration settings. This is required when one of the cards is used for the SCADA network, and the other for the PLC network.

You need to confirm a DNS setting for the communications adapter used by the PLC network.

In Windows **Network and Sharing Center** (accessible via Control Panel), select **Change adapter settings** and view the properties for the PLC network connection.

Locate TCP/IPv4 or TCP/IPv6 in the list of used items, and select **Properties** again. Open the **Advanced** properties, then go to the **DNS** settings.

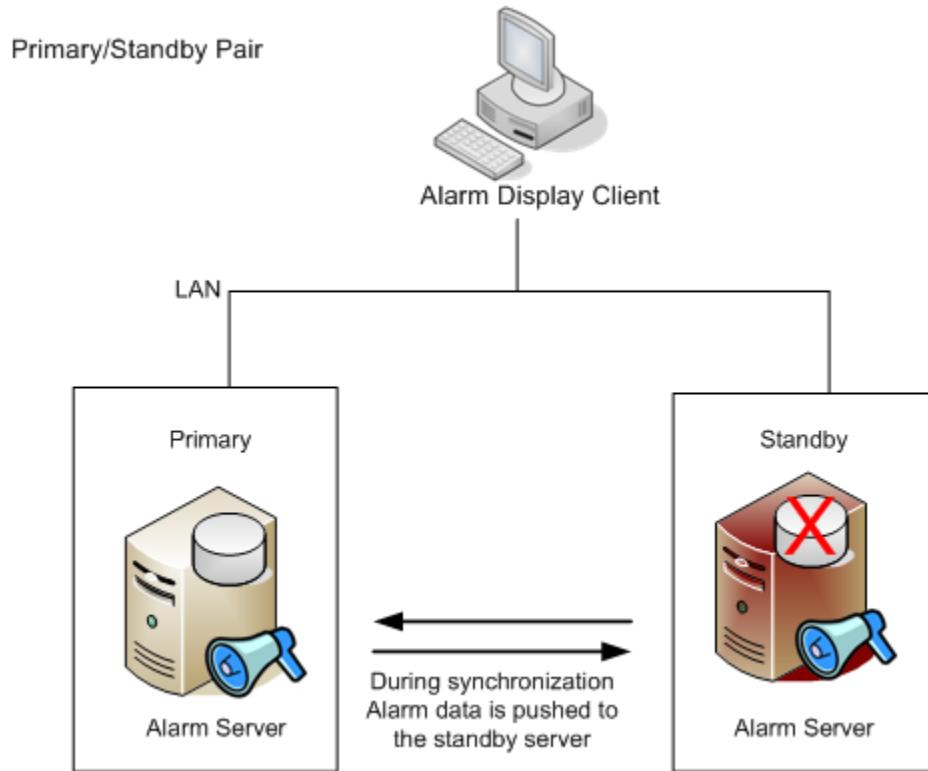

Make sure **Register this connection's addresses in DNS** is NOT selected.

## See Also

[Network Redundancy](#)

## Alarms Server Redundancy

To support alarm server redundancy you can configure a main/standby pair. To keep with the terms used in previous versions of Plant SCADA the main server is called the primary server.

With a primary/standby pair only one server (the primary) updates the database. However, the display client is able to communicate with both the primary and standby servers.

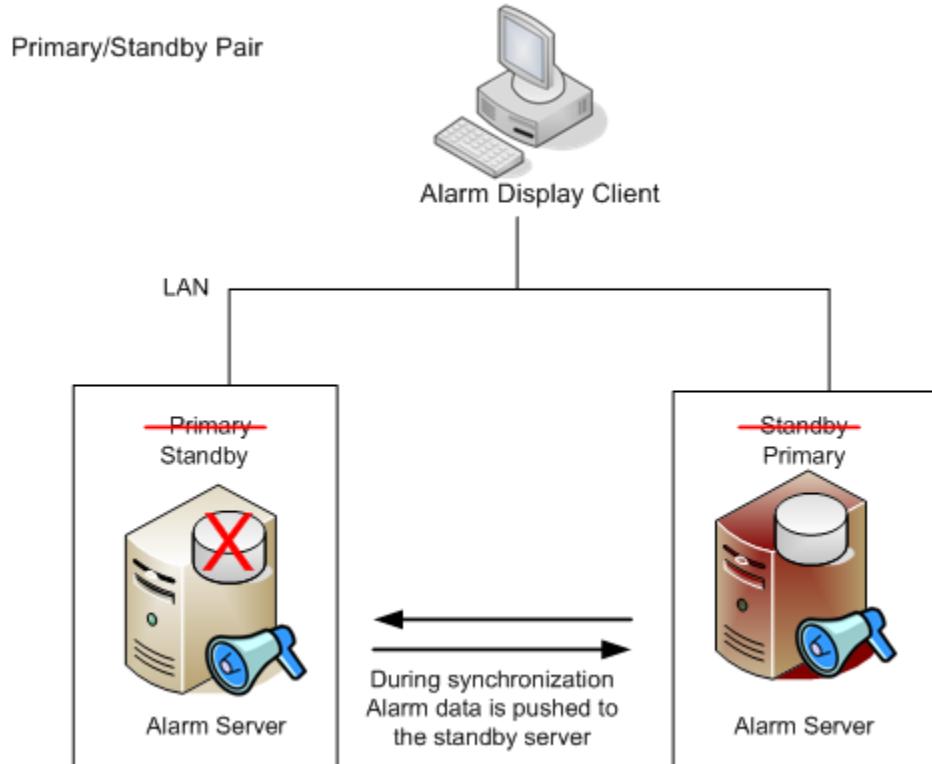

On starting up, the display client will attempt to connect to the 'main' (primary) server. By default the alarm server which starts first will become 'main'.

If you want a display client to connect to a particular server on startup, use the parameter [\[Alarm\]Priority](#). This parameter assigns a higher priority to either the primary or standby server. This means when the client starts, it

will communicate with the server assigned the highest priority, even if the lower-priority server started first (and is therefore the main server).

If the primary server becomes inoperative (including loss of communication with the I/O server), the standby server takes over the duties of the primary server. It will process alarm data and update the database. When the inoperative server resumes operations, it establishes communication with the other alarm server (which is now the main) and become the standby server.

**Note:** In cases where both the primary and standby server become isolated loss of data may occur.

During synchronization, the primary server updates the standby server. This confirms that the standby server contains data that accurately represents the data on the primary server (see [Alarm Server Side Synchronization](#)).

**Note:** Before starting your system for the first time (i.e. the database is empty), the primary and standby server should be connected. If not connected when the system starts, the primary and standby servers may create distinct IDs for the same objects.

## See Also

[Reports Server Redundancy](#)

### Alarm Server Side Synchronization

Synchronization occurs when the primary server establishes or re-establishes a connection with the standby server. Synchronization takes place on startup and then periodically during runtime while connection exists between the Primary and stand by servers. During synchronization the Primary server (or main) updates the data on the standby sever as required with alarm action and event data.

Each time the alarm primary server connects to the standby server, the synchronization process will take place. This will allow primary server to update the standby server with the most recent copy of the primary server's

data.

**Note:** Synchronization occurs only if the primary and standby alarm servers are running and connected.

To configure synchronization between the primary and standby alarm server refer to the [Alarm Parameters](#).

## Main-Main Scenario

If the standby alarm server loses its connection with the primary alarm server, a 'main-main' situation may occur, where both servers communicate and process data from the I/O server. On reconnection the data on both servers will need to be synchronized. With duty mode enabled by default, the servers determine what data to merge. In most instances the data with the latest timestamp is kept while the other is discarded.

### **WARNING**

#### **UNINTENDED EQUIPMENT OPERATION**

In a 'main-main' situation do not make any configuration changes to your system until the primary and standby server is reconnected. Configuration changes made to the system during a 'main-main' situation may cause the system to become inoperative.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

#### **Deciding which server will be 'Main' after a 'Main-Main' scenario**

When the connection between the servers is restored, the servers arbitrate to determine which server continues as main and which server becomes the standby.

In Plant SCADA, when configuring the alarm server you select which server is primary and which is standby. By default, the server configured as primary is given the highest priority, thus when the servers arbitrate to determine which becomes main, the primary server will revert to being the main server.

## Configuring Isolation Parameters

It is likely that when a redundant pair of alarm servers cannot communicate with each other, it is due to one of the servers becoming isolated from the network. The alarm server that has become isolated is also likely to be isolated from the physical devices from which it obtains data, so it will not be obtaining alarm events from the field during the period of isolation.

The parameters [\[Alarm\]IsolationDetectIP1](#) and [\[Alarm\]IsolationDetectIP2](#) can be configured so that the system knows which alarm server became isolated. The isolated alarm server can then become the standby when the connection between the alarm servers is restored. This will help avoid the loss of alarm event data during the period of an outage, as the alarm server that was not isolated becomes the main server and synchronizes the events that occurred to the standby.

## Duty Mode

Duty mode enables a standby server to transfer data to a primary server following a 'main-main' situation.

When the connection between the servers is restored, the servers arbitrate to determine which server switches to standby.

In Plant SCADA duty mode is enabled by default, and helps prevent the data on the server that is deemed to be the standby (after the arbitration process) from not being accessible. In Duty mode the timestamps of the data

on the servers are compared. The data with the recent timestamp is kept and is merged into the data on the primary server and the remainder of the data is discarded.

When the primary server receives the more recent data, from the standby server, it merges the data with its own data and then sends an update to the standby server. This allows for primary and standby server to operate with synchronized data sets.

[Add an Alarm Server Process](#)

## Reports and Trends Server Redundancy

Redundancy of Reports, Trends, and I/O servers is achieved by adding standby servers, within a defined cluster, to provide redundant system components. In addition you can also utilize the dual end point (or multiple network interfaces) capabilities of each component, effectively enabling you to specify a complete and unique network connection from a client to a server. See [Network Redundancy](#).

Consider the following diagram:

Server redundancy of each component in the diagram is achieved by providing a corresponding standby server on the same network (LAN 1). Redundancy is provided as follows:

- If any of the servers become inoperative or communications become inoperative, their standby counterpart assumes operation.
- For I/O Server redundancy, when the inoperative I/O Server comes back online, it resumes control based on the individual I/O device primary or standby priority configuration..

- For Trend and Report servers, when the inoperative primary server returns online, the client will remain with the standby unless the primary has a higher priority.
- For Reports, and Trends Server redundancy, clients connect to either the Reports, or Trends primary server or standby server. On startup, clients try to establish a connection with the primary server. If a connection with the primary server cannot be established, they will try to establish a connection with the standby server. If the primary server becomes available, any clients connected to the standby server remain connected to the standby server unless the primary has a higher priority. If the standby server becomes inoperative the client will revert to the primary server. The priority is set using the connectivity parameters described below.

Alarm Server Redundancy uses a main/standby model. Refer to [Alarms Server Redundancy](#) for more information.

## Connectivity Parameters

The client sub system runs in every SCADA client or server process. It connects to all servers within all clusters that are enabled, allowing any process to send data requests to any other server, either through internal systems or Cicode function calls.

Two Citect.ini parameters allow you to configure how the client sub system will manage its connections to redundant pairs of Reports or Trends servers.

These parameters are [Type.ClusterName.ServerName]Priority and [Type.ClusterName.ServerName]DisableConnection, where Type is the relevant server type (Report or Trend). The default setting for these parameters provides behavior as described above, in that if the client sub system is redirected to a standby server it will retain a connection to that server, providing that it is operable, even when the primary server is restored. This is also the behavior that will occur if these parameters are not added for a given server type.

The connectivity parameters can be set at the system level using the Parameters form of the project, or specifically for each computer in the local Citect.ini file.

For a detailed explanation of these parameters see:

- [\[Report.<ClusterName>.<ServerName>\]Priority](#)
- [\[Trend.<ClusterName>.<ServerName>\]Priority](#)
- [\[Report.<ClusterName>.<ServerName>\]DisableConnection](#)
- [\[Trend.<ClusterName>.<ServerName>\]DisableConnection](#)

## See Also

[Alarms Server Redundancy](#)

[Reports Server Redundancy](#)

[Trends Server Redundancy](#)

[File Server Redundancy](#)

## Reports Server Redundancy

It is possible to configure two Reports Servers in a project. That is, a primary Reports Server and a standby Reports Server.

When both Reports Servers are in operation, the scheduled reports only run on the primary Reports Server. If the primary Reports Server becomes inoperative, the scheduled reports run on the standby Reports Server (you can also configure the standby Reports Server so that it also runs the scheduled reports in parallel with the primary Reports Server). Please be aware that no report data is transferred between the primary and standby Reports Servers (Plant SCADA does not synchronize the report data because reports can write their data to any type of device).

## See Also

[Trends Server Redundancy](#)

### Trends Server Redundancy

It is possible to configure two Trends Servers in a project. That is, a primary Trends Server and a standby Trends Server.

When both Trends Servers are in operation, trends are processed on both servers in parallel, and written to disk (each server needs to write to its own disk or its own private area on the file server).

When a Trends Server starts up, it tries to establish a connection to the other Trends Server. If it can establish a connection, it will transfer the trend data from the last time it was shutdown until the current time (this minimizes the chance that trend data will be lost).

## See Also

[File Server Redundancy](#)

### File Server Redundancy

Plant SCADA allows for redundancy of the file server. The [\[CtEdit\]Backup](#) parameter specifies a backup project path. If Plant SCADA cannot find a file in the Run directory (i.e. as specified by the [\[CtEdit\]Run](#) parameter), it will look in the backup path. If the file is found in the backup path, Plant SCADA will assume that the run path has become unavailable for some reason (for example, the file server has become inoperative). It will then look for relevant files in the backup before changing over. When Plant SCADA changes over to the backup path, it will call event number 11 and generate the hardware error: "File server failed, to Standby".

File server redundancy will only operate correctly if the redirector (or shell) on the computer can respond appropriately if the file server becomes inoperative.

---

**Note:** Only Plant SCADA switches to a backup path. Any other applications that are using files on the file server will become inoperative when the file server becomes inoperative. This may cause the computer to wait for long periods for the file server (or to itself become inoperative). This includes Windows itself, so install Windows on a local drive.

---

To enable file server redundancy, set the [\[CTEDIT\]Backup](#) parameter to a backup database path. For example, if your primary path is **F:\Plant SCADA\USER\DB**, set the backup path to another file server or a local drive, such as: "C:\ProgramData\AVEVA Plant SCADA <VersionNumber>\User".

You will want to verify that the project in the Backup path is the same as the one in the Run directory - each time you compile the project in the run directory copy it into the backup directory.

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Before placing your Plant SCADA system into service, confirm that the standby file server has an identical copy of the current project, and that the [CTEDIT]Backup parameter is correctly set.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

Each of these sections provides conceptual information followed by the set of tasks that you can perform.

## Equipment

In Plant SCADA, the term "equipment" is used to describe an object-oriented architecture within a project that can be used to reference the machinery or processes being monitored. Equipment definitions create logical groupings that allow you to organize your project using a hierarchical design. Each definition brings together the

base SCADA properties into a single entity that can be easily replicated within your project.

For example, if a pump is represented in your project as a piece of equipment, it will bring together the tags, events, alarms, permissions, communications, scheduling and scripting associated with the pump. You can associate the pump with a particular geographical area, or include it as part a functional process.

**Note:** To be able to define equipment, you need to have a report server process defined (see [Add a Report Server Process](#)).

This section of the help explains the concepts that define the way equipment is configured in a Plant SCADA project. These include:

- [Equipment Hierarchy](#) — the object model that is created by the equipment definitions in a project
- [Equipment Types](#) — the templates you can use to add multiple instances of a particular piece of equipment to your project
- [Equipment Instances](#) — the representation of a physical piece of equipment in your project that can be based on a particular equipment type
- [Equipment States](#) — operational states for a piece of equipment that you can use for scheduling
- [Equipment References](#) - the link added between a piece of equipment, and/or items belonging to other equipment within your project. The equipment reference can also be to equipment, and/or items that is outside the equipment hierarchy.

This section also explains the different approaches you can take when defining equipment within a project.

- If you are creating a new project (or adding a new section to an existing project), use the Equipment Editor to build an equipment hierarchy and automatically generate tags from that hierarchy (see [Equipment Editor](#)).

For specific, task-based information that describes how to configure equipment in a Plant SCADA project using the Equipment Editor, see:

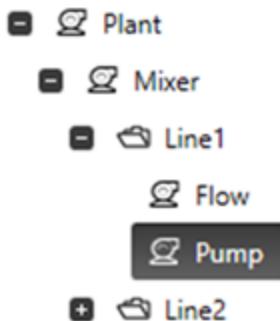

- [Configure Equipment Types Using Equipment Editor](#)
- [Configure Equipment Instances Using Equipment Editor](#).
- If you would like to add an equipment hierarchy to an existing project, you can associate your existing variable tags, trends and alarms with equipment in Plant SCADA Studio (see [Define an Equipment Association for a Tag](#)).

For specific, task-based information that describes how to configure equipment in Plant SCADA Studio, see [Configure Equipment in Plant SCADA Studio](#).

## Equipment Hierarchy

The term "equipment hierarchy" refers to the object model that is created by the equipment definitions in a project. When you define an equipment instance, its location in the hierarchy is reflected in the equipment name with a period (.) used to indicate levels in the hierarchy.

For example, the equipment name "Plant.Mixer.Line1.Pump" refers to the selected item in the following equipment hierarchy:

This type of architecture allows you to logically reference each piece of equipment based on its location in the object model, which could represent a geographical location or a functional process. Each piece of equipment becomes a parent to the items that are associated with it, including variables, trends, alarms, accumulators, and so on.

At runtime, the object model hierarchy can be used to search and display information that is aligned to the process operational model.

## Example

If your project uses Plant SCADA's built-in templates (accessible via a starter project), the equipment hierarchy is integrated into the project pages. For example, the equipment hierarchy displays in a panel on pages where a list of variable tags or alarms is displayed, allowing you to browse, sort and filter the list.

The example below shows the equipment hierarchy for the Plant SCADA Example project displayed on the active alarms page.

Active alarms		
Acknowledge page   Filter...   Auto-fit columns		
(Alarms Filtered)	Date	Time
+ Building (2)	3/06/2014	11:15:40 AM
+ Loops (3)	27/05/2014	03:56:26 PM
- Plant (19)	27/05/2014	03:55:33 PM
+ Bottler (8)	8/05/2014	03:07:59 PM
+ Mixer (11) <input checked="" type="checkbox"/>	8/05/2014	02:22:44 PM
SteelMill (1)	8/05/2014	01:50:00 PM
CoilCar	8/05/2014	01:28:02 PM
Shearer	8/05/2014	12:55:00 PM
Uncoiler	29/04/2014	01:10:00 PM
Welder (1)	29/04/2014	01:00:00 PM
	29/04/2014	12:30:00 PM

The integrated object model has been used to filter the alarms by placing a check mark next to the Mixer branch. This means the list only includes the 11 active alarms associated with the Mixer.

[Equipment Types](#)

[Equipment Instances](#)

## Equipment Types

In a Plant SCADA project, the term "equipment type" refers to a template that you can use to associate multiple instances of a particular piece equipment in your project.

For example, if you have a motor that is deployed in numerous locations across a production facility, you could create an equipment type to act as a template for the motor. This will bring together many of the configuration settings required to add each instance of the motor to your project, such as the associated variable tags, operational states, cluster associations, and so on.

To then add one of the motors to your project, you simply create a new instance of the equipment type. This offers the following benefits:

- Minimal configuration is required to deploy multiple equipment instances
- Configuration is consistent across multiple equipment instances
- Equipment instances are automatically integrated into the project's equipment hierarchy
- An equipment type maintains an association with each equipment instance that is created from it, allowing any changes to be easily applied across an entire project.

An equipment type is made up of the following:

- **Items** - used to represent attributes of the physical piece of equipment, which can include controls, actions, conditions, settings, and so on. Each item is made up of a set of elements, which can include variable tags, trends or alarms (see [Items](#))
- **Configuration Parameters** - used to define specific values associated with the piece of equipment (see [Add Configuration Parameters to an Equipment Type](#))
- **States** - used to define operational states for the associated piece of equipment that you can use for scheduling (see [Equipment States](#))
- **Linked Genie** - specifies a genie that you can use to represent the piece of equipment on your graphics pages (see [Link a Genie to an Equipment Type](#)).

To create equipment types, you use the Equipment Editor (see [Equipment Editor](#)).

Alternatively, you can create your own XML template and add it to your project as an equipment type (see [Import Equipment Using XML Templates](#)).

---

**Note:** Equipment types are primarily designed to assist with the creation of new tags. If you would like to define an equipment hierarchy for existing tags, you should use the process described in the topic [Define an Equipment Association for a Tag](#).

## See Also

[Equipment Instances](#)

## Items

The term "item" is used to describe a particular attribute of a physical piece of equipment that is represented in an equipment definition.

Items can be used to reflect different aspects of a piece of equipment, such as an associated action, condition or setting. They group the tags associated with equipment in a way that allows you to reference the particular attribute the item represents.

[Equipment Types](#) are defined as a set of items. Each item includes a number of elements that directly link to the physical device, such as variable tags, trends or alarms.

## Example

The Plant SCADA Example project includes an equipment type named "Motor". It includes the following items:

- Running
- Stopped
- Auto
- OutOfService
- Alert
- IntLock
- Start
- Stop
- IntBypass
- Reset
- FailStart
- FailStop

This list demonstrates the different types of attributes you can represent with an item, including operational states (Running, Stopped), actions (Start, Stop, Reset), alarm conditions (FailStart, FailStop) and settings (IntBypass).

In each case, the item is made up of a set of elements (tags, trends and alarms) that enable interaction with the physical device.

For example, FailStart includes a variable tag definition that is associated with the physical motor, and a digital alarm tag that indicates when an attempt to start the motor has been unsuccessful.

---

**Note:** When defining an item name, avoid using [Reserved Words](#). If you use any of these, an error message will display when you compile your project.

---

## See Also

[Equipment Instances](#)

## Equipment Instances

The term "equipment instance" refers to an equipment record in a Plant SCADA project.

When you add an equipment instance to your project, you specify a location for it within the project's equipment hierarchy. This is reflected in the complete equipment name (where a period (.) can be used to indicate levels in the hierarchy). This location can then be used to refer to the variable tags, alarms and trends that are associated with the equipment instance.

An equipment instance contains a set of properties that may be used in the generation of tags, alarms and trends for that instance. These properties can also be used at runtime in conjunction with the equipment browse functions.

Every equipment instance includes a predefined set of properties that are common to all equipment instances (see [Define Equipment in Plant SCADA Studio](#)).

If an equipment instance has been created using an equipment type as a template, it will include additional properties that reflect the items and configuration parameters specified in the associated equipment type. Each instance maintains an association with the equipment type from which it was created, allowing equipment type changes to be instantiated across all related instances.

To create equipment instances from an equipment type, you use the Equipment Editor (see [Equipment Types](#)).

---

**Note:** Equipment does not need to be associated with an equipment type. This scenario is typical in projects where equipment associations have been configured for existing variable tags. See [Define an Equipment Association for a Tag](#).

---

## See Also

[Equipment Types](#)

[Items](#)

## Equipment States

States are defined in an equipment type to identify operational conditions for a piece of equipment that you can use for scheduling.

Each state includes a set of fields that reflect the associated Equipment State properties. These fields identify the entry action that is performed when a state transition occurs, and any other settings that may apply while the state is active such as delays and repeat actions.

You can create states for an equipment type using Equipment Editor (see [Add a State to an Equipment Type](#)).

Alternatively, you can manually define equipment states in Plant SCADA Studio (see [Define Equipment States in Plant SCADA Studio](#)).

## See Also

[Equipment Types](#)

## Equipment References

Equipment references define an association between two pieces of equipment or items on equipment. They create relationships in your equipment definitions that extend beyond those that occur intrinsically within the equipment hierarchy.

Using equipment reference browse functions, you can track, group and display information for equipment and its referenced equipment in one interface at runtime.

For example, you could create a pop up for a pump that monitors the following:

- The flow of the pump.
- The pump's power and energy usage.
- The pump's running status.

When an anomaly is identified on the pump, the operator may need to look at other pieces of equipment to determine the cause. This could include the following:

- The low level alarm on the sump from which the pump is pumping.
- The level of the tank that the pump is filling.
- The position of the inlet and drain valves.

You can add multiple equipment references from the pump to these associated pieces of equipment. For example, you could create an equipment reference from the pump to the alarm on the source sump. At runtime, when the operator is viewing the information for this pump, they will be able to view the status of the low-level alarm on the sump as well.

Equipment references are defined in the **Equipment** view of the **System Model** activity. See [Define Equipment References](#) for more information.

You can use equipment references to configure interlocks in a Situational Awareness Project. See [Interlocks](#) for more information.

## See Also

- [Configure Interlocks](#)
- [EquipRefBrowseOpen](#)
- [AlarmCountEquipment](#)

## Equipment Editor

Equipment Editor is a tool designed to generate tags in a Plant SCADA project that adhere to an equipment hierarchy.

### To open the Equipment Editor:

1. In the **System Model** activity, select **Equipment**.
2. On the Command Bar, click **Equipment Editor**.

The Equipment Editor interface includes two different views:

- Equipment Types
- Equipment.

These two views are accessible via the tabs along the left edge of the Equipment Editor window, or via the **View** menu.

The View menu also includes a command to **Refresh** the Equipment Editor interface.

You can work with equipment in three easy steps:

1. Create **equipment types** (see [Configure Equipment Types Using Equipment Editor](#)).

The items you include will define the tags, alarms and trends required to support each associated equipment instance.

2. Create **equipment instances** (see [Configure Equipment Instances Using Equipment Editor](#)).

The location of an instance in the equipment hierarchy and its field values provide the information required to create the tags, alarms, trends and states defined in the associated equipment type.

3. Run an **equipment update** (see [Equipment Updates](#)).

This generates the related configuration records required to support each equipment instance.

The Equipment Editor also supports the following functionality:

- [Equipment Property Referencing](#) — syntax you can use to pass property values from an equipment instance to an equipment type
- [Configuration Parameters](#) — named placeholders that allow you to identify and associate values with a piece of equipment.

You can also use the Equipment Editor to [Link a Genie to an Equipment Type](#).

## See Also

[Equipment](#)

## Equipment Updates

An equipment update generates the configuration records associated with the equipment instances defined in the Equipment Editor. The records that are generated for each equipment instance are specified by the items and states defined in the associated equipment type.

---

**Note:** When you perform an equipment update, any numeric values in your project need to be in a format that matches the current system locale setting. For example, a decimal separator needs to be a comma (,) on systems using French, Russian or Turkish. For this reason, you are not able to run an equipment update for the Example project on some non-English locales.

By default, Plant SCADA will perform an incremental equipment update that only includes equipment and equipment types that have been modified since the last update occurred.

If you disable incremental updates, Plant SCADA will regenerate every tag associated with the equipment hierarchy each time an update is run.

### To disable incremental equipment updates:

1. In Plant SCADA Studio, select **Options** from the Activity Bar. The Options dialog will appear.
2. Locate Incremental equipment update on the Options dialog and clear its check box.
3. Click **OK**.

---

**Note:** If you deselect the Incremental equipment update program option, an equipment update will take more time to complete. The time required to complete an update may increase significantly if a project includes a large equipment hierarchy.

---

### See Also

[Update Equipment in Equipment Editor](#)

### Equipment Property Referencing

Equipment property referencing allows you to pass equipment property values from an equipment instance to an equipment type. This information is then used to generate the tags, alarms, trends and states associated with the items defined in the equipment type.

- To refer to a particular equipment property you use the following format:

{equipment.<equipment\_property>}

Where <equipment\_property> is the name of the property that is being referenced.

Be aware that any spaces and non-alphanumeric characters are removed from the field name. For example, the "I/O Device" field is referenced with "{equipment.iodevice}".

- To refer to ungrouped [Configuration Parameters](#), use the following format:

{equipment.param\_list[parameter\_name]}

Where <parameter\_name> is the name of the parameter that is being referenced.

- To refer to a grouped configuration parameter, use the following format:

{equipment.parameter.group\_name[parameter\_name]}

Equipment property referencing is used in the Equipment Editor (see [Configure Equipment Types Using Equipment Editor](#)).

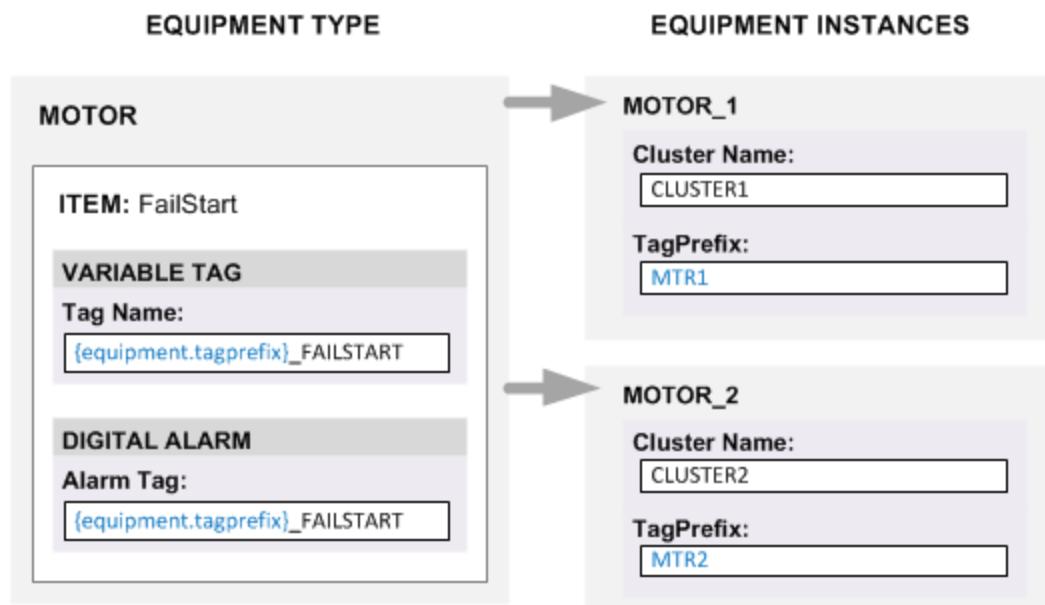

---

**Note:** If you delete a configuration parameter (either directly, or by deleting its parent parameter group), any fields that reference the parameter will also be cleared.

---

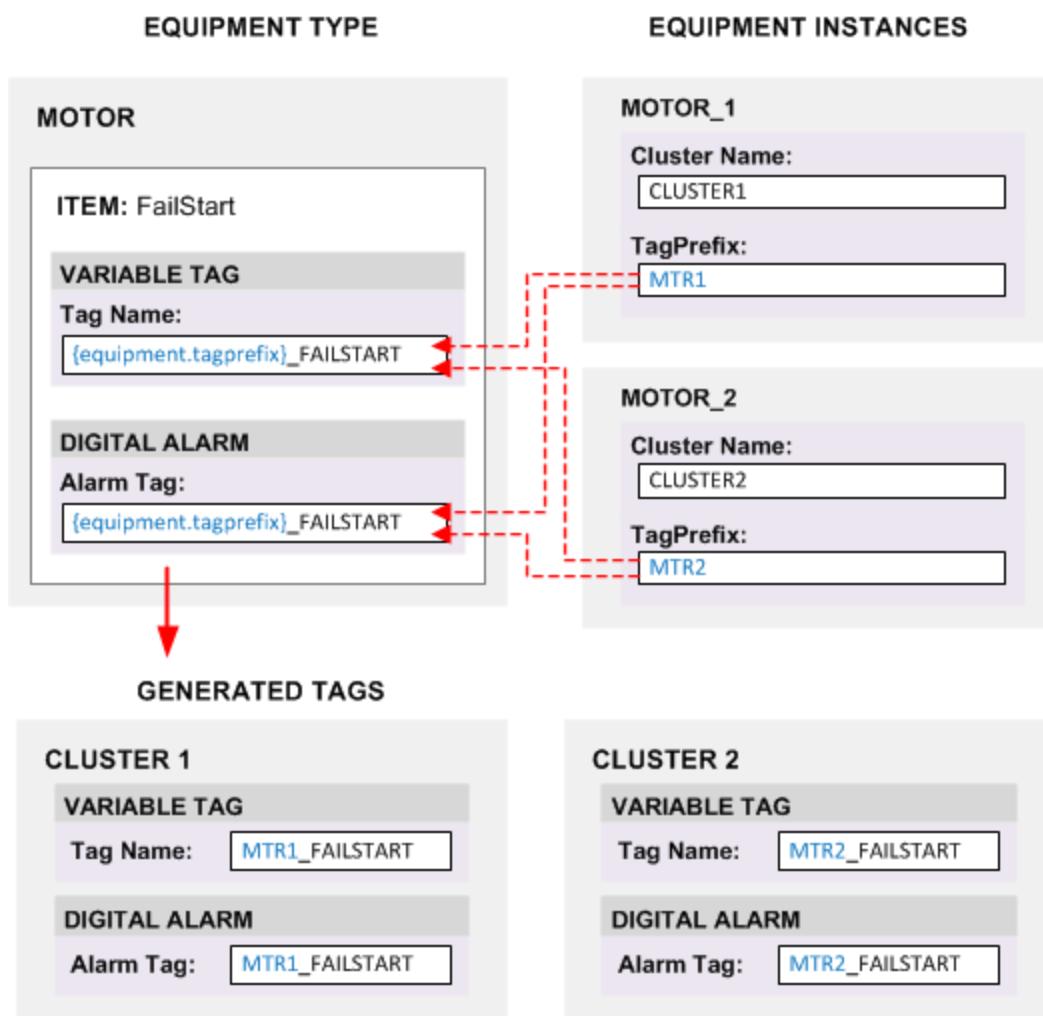

### Example

The following diagram shows two equipment instances ("Motor\_1" and "Motor\_2") based on the "Motor" equipment type. In each instance, the values defined for the **Cluster Name** and **TagPrefix** properties are displayed.

The equipment type includes an item named "FailStart" that has a variable tag and a digital alarm defined as elements. In both cases, the equipment property reference "{equipment.tagprefix}\_FAILSTART" is used to define the name of the associated tags.

In the two equipment instances, the Tag Prefix property has been set to "MTR1" and "MTR2" respectively. When an equipment update occurs, these values are applied to equipment type, causing the tags displayed below to be generated.

These tags are automatically added to the project and linked to the associated equipment instance. Each equipment instance maintains an association with the equipment type from which it was created, allowing changes to be applied across your project.

## See Also

[Edit the Field Values for an Equipment Instance](#)

## Configuration Parameters

Configuration parameters can be added to an equipment type to represent specific information about a physical piece of equipment, such as a set point or delay setting.

When you add a configuration parameter to an equipment type, it creates a named placeholder that is included as a field in each associated equipment instance. Parameters can be grouped together to provide context or added individually as ungrouped parameters.

Configuration parameters support [Equipment Property Referencing](#). You can also specify a default value that is used as the initial value for a parameter when a new instance is created.

To create configuration parameters for an equipment type, use the Equipment Editor (see [Add Configuration](#)

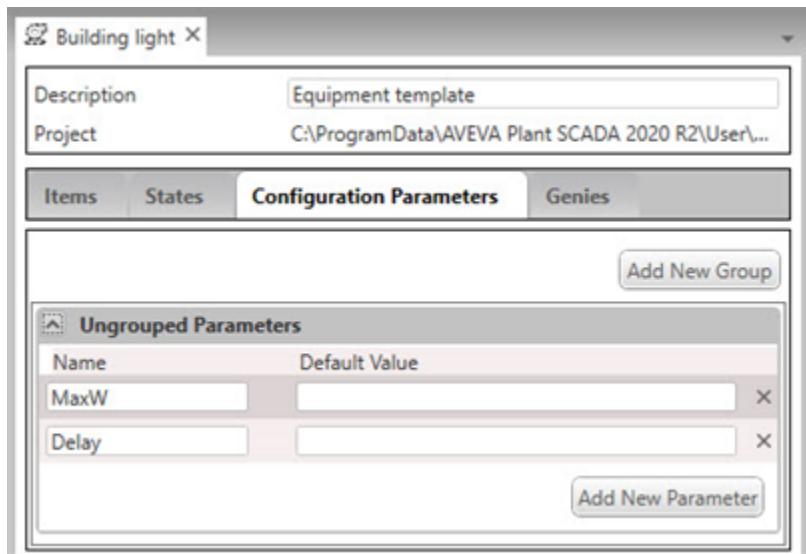

Parameters to an Equipment Type).

**Note:** In Plant SCADA 2023, configuration parameters replaced "custom parameters" as they were restricted by a limitation of 256 characters. Configuration parameters provide the same functionality as custom parameters, but they are stored in a dedicated configuration parameters database. This change required any existing equipment types to be migrated to a new format. If Equipment Editor detects any version 1.0 equipment types, a dialog will appear asking if you want to migrate them. If this occurs, see [Migrate Custom Parameters to the Configuration Parameters Database](#).

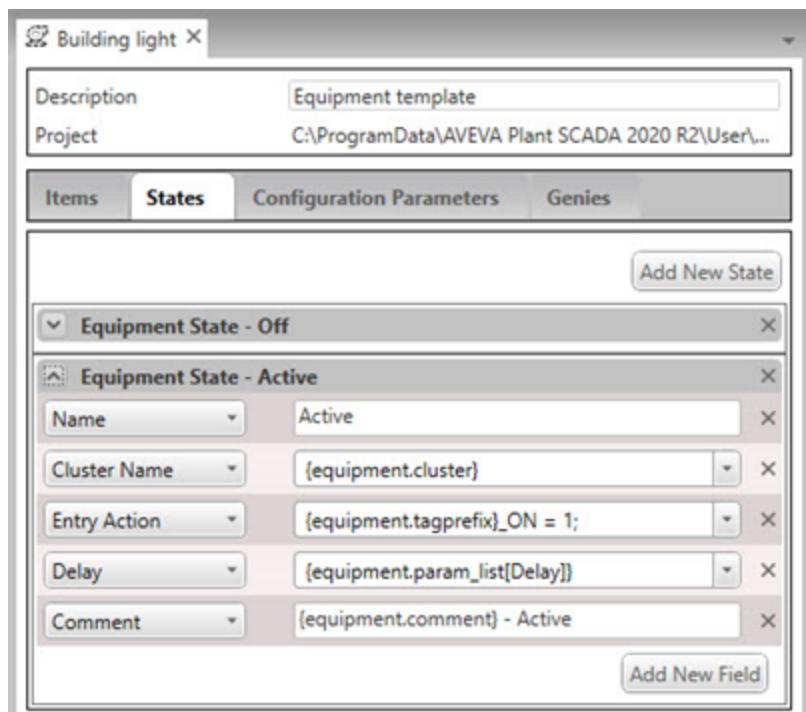

## Example

The Plant SCADA Example project includes an equipment type named "Building Light" that has two configuration parameters defined:

- MaxW
- Delay

An equipment state called "Active" is also configured for the equipment type. It includes a field called **Delay** that references the Delay parameter.

Observe that the equipment property reference in the **Delay** field uses the following syntax:

{equipment.param\_list[Delay]}

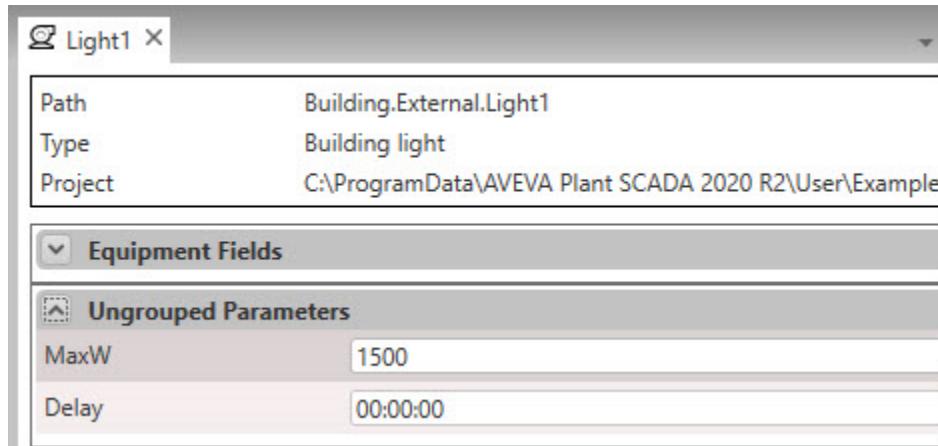

**Note:** The syntax for a grouped parameter will be:

{equipment.parameter.group\_name[parameter\_name]}

See [Equipment Property Referencing](#).

When the value is set for the Delay parameter in an associated equipment instance, it is applied to the Delay property when the equipment state is generated.

Consider the following equipment instance (defined as "Building.External.Light1").

This will result in the creation of the following equipment state (with the Delay property set to "00:00:00").

The screenshot shows the 'Equipment' tab of the 'System Model' editor. The table lists equipment states across seven rows. Row 6 is highlighted with a red border, indicating it is selected. The columns are: Row, Name, Cluster Name, Equipment, Entry Action, and Delay.

Row	Name	Cluster Name	Equipment	Entry Action	Delay
1	Off	Cluster1	Building		
2	Active	Cluster1	Building		
3	Off	Cluster1	Building.External		
4	Active	Cluster1	Building.External		
5	Off	Cluster1	Building.External.Light1	BLD_EXT_L1_ON = 0	
6	Active	Cluster1	Building.External.Light1	BLD_EXT_L1_ON = 1; 00:00:00	
7	Off	Cluster1	Building.External.Light2	BLD_EXT_L2_ON = 0	

You can also view the configuration parameters in a project directly in Plant SCADA Studio (see [Define Equipment Configuration Parameters in Plant SCADA Studio](#)).

## Configure Equipment Types Using Equipment Editor

To configure equipment types in Equipment Editor, you use the **Equipment Types** view. When displayed, it allows you to perform the following configuration tasks:

- Add an Equipment Type
- Open an Equipment Type
- Duplicate an Equipment Type
- Copy an Equipment Type to a User-created Project
- Enable Editing for an Equipment Type in a System Project
- Edit an Equipment Type
- Delete an Equipment Type
- Add an Item to an Equipment Type
- Add an Accumulator to an Equipment Type
- Add an Element to an Item
- Edit the Fields for an Element or Accumulator
- Add a State to an Equipment Type
- Add Configuration Parameters to an Equipment Type
- Link a Genie to an Equipment Type

## See Also

[Update Equipment in Plant SCADA Studio](#)

## Add an Equipment Type

To add an equipment type to a project, you use **Equipment Types** view in [Equipment Editor](#).

**Note:** You can not add an equipment type to a system project (such as a template project or library project). You can only add equipment types to user-created projects.

### To add an equipment type:

1. Open Equipment Editor.
2. Select the **Equipment Types** tab.

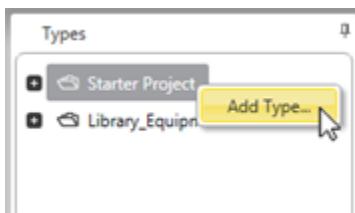

Or:

Select **Equipment Types** from **View** menu.

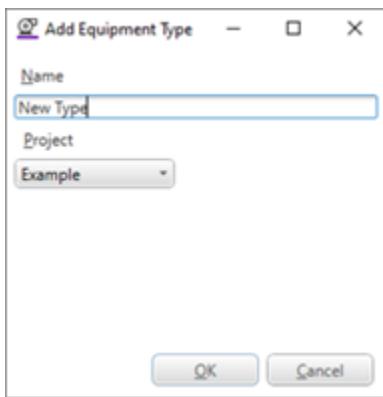

3. In the **Types** list, locate the project to which you would like to add a new equipment type.

The **Types** list includes the project that is currently selected in Plant SCADA Studio and its included projects. If the project you are after is not displayed in the **Types** list, check that the correct project is selected in Plant SCADA Studio. You can then select **Refresh** from the Equipment Editor's **View** menu to reload the **Types** list.

4. Right-click on the project and select **Add Type**.

The Add Equipment Type dialog will display.

5. Enter a **Name** for the equipment type.

**Note:** The name you give to an equipment type at this point cannot be changed once it has been saved. Equipment types cannot be renamed as this impacts the equipment associations defined within the Equipment Editor.

6. Confirm the **Project** to which you would like to add the equipment type. If required, you can select a user-created include project from the drop-down list.
7. Click **OK**.

The dialog will close and the **Types** list will display the new equipment type. The new type will also open for editing.

## See Also

- [Add an Item to an Equipment Type](#)
- [Add an Accumulator to an Equipment Type](#)
- [Add a State to an Equipment Type](#)
- [Add Configuration Parameters to an Equipment Type](#)
- [Link a Genie to an Equipment Type](#)

## Open an Equipment Type

When you open an equipment type, it displays on a tab in the Equipment Editor.

### To open an equipment type:

1. Open Equipment Editor and select the **Equipment Types** tab.
2. Double-click on the required equipment type in the **Types** list.

Or:

Right-click on the equipment type and select **Open** from the menu that appears.

Or:

Select the equipment type and press the **Enter** key.

The equipment type will display on a new tab.

3. Add, delete or modify the items, states and parameters as required. An asterisk will appear in the tab to indicate there are unsaved changes.
4. To save the changes select **Save** or **Save All** from the **File** menu, or use the **Ctrl+S** keyboard shortcut.

**Note:** An equipment type cannot be modified if any associated instances are currently open with unsaved changes.

## See Also

- [Equipment Types](#)

- [Add an Accumulator to an Equipment Type](#)
- [Add an Element to an Item](#)
- [Edit the Fields for an Element or Accumulator](#)
- [Add a State to an Equipment Type](#)
- [Add Configuration Parameters to an Equipment Type](#)
- [Link a Genie to an Equipment Type](#)

## Duplicate an Equipment Type

When you duplicate an equipment type, the new instance will have "\_n" appended to its name (where "n" is the next integer required to create a unique name).

**Note:** An equipment type cannot be duplicated if any associated instances are currently open with unsaved changes.

#### To duplicate an equipment type:

- Right-click the required equipment type in the Types list and select **Duplicate** from the menu that appears.

The duplicated type will appear in the Types list in the same project branch as the original (with the appended name). The name is highlighted, allowing you to enter a new name if required.

**Note:** The name you give to an equipment type at this point cannot be changed once it has been entered. Equipment types cannot be renamed as this impacts the equipment associations defined within the Equipment Editor.

#### See Also

[Delete an Equipment Type](#)

#### Copy an Equipment Type to a User-created Project

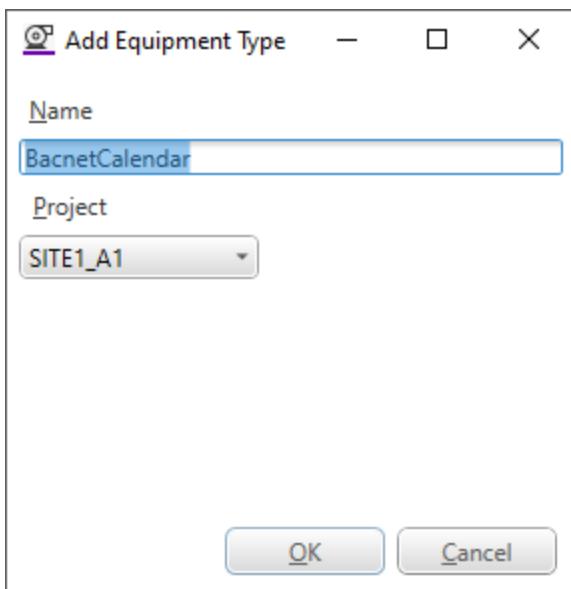

Equipment Types that belong to a system project (such as template or library project) are read-only and cannot be modified. However, you can copy an equipment type to a non-system project and then modify it.

#### To copy an equipment type to a user-created project:

- Open Equipment Editor and select the **Equipment Types** tab.
- In the **Types** list, locate the system project that contains the equipment type you would like to copy.
- Within the project branch, right-click on the required equipment type and select **Copy to project...** from the menu that appears.

- The **Add Equipment Type** dialog will open.

5. If required, enter a new **Name** for the equipment type.  
If a new name is not specified, "*\_n*" will be automatically appended to the existing name (where "*n*" is the next integer required to create a unique name).
6. Select the destination **Project** from the list of available user-created projects.
7. Click **OK**.

The copied equipment type will appear in the **Types** list within the destination project.

## See Also

[Move an Equipment Type to an Included Project](#)

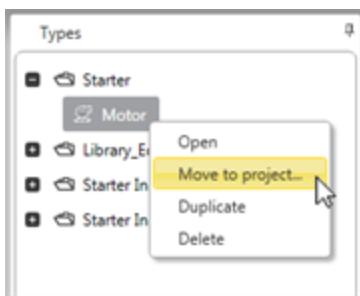

### Move an Equipment Type to an Included Project

You can move an equipment type from its current project to any non-system included projects.

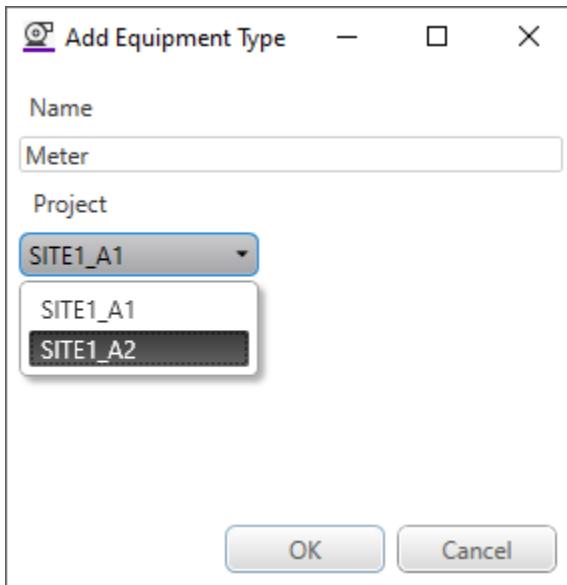

**Note:** An equipment type cannot be moved if any associated instances are currently open with unsaved changes.

#### To move an equipment type to a user-created include project:

1. Open Equipment Editor and select the **Equipment Types** tab.
2. In the **Types** list, locate the project that contains the equipment type you would like to move.
3. Within the project branch, right-click on the required equipment type and select **Move to project** from the menu that appears.

4. The **Add Equipment Type** dialog will open.

5. If required, enter a new **Name** for the equipment type.

If a new name is not specified, "\_n" will be automatically appended to the existing name (where "n" is the next integer required to create a unique name).

6. Select the destination **Project** from the list of user-created included projects.  
7. Click **OK**.

The equipment type will appear in the **Types** list within the selected destination project.

## See Also

[Equipment Types](#)

[Copy an Equipment Type to a User-created Project](#)

## Enable Editing for an Equipment Type in a System Project

Equipment Types that belong to a system project are read-only by default. To make changes to a system project equipment type, you need to make it writable.

**To enable editing for an equipment type in a system project:**

1. Open Equipment Editor and select the **Equipment Types** tab.

2. In the **Types** list, locate the system project that contains the equipment type you would like to edit.
3. Within the project branch, right-click on the required equipment type and select **Enable editing** from the menu that appears.

You will now be able to make changes to the equipment type.

**Note:** You can also copy an equipment type to a non-system project and then modify it (see [Copy an Equipment Type to a User-created Project](#)).

## See Also

[Move an Equipment Type to an Included Project](#)

## Edit Equipment Types

To create and edit **Equipment Types** in Equipment Editor, you need to display the **Equipment Types** view.

**Note:** An equipment type cannot be modified if any associated instances are currently open with unsaved changes.

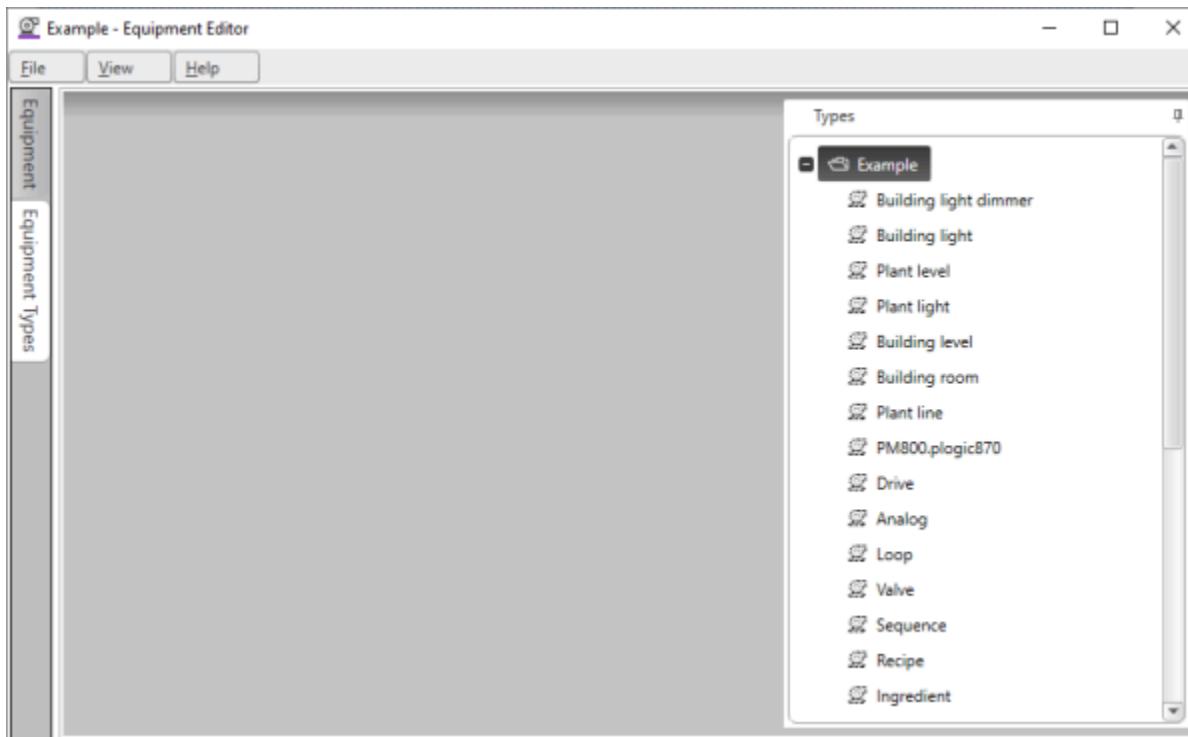

### To edit an Equipment Type:

- Select the **Equipment Types** tab on the left edge of the Equipment Editor window.

Or:

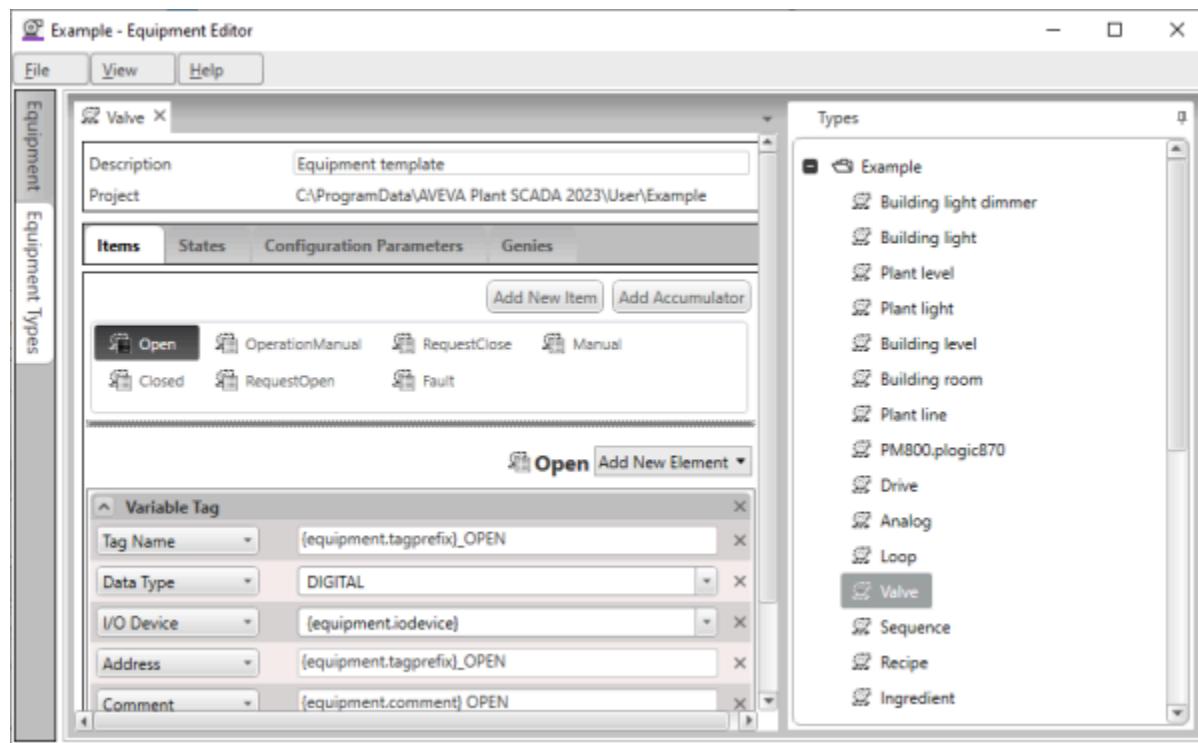

Select **Equipment Types** from the **View** menu.

The **Types** panel lists the existing equipment types in the current project and its included projects.

When you open an equipment type, it displays in the main work area of the Equipment Editor. If two or more

equipment types are open at the same time, each will appear on its own tab.

**Note:** Equipment types that belong to system projects (such as a template or library project) are read-only and cannot be modified.

## See Also

[Configure Equipment Types Using Equipment Editor](#)

## Delete an Equipment Type

Before you can delete an equipment type, you need to save your changes for any associated instances that are currently open.

### To delete an equipment type:

1. Right-click the required equipment type in the Types list and select **Delete** from the menu that appears.  
Or:  
Select the type and press the **Delete** key.  
A confirmation dialog will appear.
2. Click **Yes** to continue with the deletion, or **No** to cancel.

**Note:** If you delete an equipment type, any tags that were generated for the associated equipment instances will also be deleted from your project the next time an equipment update is run. The associated equipment instances themselves are not deleted, however, the Type field for each instance will be updated to 'No type'.

Before you delete an equipment type, it is recommended that you backup your project so that the equipment type can be restored if required.

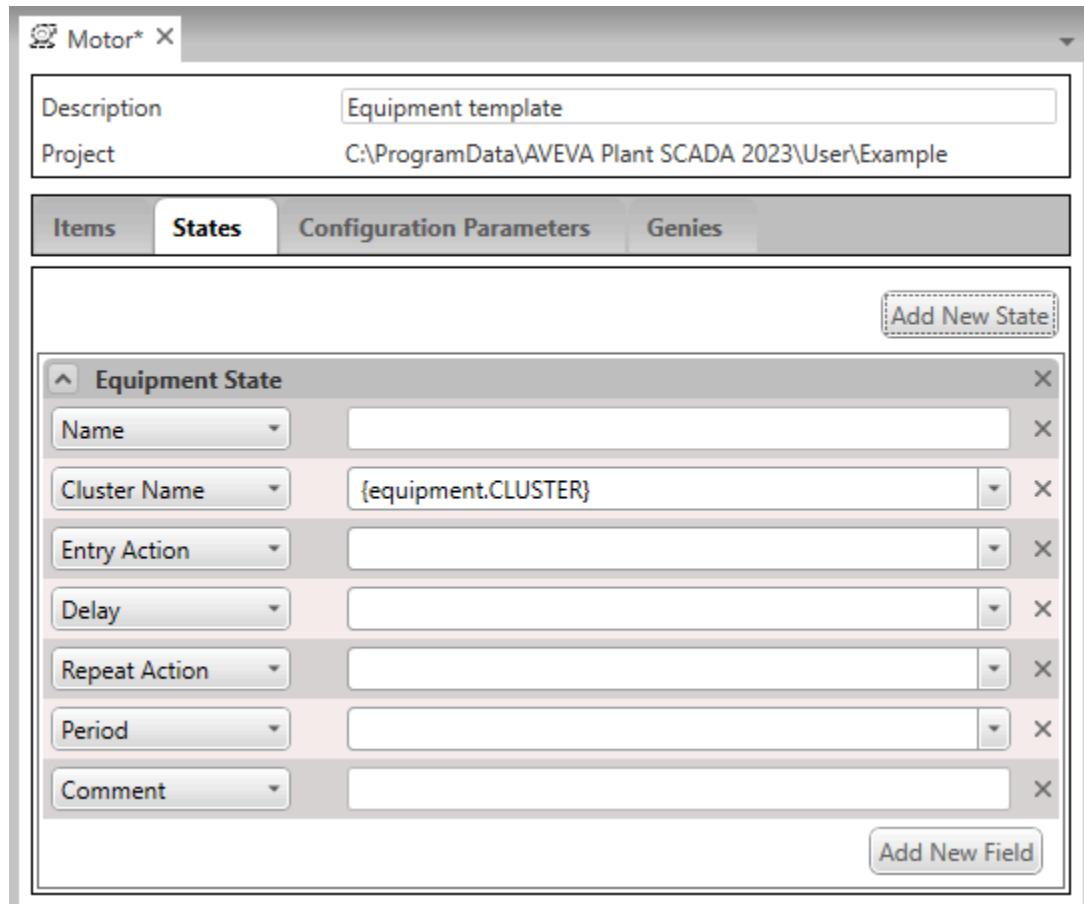

## Add a State to an Equipment Type

You can define multiple [Equipment States](#) for an equipment type to assist with scheduling.

### To add a state to an equipment type:

1. Open Equipment Editor and select the **Equipment Types** tab.
2. Open the equipment type to which you would like to add a state.
3. Select the **States** tab, and click on the **Add New State** button.

A new Equipment State will appear with a set of associated fields displayed.

4. Enter a **Name** for the state.

The name needs to be unique among the states defined for the equipment type. If this is not the case, the Name field will display a red border. This indicates that you need to enter a different name.

5. Enter the required values for the fields. You can use [Equipment Property Referencing](#) if required. In some cases, a menu of suggested options will appear when you select the field.
6. If required, you can add an additional fields by clicking on the **Add New Field** button. The label on a new field is derived from the next available property for the state. (For information on state properties, see [Define Equipment States in Plant SCADA Studio](#).)

To associate a field with a property other than the one indicated by the current label, click on the label and select the required property from the menu that appears.

To remove a field that is not required, click on the close button to the right of the field (x).

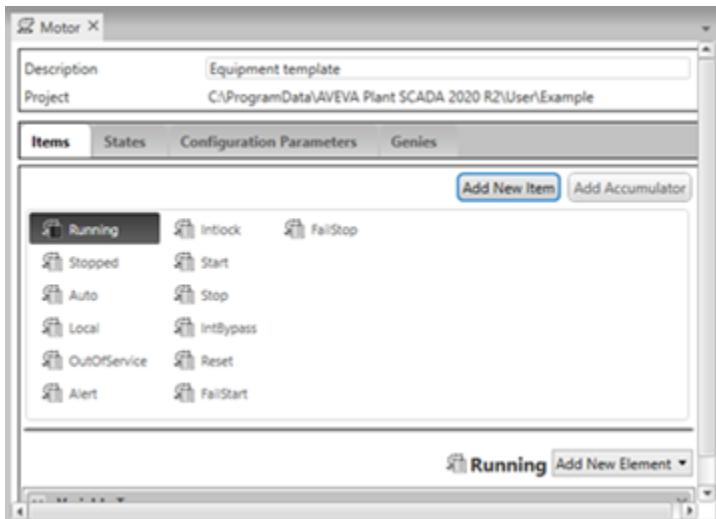

- To save your changes, select **Save** from the **File** menu, or use the **CTRL+S** keyboard shortcut.

## Add an Item to an Equipment Type

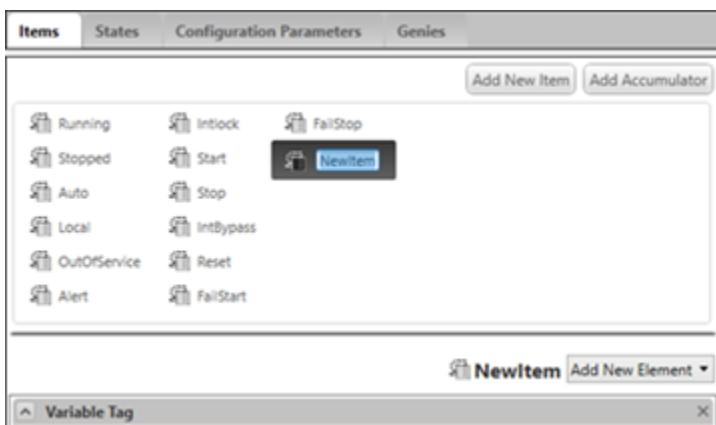

**Items** bring together a set of elements that connect an equipment type to the physical piece of equipment it represents. You can use an item to reflect a particular aspect of a piece of equipment, such as an associated action, condition or settings.

### To add an item to an equipment type:

- Open Equipment Editor and select the **Equipment Types** tab.
- Open the equipment type to which you would like to add an item (see [Open an Equipment Type](#)).
- Select the **Items** tab.
- Click on the **Add New Item** button.

The new item will appear in the list of items with the name "NewItem" highlighted, allowing you to enter a name. Each item requires a unique name.

#### Note:

- When defining an item name, avoid using [Reserved Words](#). If you use any of these, an error message will display when you compile your project.
- You cannot use "me" as an item name, as it is reserved for use with Industrial Graphics.

By default, the new item will include a variable tag as an element.

5. To save your changes, select **Save** from the **File** menu, or use the **Ctrl+S** keyboard shortcut.

## See Also

[Add an Element to an Item](#)

[Add an Accumulator to an Equipment Type](#)

### Add an Element to an Item

Elements represent the configured components of a Plant SCADA project that link an equipment type to the physical device it represents. They are grouped together as [Items](#).

An item can comprise the following elements:

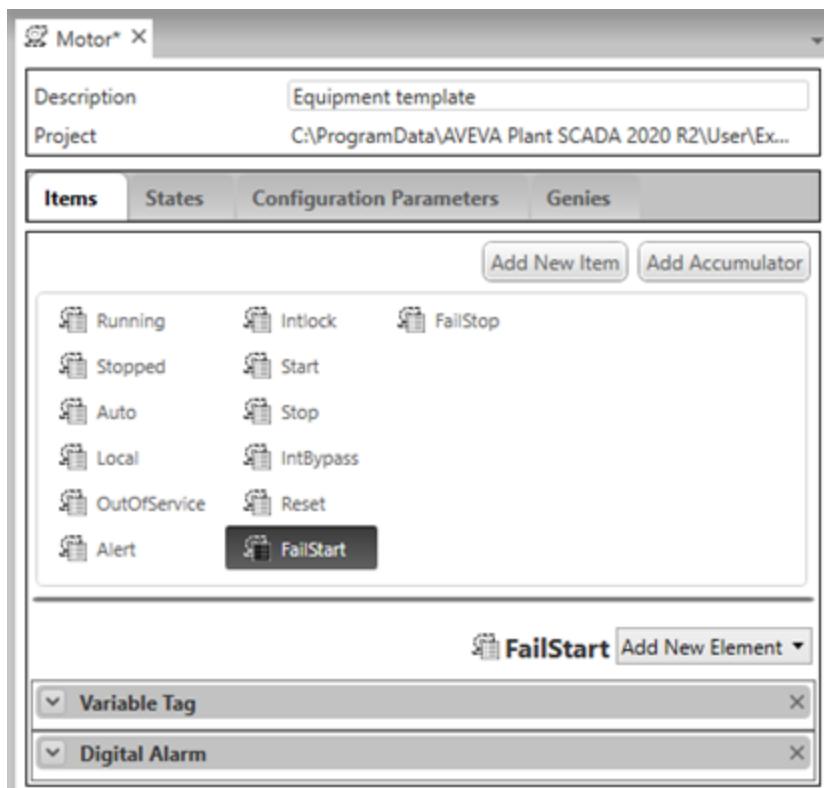

- one variable tag
- one alarm
- one trend tag or SPC tag.

The **Add New Element** menu enforces this limitation.

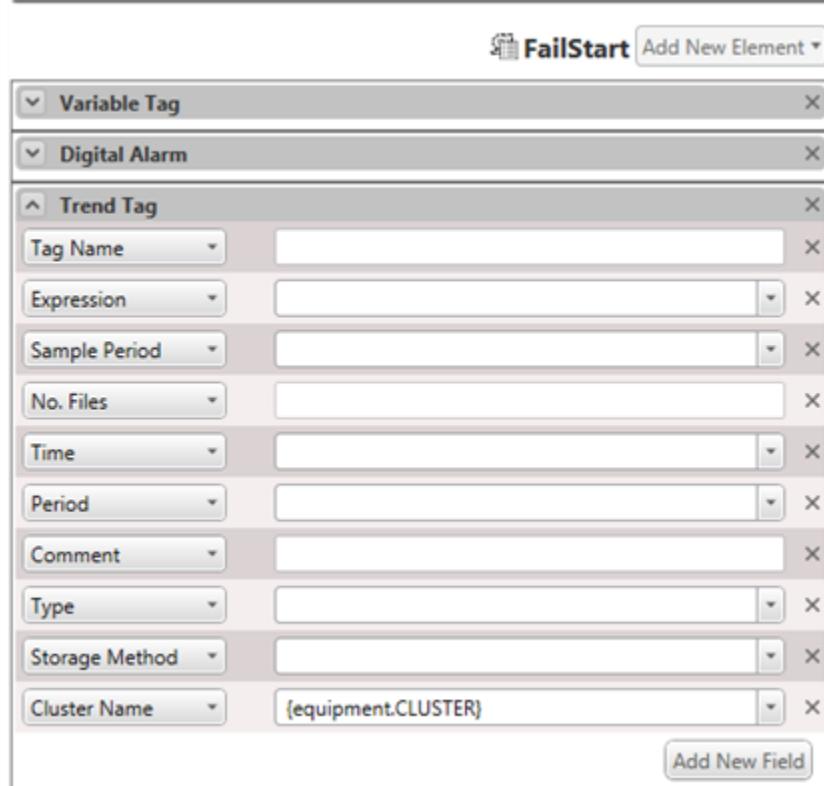

#### To add an element to an item:

1. Open Equipment Editor and select the **Equipment Types** tab.
2. Open the required equipment type (see [Open an Equipment Type](#)).
3. Click on the **Items** tab, and select the item to which you would like to add an element.

The elements that are currently configured for the selected item will appear as a list. In the example below, the **FailStart** item has two elements configured (a variable tag and a digital alarm).

4. Click on the **Add New Element** button and select a type from the list that appears. The new element will appear with its associated fields displayed.

Observe that the **Add New Element** list does not include elements that have already been added to the

item. If this means you need to delete an existing element, select the close button to the right of the element title bar.

5. To save your changes, select **Save** from the **File** menu, or use the **Ctrl+S** keyboard shortcut.

## See Also

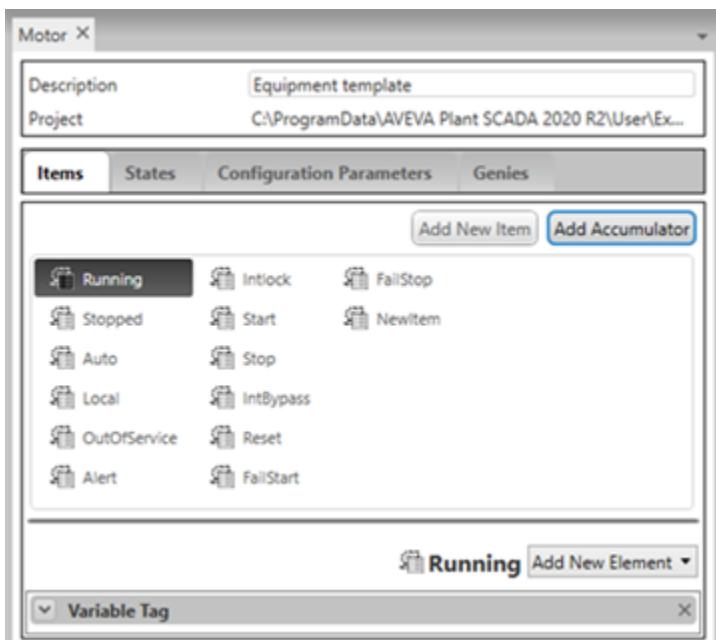

[Edit the Fields for an Element or Accumulator](#)

## Add an Accumulator to an Equipment Type

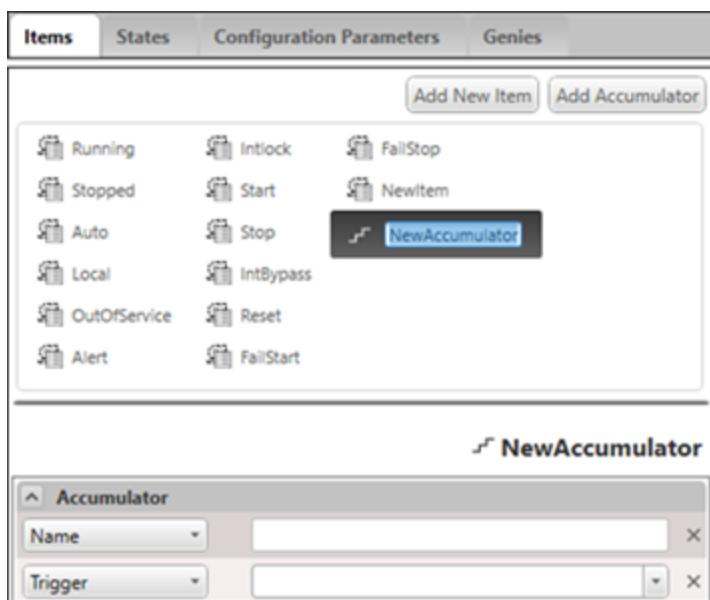

You can associate an accumulator with an equipment type.

### To add an accumulator to equipment type:

1. Open Equipment Editor and select the **Equipment Types** tab.
2. Open the equipment type to which you would like to add an accumulator (see [Open an Equipment Type](#)).
3. Select the **Items** tab.
4. Click on the **Add Accumulator** button.

A new accumulator will appear in the list of items with the name "NewAccumulator" highlighted, allowing you to enter a unique name.

5. To save your changes, select **Save** from the **File** menu, or use the **CTRL+S** keyboard shortcut.

You can add multiple accumulators to an equipment type, however each will require a unique name.

The fields that display for an accumulator are edited in the same way as those associated with an element. For more information, see [Edit the Fields for an Element or Accumulator](#).

## See Also

[Add an Item to an Equipment Type](#)

[Accumulators](#)

## Edit the Fields for an Element or Accumulator

The elements and accumulators associated with an equipment type include a set of fields that you can display and edit in Equipment Editor. These fields reflect the properties of the tag type associated with an element, or the accumulator properties.

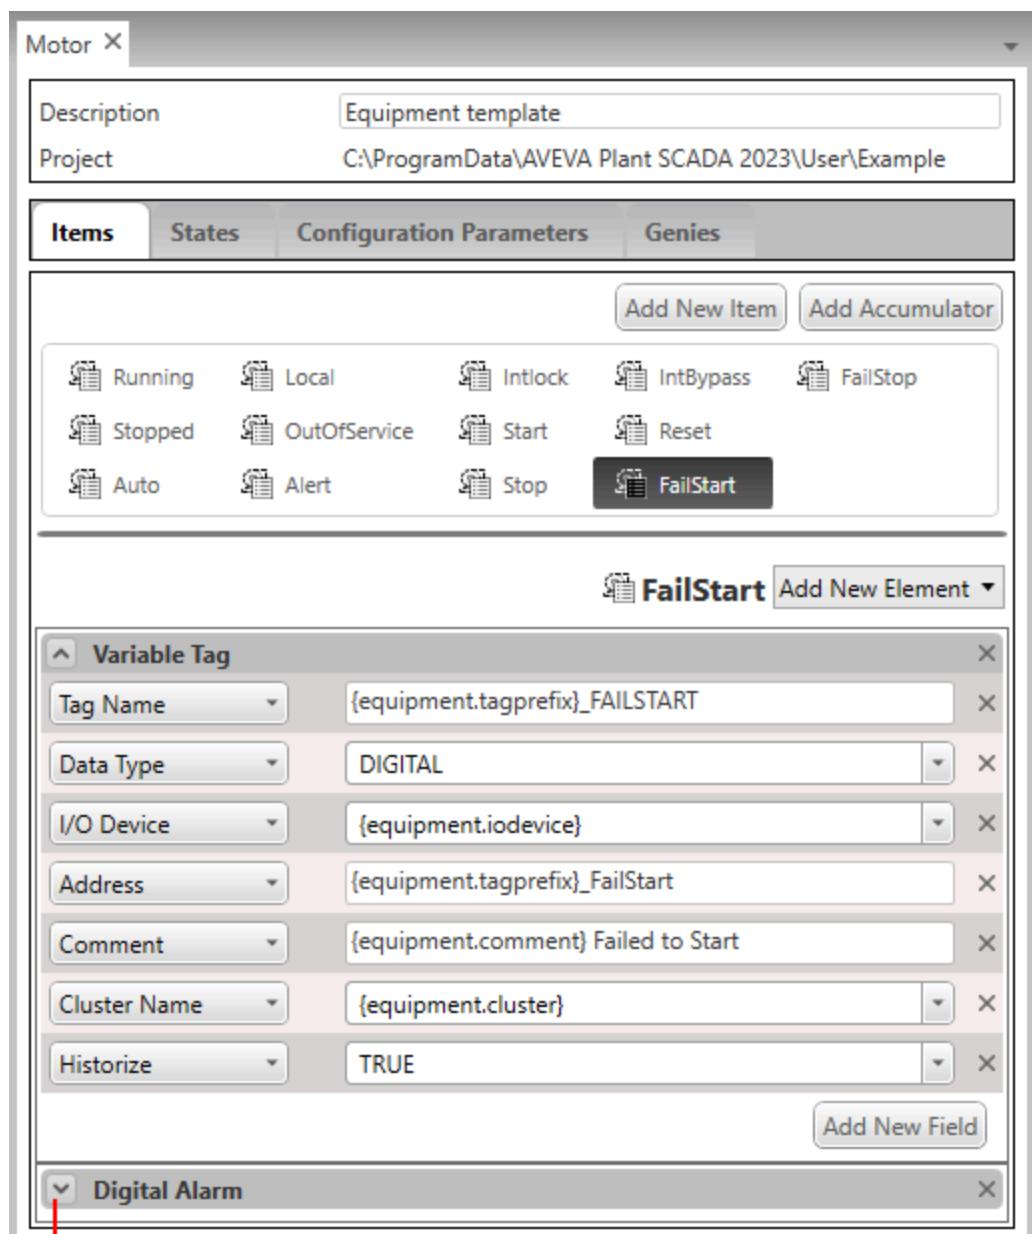

By default, some of the properties associated with a particular tag type or accumulator are not displayed. If required, you can add and remove properties to create a list that contains the fields you need.

You can also apply a value to a field, or use [Equipment Property Referencing](#).

### To edit the fields for an element or accumulator:

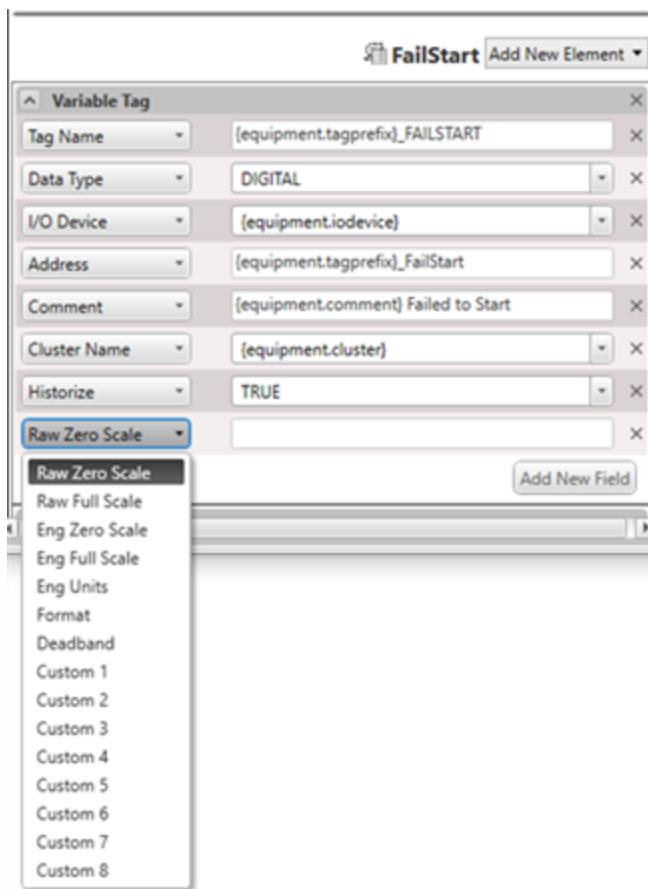

1. Open Equipment Editor and select the **Equipment Types** tab.
2. Open the equipment type you would like to edit (see [Open an Equipment Type](#)).
3. Select the **Items** tab.
4. On the Items tab, select the required item or accumulator. The associated elements/accumulators will display.

You can use the drop-down button on the title bar of each element or accumulator to show or hide the associated fields.

Click here to hide or display the fields for a particular element or accumulator.

5. To add an additional field, click the **Add New Field** button.  
The label on the new field is derived from the next available property for the tag type that is associated with the element.
6. To associate a field with a property other than the one indicated by the current label, click on the drop-down menu and select the required property.

To remove a field that is not required, click on the close button to the right of the field (x).

7. To apply a value to the field, select it and enter the value. You can use [Equipment Property Referencing](#) if required.  
In some cases, a menu of suggested options will appear when you select the field.
8. To save your changes, select **Save** from the **File** menu, or use the **Ctrl+S** keyboard shortcut.

[Add an Element to an Item](#)

[Add an Accumulator to an Equipment Type](#)

## Add Configuration Parameters to an Equipment Type

[Configuration Parameters](#) are used to represent specific information about a physical piece of equipment, such as a set point or delay setting.

You can use Equipment Editor to add parameters to an equipment type as part of a created **group**, or you can add them individually as **ungrouped** parameters.

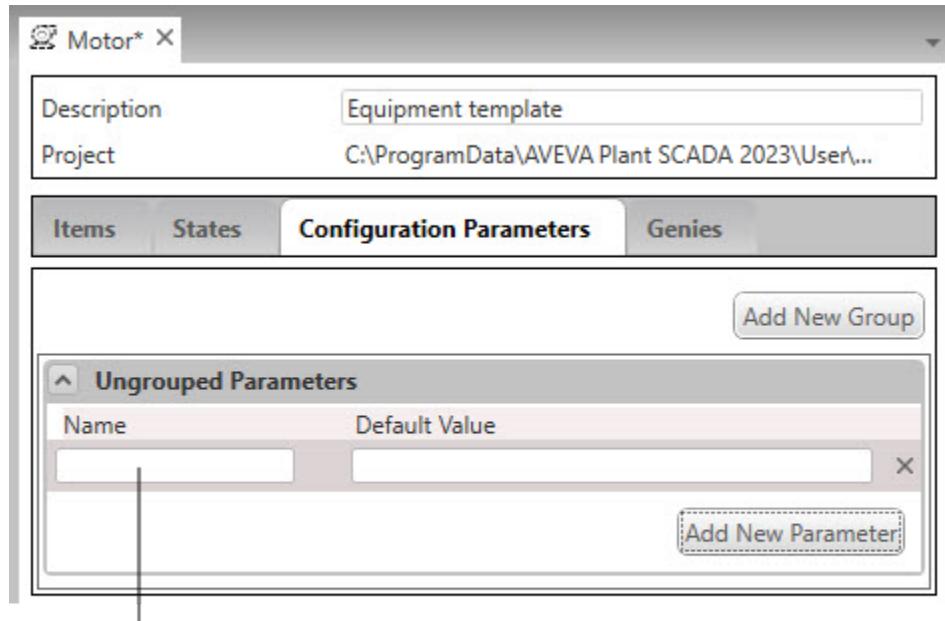

---

**Note:** When you access the Equipment Types tab, a dialog may appear asking if you want to migrate version 1 equipment types and instances. If this occurs, see [Migrate Custom Parameters to the Configuration Parameters Database](#).

### Add an ungrouped parameter to an equipment type:

1. Open Equipment Editor and select the **Equipment Types** tab.
2. Open the Equipment Type to which you would like to add a parameter.
3. Select the **Configuration Parameters** tab.
4. In the **Ungrouped Parameters** panel, click the **Add New Parameter** button.

A new entry is added to the list of ungrouped parameters.

Each time you click on the **Add New Parameter** button, a new entry is added to the list of ungrouped parameters.

5. Enter a **Name** for the parameter.

The name needs to be unique among the ungrouped parameters. If this is not the case, the Name field will display a red border. This indicates that you need to enter a different name.

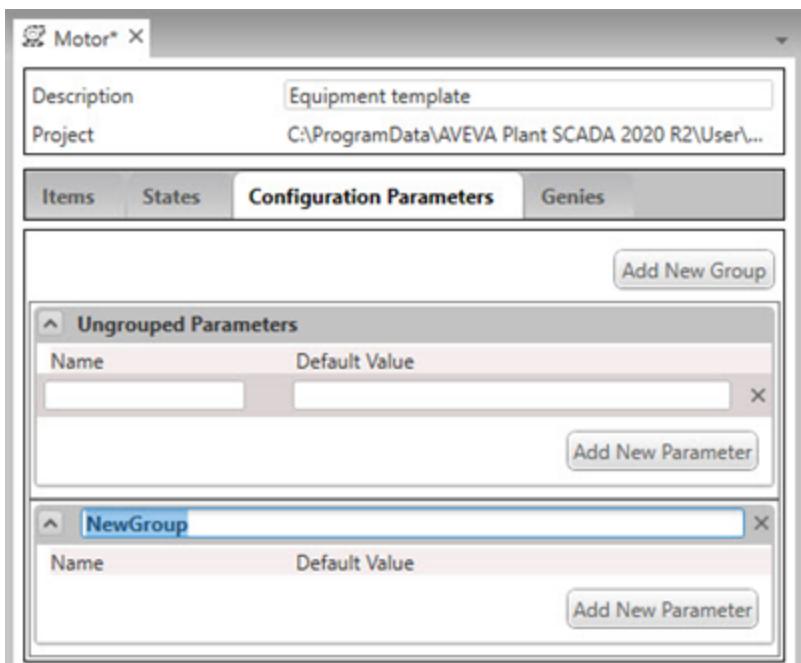

6. If required, enter a **Default Value** for the parameter.
7. To save your changes, select **Save** from the **File** menu, or use the **Ctrl+S** keyboard shortcut.

To delete a configuration parameter, click on the button marked with an "x" within the parameter row.

### Add a parameter to a parameter group:

1. Open Equipment Editor and select the **Equipment Types** tab.
2. Open the Equipment Type to which you would like to add a parameter.
3. On the **Configuration Parameters** tab, click the **Add New Group** button.

A new parameter group will appear with the name "NewGroup" highlighted, allowing you to enter a name. Each parameter group requires a unique name.

4. To add a parameter to the group, click the **Add New Parameter** button within the group you have created. A new entry is added to the parameters group.

5. Enter a **Name** for the parameter.

The name needs to be unique among the parameters in the group. If this is not the case, the Name field will display a red border. This indicates that you need to enter a different name.

6. If required, enter a **Default Value** for the parameter.

7. To save your changes, select **Save** from the **File** menu, or use the **Ctrl+S** keyboard shortcut.

To delete a configuration parameter group, click on the button marked with an "x" next to the group name.

**Note:** If you delete a configuration parameter (either directly, or by deleting its parent parameter group), any fields that reference the parameter will also be cleared.

## See Also

[Equipment Property Referencing](#)

## Link a Genie to an Equipment Type

You can use the Equipment Editor to link a genie to an equipment type. This can help simplify the process of creating graphics pages for your project, as you are able to deploy multiple equipment instances as genies from within the Equipment Editor's equipment hierarchy.

You may want to use the following genie to represent multiple instances of a motor on your graphics pages.

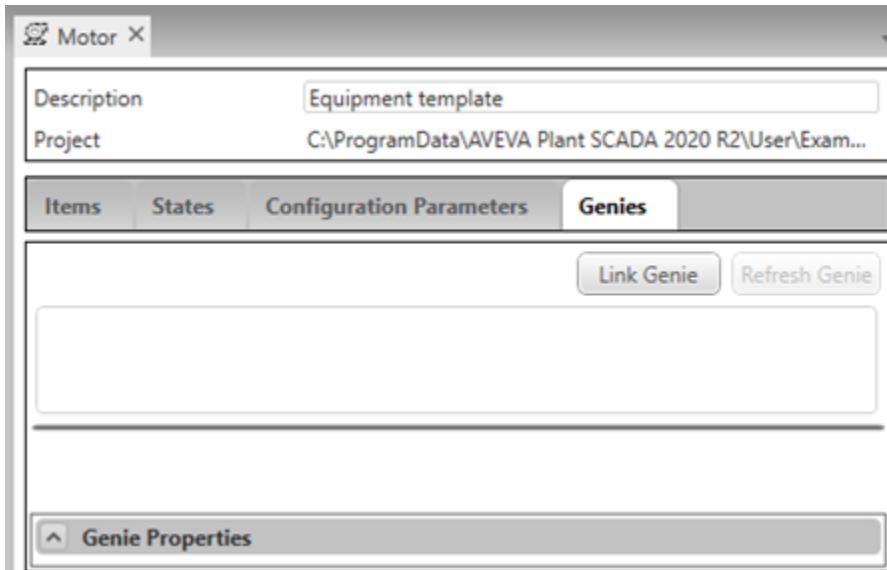

If you were to add multiple instances of the genie to a graphics page, you would have to manually configure the

properties for each copy.

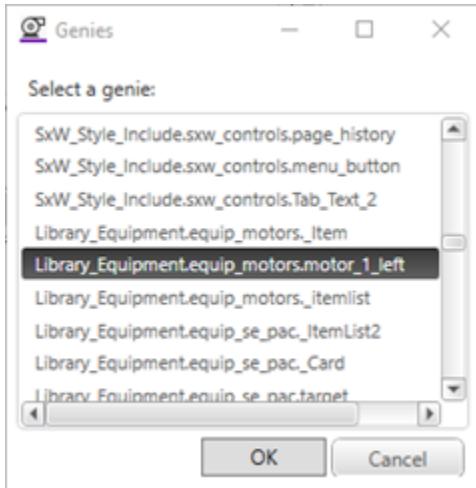

If you were to link the genie to an equipment type, you could deploy the genie from within the Equipment Editor. Any genie properties that are defined within the equipment type will be pre-configured in each pasted genie.

#### To configure the link to a Genie:

1. Open the required equipment type in Equipment Editor.
2. Select the **Genies** tab.

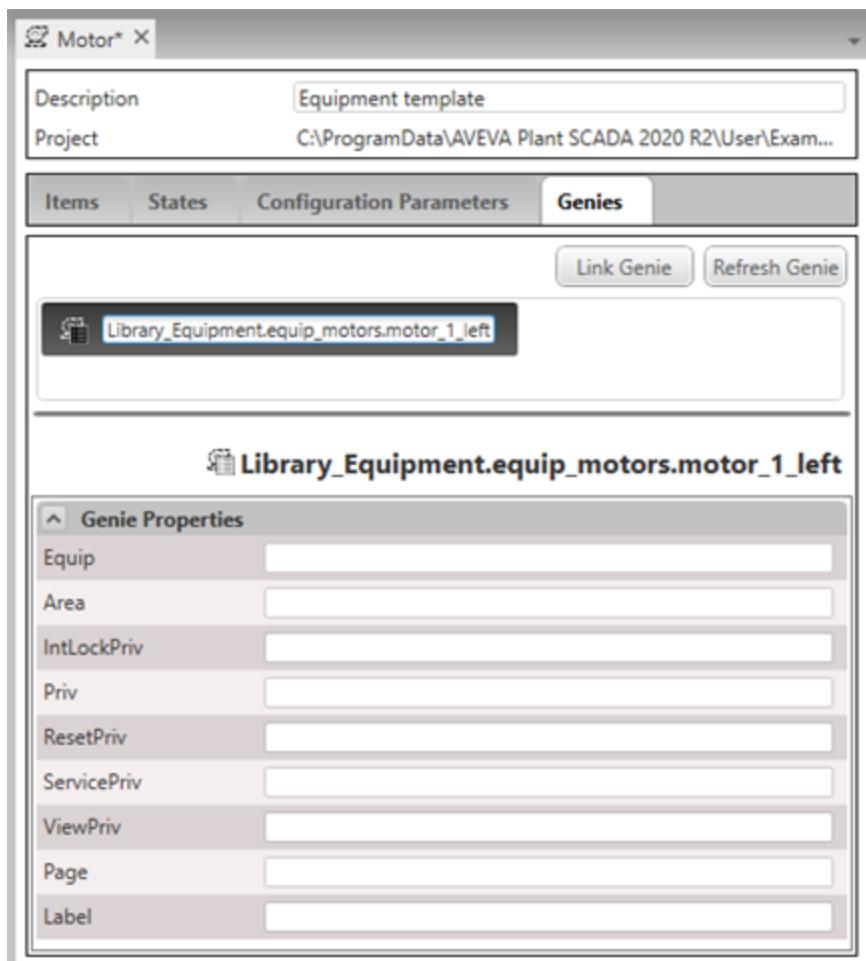

3. Click the **Link Genie** button to open the Genies dialog. The dialog includes a list of the genies defined in the current project and its included projects.

4. Select the genie you would like to link to the equipment type from the list included in the **Select a Genie** field. The list will display the full name for each available genie in the following format:  
<Project name>.<Library name>.<Genie name>
5. Click **OK** to confirm your selection.

The selected genie will appear on the Genies tab for the equipment type to which it is now linked. The associated Genie Properties will also appear.

6. You can edit the values for the **Genie Properties**, except for properties named "Equip" or "Equipment" as they are reserved for the equipment name.

The values you enter will be passed through to each associated equipment instance, and will be retained by the genie when it is pasted on to a graphics page.

If a linked genie has been modified in Graphics Builder, you can use the **Refresh Genie** button to update the Genie Properties.

7. Save your changes to the equipment type.

---

**Note:** You can only associate one genie with an equipment type.

---

#### To change the genie that is linked to an equipment type:

1. On the Genies tab, right-click on the current genie and select **Delete**.
2. Link to a new genie using the steps described in the procedure above.

Or:

1. On the Genies tab, right-click on the current genie and select **Edit**.

Or:

Select the current genie and press the **F2** key.

2. Manually enter the name of a different genie using the following format:

<Project name>.<Library name>.<Genie name>.

---

**Note:** If the specified genie does not exist in the main project or one of its included projects, the genie will display a red border. This indicates that the current genie name is invalid.

---

## See Also

[Paste a Linked Genie on a Graphics Page](#)

### Update Equipment in Equipment Editor

When you run an equipment update, Plant SCADA generates the tags associated with the equipment hierarchy and adds them to your project.

#### To run an equipment update from Equipment Editor:

1. Select **Update Equipment** from the **File** menu or use the keyboard shortcut **Ctrl+Q**.
2. After the equipment update is complete, click **Show Log** to view the log messages.

---

**Note:** If you duplicate an equipment instance with a new name (without changing the tag prefixes) and then run the equipment update, Plant SCADA does not generate tags for the new equipment due to duplicated tag names. The log file provides a record of the tags not generated.

---

By default, Plant SCADA performs an incremental equipment update. It includes only the modified equipment and equipment type after the last update.

If you disable the incremental updates, Plant SCADA regenerates every tag associated with the equipment hierarchy each time an update runs.

#### To disable incremental equipment updates:

1. On the Activity Bar, select **Options**.
2. The **Options** dialog box appears. Locate **Incremental equipment update** on the **Options** dialog box and clear its check box.

---

**Note:** If you clear the **Incremental equipment update** program option, an equipment update takes more time to complete. The time required to complete an update may increase significantly if the project includes a large equipment hierarchy.

---

[Update Equipment in Plant SCADA Studio](#)

### Configure Equipment Instances Using Equipment Editor

To configure equipment instances in Equipment Editor, you use the **Equipment** view.

When displayed, it allows you to perform the following configuration tasks:

- [Add an Equipment Instance](#)

- Add an Equipment Instance to a New Hierarchy Level
- Open an Equipment Instance
- Delete an Equipment Instance
- Duplicate an Equipment Instance
- Edit the Field Values for an Equipment Instance
- Paste a Linked Genie on a Graphics Page.

## See Also

[Equipment Instances](#)

[Equipment Updates](#)

### Add an Equipment Instance

To add [Equipment Instances](#) to a project, you use the Equipment Editor's **Equipment** view.

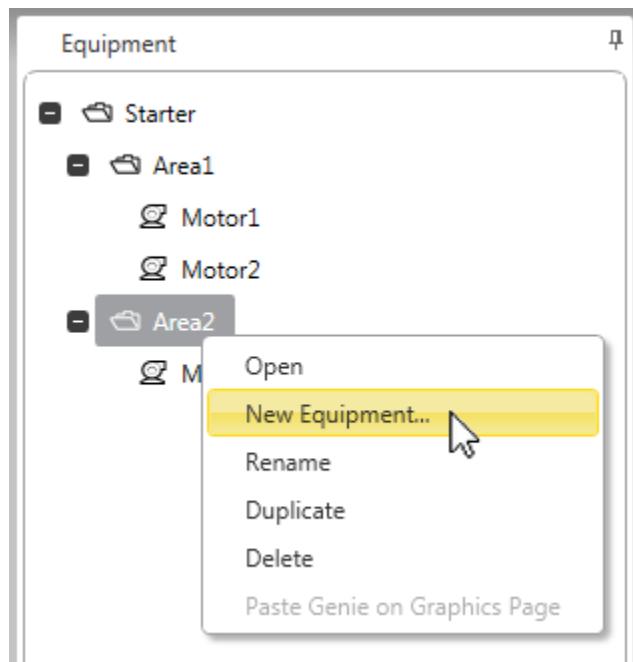

#### To add an equipment instance:

1. Open Equipment Editor.
2. Select the **Equipment** tab.

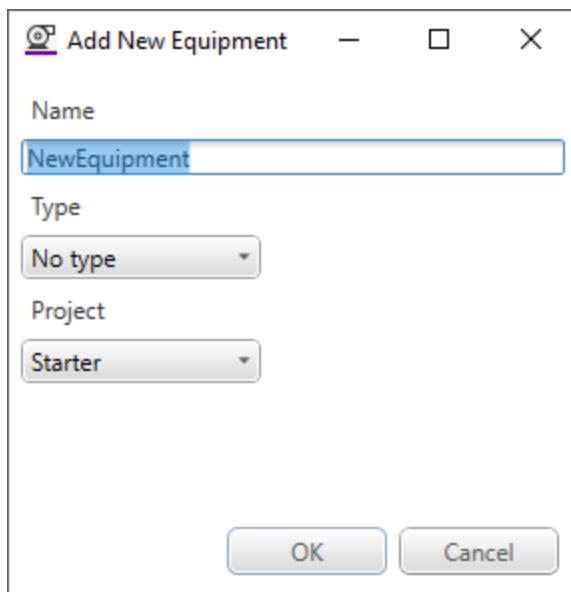

Or:

Select **Equipment** from **View** menu.

3. In the **Equipment** panel, select a location for the equipment instance within the [Equipment Hierarchy](#) for the current project.
4. Right-click and select **New Equipment**.

The Add New Equipment dialog will display.

5. Enter a **Name** for the equipment instance.

The equipment name needs to begin with either an alphabetical character (A-Z or a-z) or the underscore character (\_). Any following characters needs to be either alphanumeric characters (A-Z, a-z or 0-9), backslash characters (\), or underscore characters (\_). An equipment name does not support spaces.

---

**Note:** When defining an equipment name, avoid using the reserved words. If you use any of these, an error message will display when you compile your project.

---

6. In the **Type** field, use the drop-down list to select the equipment type on which the equipment instance will be based. If you select **No Type**, the equipment instance will not maintain an association with an equipment type.

---

**Note:** You cannot create an equipment instance using an equipment type that is currently open with unsaved changes.

---

7. Select the **Project** to which you would like to add the equipment instance. The drop-down list includes the current project and its included projects.
8. Click **OK**.

The new equipment instance will open for editing, and will appear within in the equipment hierarchy in the specified location.

You can also use the Add New Equipment dialog to add levels to the equipment hierarchy when new equipment is added. For more information, see [Add an Equipment Instance to a New Hierarchy Level](#).

## See Also

- [Equipment Instances](#)
- [Open an Equipment Instance](#)
- [Delete an Equipment Instance](#)
- [Duplicate an Equipment Instance](#)

## Open an Equipment Instance

When you open an equipment instance, it displays on a tab in the Equipment Editor.

### To open an equipment instance:

1. Open Equipment Editor and select the **Equipment** tab.
2. Double-click on the required equipment instance in the **Equipment** list.

Or:

Right-click on the equipment instance and select **Open** from the menu that appears.

Or:

Select the equipment instance and press the **Enter** key.

The equipment instance will display on a new tab.

3. Edit the field values as required. An asterisk will appear in the tab to indicate there are unsaved changes.  
To learn more about the fields, see [Define Equipment in Plant SCADA Studio](#).
4. To save the changes select **Save** or **Save All** from the **File** menu, or use the **Ctrl+S** keyboard shortcut.

---

**Note:** You cannot make changes to an equipment instance if its associated equipment type is currently open with unsaved changes.

## See Also

[Equipment Instances](#)

[Edit the Field Values for an Equipment Instance](#)

[Delete an Equipment Instance](#)

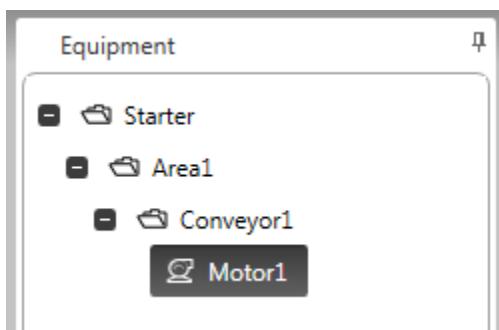

[Duplicate an Equipment Instance](#)

## Add an Equipment Instance to a New Hierarchy Level

When you add a new equipment instance to a project, you can include additional hierarchy levels by using the period character (.) within the equipment name. For example, you could create a new equipment instance in the root directory of a project with the following equipment name:

Area1.Conveyor1.Motor1

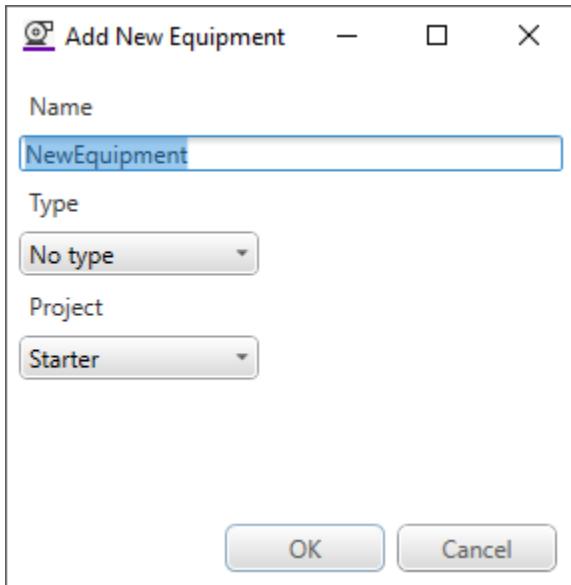

This would result in the following addition to the project's equipment hierarchy:

**To add an equipment instance to a new hierarchy level:**

1. Open Equipment Editor and select the **Equipment** tab.
2. In the **Equipment** panel, select a location for the equipment instance (and any additional hierarchy levels) within the **Equipment Hierarchy**.
3. Right-click and select **New Equipment**.

The Add New Equipment dialog will display.

4. Enter a **Name** for the equipment instance and any additional hierarchy levels using the following syntax:

<hierarchy level>.<hierarchy level>.<equipment name>

The maximum number of levels that can be defined in a hierarchy is 14.

Remember that the equipment name needs to begin with either an alphabetical character (A-Z or a-z) or the underscore character (\_). Any following characters needs to be either alphanumeric characters (A-Z, a-z or 0-9), backslash characters (\), or underscore characters (\_). An equipment name does not support spaces.

---

**Note:** You cannot use "me" as an equipment name, as it is reserved for use with Industrial Graphics.

5. In the **Type** field, use the drop-down list to select the equipment type on which the equipment instance will be based. If you select **No Type**, the equipment instance will not maintain an association with an equipment type.
6. Select the **Project** to which you would like to add the equipment type. The drop-down list includes the current project and its included projects.
7. Click **OK**.

The equipment instance will open for editing on a new tab, and will appear within in the equipment hierarchy in the specified location.

**See Also**

- [Open an Equipment Instance](#)
- [Delete an Equipment Instance](#)

## Duplicate an Equipment Instance

### Delete an Equipment Instance

#### To delete an equipment instance:

1. Right-click the required equipment instance in the Equipment hierarchy and select **Delete** from the menu that appears.

Or:

Select the instance and press the **Delete** key.

A confirmation dialog will appear.

2. Click **Yes** to continue with the deletion, or **No** to cancel.

**Note:** If you delete an equipment instance, any associated tags that were generated will also be deleted from your project the next time an equipment update is run.

### See Also

[Delete an Equipment Type](#)

### Duplicate an Equipment Instance

When you duplicate an equipment instance, the new instance will have "\_n" appended to its name (where "n" is the next integer required to create a unique name).

**Note:** You cannot duplicate an equipment instance if its associated equipment type is currently open with unsaved changes.

#### To duplicate an equipment instance:

- Right-click the required equipment instance in the Equipment panel hierarchy and select **Duplicate** from the menu that appears.

The duplicated instance will appear in the same hierarchy branch as the original (with the appended name). The name is highlighted, allowing you to enter a new name if required.

**Note:** If you duplicate an equipment instance with a new name (without changing the tag prefixes) and then run the equipment update, Plant SCADA does not generate tags for the new equipment due to duplicated tag names. The log file provides a record of the tags not generated.

### See Also

[Open an Equipment Instance](#)

### Edit the Field Values for an Equipment Instance

You can edit the equipment fields and custom parameter values for an equipment instance.

If the associated equipment type is configured to use equipment property referencing, the values you enter may be used to generate the tags, alarms and trends associated with the equipment type (see [Equipment Property](#)

Referencing).

---

**Note:** You cannot make changes to an equipment instance if its associated equipment type is currently open with unsaved changes.

**To edit the field values for an equipment instance:**

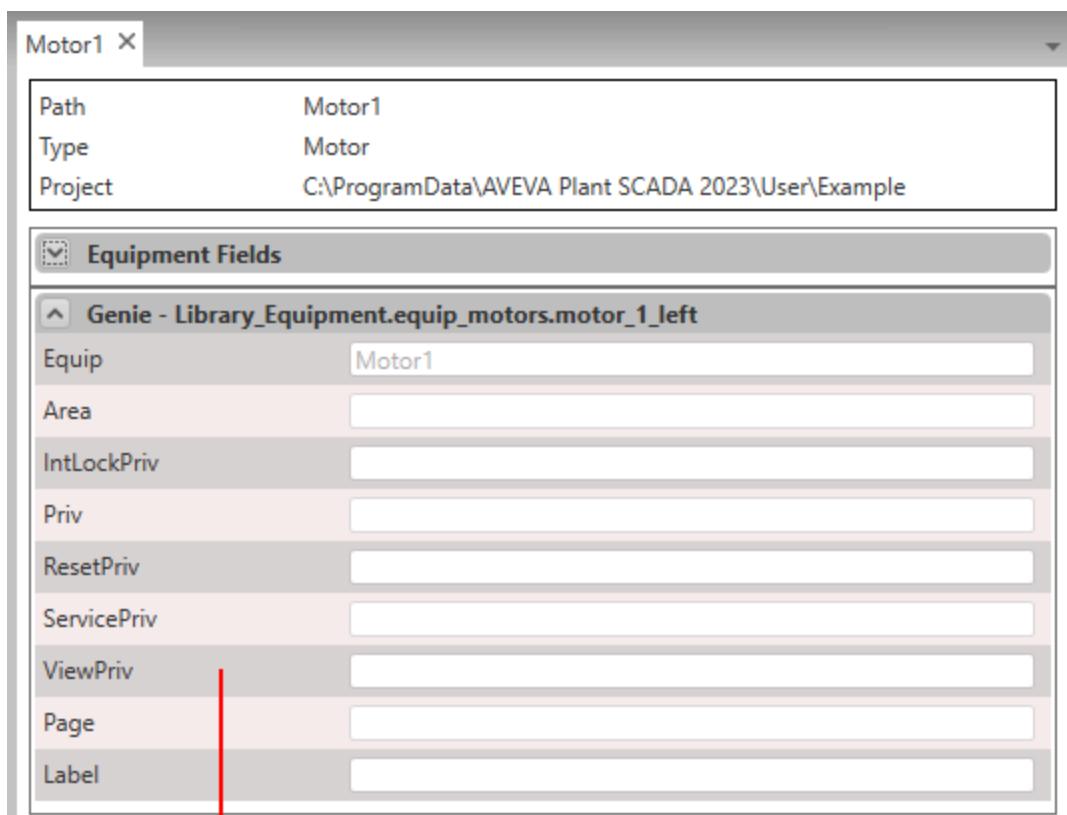

1. Open Equipment Editor and select the **Equipment** tab.
  2. Open the equipment instance for which you would like to edit the fields values (see [Open an Equipment Instance](#)).
- The equipment fields and configuration parameters that are associated with the equipment instance will be available to display. To learn more about the fields, see [Define Equipment in Plant SCADA Studio](#).
3. Locate the equipment field or custom parameter you would like to edit.
  4. Enter the required value.
  5. To save your changes, select **Save** from the **File** menu, or use the **Ctrl+S** keyboard shortcut.

**Paste a Linked Genie on a Graphics Page**

If an equipment instance is associated with an equipment type that has a genie linked to it, you can paste the genie on a graphics page using the Equipment Editor.

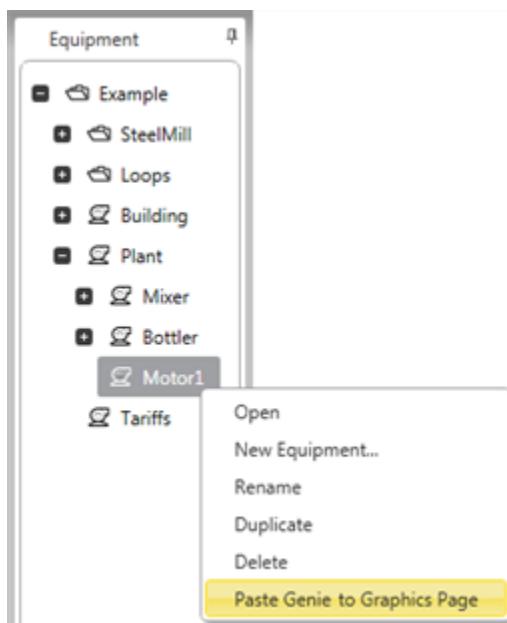

**To paste a linked genie on a graphics page for an equipment instance:**

1. In Graphics Builder, open the graphics page that will be the destination for the genie.
  2. In Equipment Editor, select the **Equipment** tab.
  3. In the Equipment tree, locate the equipment instance you would like to represent with a linked genie.
- If required, you can confirm that the associated equipment type has a genie linked to it by checking the equipment properties for a section named "Genie".

If an equipment instance has a set of Genie properties, it indicates that the associated equipment type has a Genie linked to it.

4. Right-click on the equipment instance in the Equipment tree and select **Paste Genie on to Graphics Page**. If this menu option is not available, it indicates that you need to open a page in Graphics Builder.

The linked genie will appear on the graphics page that is currently open in Graphics Builder.

If you repeat this process multiple times, the genies will be pasted on top of each on the destination graphics page. You will need to manually relocate each genie to display them individually.

If the paste is unsuccessful for a particular reason (for example, the linked genie no longer exists), a notification dialog will appear.

## See Also

[Link a Genie to an Equipment Type](#)

## Configure Equipment in Plant SCADA Studio

The way you configure equipment in Plant SCADA will initially depend on whether or not your project has existing tags. If you have a project with existing tags, you can use Plant SCADA Studio to associate equipment with your tags (see [Define an Equipment Association for a Tag](#)).

Equipment can be manually configured in the System Model activity of Plant SCADA Studio. Here you can perform the following tasks:

- [Define Equipment in Plant SCADA Studio](#)
- [Define Equipment Types in Plant SCADA Studio](#)
- [Define Equipment States in Plant SCADA Studio](#)
- [Define Equipment Configuration Parameters in Plant SCADA Studio](#)
- [Define Equipment References](#)
- [Define Equipment Runtime Parameters](#)
- [Update Equipment in Plant SCADA Studio](#).

---

**Note:** If you are starting a new project (or adding a new area or process to an existing project) you can use the Equipment Editor to generate tags (see [Equipment Editor](#)).

---

## Associate Existing Tags with an Equipment Hierarchy

Plant SCADA allows you to build an [Equipment Hierarchy](#) into a project that is already configured to include tags, alarms, trends, and so on.

When you build an equipment hierarchy into an existing system, you create a way to reference your tags using logical groupings that may reflect geographical areas or functional processes.

Associating equipment with tags in an existing project is a two-step process:

1. Define the required equipment.  
To achieve this, manually add the required equipment definitions to **Equipment** list in the **System Model** activity (see [Define Equipment in Plant SCADA Studio](#)).
2. Associate tags with the equipment you have defined.  
To achieve this, you set the Equipment property for a tag in the **System Model** activity (see [Define an Equipment Association for a Tag](#)).

You can also define equipment associations for your tags directly in the project database using Microsoft Excel™

(see [Use the Project DBF Add-In to Define Equipment Associations](#)).

## See Also

[Equipment](#)

### Define Equipment in Plant SCADA Studio

You can manually add equipment definitions to a Plant SCADA project that adhere to an [Equipment Hierarchy](#).

The hierarchy is created from the names you apply to the equipment you define. If you include a period (.) in a name, it specifies a hierarchy level. You can then use this hierarchy as a way to reference the tags in your project using logical equipment groupings (see [Define an Equipment Association for a Tag](#)).

To link equipment to equipment and equipment.items outside the equipment hierarchy, you can create equipment references (see [Define Equipment References](#)).

---

**Note:** If you are adding equipment to an existing project, it is recommended that you leave the **Type** field blank. An equipment type is primarily used to generate new tags from Equipment Editor, and this is not required if your tags already exist. If you want to define equipment that is associated with an equipment type, you should use the Equipment Editor instead of Plant SCADA Studio (see [Equipment Editor](#)).

#### To manually define equipment:

1. In the **System Model** activity, select **Equipment**.
2. On the menu below the Command Bar, select **Model**.  
The list of equipment definitions will display in the Grid Editor.
3. Add a row to the Grid Editor.
4. Type the required information in each column, or in the Property Grid (see below for a description of the properties).
5. Click **Save**.

The equipment you have defined will now be available to associate with the existing tags in your project (see [Define an Equipment Association for a Tag](#)).

You can also [Define Equipment States in Plant SCADA Studio](#) for the equipment to support scheduling.

## Equipment Properties

### General Properties

Property	Description
<b>Name</b>	<p>The name of the equipment. This can be a name that represents a single piece of equipment, or a name that also reflects the location of the equipment within an <a href="#">Equipment Hierarchy</a> (where a period (. ) is used to indicate levels in the hierarchy).</p> <p>The length of the complete name for the equipment is recommended to be less than 128 characters. The</p>

Property	Description
	<p>maximum length is 254 chars, however, long names can be harder to use within configuration expressions and Cicode.</p> <p>When naming equipment the following rules apply:</p> <ul style="list-style-type: none"> <li>• Equipment names need to be unique within the same cluster.</li> <li>• Equipment names cannot be the same as alarm tag names.</li> <li>• A period (.) may be used in equipment name to specify equipment hierarchy levels, for example:</li> <li>• Plant1.Filling.Tank1.</li> <li>• Each period delimiter denotes an extra level in the equipment hierarchy.</li> <li>• Up to 14 hierarchy levels are supported. The name applied to each hierarchy level may not exceed 63 characters.</li> <li>• Individual names (delimited by a period) within an equipment path need to follow tag name syntax. For example, characters such as '%', '?' and '/' are not allowed.</li> <li>• The name of root level equipment may not be the same as any cluster names.</li> <li>• The name of the root level equipment may not be a reserved word, such as IF, FOR, WHILE, END, OR, or AND.</li> </ul>
<b>Display Name</b>	A meaningful name for the equipment that can be used at runtime to easily identify it. Enter a value of 254 characters or less.
<b>Cluster Name</b>	The name of the cluster to which the equipment is assigned. The specified cluster should be configured otherwise a compile will not be successful. If no cluster name is set, the equipment will run on every cluster.
<b>Type</b>	The specific type of equipment in the system. This drop down box is populated from the types database created in the <a href="#">Equipment Types</a> settings.
<b>Location</b>	A string describing the location of the equipment. Enter a value of 254 characters or less.
<b>Page</b>	<p>The name of the page on which this equipment appears. Enter a value of 254 characters or less.</p> <p>This enables an operator to navigate directly to the page that hosts the piece of equipment. If the graphic</p>

Property	Description
	<p>object appears on more than one page, the page specified here should represent its primary operational context.</p> <p>Where duplicated variations of a page exist to suit HD1080 and UHD4K screen resolutions, the page that is used is determined by the resolution of the host workspace. This means you do not need to add the suffix "_HD1080" or "_UHD4K" to the end of a name to specify a particular page. For more information, see <a href="#">Configure a Project that Supports Multiple Screen Resolutions</a>.</p>
<b>Content</b>	<p>A comma-separated list that names the content associated with the piece of equipment. This can include pages, faceplates and documents. For example:</p> <p>Area1_Page_L1, Process1_Page_L2, Pump_Faceplate_FP</p> <p>This content will be available at runtime when the equipment comes into context.</p> <p>Where duplicated variations of a faceplate or page exist to suit HD1080 and UHD4K screen resolutions, the content that is called is determined by the resolution of the host workspace. This means you do not need to add the suffix "_HD1080" or "_UHD4K" to the end of a name. For more information, see <a href="#">Configure a Project that Supports Multiple Screen Resolutions</a>.</p>
<b>Help</b>	The help context string. Enter a value of 254 characters or less.
<b>Comment</b>	Any useful comment. Enter a value of 254 characters or less.
<b>Tag Prefix</b>	Designed to store a prefix that can be applied to the tags generated for the equipment instance. It can be used at runtime to find tags associated with the equipment.
<b>I/O Device</b>	The I/O device used to communicate with this piece of equipment. Specify redundant devices with a comma between primary and standby, for example, "IODev1,IODev2". Enter a value of 254 characters or less.

Property	Description
<b>Hidden</b>	<p>When set to true the Equipment will not be visible in the Equipment Tree at runtime.</p> <p><b>Note:</b> The functionality of the Equipment does not change and will continue to function as configured.</p>
<b>Unique ID</b>	<p>A unique ID is applied to each piece of equipment in a Plant SCADA project to provide consistent identification for integration with future software releases. This field is read-only in Plant SCADA Studio.</p> <p>Each unique IDs is a Globally Unique Identifier (GUID) generated by Plant SCADA using the following format: XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX</p> <p>For more information, see <a href="#">Unique IDs for Variable Tags and Equipment</a>.</p> <p><b>Note:</b> It is highly recommended that you only use Plant SCADA to generate the unique identifiers for the equipment in your system. If for some reason this is not possible, use a reputable tool to generate GUIDs that match the format described above.</p> <p>If you use an external tool to modify the equipment database, the compiler will indicate if a Unique ID is invalid, duplicated or missing.</p>

### Security Properties

Property	Description
<b>Area</b>	<p>The area number or label to which this equipment belongs. Only users with access to this area (and any necessary privileges) will be able to perform operations on the equipment. For example, if you enter Area 1 here, operators need to have access to Area 1 (plus any necessary privileges) to perform operations on the equipment. Enter a value of 16 characters or less.</p>

### Custom Properties

Property	Description
<b>Custom1 .. Custom8</b>	<p>User-defined strings that can be used for filtering equipment when using the Cicode search functions (maximum 254 characters each). Labels or tags are not supported.</p>

### Scheduling Properties

**Note:** The following fields, **Default State** and **Scheduled**, are used when configuring schedules for equipment

(see [Configure Equipment for Scheduling](#)).

Property	Description
<b>Default State</b>	The default state applied to the equipment.
<b>Scheduled</b>	Specifies if the equipment is included in any scheduled actions. The options are "TRUE" or "FALSE". The following fields, <b>Schedule ID</b> and <b>Device Schedule</b> , are only required when using a schedule configured locally on a BACnet device (see <a href="#">Integrate BACnet Schedules into Scheduler</a> ). They require the <b>Scheduled</b> property to be set to "TRUE".
<b>Schedule ID</b>	The ID used to identify the required schedule on the BACnet device. This field is only required if the <b>Device Schedule</b> property is set to "TRUE".
<b>Device Schedule</b>	Specifies whether or not the report server should retrieve the required schedule from the BACnet device. The options are "TRUE" or "FALSE".

#### Deprecated Properties

Property	Description
<b>Parameters</b>	Prior to the release of Plant SCADA 2023, "custom parameters" were used to apply specific values to an equipment type. In Plant SCADA 2023, custom parameters were replaced with <a href="#">Configuration Parameters</a> . If an equipment instance is based on an equipment type that uses a version 1 template, this field will show the associated custom parameters. <b>Note:</b> Version 1 equipment types that support this parameter are flagged as deprecated and may not be supported in future release. To migrate your equipment types, see <a href="#">Migrate Custom Parameters to the Configuration Parameters Database</a> . Following migration, the content of this field will be populated at runtime from the content of the configuration parameters for this equipment instance. You should not make any changes to this field in the configuration environment.

#### Project Properties

Property	Description
<b>Project</b>	The project in which the equipment type is

Property	Description
	configured.

**Note:** Advanced users can use the Project DBF plug-in for Microsoft Excel to edit and save records directly in the EQUIP.DBF file (see [Use the Project DBF Add-In to Define Equipment Associations](#)).

## See Also

- [Define Equipment Types in Plant SCADA Studio](#)
- [Define Equipment States in Plant SCADA Studio](#)

### Define Equipment Types in Plant SCADA Studio

You can manually add equipment types to a Plant SCADA project. You would typically do this to incorporate an external XML template for an equipment type (see [Import Equipment Using XML Templates](#)).

#### To manually define an equipment type:

1. In the System Model activity, select **Equipment**.
2. On the menu below the Command Bar, select **Types**.  
The list of equipment types will display in the Grid Editor.
3. Add a row to the Grid Editor.
4. Type the required information in each column, or in the Property Grid (see below for a description of the properties).
5. Click **Save**.

**Note:** You can also use the Equipment Editor to create equipment types. These equipment type definitions will appear in the equipment type list alongside those you create manually. See [Add an Equipment Type](#).

## Equipment Type Properties

### General Properties

Property	Description
<b>Name</b>	A name that reflects the physical piece of equipment the equipment type represents, such as "pump", "light" or "valve". Enter a value of 254 characters or less. The names in this field populate the Type drop down in Equipment Properties (see <a href="#">Define Equipment in Plant SCADA Studio</a> ).
<b>Template</b>	The file name for the XML template that defines the equipment type. Enter a value of 254 characters or less.

	If the equipment type was created using Equipment Editor, this file will have the same name as the equipment type (with the .xml extension).  If you are using an externally created equipment XML template, enter the file name here to associate it with the equipment type (see <a href="#">Import Equipment Using XML Templates</a> for more information).
<b>Comment</b>	Any useful comment. Enter a value of 254 characters or less.
<b>Unique ID</b>	A unique ID is applied to each equipment type in a Plant SCADA project to provide consistent identification for integration with future software releases. This field is read-only in Plant SCADA Studio.  Each unique IDs is a Globally Unique Identifier (GUID) generated by Plant SCADA using the following format: XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX  For more information, see <a href="#">Unique IDs for Variable Tags and Equipment</a> .  <b>Note:</b> It is highly recommended that you only use Plant SCADA to generate the unique identifiers for the equipment types in your system. If for some reason this is not possible, use a reputable tool to generate GUIDs that match the format described above.  If you use an external tool to modify the equipment types database, the compiler will indicate if a Unique ID is invalid, duplicated or missing.

### Project Properties

Property	Description
<b>Project</b>	The project in which the equipment state is configured.

### See Also

[Define Equipment in Plant SCADA Studio](#)

### Define Equipment States in Plant SCADA Studio

You can manually add [Equipment States](#) to a Plant SCADA project and associate them with your equipment definitions.

#### To manually define an equipment state:

1. In the System Model activity, select **Equipment**.

2. On the menu below the Command Bar, select **States**.  
The list of equipment states will display in the Grid Editor.
3. Add a row to the Grid Editor.
4. Type the required information in each column, or in the Property Grid (see below for a description of the properties).
5. Click **Save**.

**Note:** Updates made to the fields on Equipment States will come into effect at runtime once the project is compiled and reloaded.

## WARNING

### UNINTENDED EQUIPMENT OPERATION

Do not use the Scheduler in situations where equipment state actions must be executed. The engine does not ensure that defined actions are executed for every state transition. The Scheduler engine will not be able to run actions when other state actions for the same equipment take longer time to complete or a communication fault occurs.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

## Equipment State Properties

### General Properties

Property	Description
<b>Name</b>	Name of the State. Usually this would be an 'action' the equipment could be scheduled to do. For example, a light could have the action 'on' or 'active' defined.
<b>Cluster Name</b>	The name of the cluster to which this State will belong.
<b>Equipment</b>	The equipment associated with this state. For example: "Factory.Floor.Line1.Light1". See <a href="#">Equipment</a> . Equipment should be an existing item on the selected cluster.

### Actions Properties

Property	Description
<b>Entry Action</b>	The action the State will take when triggered. For example the entry action for light 1 could be tag_light1=1. When light 1 is scheduled, this will trigger the light to turn on. The Entry Action can be a Cicode expression.

Property	Description
	<p><b>Note:</b> You should not enter a Cicode function that relates to a graphics page in this field, as this type of function will only execute successfully on a display client.</p> <p>Be aware that long actions on this field may delay or prevent other scheduled actions from running. For example, if there is "action1" for startup and "action2" for repeat, if "action1" is an infinite loop, "action2" will be prevented from running. If "action2" takes a long time to complete, no new "action2" actions will run until the former finishes. If you need to run a long task, create an independent Cicode task using <a href="#">TaskNew</a> function.</p> <p>You can use the INI parameter <a href="#">[Scheduling]AlwaysExecuteEntryAction</a> to specify that the entry actions for all equipment resource states are executed, regardless of whether or not their internal states are the same. By default, this parameter is set to false (0), which means only changes that have been made to the selected equipment will take effect.</p>
<b>Delay</b>	<p>The time that needs to elapse before the state will initially become active.</p> <p>If delay is defined the Entry Action for the state will not occur until the delay period has elapsed. For example; this would allow you to turn on every light sequentially to avoid a power spike.</p>
<b>Repeat Action</b>	<p>An action set to run periodically when state is active. Repeat Actions can be a Cicode expression.</p> <p><b>Note:</b> You should not enter a Cicode function that relates to a graphics page in this field, as this type of function will only execute successfully on a display client.</p> <p>Be aware that long actions on this field may delay or prevent other scheduled actions from running. For example, if there is "action1" for startup and "action2" for repeat, if "action1" is an infinite loop, "action2" will be prevented from running. If "action2" takes a long time to complete, no new "action2" actions will run until the former finishes. If you need to run a long task, create an independent Cicode task using <a href="#">TaskNew</a> function.</p>
<b>Period</b>	<p>Sets the frequency of the 'Repeat Action'. For example set the repeat action to occur every hour.</p>

Property	Description
	<b>Note:</b> The repeat period will not start until the entry action has completed. The first repeat action will occur after the entry action completes plus one repeat time period. For example, if the Entry Action takes ten minutes to complete, the Repeat Action will not start until after ten minutes even though the Repeat Action is set to occur every two minutes.
<b>Priority</b>	Number used to determine which schedule entry will run if a schedule conflict occurs between more than one state.
<b>Comment</b>	Any useful comment.
<b>DR Mode</b>	Demand and Response (DR) mode (see <a href="#">Configure a Demand and Response Solution</a> ). The default DR mode value is 0.

### Project Properties

Property	Description
<b>Project</b>	The project in which the equipment state is configured.

**Note:** If the report server is run in single process mode and no user is logged in, all tag writes attempted by the scheduler when actions are run will not succeed. We recommend running the report server(s) in multi-process mode to avoid this issue (the server user will be logged in), or setting the citect.ini parameter [\[Client\]AutoLoginMode](#) to either 2 or 6 to make sure a user is always logged in.

### See Also

[Define Equipment in Plant SCADA Studio](#)

### Define Equipment Configuration Parameters in Plant SCADA Studio

Equipment configuration parameters can be applied to an equipment type to represent specific information about a physical piece of equipment, such as a set point or delay setting. A value can then be applied to this parameter for each associated equipment instance.

You can manually add equipment configuration parameters to a Plant SCADA project in Plant SCADA Studio.

#### To define an equipment configuration parameter:

1. In the System Model activity, select **Equipment**.
2. On the menu below the Command Bar, select **Configuration Parameters**.

A list of the configuration parameters included in the active project will display in the Grid Editor.

**Note:** When you access the Configuration Parameters view, a dialog may appear asking if you want to

migrate version 1 equipment types and instances. If this occurs, see [Migrate Custom Parameters to the Configuration Parameters Database](#).

3. Add a row to the Grid Editor.
4. Type the required information in each column, or in the Property Grid (see below for a description of the properties).
5. Click **Save**.

## Equipment Configuration Parameter Properties

### General Properties

Property	Description
<b>Cluster</b>	The name of the cluster to which the equipment is assigned.
<b>Equipment</b>	The equipment associated with this parameter. For example: "Factory.Floor.Line1.Light1". See <a href="#">Equipment</a> . Equipment should be an existing item on the selected cluster.
<b>Group</b>	If a parameter has been added to an equipment type as part of a created group, this field will indicate the group name. The field will be blank for any ungrouped parameters.
<b>Name</b>	A name for the parameter. Enter a value of 254 characters or less.
<b>Value</b>	Value assigned to the parameter. This could be a value or a tag name.

### Project Properties

Property	Description
<b>Project</b>	The project in which the equipment runtime parameter is configured.

## See Also

[Add Configuration Parameters to an Equipment Type](#)

### Define Equipment References

You can add equipment references to a Plant SCADA project. See [Equipment References](#) for more information.

**To manually define an equipment reference:**

1. In the System Model activity, select **Equipment**.
2. On the menu below the Command Bar, select **References**.  
The list of equipment references will display in the Grid Editor.
3. Add a row to the Grid Editor.
4. Type the required information in each column, or in the Property Grid (see below for a description of the properties).
5. Click **Save**.

**Equipment Reference Properties****General Properties**

Property	Description
<b>Cluster</b>	The name of the cluster to which the equipment is assigned.
<b>Equipment</b>	The name of the main piece of Equipment to which referenced equipment is linked from.
<b>Referenced Cluster</b>	The name of the cluster to which the referenced equipment is assigned.
<b>Referenced Equipment</b>	The name of the Equipment that you want to reference (link to).
<b>Referenced Item</b>	The name of the item belonging to the "referenced" Equipment. If the Item is listed only that referenced item will be returned using EquipRefBrowse functions. If this field is left blank items belonging to the referenced equipment will be available.
<b>Category</b>	A category that will be used to filter equipment references using EquipRefBrowse functions. You can use any separator between filter strings. For example, "Equipment.MT", "Equipment-MT" and "Equipment:MT" are all valid.  If you are configuring an interlock, the Situational Awareness Starter Project provides the following categories (see <a href="#">Interlocks</a> for definitions): <ul style="list-style-type: none"><li>• Interlock.Process</li><li>• Interlock.Safety</li><li>• Interlock.Permissive.</li></ul> Enter the whole name of the category type (for

Property	Description
	example, "Interlock.Process").
<b>Order</b>	A unique index per reference category that will be used in the ordering for the EquipRefBrowse functions.
<b>Association</b>	Controls the name of the association used in the <a href="#">AssEquipReferences</a> Cicode function. For each reference, a super-genie association is created which uses the name specified in the Association column. <b>Note:</b> Association names are also passed into the 'meo_selector_xx' genie instances on faceplates e.g ?MEO2?. See <a href="#">Configure Equipment Selection for Group Objects</a> for more information.
<b>Comment</b>	Any useful comment. Enter a value of 254 characters or less.

**Custom Properties**

Property	Description
<b>Custom1 .. Custom8</b>	User-defined strings that can be used for filtering equipment when using the EquipRefBrowse functions (maximum 254 characters each).

**Project Properties**

Property	Description
<b>Project</b>	Name of project

**See Also**

**Define Equipment Runtime Parameters**

Equipment runtime parameters are a set of parameters that are passed into content pages as associations. For example, a sub-page with a faceplate that displays information for multiple pieces of equipment.

---

**Note:** Equipment runtime parameters can be used with the [AssEquipParameters](#) and [EquipGetParameter](#) Cicode functions.

You can manually add equipment runtime parameters to a Plant SCADA project.

**To define an equipment runtime parameter:**

1. In the System Model activity, select **Equipment**.
2. On the menu below the Command Bar, select **Runtime Parameters**.  
The list of equipment runtime parameters will display in the Grid Editor.
3. Add a row to the Grid Editor.
4. Type the required information in each column, or in the Property Grid (see below for a description of the properties).
5. Click **Save**.

**Equipment Runtime Parameter Properties****General Properties**

<b>Property</b>	<b>Description</b>
<b>Cluster</b>	The name of the cluster to which the equipment is assigned.
<b>Equipment</b>	The equipment associated with this runtime parameter. For example: "Factory.Floor.Line1.Light1". See <a href="#">Equipment</a> . Equipment should be an existing item on the selected cluster.
<b>Name</b>	A name for the parameter. Enter a value of 254 characters or less.
<b>Value</b>	Value assigned to the parameter. This could be a value or a tag name.
<b>Is Tag</b>	By default, this is TRUE. If the value is set to a tag name, the tag value will be evaluated as such. Set this to FALSE if you have set a value manually instead of specifying a tag name. <b>Note:</b> If this is a tag name it can be used in conjunction with the Cicode function <a href="#">AssEquipParameters</a> to pass those tags as Super Genie associations.
<b>Comment</b>	Any useful comment. Enter a value of 254 characters or less.

**Project Properties**

<b>Property</b>	<b>Description</b>
<b>Project</b>	The project in which the equipment runtime

Property	Description
	parameter is configured.

## Define an Equipment Association for a Tag

You define equipment in a Plant SCADA project to create logical groupings that reflect the machinery or processes being monitored. When you specify an equipment association for a tag, you are simply adding the tag to one of the equipment groups you have defined.

This allows you to use a project's equipment hierarchy as a way to reference your tags.

You can associate equipment with the following tag types:

- Advanced alarms
- Analog alarms
- Multi-digital alarms
- Digital alarms
- Time stamped alarms
- Time stamped analog alarms
- Time stamped digital alarms
- Variable tags
- Trend tags
- SPC tags
- Accumulators

### To specify an equipment association for a tag:

1. Locate the tag record that you would like to update.
2. In the **Equipment** field, enter the name of the equipment with which you would like to associate the tag. You can select the required equipment name from the drop-down menu. The list includes the current equipment definitions.
3. If required, specify a **Cluster** for the tag. This is only useful if the associated equipment is defined for every cluster and you want to specify a specific cluster for this particular tag.
4. Click **Save** to update the tag with your changes.

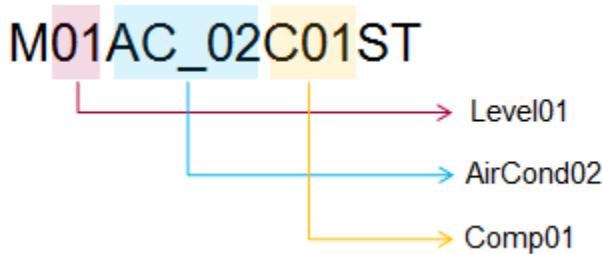

See [Define Equipment in Plant SCADA Studio](#).

If required, you can use Plant SCADA's Project DBF Add-In tool to define equipment associations for the tags in your project. This could be particularly useful if your project adheres to a tag naming convention that could be adopted as the basis of an equipment hierarchy (see [Use the Project DBF Add-In to Define Equipment Associations](#)).

## Example

You may have a project with tags that comply with a maintenance naming code. A typical tag name may be

"M01AC\_02C01ST". Using the naming code as a reference, it is possible to determine that this tag monitors the running status of a compressor on air conditioner 2 on level 1.

This demonstrates how an existing naming convention may be used as the framework for an equipment hierarchy. For example, you could associate the following equipment definition with the tag described above (and any others that apply to the same compressor):

Level01.AirCond02.Comp01

This would allow you to keep your site-based maintenance IDs while also providing a way to work with the data points using a logical, hierarchical structure.

## Update Equipment in Plant SCADA Studio

When you run an equipment update, Plant SCADA generates the tags associated with the equipment hierarchy and adds them to your project.

### To run an equipment update from the Plant SCADA Studio:

1. In the **System Model** activity, select **Equipment**.
2. Select **Update Equipment** from the Command Bar.
3. After the equipment update is complete, click **Show Log** to view the log messages.

**Note:** If you duplicate an equipment instance with a new name (without changing the tag prefixes) and then run the equipment update, Plant SCADA does not generate tags for the new equipment due to duplicated tag names. The log file provides a record of the tags not generated.

By default, Plant SCADA performs an incremental equipment update. It includes only the modified equipment and equipment type after the last update.

If you disable the incremental updates, Plant SCADA regenerates every tag associated with the equipment hierarchy each time an update runs.

### To disable incremental equipment updates:

1. On the Activity Bar, select **Options**.
2. The **Options** dialog box appears. Locate **Incremental equipment update** on the **Options** dialog box and clear its check box.

**Note:** If you clear the **Incremental equipment update** program option, an equipment update takes more time to complete. The time required to complete an update may increase significantly if the project includes a large equipment hierarchy.

## See Also

[Update Equipment in Equipment Editor](#)

### Use the Project DBF Add-In to Define Equipment Associations

You can use Plant SCADA's Project DBF Add-In to edit equipment associations directly in a project's database tables using Microsoft Excel™. This may allow you to rapidly deploy an equipment hierarchy for an existing project, particularly if your tags adhere to a naming convention that replicates a hierarchical architecture.

The Project DBF Add-In operates from within Excel. It connects you to the MASTER.DBF file for a selected project, and provides access to a list of included tables (see [Using Microsoft Excel to Edit .dbf Tables](#)).

#### To use the Project DBF Add-In to edit your equipment associations:

1. You will firstly need to [Define Equipment in Plant SCADA Studio](#) required to support your tags.  

---

**Note:** The **Type** and **Prefix** properties (or columns) are not required when configuring equipment for an existing project as they are only used when generating records in Equipment Editor.

---
2. You then need to open the table for a particular tag type to associate the **Equipment** property with one of your equipment definitions. The following tables include the Equipment column:
  - Advanced alarms
  - Analog alarms
  - Multi-digital alarms
  - Digital alarms
  - Time stamped alarms
  - Time stamped analog alarms
  - Time stamped digital alarms
  - Variable tags
  - Trend tags
  - SPC tags
  - Accumulators
3. Save your changes.

The compiler will check the existence of the equipment you have referenced and will generate an error message if required.

## See Also

[Define an Equipment Association for a Tag](#)

### Import Equipment Using XML Templates

Equipment tags can be created by importing them in much the same way as tags can be imported using TagGen. An XML template is used to specify the fields of input and output databases, and define filters and transformation rules that create tags from existing database fields.

Equipment XML templates are configuration files that are linked with equipment types that you create (see [Define Equipment Types in Plant SCADA Studio](#)). Each equipment type can have an associated template file specified.

The Equipment Update tool (accessible via the Command Bar when **Equipment** is selected in the **System Model** activity) processes the template for each piece of equipment to manage the associated configuration records. When updating the equipment configuration, the associated records are updated by modifying, adding or deleting as required. See [Update Equipment in Plant SCADA Studio](#).

For example, a set of associated records defined by the template may consist of a set of variable tags, alarms and trends. When an equipment record is added, the update tool will create the associated records. If the template is modified, the update tool will modify the associated records. If the equipment record is deleted, the update tool will delete the associated records.

## See Also

[Equipment XML Template](#)

[Calculator Examples](#)

## Equipment XML Template

The equipment template is an XML file that uses proprietary tags and attributes to specify the fields of input and output databases, and define filters and transformation rules that create tags from existing database fields. It uses the existing [TagGen XML Template](#) syntax rules.

The template file is linked to a specific equipment type. Equipment types can be supplied from different sources:

- The SCADA product
- An add-on pack
- External library
- User-defined.

Types defined by your project should use a project specific prefix to avoid conflicting with templates from another source. You should not use 'SE' or 'LIB' as prefixes for your template type names to avoid conflict with future product supplied templates.

It is recommended that the template file name should use the corresponding equipment type name for consistency. When adding the template to your project, the equipment type name should be the type name used by the template (see [Equipment Templates: Parameters](#)).

An equipment template XML file consists of five sections:

- [Equipment Templates: Header](#)
- [Equipment Templates: Parameters](#)
- [Equipment Templates: Input](#)
- [Equipment Templates: Outputs](#)
- [Equipment Templates: Footer](#)

Sample template files are located in the example project directory, and include Building Level.xml, Building Light Dimmer.xml, Building Light.xml, Building Room.xml, Plant Level.xml, Plant Light.xml, and Plant Line.xml.

## See Also

[Import Equipment Using XML Templates](#)

### Equipment Templates: Header

The template (XML) file should contain the header section that defines the:

- version
- start of the template node
- template description

The example below can be used without modification. However the header should reflect the actual encoding and the characters used. There are two ways to achieve this, either:

- change the encoding in the header e.g. to iso-8859-1 (latin-1) if using ANSI characters.  
or
- change any ANSI characters used to their Unicode equivalent.

## Example

```
<?xml version="1.0" encoding="utf-8"?>
<template desc="Equipment template">
```

## See Also

[Equipment XML Template](#)

[Import Equipment Using XML Templates](#)

### Equipment Templates: Parameters

The template (XML) file needs to contain a parameter section that defines the equipment type parameter. Other parameters can be added within this node as needed. Refer to the advanced section below or the 'TagGen' help topic in the product help for additional information.

The parameter string is used to define the template type name that is referenced in other parts of the template file. To use the example below, replace:

- [Type] with the name of your equipment type.

This should be unique across the templates used in your project(s). It needs to match the value specified in the name field of the record that defines the template type in the project.

- [TypeRef] with an abbreviation (if required) of the type name.

This is recommended to be less than 16 chars. When using an abbreviation, it should follow the same rules as the type name, such that it has to be unique across the templates used in your project(s).

## Example

```
<param name="type" desc="equipment type parameters">
<string name="name">[Type]</string>
<string name="ref">[TypeRef]</string>
</param>
```

## See Also

[Equipment XML Template](#)

[Import Equipment Using XML Templates](#)

### Equipment Templates: Input

The template (XML) file should contain an input section that defines the input node for the equipment database (DBF) file source. The input node is defined within the XML template node and contains the list of database fields that are to be available for use by the template. Only one input node can be defined within the template.

The example below can be used without modification and lists the complete set of the available data fields from the equipment database (DBF) file.

There are three built-in functions that can be used to manipulate strings in the XML template:

- SubString(string, start, count)
- Split(string, delimiter)
- ToProperty(string, separator, delimiter)

These functions are the same as used in the TagGen XML templates and are described in [Built-In Functions](#).

## Example

```
<!-- =====
Input Section - Equipment
=====

-->
<input name="equipment" file="equip.dbf" desc="Equipment Database">
<field name="name"></field>
<field name="cluster"></field>
<field name="type"></field>
<field name="iodevice"></field>
<array name="iodevice_list">{Split('{iodevice}',',')}</array>
<field name="tagprefix"></field>
<field name="area"></field>
<field name="page"></field>
<array name="page_list">{Split('{page}',',')}</array>
<field name="help"></field>
<field name="location"></field>
<field name="comment"></field>
<field name="scheduled"></field>
<field name="defstate"></field>
<field name="param"></field>
```

```
<array name="param_list">{ToProperty('{'param'}','=',';')}</array>
<field name="custom1"></field>
<field name="custom2"></field>
<field name="custom3"></field>
<field name="custom4"></field>
<field name="custom5"></field>
<field name="custom6"></field>
<field name="custom7"></field>
<field name="custom8"></field>
</input>
```

## See Also

[Equipment XML Template](#)

[Import Equipment Using XML Templates](#)

### Equipment Templates: Outputs

The template (XML) file can contain 1 or more output sections that define the configuration records that are to be created in other database (DBF) files. The output nodes are defined within the template node and contain the list of database fields that are to be updated in the new record. An [Equipment Templates: Output Node](#) should be added for each record that is to be created, such as a variable tag, alarm, trend, etc.

The values specified for each of the [Equipment Templates: Output Field](#) elements will be written to the database (DBF) field of the output file. Values from input fields and parameter strings can be referenced within this section to construct the resulting value for the output record field. Each output node should have a unique output name specified across the records in the template.

Refer to the following available output databases section for specific details on each of the available output databases and other advanced topics.

The example below shows a sample for an output to the variable database (DBF). For each output section, the field names specified should include the [Equipment Templates: Output Common Fields](#) and the fields specific to each [Output Database](#).

To use the example below, replace the following in your template:

- [FileRef] with a short string reference for the output destination database. Such as 'Var', 'Trend', 'AlmDig', 'Menu', etc. Examples are provided with the list of available databases
- [RefID] with a unique index (1, 2, 3, etc.) or a related string value for the entry (such as ON, STOP, etc.) for the specific output record.
- [TypeRef] with the abbreviation of the type name as defined in the parameter section. This may need to be an abbreviation of the full type name as the total length of [TypeRef].[RefID] should be 32 chars or less to fit the 'taggenlink' field.

## Example

```
<!-- =====
Output Section - <my variable tag>
=====
-->
<output name="[FileRef].[RefID]" file="variable.dbf"
```

```
filter="'{equipment.type}={type.name}'">
<field name="taggenlink" load="true">[TypeRef].[RefID]</field>
<field name="linked">1</field>
<field name="editcode">11</field>

<field name="name" key="true">{equipment.tagprefix}[Tag Suffix]</field>
<field name="type">[Tag Data Type]</field>
<field name="unit">{equipment.iodevice_list[0]}</field>
<field name="addr">[Tag Address]</field>
<field name="comment">[Tag Comment]</field>
</output>
```

[Equipment XML Template](#)

[Import Equipment Using XML Templates](#)

# Equipment Templates: Output Node

The output node contains the following attributes:

- **Output Name**

The output node name attribute should be unique across the output nodes in the template. One way to achieve this consistently is to use the format of [FileRef]. [RefID] (as outlined in [Equipment Templates: Outputs](#)). The recommended value for [FileRef] is listed with each output database.

- **Output File**

The output node file attribute refers to the filename for the associated database (DBF) file.

- **Output Filter**

The output node filter attribute is used to match the equipment defined in the equipment database (DBF). The filter value needs to match the type name specified in the type field of the equipment. The recommended value for the filter is the parameter string for the type defined at the beginning of the template file.

Each output node defines the associated Output Common fields and Output Database fields for the record that is to be created.

## See Also

[Equipment Templates: Outputs](#)

# Equipment Templates: Output Field

The output node fields can reference the values from the associated equipment input record. The following is a list of the fields that can be used based on the input section of the template (XML) file. The value is referenced using the syntax '{equipment.<Field Name>}' where <Field Name> can be used from the list below:

Input Name	Description
Area	The required area
Cluster	The associated cluster
Comment	The configuration comment
custom1 .. 8	The custom runtime fields
Defstate	The default state for the scheduler
Help	The help reference
lodevice	The list of IO devices
iodevice_list[n]	The array of IO devices, where n in the zero based index
Location	The location reference
Name	The full equipment name
Page	The list of pages
page_list[n]	The array of pages, where n in the zero based index
Param	The list of parameters
param_list[name]	The list of parameters, where name is the specific parameter name
scheduled	The configuration of scheduler participation
Tagprefix	The prefix for the associated tags
Type	The equipment type

## See Also

[Equipment Templates: Outputs](#)

# Equipment Templates: Output Common Fields

There are three common fields that should be used with each output node:

- **Output Tag Gen Link**

The taggenlink field specifies a name that is used to identify the record in the database so that it is linked with the template. This allows the record to be found for an update or delete operation.

The value should include a unique reference to the template type and a reference to the output record within the template. The recommended way to achieve this consistently is to use the format of [TypeRef].[RefID] (as outlined in Template Section: Outputs).

- **Output Linked**

The linked field should be set to '1'.

- **Output Edit Code**

The edit code is a number that represents the bitmask of the database (DBF) fields based on the physical order in the DBF file. When the bit in the mask is set, the corresponding field will be marked read-only in the Project activity. If no fields are to be marked as read only, this field can be left blank or removed from the output definition.

The algorithm to determine an edit code is listed in [Equipment Templates: Output Database](#). The combined edit code for few fields is a sum of edit codes of all fields. For example, the edit code for first (edit code = 1), second (edit code = 2), fourth (edit code = 8) and 20th fields (edit code = 524288) is  $1 + 2 + 8 + 524288 = 524299$ , or in decimals: 0x000001 (edit code for first field) + 0x000002 (edit code for second field) + 0x000008 (edit code for third field) + 0x80000 (edit code for 20th field) = 0x8000B

## To determine acceptable field names for Tags and Alarms

To determine the acceptable field names and, respective edit codes, either open citect.frm and find the respective output file without an extension (for example, advalm for advanced alarms) or open the respective dbf in the DBF Add-In. Every field listed in the dbf are acceptable field names. The edit code of the first field in the table is initialized to 1. The edit code of the fields other than 1 equals the edit code of the previous field times 2 (i.e. the edit code of the second field is 2, third is 4, fourth is 8 and so on).

[Equipment Templates: Outputs](#)

## Equipment Templates: Footer

The template (XML) file should contain a footer section to help so that the XML is formatted correctly. The footer contains the end marker for the template node.

The example below can be used without modification.

## Example

```
</template>
```

## See Also

[Equipment XML Template](#)

## Calculator Examples

The following examples demonstrate five cases where the calculator function could be applied to an equipment XML template. In each case, you need to add an additional line to the XML template:

```
<calculator>{parameter} + 1</calculator>
```

1. Calculator based on string parameter in the input section of the XML. This is only recommended if the calculated parameter is constant for each instance of equipment for this type; however, this is not a typical scenario.

```
<string name="MyString">1000</string>
<calculator name="MyCalc">{MyString} + 1</calculator>
```

See [Example 1](#).

2. Calculator based on equipment field, for example, {equipment.Custom1}.

```
<calculator name="MyCalc">{equipment.Custom1} + 1</calculator>
```

See [Example 2](#).

3. Calculator based on ungrouped parameter (defined in Equipment Editor).

```
<calculator name="MyCalc">{equipment.param_list[Param1]} + 1</calculator>
```

See [Example 3](#).

4. Calculator based on grouped parameter (defined in Equipment Editor).

```
<calculator name="MyCalc">{equipment.ParamGroup[Param2]} + 1</calculator>
```

These can then be used in fields for an element:

```
<field name="addr">MW_{MyCalc}_2</field>
```

See [Example 3](#).

5. Calculator based on grouped parameter (in the output section).

```
<output name="Element" file="variable.dbf" filter="'{equipment.type}={type.name}'>
<calculator name="TagAddress">{equipment.TagAddressing[StructOffset]} + 0</calculator>
...
</output>
```

These can then be used in fields for an element:

```
<field name="addr">MW_{MyCalc}_2</field>
```

See [Example 4](#).

## Example 1 - Type with Calculator based on STRING

```

## Troubleshooting - Equipment XML Templates

- **After running an equipment update there are no records created in the output database files.**

Check that the type name defined in the [Equipment Templates: Parameters](#) of the template file is the same as the name defined for the [Define Equipment Types in Plant SCADA Studio](#) record of the project.

- **After running an equipment update there are duplicate records in the output database files.**

Check that the 'taggenlink' field in the [Equipment Templates: Outputs](#) of the template was not changed. When this field is changed, any previously generated entries need to be manually deleted.

- **After running an equipment update some tags were not created. Is there a log file I can check?**

You can check the log file called EquipGen.log; however you should set the ini parameter [\[CtEdit\]LogLevel](#) to turn it on.

[\[CtEdit\]LogLevel](#) increases the verbosity of the log file so that more information can be recorded. The following values are accepted:

Error=3

Summary=5

Details=10

Verbose=15 (set this to 15 when more detailed logging relating to EquipGen is required.)

The log file is located in the default log directory which is set using [\[CtEdit\]Logs](#). To access the log file, in Plant SCADA Studio select **Log Folder** from the [The System Menu](#).

---

**Note:** If you leave LogLevel on during runtime, it can affect system performance as other logging functions may be impacted.

- **What happens if the Equipment type XML file is corrupted?**

When the equipment type is saved in the Equipment Editor, a file called EquipType.xml.backup is created. This file is of the previous configuration before the last save. If the XML file is corrupted, it can be replaced with the xml.backup file.

## Migrate Custom Parameters to the Configuration Parameters Database

Prior to the release of Plant SCADA 2023, "custom parameters" were used to apply specific values to an equipment type. However, there was limitation of 256 characters on the database field that was used to store these parameters.

In Plant SCADA 2023, custom parameters were replaced with "configuration parameters". These parameters support the same functionality, but they are stored in a dedicated configuration parameter database that

removes the 256 character limitation.

Equipment types that support the configuration parameters database can be identified by a "2.0" version tag in the source XML.

```
<template version="2.0" desc="Equipment template">
```

### To migrate your equipment types (and any associated instances) to version 2.0:

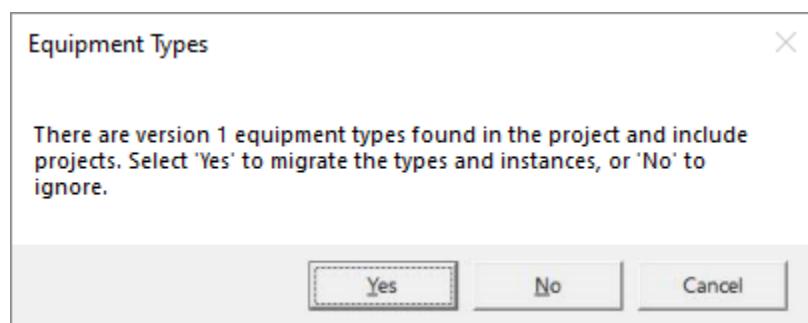

1. From the **Projects** view in Plant SCADA Studio, select **Migration Tool** on the command bar.  
The **Project Migration Tool** will display with the active project selected.
2. In the list of migration options, confirm that **Migrate equipment database, types and parameters** is selected.  
If required, you can clear the check boxes for any other migration options.
3. Click **Migrate**.

When the migration process is complete, an information dialog will appear listing the changes that have been made. This will include a tally for "Equipment types and instances upgraded".

4. Click **OK**.

The configuration parameters that were generated by the migration process will now be available to view in the **Equipment | Configuration Parameters** view in the **System Model** activity.

You can also initiate this process from **Equipment Editor**. If Plant SCADA detects a version 1 equipment type when you open the Equipment Editor, the following dialog will appear:

To migrate the version 1 equipment types, click **Yes** to open the Project Migration dialog and follow the steps above. To keep the existing version 1 templates, select **No**.

---

**Note:** If you are using equipment templates that were not created by Equipment Editor, you need to check the validity of these templates following the migration process. Before you launch runtime, perform an equipment update and review the configuration data associated with these templates (for example, the alarms and variable tags) to confirm that everything has migrated correctly.

[Define Equipment Configuration Parameters in Plant SCADA Studio](#)

## Variable Tags

A variable tag is a label that you can use to reference the current data value for an I/O device register at a

specified address.

This has several benefits:

- The address in the I/O device is defined only once. If you change the address, you only need to update the variable tag definition.
- You can use a tag name that is logical and descriptive.
- You can scale the raw data to an appropriate range in the same declaration.

Variable tags are a fundamental component of much of the functionality supported by a Plant SCADA system. For example, you can use variable tags to:

- Display production data on a graphics page (see [Display Tags on a Page](#)).
- Animate objects on a graphics page in response to tag value changes (see [Configure Graphics Objects](#)).
- Define commands that control equipment and processes (see [Interact with Graphics Pages at Runtime](#)).
- Create alarms that monitor variables tags for specific value changes (see [Alarms](#)).
- Store tag data for trending and analysis (see [Trends](#)).

When you define a variable tag, you need to give it a [Tag Names](#) and specify its [Tag Data Types](#). The most common variables supported by I/O devices are digital and integer. However, Plant SCADA also supports REAL, STRING, BYTE, BCD, LONG and LONGBCD data types.

Variable tags also support a set of [Tag Elements](#) that provide different views of a tag's data. This includes extended data values, quality validation and timestamp information. You can read and write to tag elements using [Tag Extensions](#).

You can use the following types of variable tags:

1. [Arrays](#) allow you to use a single variable tag to represent a set of variables are stored in consecutive memory registers on an I/O device.
2. [Local Variables](#) allow you to store data in memory when you start your runtime system.
3. [Calculated Variables](#) allow you to generate a tag value at runtime that is the result of a Cicode expression.

---

**Note:** You can use Cicode to create a tag browsing session at runtime. See [Configure Tag Browsing](#).

---

## See Also

[Configure Variable Tags](#)

[Refer to Variable Tags](#)

[Link Tags to an External Data Source](#)

## Tag Names

Plant SCADA places some restrictions on the names you can use for variable tags:

- Tags names need to adhere to specific syntax (see [Tag Name Syntax](#)).
- There is a set of reserved words that you need to avoid when naming a tag (see [Reserved Words](#)).
- Do not give a tag the same name as a Cicode function that is used within the project or its included projects.

A compile error message will occur if a tag has the same name as a Cicode function and is placed on a graphic page.

You can reference variable tag names (as a string) in your project, using the following formats:

- <tag name>
- <cluster>.<tag name> (used in multi-cluster systems).

---

**Note:** If your Plant SCADA project incorporates an equipment hierarchy, you may need to include a location in the hierarchy when you refer to a tag. This is reflected in the tag reference by using a period (.) to indicate levels in the equipment hierarchy (for example, "Plant.Line1.Pump.Tag1"). For more information, see [Equipment Hierarchy](#).

---

## See Also

[Structured Tag Names](#)

## Tag Name Syntax

Plant SCADA tags (variable tags, alarm tags and trend tags) need to use the following syntax:

- The fields are not case sensitive and need to begin with either an alpha character (A-Z or a-z) or the underscore character (\_).
- Any following characters need to be either alpha characters (A-Z or a-z), digit characters (0 - 9), backslash characters (\), or underscore characters (\_).

The use of any other characters will result in a compile error message.

For example:

- "\_MyTag123" and "my\New\Tag" are both valid tag names.
- "\NewTag\" is invalid.

Tag names that begin with a numeric character, such as '12TagName', are only valid if the INI parameter **[General]TagStartDigit** is set to 1 (the default value is zero).

---

**Note:** In the case of alarms, the **Alarm Tag** property needs to follow this syntax, but the **Alarm Name** property does not.

---

## See Also

[Structured Tag Names](#)

[Reserved Words](#)

## Structured Tag Names

The following naming convention is recommended for a system, to obtain maximum benefit when using features such as Genies and Super Genies. (If you are already using a naming system that differs from the following convention, you can still use Genies and Super Genies supplied with Plant SCADA by modifying the Genies that you want to use.)

Each tag name can contain up to 79 characters. To establish a convention, you need to divide the characters in the tag name into sections that describe characteristics of the tag, for example, the area where the tag is located, the type of variable, and any specific attributes.

Four basic sections are suggested for a Plant SCADA naming convention:

*Area\_Type\_Occurrence\_Attribute*

## See Also

[Reserved Words](#)

## Reserved Words

You cannot use certain reserved words when configuring a Plant SCADA project. You need to check the following lists before you create a name for any element:

### Tag Names

You cannot use Cicode function names and the following reserved words when defining a tag name for a variable tag:

&	*	**	-
/	+	<	<=
>=	<>	=	>
ACTION	AND	ANY_NUM	AREA
ARRAY	BOOL	CASE	CONFIGURATION
CONSTANT	DATE	DINT	DO
DUT	DWORD	ELSE	EN
END_CASE	END_CONFIGURATION	END_FOR	END_IF
END_PROGRAM	END_VAR	END WHILE	END
EXIT	FALSE	FOR	FUNCTION
IF	INT	ME	MOD
NOT	OF	OR	PROGRAM
REAL	REPEAT	STRING	TASK
TIME	TO	TRUE	UNTIL
VAR_EXTERNAL	VAR_GLOBAL	VAR_IN_OUT	VAR_INPUT
VAR_OUTPUT	WHILE	WORD	XOR

**Note:** When defining an alarm tag name, following are some additional reserved words that you need to avoid:

- ServerStatus
- SummaryRecordId
- RDBTimeInDB
- CitectArchiveObject

If you use any of these reserved words for alarm tag, an error message will display when you compile your project.

### Cluster Names

You cannot use the following reserved words when defining a cluster name:

&	*	**	-
/	+	<	<=
>=	<>	=	>
ACTION	AND	ANY_NUM	AREA
ARRAY	BOOL	CASE	CONFIGURATION
CONSTANT	DATE	DINT	DO
DUT	DWORD	ELSE	EN
END_CASE	END_CONFIGURATION	END_FOR	END_IF
END_PROGRAM	END_VAR	END WHILE	END
EXIT	FALSE	FOR	FUNCTION
IF	INT	ME	MOD
NOT	OF	OR	PROGRAM
REAL	REPEAT	STRING	TASK
TIME	TO	TRUE	UNTIL
VAR_EXTERNAL	VAR_GLOBAL	VAR_IN_OUT	VAR_INPUT
VAR_OUTPUT	WHILE	WORD	XOR

### Equipment Names

You cannot use the following reserved words when defining an equipment name:

&	*	**	-
/	+	<	<=
>=	<>	=	>
ACTION	AND	ANY_NUM	AREA

ARRAY	BOOL	CASE	CONFIGURATION
CONSTANT	DATE	DINT	DO
DUT	DWORD	ELSE	EN
END_CASE	END_CONFIGURATION	END_FOR	END_IF
END_PROGRAM	END_VAR	END WHILE	END
EXIT	FALSE	FOR	FUNCTION
IF	INT	ME	MOD
NOT	OF	OR	PROGRAM
REAL	REPEAT	STRING	TASK
TIME	TO	TRUE	UNTIL
VAR_EXTERNAL	VAR_GLOBAL	VAR_IN_OUT	VAR_INPUT
VAR_OUTPUT	WHILE	WORD	XOR

**Note:** When defining an Item Name, there are a number of reserved words that you need to avoid. These reserved words relate to syntax that is used for [Tag Extensions](#). They are:

- field
- valid
- override
- overridemode
- controlmode
- status
- v
- vt
- q
- qt
- t

If you use one of these reserved words, an error message will display when you compile your project.

**Note:** Using a reserved word for a name may generate a compile error message.

## Tag Data Types

Tags in Plant SCADA hold data values that can be defined as one of the following data types.

Data Type	Variable	Size	Allowed Values
BCD	Binary- Coded Decimal	2 bytes	0 to 9,999
BYTE	Byte	1 byte	0 to 255

Data Type	Variable	Size	Allowed Values
DIGITAL	Digital	1 byte	0 or 1
INT	Integer	2 bytes	-32,768 to 32,767
UINT	Unsigned Integer	2 bytes	0 to 65,535
LONG	Long Integer	4 bytes	-2,147,483,648 to 2,147,483,647
ULONG	Unsigned Long Integer (Only for display on a screen. Arithmetic operations are not supported.)	4 bytes	0 to 4,294,967,295
LONGBCD	Long Binary-Coded Decimal	4 bytes	0 to 99,999,999
REAL	Floating Point	4 bytes	-3.4E38 to 3.4E38
STRING	String	256 bytes (maximum)	ASCII (null terminated) <b>Note:</b> Non printable characters within string tag values will be substituted with spaces. For example, string [ 0x01, 0x41, 0x10, 0x42 ] will appear as "A B" so cache loading continues to operate.

While numeric variables are more common, some I/O devices also support ASCII strings. You can use strings to store text data (for example, from a bar code reader). All strings need to be NULL-terminated in the I/O device, as Plant SCADA uses the NULL character to check for the end of a string. If no NULL character is present, Plant SCADA reads (and displays) any extra characters in memory, after the end of the string.

When you are using a disk I/O device, you can also specify a string data type for storage of recipes, or for operator display information.

Not every I/O device supports strings. However, if your I/O device does support integer data types, Plant SCADA can use these integer registers to store ASCII strings in your I/O device. Plant SCADA strings can only be stored in contiguous blocks (consecutive registers), and are stored as an array.

A Cicode variable of INT data type can be used to store Tag data types: BCD, BYTE, DIGITAL, INT, UINT, LONG, ULONG and LONGBCD.

A Cicode variable of the QUALITY or TIMESTAMP data type can be used to store the Tag quality and timestamp items.

Tag values can be used with the Cicode variable data types (see [Declaring the Variable Data Type](#)).

## Tag Elements

A variable tag is a representation of data elements. Each element provides access to a view of the data value for the tag.

Each variable tag can be used on its own or by referencing a particular element to access the following information:

Element	Description
.field	The field element, which represents the latest field data received from the device.
.valid	The valid element, which represents the last field data which had 'Good' quality.
.override	The override element, which represents the overridden tag value.
.overridemode	The override mode, which is used to set the override behavior of the tag.
.controlmode	The control mode, which is used to set the control inhibit mode of the tag.
.status	The tag status element, which is used to represent the current status of the tag.

The tag and each element have items that can be referenced to access the following information:

Item	Description
v	The value item. Use this to retrieve the current data value of the tag or element.
vt	The value timestamp item. Use this to retrieve a timestamp that represents when the value last changed.
q	The quality item. Use this to retrieve the quality of the value.  The quality item differs to other elements as it offers several layers of information. For more information, see <a href="#">The Quality Item</a> .
qt	The quality timestamp item. Use this to retrieve a timestamp that represents when the quality last changed.
t	The timestamp item. This will access the timestamp of when the tag or element was last updated.

To refer to tag elements in your project, you use [Tag Extensions](#).

## The Quality Item

The majority of data which is contained within the variable tag is represented as an element which includes the items "Value", "ValueTimestamp", "Quality", "QualityTimestamp" and "Timestamp". With the exception of "Quality" these items are absolutes of a single value. However the "Quality" item has several layers of information within it. These layers of information are covered by the following categories:

The primary layer identifies the **General Quality Values**.

Cicode Label Name	Value	Description
QUAL_BAD	0x00	Value is not useful for reasons indicated by the Substatus Bit Field.
QUAL_UNCR	0x01	The Quality of the value is uncertain for reasons indicated by the Substatus Bit Field.
QUAL_GOOD	0x03	The Quality of the value is Good.

These can be accessed from a text object on a graphics page at runtime, or with the Cicode function [QualityGetPart](#) using the necessary value for the *Part* parameter.

Within each of these quality values is a substatus layer, and a third extended substatus layer. These layers of information can also be accessed using the [QualityGetPart](#) Cicode function.

## Tag Extensions

Tag extensions allow you to refer to the [Tag Elements](#) of a tag. They support the following functionality:

- Provide access to the quality and time stamp information associated with a tag value.
- Provide extended data to Plant SCADA client components, such as a display client, trend server, alarm server, report server, Cicode and CtAPI.
- Allow you to apply an override to a tag, and prohibit writing to the tag value.
- Allow you to display and trend tag values even if their quality is not "good".
- Enable tag value persistence, and replication of tag data.

The tag reference syntax used for tag extensions is as follows:

**[Cluster.]Tag[.Element][.Item][ [n]]**

Where:

Cluster	The optional <a href="#">Clusters</a> name.
Tag	The tag name or Super Genie <a href="#">Super Genies</a> .
Element	The optional element name. If the element name is not specified, the requested element will be

	determined at runtime.
Item	The optional item name. If the item name is not specified, the whole element is referenced.
n	The optional array index if the tag is defined as an <a href="#">Arrays</a> .

The array index is at the end of the reference (MyArray.v[n], MyArray.Field[n], MyArray.Field.v[n]). There is only a single quality and timestamp for each array, each member will return the same quality and timestamp.

**Note:** Consider the impact on network traffic when configuring tag extensions, as the distribution of quality and value timestamps increases the amount of data being sent between servers.

You can use tag extensions to access tag data in the following ways:

- Reference tag data using only the tag name, for example:

"MyTag" (unqualified tag reference).

This will provide default access to the **.field** element information, unless the tag is in one of the override modes.

- Reference tag data using the tag name and the item name, for example:

"MyTag.q" (unqualified tag reference)

This will provide access to the item information for the tag, either default from **.field** or **.override** element.

- Reference the tag data by using the tag name and the element name, for example:

"MyTag.field" (qualified tag reference)

This reference will provide access to the specified tag element information.

- Reference the tag data by using the tag name, element name and the item name, for example:

"MyTag.field.vt" (qualified tag reference)

This reference will provide access to the specific tag element item.

You can also access alarm data in a similar way. See [Using Alarm Properties as Tags](#).

**Note:** Consider the impact on network traffic when configuring tag extensions, as the distribution of quality and value timestamps increases the amount of data being sent between servers.

## Controlling Tag Extension Behavior

By default, the tag data referenced without an element will provide access to the data value when the value is of quality is good and an error (#BAD, #COM, etc) when the quality is bad. The configuration parameter [\[Page\]IgnoreValueQuality](#) can be used to change this behavior, including automatically changing the background color of text and number graphics objects on a page with changes in quality of the tag.

Tag extension behavior is controlled by several citect.ini file settings which are described in the Parameters Reference. For each of these settings there is a corresponding setting in the project database parameters (param.dbf).

A citect.ini file setting specifies behavior for a particular machine and a parameter database setting is applied system-wide.

**Note:** By default, the TagSubscribe Cicode function is set to retrieve "lightweight" tag values that exclude quality

---

and value timestamps. If you need a subscription to retrieve timestamp data, you need to set the "bLightweight" argument to 0 (false).

---

## Arrays

An array is a collection of variables (all of the same data type) that are stored in consecutive memory registers in an I/O device.

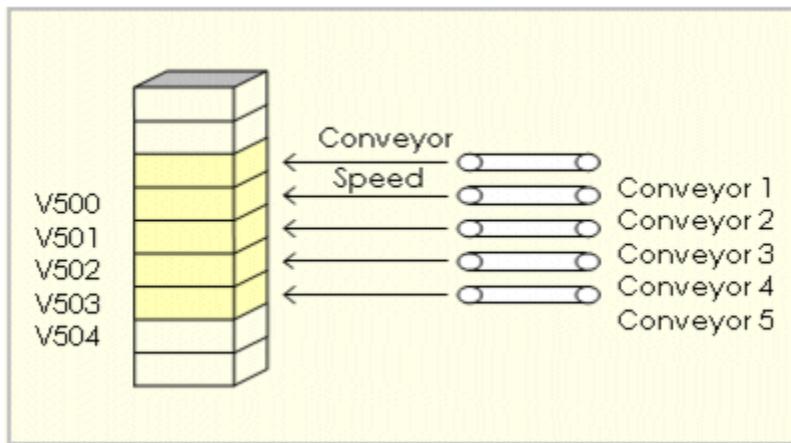

Plant SCADA supports two types of arrays:

- Numeric arrays
- String arrays.

## Numeric Arrays

Numeric arrays are useful when you have separate devices (or processes) performing similar functions. You can program the I/O device to store, in consecutive memory registers, variables that relate to each of these processes.

In the following example, five consecutive variables (V500, V501, V502, V503, and V504) store the conveyor speed of five conveyors (1 to 5).

Instead of configuring five separate variable tags (one for each conveyor), you can configure a single tag as an array.

To specify a single variable tag for an array, define the first address and add the size of the array (the number of consecutive addresses) to the register address.

Variable Tag Name	Conveyor_Speed
Address	V500[5]

Here, five register addresses are referred to by the variable tag Conveyor\_Speed.

## String Arrays

If you are using a Plant SCADA string data type, you need to specify an array of integer data types. One INT register stores two string characters.

To calculate the size of an array (for string data types), use the following formula:

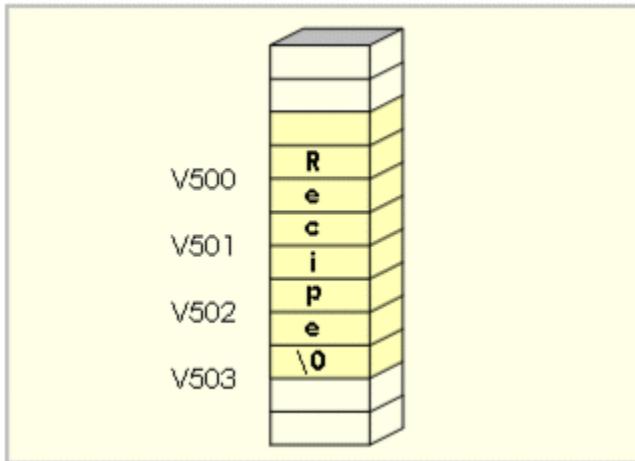

$$\text{Size of Array} = \frac{(\text{number of characters} + 1)}{2}$$

The last element of the array is always used to store the null character '\0'. This character marks the end of the string.

To store the word "Recipe", you need to specify an array with 4 elements, for example:

Variable Tag Name	Recipe_Tag
Address	V500[4]

Two characters are stored in each register, that is:

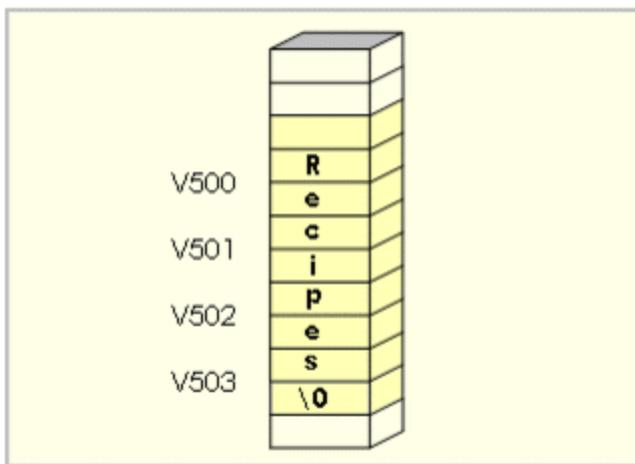

You can then refer to the entire string by specifying the tag:

<Tag Name>

For example:

Variable Tag	Recipe_Tag
--------------	------------

To store the word "Recipes", you would also specify an array with 4 elements. The characters are stored as follows:

**Note:** If your I/O device supports string data types, you need to specify the address in the format determined by the I/O Device you are using.

## See Also

[Refer to Array Elements](#)

## Local Variables

Local variables allow you to store data in memory when you start your runtime system. They are created each time the system starts, and therefore do not retain their values when you shut down.

Every Plant SCADA process has its own copy of the local variables configured in a project. This is useful when you need each process to have a separate copy of the associated data. The values in a local variable are only available to the process in which they were written.

Local variables may be of any data type supported by Plant SCADA, including two-dimensional arrays.

## See Also

[Add a Local Variable](#)

## Calculated Variables

A calculated variable allows you to do the following:

- Generate a tag value at runtime that is the result of a Cicode expression.
- Call an internal Cicode function as a variable tag.

Calculated variables are evaluated on the I/O server only when a subscription to the calculated variable exists.

The following data types are supported for calculated variables:

- Int
- Long

- Real
- Digital
- String

To configure a calculated variable, you use a variable tag that addresses an I/O device with its protocol set to "CICODE". If the variable tag address is a valid Cicode expression, the Cicode I/O device will calculate the result of the expression and present it as the tag value.

**Note:**

- The same Cicode function can generate different results depending on whether or not the Cicode function was called from a process, an event, or if it was called from a Cicode I/O device.
- When used as an address of a calculated variable, if there is at least one argument in #BAD then a function will return #BAD even if it executed properly.

If the expression in the **Address** field reads from or writes to another tag in the system, the calculated variable is added towards the point count.

**Note:** When a primary I/O server is starting up, it loads and initializes all of its I/O devices. For large projects, this process can have a heavy impact on system performance especially when there are Cicode devices supporting calculated variables. To minimize the potential impact on display client updates, you can apply a delay that will stop client tag subscriptions from switching to a primary device while the I/O server is still starting up. See Use a Client Tag Subscription Delay for Calculated Variables.

## Example 1

The Plant SCADA Example Project includes a number of tags that support the Steel Mill page. These tags include two tags that identify the length and width of the coil that is currently loaded on the uncoiling station.

Tag Name	I/O Device	Address	Data Type	Units
Entry_CoilLength	SteelMillDisk	R10	REAL	meters
Entry_CoilWidth	SteelMillDisk	R13	REAL	millimeters

Using a calculated variable, you could determine how many square meters of steel will be produced by the coil that is currently uncoiling. To do this, you could create the following calculated variable on an I/O device called "CicodeIODevice".

Tag Name	I/O Device	Address	Data Type	Units
Entry_CoilArea	CicodeIODevice	Entry_CoilLength * (Entry_CoilWidth)/1000	REAL	m2

You could then use the value generated by this tag at runtime to estimate the production potential of the current coil.

## Example 2

Using a calculated variable, you can call a Cicode function for diagnostics and determine the state of an I/O device.

Tag Name	I/O Device	Address	Data Type
IOServer_Mixer_PM800_S state	CicodeIODevice	IODeviceInfo("IOServer_Mixer_PM800", 10)	STRING

In the example above, a CICODE function has been used in a calculated variable to determine the state of the specified mixer (for example, online or offline).

**Note:** Cicode functions used for calculated variables need to be non-blocking functions.

### Example 3

Using a calculated variable, you can trigger an alarm when an I/O device goes offline. In this case, you will need to:

- create a variable tag with a calculated variable to determine the state of an I/O device
- create an advanced alarm with an expression that will trigger an alarm when the expression evaluates to TRUE.

Tag Name	I/O Device	Address	Data Type
IOServer_Mixer_PM800_S state	Mixer	IODeviceInfo("IOServer_Mixer_PM800", 10)	STRING

Alarm Tag	I/O Device	Expression
IOServer_Mixer_PM800_Offline	Mixer	(StrToInt(IOServer_Mixer_PM800_State) = 16) OR (StrToInt(IOServer_Mixer_PM800_State) = 32)

In the example above, the variable tag calculates the state of the mixer. The alarm will be triggered if the tag is calculated to be 16 (offline) or 32 (disabled).

### Example 4

Using a calculated variable, you can perform mathematical calculations. In this example, the variable tag calculates the quotient of two integers and in the event of the divisor being 0 returns an error code.

Tag Name	I/O Device	Address	Data Type
Divide_Tag_Value	CicodeIODevice	Divide(4,9)	REAL

```
REAL FUNCTION Divide( INT iDividend, INT iDivisor)
    REAL iResult;
    INT iError;
    Errset(1);
    iResult = iDividend / iDivisor
    iError = isError();
```

```
Errset(0);
RETURN iResult;
END
```

[Add a Calculated Variable](#)

## Tag Data Persistence

Each I/O device has a tag data cache on its I/O server. This cache is periodically saved to disk to maintain the last known value (LKV) for each tag. This allows the tags on an I/O device to be initialized to their corresponding LKVs when the device is restarted. On load, the original persisted quality is substituted by the BadLastKnown quality value.

The tag cache file is saved as an [XML DataSource Schema](#), preserving the necessary information about each tag's value, quality, and timestamp. The file is saved in the Plant SCADA Data Folder with the following default name:

<ClusterName>.<IOServerName>.<IODeviceName>.cache

When the time comes to save a tag cache file, a temporary file is used. After it is written, it simply gets renamed to the original file name. This is done to avoid partial master file updates.

If during the file load the schema validation is unsuccessful, the entire file is considered invalid and the tags LKVs are lost. If during the file load a particular tag's value, quality, or timestamp is invalid, the corresponding invalid entry is simply ignored (and logged as such).

Persistence can be configured using the **Persist**, **Persist Period** and **File Name** properties (see [Add an I/O Device](#)).

## Minimum Update Rate

An I/O device can send tag update notifications to subscription clients after a pre-defined period of time expires. This is configured via the **Min Update Rate** property.

Devices that are configured for redundant operation needs to have minimum update rate set according to the rules specified in the table below.

Primary Device - <b>Min Update Rate Value</b>	Standby Device - <b>Min Update Rate Value</b>	<b>Compilation Result</b>
Blank (Default)	Blank (Default)	OK
Blank (Default)	Value Defined	Error
Value Defined	Blank (Default)	OK
Value Defined	Same value as primary	OK
Value Defined	Value is different than on primary	Error

## Staleness Period

You can specify a "staleness period" for tag values received from an I/O device. If a subscription client does not

receive a tag update from the I/O device within this specified period of time, the tag element value is considered to be "stale". The [The Quality Item](#) substatus **QUAL\_EXT\_STALE** will indicate this condition. Processing of staleness period for tags is performed on the client side of the connection.

A staleness period can be configured in the following ways:

- On the **server** side you can set the staleness period for a particular I/O device by setting the **Staleness Period** property (see [Add an I/O Device](#)). The value you enter should represent the total number of seconds that can elapse after the last update before **QUAL\_EXT\_STALE** is set to "stale".

For devices configured for redundant operation, the Staleness Period settings must conform to the same rules outline for Min Update Rate in the table above.

- On the **server** or **client**, you can use the [\[Client\]StalenessPeriod](#) parameter. This specifies the total number of seconds that can elapse following the last update before **QUAL\_EXT\_STALE** is set to "stale".
- On the **client** only, you can use the [\[Client\]StalenessPeriodTolerance](#) parameter. Staleness period tolerance specifies an amount of time as a percentage of the total staleness period, after which a check of stale client tag elements will be performed. The default value is 10%. This means that if the staleness period is set to 600 seconds, a check for stale client tag elements will be performed every 60 seconds.

## XML DataSource Schema

```

## Configure Variable Tags

You can configure the following types of variables in a Plant SCADA project:

- [Add a Variable Tag](#)
- [Add a Calculated Variable](#)
- [Add a Local Variable.](#)

## See Also

[Refer to Variable Tags](#)

### Add a Variable Tag

Variable tags allow you to reference a specific I/O device variable.

**To add a variable tag:**

1. In the **System Model** activity, select **Variables**.
2. On the menu below the Command Bar, select **Variables**.
3. Add a row to the Grid Editor.
4. Type the required information in each column, or in the fields in the Property Grid.  
For a description of the properties, see below.
5. Click **Save**.

To successfully configure a variable, you need to complete the **Tag Name**, **I/O Device**, **Address** and **Data Type** fields. All other fields are optional.

### Variable Tags Properties

**Note:** If a variable tag was generated by the Equipment Editor, a number of fields on the properties form will be shaded. To configure these fields, you will need to use [Equipment Editor](#).

#### Equipment Properties

Property	Description
Equipment	The name of the equipment associated with the variable tag. Select a name from the drop-down list of existing equipment definitions, or enter a name.

Property	Description
	<p>There is a limit of 254 characters across the <b>Equipment</b> and <b>Item Name</b> fields, including any separating periods (.).</p>
<b>Item Name</b>	<p>The name of the item with which the variable tag is associated.</p> <p>Items form part of an equipment hierarchy. They can be used to associate tags, alarms and trends with a particular attribute of a physical piece of equipment (see <a href="#">Items</a>).</p> <p>There is a limit of 254 characters across the <b>Equipment</b> and Item Name, including any separating periods (.).</p> <p><b>Note:</b> When entering an item name, avoid using any <a href="#">Reserved Words</a>. If you use any of these, an error message will display when you compile your project.</p>

#### General Properties

##### **WARNING**

###### **UNINTENDED EQUIPMENT OPERATION**

Do not mix the use of odd and even variable addresses as boundaries when you are concatenating registers.  
**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

Field	Description
<b>Tag Name</b>	<p>You can use any name for a tag (79 characters) provided it follows the <a href="#">Tag Name Syntax</a> rules and is not the same as the name of a Cicode function within the project (or any included projects). See <a href="#">Reserved Words</a> for a list of restrictions on naming.</p> <p>If you have many tags, use a naming convention (see <a href="#">Structured Tag Names</a>). This makes it easier to find and debug your tags. When the tag name is referenced on a graphics page, Cicode, etc., it can be used with or without a specific tag element or item.</p> <p>If you are using distributed servers, the name needs to be unique to the cluster (for example, you cannot have the same variable tag name in more than one cluster).</p> <p><b>Note:</b> Plant SCADA will automatically resolve tags without a cluster context specified if every tag name in the project is unique. See <a href="#">Clusters</a>.</p>
<b>Cluster Name</b>	<p>The name of the cluster that runs the variable tag. This field needs to be defined if your project has more than one cluster.</p> <p>You can leave this field blank in a multi-cluster system if cluster replication is enabled (see the parameter [General]ClusterReplication).</p>
<b>I/O Device</b>	<p>The name of the I/O device where the variable is stored (31 characters). If using I/O device redundancy, you need to specify the primary I/O device name here, not the standby.</p> <p><b>Note:</b> Avoid changing the tag's I/O device name from this FORM as the variable.dbf will not be updated. If you do change the tag's I/O device name you will need to clear the tag's reference fields.</p>
<b>Data Type</b>	<p>The type of I/O device variable (16 characters). I/O devices support several data types that are used to exchange data with Plant SCADA. Because of the lack of an industry standard, many I/O device manufacturers use individual naming conventions for their I/O device variables. However, every variable corresponds to one of the <a href="#">Tag Data Types</a>.</p> <p><b>Note:</b> If you do not specify a range for your tag, then an out of range alert message will be generated if you write a value which is outside the range of the type.</p> <p>You need to specify the correct data type that</p>

Field	Description
	<p>corresponds to the data type of the I/O device variable you are configuring. Each data type has a unique address format. You need to use this format when you are specifying the address of the variable (as the Address property).</p> <p>You will want to verify that you only use data types that are valid for your I/O device. If you do not specify a data type, the variable will be treated as 16-bit integer.</p> <p>Plant SCADA supports concatenation of I/O device registers. For example, you can define a real data type (in Plant SCADA) as two contiguous int data types (in the I/O device). Plant SCADA reads across the boundary of the two INTs and returns a REAL.</p> <p>If you use concatenation of registers, the address of the variables needs to be on odd boundaries or even boundaries. You cannot mix address boundaries. For example, V1, V3, V5 are valid addresses.</p> <p>Be careful when using this feature: the I/O device needs to maintain the integrity of the second register. (If the I/O device writes to the second int, the value of the real could be corrupted.) The structure of some I/O devices might not support this feature, and might therefore behave unpredictably.</p>
<b>Address</b>	<p>The register address in the I/O device where the variable is stored (254 characters). The format and prefix of an address will depend on the protocol configured for the I/O device, which can be determined by checking the <b>Protocol</b> field on the I/O devices view in Plant SCADA Studio.</p> <p><b>Note:</b> The address of the variables for all I/O devices using the same protocol needs to be on odd boundaries or even boundaries. You cannot mix address boundaries.</p>
<b>Comment</b>	Any useful comment (254 characters).
<b>Deadband</b>	(11 characters). A deadband allows the value of a variable tag to fluctuate within a defined threshold without updates being sent through the system. This may be useful if a tag produces many small, insignificant value changes. The threshold is represented as a percentage of the tag's engineering range. The default value is 0 (zero), which captures every value change.

Field	Description
	<p>For example, if a variable tag has an engineering range of zero to 10000, a deadband of 1 would mean a change in value would have to be greater than 100 (or 1 percent of the range) to be recognized. If the current value was 5600, the tag in the PLC would have to change to a value greater than 5700 or less than 5500 before an update would be sent through the system.</p> <p>The deadband setting for a variable tag will not apply to an associated trend tag. If a trend tag requires a deadband setting, it should be configured independently in the trend tag properties.</p> <p><b>Note:</b> Some data types support an engineering range that includes negative values. For example, a two-byte integer has a range of -32,768 to 32,767. In this case, the deadband percentage specified would need to be measured against a possible range of 65535. See the topic <a href="#">Tag Data Types</a> to determine the default range for each of the different data types supported by Plant SCADA.</p>
<b>Eng Units</b>	(8 characters.) The engineering units that the value represents (for example %, deg, mm/sec, etc.). This property is optional. If you do not specify engineering units, no engineering units are used.
<b>Format</b>	<p>(11 characters). The display format of the value (of the variable) when it is displayed on a graphics page, written to a file, or passed to a function (that expects a string). This property is optional. If you do not specify a format, the format defaults to #####.##.</p> <p>For more information, see <a href="#">Format Specifiers</a>.</p>
<b>Unique ID</b>	<p>A unique ID is applied to each of the variable tags in a Plant SCADA project to provide consistent identification for integration with future software releases. This field is read-only in Plant SCADA Studio.</p> <p>Each unique IDs is a Globally Unique Identifier (GUID) generated by Plant SCADA using the following format: XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX</p> <p>For more information, see <a href="#">Unique IDs for Variable Tags and Equipment</a>.</p> <p><b>Note:</b> It is highly recommended that you only use Plant SCADA to generate the unique identifiers for the variables in your system. If for some reason this is not possible, use a reputable tool to generate GUIDs that</p>

Field	Description
	<p>match the format described above.</p> <p>If you use an external tool to modify the variables database, the compiler will indicate if a Unique ID is invalid, duplicated or missing.</p>

**Scale Properties**

Field	Description
<b>Raw Zero Scale / Raw Full Scale</b>	<p>The unscaled (raw) values (of the variable) that represent the zero point and full scale point for the data (11 characters). The raw values are the values that Plant SCADA reads from the I/O device.</p> <p><b>Note:</b> If not defined, the <b>Raw Zero Scale</b> and <b>Raw Full Scale</b> will default to the full range based on the data type. See the topic <a href="#">Tag Data Types</a> to determine the default range for each of the different data types supported by Plant SCADA.</p>
<b>Eng Zero Scale / Eng Full Scale</b>	<p>The scaled values that Plant SCADA calculates from the raw values (11 characters). The Raw Zero Scale is scaled to the Eng Zero Scale and the Raw Full Scale is scaled to the Eng Full Scale. These properties are represented in engineering units and are used as the upper and lower limits of trends and bar graphs.</p> <p>Many I/O devices return an integer to indicate the value of an analog input. To return a usable value, the I/O device converts an input signal (usually 4-20 mA) to a raw scale variable, usually in the range 6400 to 32000.</p> <p>To present this variable as a meaningful value, you can specify a scaling calculation. Plant SCADA then scales every value accordingly, as in the following diagram.</p>

Field	Description
	<p>The scaled value of the variable (engineering value), not its raw value, is used throughout the system.</p> <p>The scaling properties are optional. If you do not specify scaling, Eng Zero Scale defaults to Raw Zero Scale, and Eng Full Scale defaults to Raw Full Scale; that is, no scaling occurs.</p> <p>A value that is below the specified Raw Zero Scale or above the specified Raw Full Scale causes an "Out of Range" alert message in your runtime system.</p>

**Custom Properties**

Field	Description
<b>Custom 1 to Custom 8</b>	A user-defined string can be used for storage of static information. Information contained within custom1...8 can be used for categorization purposes, as such, it does not usually change during runtime.

**Security Properties**

Field	Description
<b>Write Roles</b>	<p>Used to determine which Roles have write permissions for a variable tag when using an OPC UA or Industrial Graphics client. Only users included in the specified role(s) will be able to send values to a variable tag from a client application.</p> <p>Use the drop-down menu to select one of the roles configured in your Plant SCADA project, or manually enter a comma-separated list to include multiple roles.</p> <p>For more information, see <a href="#">Enable Tag Writes for Industrial Graphics Applications</a>.</p>

**Historian Properties**

Field	Description
<b>Historize</b>	<p>This field enables you to automatically historize and publish the specified variable tag in CitectHistorian. If you set this field to "TRUE", the variable will be included in an automated configuration process within the Historian environment. If you set the field to "FALSE" (or leave it blank), the variable will not be included.</p> <p>See <a href="#">Integration with Historian</a>.</p>

## Project Properties

Property	Description
Project	The project in which the variable tag is configured.

## See Also

[Configure Variable Tags](#)

### Unique IDs for Variable Tags and Equipment

A unique ID is applied to each of the following in a Plant SCADA project:

- Variable tags
- Equipment instances
- Equipment types.

This is done to provide consistent identification for integration with future software releases.

Each unique ID is a Globally Unique Identifier (GUID) generated by Plant SCADA using the following format:

XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX

A unique ID is automatically generated whenever the following occurs:

- A new variable, equipment instance or equipment type is created in Plant SCADA Studio.
- A new variable, equipment instance or equipment type is generated by Equipment Editor during an [Equipment Updates](#).
- The Migration Tool is run with the **Create unique IDs for Variables and Equipment** option selected.
- A variables database is imported as a CSV file (see [Import from Microsoft Excel](#)).
- Tags are imported from a device (see [Import Variable Tags from an External Data Source](#)).

---

**Note:** It is highly recommended that you only use Plant SCADA to generate the unique identifiers for the variables in your system. If for some reason this is not possible, use a reputable tool to generate GUIDs that match the format described above.

---

Using an external tool to modify the variables and/or equipment databases can result in unique IDs that are invalid or duplicated. The Plant SCADA compiler will use the following messages to indicate if this occurs.

#### E2182 - Invalid Unique ID format

To resolve this, do one of the following:

- If a small number of invalid IDs are detected, you can copy an identified variable into a new row in Plant SCADA Studio. The paste function will create a new ID. You can then delete the original variable with the invalid ID.
- If a large number of invalid IDs are detected, you can export the variables database to Excel and use the compiler results to delete the invalid IDs. New IDs will be created when you import the variables again.

#### E2183 - Duplicate Unique ID for variable

To resolve this, do one of the following:

- If a small number of duplicate IDs are detected, you can copy one of the identified variables into a new row in Plant SCADA Studio. The paste function will create a new ID. You can then delete the original variable with the duplicated ID.
- If a large number of duplicated IDs are detected, you can export the variables database to Excel and use the compiler results to delete the duplicated IDs. New IDs will be created when you import the variables again.

**Note:** If the compiler generates a warning message stating that some equipment or variable tags do not have a unique ID, it indicates that a project has not been migrated to the current version of Plant SCADA. To resolve this, run the [Project Migration Tool](#) with the **Create unique IDs for Variables and Equipment** option selected.

## Format Specifiers

Format specifiers are keyboard characters that you can use to define the format for a numeric variable. The specifiers that you can use are:

Specifier	Function	Description
#	The number of characters to display	<p>The hash character specifies how far digits display to the right of an animation point, for example:</p> <p>Format: #####</p> <p>This will display at least four digits (or spaces) to the right of the animation point. If the number contains more than four digits, the first digit is located at the animation point.</p> <p><b>Note:</b> As an alternative to the hash (#) notation, you can use shortform notation (see below).</p>
0	Padding	<p>When a number contains fewer digits than your format specifies, Plant SCADA only displays the meaningful digits. You can use the padding character, zero (0) as the second character in the format string to fill the number with zeros, for example:</p> <p>Format: #0##</p> <p>This will display:</p>

Specifier	Function	Description
		0075 for 75 0005 for 5
-	Justification	By default, numeric variables are right-justified (within their field). You can change the default justification by using a minus (-) sign as the second character in the format string, for example: Format: #-###
.	Decimal notation	To specify decimal notation, use a period (.), for example: Format: ###.## In this example, Plant SCADA displays three digits before the decimal point and two digits after. If the variable is 12.3, Plant SCADA displays 12.30. All numbers are automatically rounded, for example: 12.306 displays as 12.31.
EU	Engineering units	You can specify engineering units (such as %, deg, rpm, M, mm/sec, and so on) when you define a variable tag. To include these units in the format of the number, type <b>EU</b> in the appropriate position. Format: #####.##EU <b>Note:</b> If you do not specify an engineering unit for the variable, only the number is displayed (or logged).
S	Exponential notation	To specify exponential notation, include the exponential character ( <b>s</b> ), for example: Format: #s### In this example, Plant SCADA displays the number in exponential notation format, for example: 1.234e+012.

You can combine format specifiers, for example:

Format: #0-###.##EU

This format string displays six digits before the decimal point and two digits after. The number is left justified, padded, and displayed with engineering units (if specified).

## Shortform Notation

As an alternative to the hash (#) notation, you can use shortform notation. With shortform notation, you use a number to specify the format of the numeric variable, for example:

Format: 3.2

This format string displays three digits before the decimal point and two digits after. This format string is equivalent to the ###.## format specification. You can also include engineering units with shortform notation, for example:

Format: 6.0EU

This format string displays six digits before the decimal point and no digits after. The number is displayed with engineering units (if specified). This format string is equivalent to the #####EU format specification.

You cannot use padding or left justification with shortform notation.

---

**Note:** If the value of a numeric variable is extremely large, it is displayed in exponential notation (for example 1.2345E012). If no format is specified for a variable, the default ####.# (or 4.1) is used.

---

## Add a Calculated Variable

[Calculated Variables](#) allows you to generate a tag value at runtime that is the result of a Cicode expression.

---

**Note:** A calculated variable will contribute to the point count if it refers to variable tag(s) in its Cicode expression that has been configured in its address field. If the calculated variable only refers to Cicode functions, and these functions do not refer to variable tags, then it will not contribute to the point count.

---

To configure calculated variables, you need to perform two procedures:

- Create an I/O device with its protocol set to "CICODE".
- Create a variable tag on a Cicode I/O device that has a Cicode expression as its address.

---

**Note:** Projects created from a starter project in Plant SCADA 2016 (or later) will include a pre-configured Cicode I/O device.

---

## Create a Cicode I/O Device

You can use one of the following methods to create a Cicode I/O device:

### Create a Cicode I/O device in the Topology activity

1. In the **Topology** activity, select **I/O Devices**.  
The I/O devices list will display in the Grid Editor.
2. In the **Project** field, select the project that will host the Cicode I/O device.
3. In the **Server Name** field, select the I/O server that will host the Cicode I/O device.
4. In the **Name** field, enter a name for the Cicode I/O device. The name needs to be unique to the selected I/O server.

5. In the **Number** field, enter a unique number for the Cicode I/O device (0-16383).
6. In the **Protocol** field, select "CICODE".
7. The remaining fields are not required for a Cicode I/O device.
8. Click **Save**.

### Create a Cicode I/O device using the Device Communications Wizard.

1. In the **Topology** activity, select **I/O Devices**.
2. On the Command Bar, select **New Device**.  
The [Using the Device Communications Wizard](#) will display.
3. When asked to select the "type of the I/O Device", select **Persisted Memory I/O Device**.
4. When asked to select the "manufacturer, model and method of communication" for the I/O device, select **Cicode Protocol**.
5. When you have finished stepping through the wizard, the Cicode I/O device will appear in the I/O Devices list.

---

**Note:** The **Startup Mode** field should be configured appropriately if device redundancy is required for the Cicode I/O device you have created.

---

### Create a Calculated Variable on a Cicode I/O Device

#### To create a calculated variable on a Cicode I/O device:

1. In the **System Model** activity, select **Variables**.
2. On the menu below the Command Bar, select **Variables**.
3. The variables list will display in the Grid Editor.
4. Add a row to the Grid Editor.
5. In the **Tag Name** field, enter a name that describes the calculated variable.
6. In the **I/O Device** field, select the name of the Cicode I/O device you would like to use.
7. In the **Data Type** field, select a data type that is appropriate to the value that will be returned by the specified calculation or Cicode expression.
8. In the **Address** field, enter a valid Cicode expression.

---

**Note:** Cicode functions used for calculated variables need to be non-blocking functions.

---

9. Click **Save**.

---

**Note:** If an error is trapped in the Cicode that has been placed in the **Address** field of a calculated variable (either internally via a built-in Cicode function or by calling the function ErrTrap), the variable tag will have bad quality and will raise a Cicode error when the tag is read. After reading the tag, call IsError() to get the error number and clear it.

---

[Configure Variable Tags](#)

## Add a Local Variable

[Local Variables](#) allow you to store data in memory when you start your runtime system.

### To add a local variable:

1. In the **System Model** activity, select **Variables**.
2. On the menu below the Command Bar, select **Local**.
3. The local variables list will display in the Grid Editor.
4. Add a row to the Grid Editor.
5. Type the required information in each column, or in the fields in the Property Grid.  
For a description of the properties, see below.
6. Click **Save**.

## Local Variables Properties

### General Properties

Field	Description
<b>Name</b>	You can use any name for a tag (79 characters) provided it follows <a href="#">Tag Name Syntax</a> and is not the same as the name of a Cicode function within the project or any included projects. See <a href="#">Reserved Words</a> for a list of restrictions on naming.
<b>Data Type</b>	The data type of the variable (16 characters). Select one of the following supported data types: <ul style="list-style-type: none"><li>• BCD (Binary) - Coded Decimal - 2 bytes (0 to 9,999)</li><li>• BYTE (Byte) - 1 byte (0 to 255)</li><li>• DIGITAL (Digital) - 1 bit or 1 byte (0 or 1)</li><li>• INT (Integer) - 2 bytes (-32,768 to 32,767)</li><li>• UINT (Unsigned Integer) - 2 bytes (0 to 65,535)</li><li>• LONG (Long Integer) - 4 bytes (-2,147,483,648 to 2,147,483,647)</li><li>• LONGBCD (Long Binary Coded Decimal) - 4 bytes (0 to 99,999)</li><li>• REAL (Floating Point) - 8 bytes (-1.7e308 to 1.7e308)</li><li>• STRING (String) - up to 256 bytes</li><li>• SCII (null terminated)</li></ul> Numeric and digital variables have a default value

Field	Description
	of 0 and string variables default to "" (empty string). If you do not specify a data type, the local variable will be treated as 16-bit integer.
<b>Array Size</b>	<p>In the <b>Array Size</b> field (8 characters), enter the size of the array (number of elements) used to store the local variable. The array will be of the data types specified in the <b>Data Type</b> field. The array can be one or two-dimensional.</p> <p>Up to 32766 elements can be used, which, for a two dimensional array, means that the size of the first dimension multiplied by the size of the second is less than or equal to 32766. When specifying a multi-dimensional array, separate the dimensions with a comma, for example "20,30".</p>
<b>Eng Units</b>	The engineering units that the value represents (for example, %, deg, or mm/sec). This property is optional. If you do not specify engineering units, no engineering units are used.
<b>Format</b>	<p>(11 characters). The display format of the value (of the variable) when it is displayed on a graphics page, written to a file, or passed to a function (that expects a string). This property is optional. If you do not specify a format, the format defaults to #####.##.</p> <p>For more information, see <a href="#">Format Specifiers</a>.</p>
<b>Comment</b>	Any useful comment (254 characters).

### Scale Properties

Field	Description
<b>Zero Scale</b>	Enter the value that represents the zero point for the local variable's data (11 characters). The zero scale value is used as the lower limit for trend and bar graphs, and values below the zero scale value will cause an "Out of Range" alert message in the runtime system.
<b>Full Scale</b>	Enter the value that represents the full scale point for the local variable's data (11 characters). The full scale value is used as the upper limit for trend and bar graphs, and values above the full scale value will cause an "Out of Range" alert message in the runtime

Field	Description
	system.

### Project Properties

Property	Description
Project	The project in which the local tag is configured.

## See Also

[Configure Variable Tags](#)

## Refer to Variable Tags

There are a number of ways you can reference the information that is made available by the variables within a Plant SCADA system.

- If a set of variables are configured as an array, see [Refer to Array Elements](#).
- If the elements of a tag are configured as tag extensions, see [Refer to Tag Extensions](#).
- To access a tag associated with an equipment item, see [Use an 'Equipment.Item' Reference](#).
- To browse a list of variable tags at runtime, see [Configure Tag Browsing](#).

## See Also

[Variable Tags](#)

## Refer to Array Elements

Each entry in an array is referred to by an index. You can extract individual variables (from the array) by specifying the tag name and index using the following format:

`<Tag Name>[Index]`

For example, to refer to the third variable of the array "Conveyor\_Speed", use the following syntax:

`Conveyor_Speed[2]`

The index of the first entry in an array is always 0 (zero).

Note the following when using arrays:

- Do not define large arrays, because each time an individual array entry is requested, Plant SCADA reads the entire array from the I/O device. With large arrays, system performance could be reduced.
- The size of the array needs to be less than the maximum request length for the driver used to connect to the I/O device. To determine the maximum request length, refer to the driver documentation.
- Declare digital arrays on a 16 bit boundary. Plant SCADA rounds each digital array down to the nearest 16 bit boundary. Consequently, digits in the array are changed. For example, if you declare an array Test to start

at bit 35, and Plant SCADA starts the array at bit 32. The index to the array also starts at bit 32; Test[0] refers to bit 32, not bit 35.

- Each individual array entry has its own data value for the field, valid and override elements, but the entries within an array share the override and control mode elements, quality and timestamps. Reading the quality or timestamp for an indexed array entry will return the quality or timestamp for the entire array. Writing to the value for an indexed array entry will change the timestamps and quality for the entire array. Changing the override mode and the control mode for an array entry will change it for the entire array.

[Tag Extensions](#)

## Refer to Tag Extensions

You can reference [Tag Extensions](#) in the following ways:

- [Read a Tag Value](#)
- [Write to a Tag Value](#)
- [Set a Tag to Control Inhibit Mode](#)
- [Set a Tag to Override Mode](#)
- [Determine Tag Status.](#)

## See Also

[Refer to Variable Tags](#)

## Read a Tag Value

Data received from the field is represented by the Field and Valid tag elements.

- The **Field** element represents the latest tag field data received from the device.
- The **Valid** element represents the last field data which had "Good" quality.

**Note:** The Valid tag element initially has bad quality. The quality will only become good when the first read request is successfully finished for the tag, which will only occur when the IO device is online and either background polling is enabled, the tag has been subscribed to, or a TagRead has been initiated.

You can access these elements by using a qualified tag reference (a tag referenced by the tag name and the element name, for example 'MyTag.Field'). The following tables describe each of these elements.

## Field Tag Element

Reference Syntax	Plant SCADA Data type	Description
TagName.Field	INT	Implied value of Field element

Reference Syntax	Plant SCADA Data type	Description
	REAL STRING	
TagName.Field.V	INT REAL STRING	Value
TagName.Field.VT	TIMESTAMP	Timestamp of when the value last changed
TagName.Field.Q	QUALITY	Quality
TagName.Field.QT	TIMESTAMP	Timestamp of when the quality last changed
TagName.Field.T	TIMESTAMP	Timestamp of when the element was last updated

## Valid Tag Element

Reference Syntax	Plant SCADA Data type	Description
TagName.Valid	INT REAL STRING	Implied value of Valid element
TagName.Valid.V	INT REAL STRING	Value
TagName.Valid.VT	TIMESTAMP	Timestamp of when the value last changed
TagName.Valid.Q	QUALITY	Quality
TagName.Valid.QT	TIMESTAMP	Timestamp of when the quality last changed
TagName.Valid.T	TIMESTAMP	Timestamp of when the element was last updated

If you determine that the tag value is incorrect because of a sensor or communication becoming inoperative, the

tag value may need to be overridden. The Override tag element is used to store the overridden tag value. For further information, refer to [Set a Tag to Override Mode](#).

## See Also

[Set a Tag to Control Inhibit Mode](#)

### Write to a Tag Value

The tag elements which have read/write access can be modified. However, these elements can only be updated as a whole; writes to an individual element item is not allowed.

The following table shows the result of writing to each of the tag elements:

Element Name	Write allowed	Write Result
Not specified (unqualified tag reference)	Yes	Write to the Field element and propagate the value to the I/O device.
Field	Yes	Write to the Field element and propagate the value to the I/O device.
Valid	No	Will not succeed.
Override	Yes	Write to the Override element.
Override Mode	Yes	Write to the Override Mode element. See the appropriate function references for the available override mode values. <b>Note:</b> When the tag is in Override mode, an unqualified tag reference will refer to the Override element.
Control Mode	Yes	Write to the Control Mode element The Value item can be one of the following: 0 – Control inhibit mode is Off. 1 – Control inhibit mode is On. <b>Note:</b> When Control inhibit mode is On, writing to the Field element is prohibited.
Tag Status	No	Will not succeed.

If you determine that the tag value is incorrect because of a sensor or communication interruption, the tag value

may need to be overridden. The Override element tag element is used to store the overridden tag value. For further information, refer to [Set a Tag to Override Mode](#).

## See Also

[Set a Tag to Control Inhibit Mode](#)

### Set a Tag to Control Inhibit Mode

#### PERFORMING A CONTROL OPERATION WHICH DOES NOT IN FACT OCCUR.

When the tag is put into the control inhibit mode, writing to the Field element value is prohibited. If the system is configured in such a way that it does not give the operator any indication that the tag is in the control inhibit mode, the operator may assume that he is performing a control operation which does not, in fact, occur.

Configure the system in such a way that it provides a visual indication to the operator that a tag is in the control inhibit mode.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

To provide a visual indication to the operator that a tag is in the control inhibit mode the following can be done:

Set any of the following Citect.ini parameters in such a way that control inhibit mode will be indicated by changing the background color or overlaying the numeric or text graphics objects and symbol set objects with a dithered pattern:

- [Page]ControlInhibitDitheringColor
- [Page]ControlInhibitDitheringDensity
- [Page]ControlInhibitTextBackgroundColor

Then set [Page]IgnoreValueQuality parameter to a value of 0 or 2.

Or:

Use the Control Mode element value (0 if the tag is not in the control inhibit mode or 1 otherwise).

Or:

Use the Field element quality Tag Status ControlInhibit bit (1 if the tag is in the control inhibit mode or 0 otherwise).

## Control Mode

Control inhibit mode allows you to prohibit writing to the Field tag element. Setting a tag in Control inhibit mode is applied system wide. Writing to the Field element will be prohibited for each of the I/O data consumers.

Control inhibit mode is controlled by the "Control Mode" element which is described in the following table.

Reference Syntax	Plant SCADA Data type	Description
TagName.ControlMode	INT	Value of Control Mode element.
TagName.ControlMode.V	INT	Value. Allowed values are: 0 – Control inhibit mode is Off. 1 – Control inhibit mode is On. Default value: 0.
TagName.ControlMode.VT	TIMESTAMP	Timestamp of when the value last changed.
TagName.ControlMode.Q	QUALITY	The Control Mode quality is QUAL_GOOD if the tag was put into the control inhibit mode on the primary server and it was propagated to redundant servers. Otherwise the general quality status will be QUAL_UNCR and the extended substatus will be QE_NOT_REPLICATED to indicate that not every redundant server is aware of the fact that the tag is in control inhibit mode.
TagName.ControlMode.QT	TIMESTAMP	Timestamp of when the quality last changed.
TagName.ControlMode.T	TIMESTAMP	Time of when the tag was put in or out of the control inhibit mode (equal to 0 at startup).

**Note:** The quality of tags referenced by items (Tag1.v or Tag1.Field.t) is GOOD and its timestamps are 0 (INVALID TIMESTAMP). Therefore they give no visual indication of any not good quality, error or change in handling state such as control inhibit or override mode regardless of the setting used for the [Page]IgnoreValueQuality parameter.

## See Also

[Set a Tag to Override Mode](#)

### Set a Tag to Override Mode

**PERFORMING A CONTROL OPERATION BASED ON INACCURATE DATA.**

When the tag is put into the override mode, the default tag element value will be equal to the Override element value instead of the Field element value. If the system is configured in such a way that it does not give the operator any indication that the tag is in override mode, the operator may assume that he is seeing the Field element value (live data) and consequently may operate the plant inappropriately.

Configure the system in such a way that it provides a visual indication to the operator that a tag is in override mode.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

To provide a visual indication to the operator that a tag is in the override mode the following can be done:

Set any of the following Citect.ini parameters in such a way that override mode will be indicated by changing the background color or overlaying the numeric or text graphics objects and symbol set objects with a dithered pattern:

- [\[Page\]OverrideDitheringColor](#)
- [\[Page\]OverrideDitheringDensity](#)
- [\[Page\]OverrideTextBackgroundColor](#)

Then set [\[Page\]IgnoreValueQuality](#) parameter to a value of 0 or 2.

Or:

Use the Override Mode element value (0 if the tag is not in the Override Mode or 1,2,3,4 otherwise).

Or:

Use the default or override element quality Tag Status Override bit (1 if the tag is in the override mode or 0 otherwise).

## Using Override Mode

If you determine that the tag value is incorrect because of a sensor or communication interruption, the tag value may need to be overridden. The Override tag element is used to store the overridden tag value.

You can put the tag into the Override Mode which will cause each unqualified tag reference (a tag referenced only by the tag name, for example 'MyTag') in every I/O Data Consumer (Control Client, Trend Server, Alarm server, and so on) to return the Override element. The quality of the tag will indicate that the tag is in override mode.

Tag override is controlled by the Override and Override Mode tag elements. The Override element contains the override value and the Override Mode tag element is used to set the specific override mode.

The following tables describe each of these elements.

## Override Tag Element

Reference Syntax	Plant SCADA data type	Description
TagName.Override	INT REAL STRING	Implied value of Override element
TagName.Override.V	INT REAL STRING	Value
TagName.Override.VT	TIMESTAMP	Timestamp of when the value last changed
TagName.Override.Q	QUALITY	Quality. The Override value has "Good" quality except when it is out of range
TagName.Override.QT	TIMESTAMP	Timestamp of when the quality last changed
TagName.Override.T	TIMESTAMP	Timestamp of when the element was last updated

**Note:** The quality of tags referenced by items (Tag1.v or Tag1.Field.t), is constantly GOOD and its timestamps are constantly 0 (INVALID TIMESTAMP). Therefore they give no visual indication of any not good quality, error or change in handling state such as control inhibit or override mode regardless of the setting used for the [\[Page\]IgnoreValueQuality](#) parameter.

## Override Mode Tag Element

Reference Syntax	Plant SCADA data type	Description
TagName.OverrideMode	INT	Value of Override Mode element.
TagName.OverrideMode.V	INT	Override mode value. See the appropriate function references for the available override mode values.
TagName.OverrideMode.VT	TIMESTAMP	Timestamp of when the value last changed.
TagName.OverrideMode.Q	QUALITY	The Override Mode quality is

Reference Syntax	Plant SCADA data type	Description
		QUAL_GOOD if the tag was put into the override mode on the primary server and it was propagated to any redundant servers. Otherwise the general quality status will be QUAL_UNCR and the extended substatus will be QE_NOT_REPLICATED to indicate that some redundant servers are unaware of the fact that the tag has been overridden.
TagName.OverrideMode.QT	TIMESTAMP	Timestamp of when the quality last changed.
TagName.OverrideMode.T	TIMESTAMP	Time when the tag was put in or out of override mode. (equal to 0 at start up).

## Override Modes

Override Mode Value	Description
0	The override mode is Off.
1	The tag is in static override mode and the override value is initially set to the value of the tag's Field element.
2	The tag is in static override mode and the override value is initially set to the value of the tag's Valid element.
3	The tag is in static override mode and the override will remain at the previously set value of the tag's Override element.
4	The tag is in the dynamic override mode and the override value will continually track the value of the tag's Valid element. The ability to write to the value of the tag's override element is disabled in

Override Mode Value	Description
	this mode.

[Set a Tag to Control Inhibit Mode](#)

### Determine Tag Status

The Tag Status element is used to represent the current status of the tag. The value of this element is affected only for those tag operations that involve a physical device (for example, writing to the Field element will affect the status element, but writing to the Control Mode will not). Tag Status element is reset after I/O server restart. The element value contains a set of bit flags.

The following table describes the Tag Status element:

Reference Syntax	Plant SCADA Data type	Description
TagName.Status	INT	Value of Tag Status element
TagName.Status.V	INT	Value. A set of bit flags representing the following data: - 0x1: Read Pending. - 0x2: Write Pending. - 0x4: Write Successful. - 0x8: Write Unsuccessful. Default value: 0.
TagName.Status.VT	TIMESTAMP	Timestamp of when the value last changed.
TagName.Status.Q	QUALITY	Quality.
TagName.Status.QT	TIMESTAMP	Timestamp of when the quality last changed.
TagName.Status.T	TIMESTAMP	Timestamp of when the element was last updated.

## Use an 'Equipment.Item' Reference

You can reference a variable tag using 'equipment.item' instead of a tag name.

For example, an equipment type named "Motor" includes the item "FailStart". FailStart includes a variable tag definition that links to an I/O point on the physical motor. To refer to this variable tag, you can use "Motor.FailStart" instead of the tag name. (For more information, see [Items](#).)

To do this, use the following syntax:

[Cluster.]Equipment.Item[.ExtItem]

Where:

Cluster	The cluster name (optional).
Equipment.Item	A substitution for a tag name using an "equipment.item" reference.
ExtItem	The <a href="#">Tag Extensions</a> item name (optional). If the item name is not specified, the value of the property is referenced.

This means you can:

- Use equipment.item in place of variable tags in all expression fields in graphic pages.
- Use equipment.item to reference variable tags in Genie and Super Genie substitutions.
- Use equipment.item in the value field to represent a variable tag when associating super genie substitutions via metadata.
- Pass equipment.item to Cicode functions in which the variable tag name is an argument.
- Pass equipment.item to CTAPI functions in which the variable tag name is an argument.

## **WARNING**

### **UNINTENDED EQUIPMENT OPERATION**

If you update the Equipment Name or Equipment Item for a variable tag and restart the I/O Server, these changes will not be automatically reflected in tag references in Equipment.Item syntax within the system. After updating the Equipment or Item name for a tag, restart all servers and clients in the system.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** You can also access alarm data in a similar way. See [Using Alarm Properties as Tags](#).

## **See Also**

[Tag Extensions](#)

## **Configure Tag Browsing**

Tag browsing enables you to browse a list of variable tags owned by a data source at runtime, in the same way that you can with alarm and trend browsing. You can create a tag browsing page in the Graphics Builder that will be available to the runtime operator. The tag browsing page can present any of the following information to the operator:

- Any property available for a [Add a Variable Tag](#), including a newly added equipment field.
- Some fields available from the Cicode functions [TagInfo](#) and [TagInfoEx](#).
- Tags which are in [Set a Tag to Override Mode](#).

- Tags which are in Set a Tag to Control Inhibit Mode.
- The Number of current subscriptions.

Tag browsing enables you to browse to the tag element level only, for example, '.field'. Refer to the [TagBrowseOpen](#) Cicode function for a list of supported fields.

For more details on the above Value, Quality, Timestamp tag elements and sub elements refer to [Tag Extensions](#).

## See Also

[The Browsing Session](#)

[Open a Browsing Session](#)

### The Browsing Session

In order to access the tag information at runtime, the client computer initiates a connection to the servers specifying the browsing session parameters such as required fields and filters. It is possible to open and maintain multiple browsing sessions simultaneously.

Each server in a session prepares a snapshot of its data and sends records in batches to the client. As the server records arrive, the client reconciles them against each other in the event that duplicate or conflicting data arrives from different servers.

The records reconciliation is based on records with the "best device status" which are selected, and the others are discarded.

"Best device status" is calculated as follows:

- Data Source online state (ONLINE is picked over OFFLINE), then
- Data Source active state (ACTIVE is picked over INACTIVE), then
- Data Source priority (higher priority is picked over a lower one, with highest being 1 – for primary I/O device)

If records from different I/O servers fully match on "best device status" the browsing records are taken on the first-come basis. Be aware that there may be project inconsistencies (on different machines) which can affect tag browsing functionality. This can occur if a project is being updated across a number of servers, but only gradually, so there may exist several versions of the project across the network. Tag Browsing will try to reconcile the conflicting data the best way possible, but in such cases check that the returned data is correct.

For each server session the client keeps track of how many records are expected, and what the last record received was. The [TagBrowseNext](#) Cicode function will either cause the client to look at the next cached record which was received earlier and fully reconciled, or request the next batch of records from the I/O servers.

If a communication disruption occurs during the browsing process, or when the client explicitly closes the browsing session, the session will be terminated.

## See Also

[Open a Browsing Session](#)

## Open a Browsing Session

Open a browsing session by using the [TagBrowseOpen](#) Cicode function. The server then builds a snapshot of the data requested (representing the state of the data at the time TagBrowseOpen was called).

A snapshot from a given server contains the same number of records as the number of tags available from all I/O devices. Requesting only the "CLUSTER" field with 10000 tags belonging to three clusters will produce a snapshot with 10000 records where entries Cluster1, Cluster2, Cluster3 will be repeating a number of times.

The snapshot will exist on the server until all the records have been fetched by the client, or the browse session is closed, or an existing connection is lost, or a new connection is established.

When you use the [TagBrowseOpen](#) function you have the option to specify several parameters which will determine which tags will be displayed. These parameters are used to select tags to display in the browsing session.

## See Also

[The Browsing Session](#)

[Specify Browsing Field](#)

[Browsing Filter](#)

[Browsing Clusters](#)

[Specify a Sort Order](#)

## Browsing Filter

A browsing filter can be used to specify the records to return during the browsing session, using a set of predefined field names, shown below, within a regular expressions separated by a semicolon.

For example, consider the following filter:

NAME=Tag\_IO\_\*;TYPE<2

This would request all tags from all clusters where the tag name matches the pattern "Tag\_IO\_\*", and tag type is 0 (DIGITAL) or 1 (INTEGER). If you do not specify a filter string then all tag records will be displayed.

If any of the filter names are invalid, opening a browsing session will not succeed and will return an invalid handle.

## See Also

[The Browsing Session](#)

[Open a Browsing Session](#)

[Specify Browsing Field](#)

[Browsing Clusters](#)

[Specify a Sort Order](#)

## Specify Browsing Field

Fields are specified using a set of predefined field names, separated by a comma. For example,

"TAG,TYPE,ENG\_UNITS". Each browsing record arriving from the server in response to the request will be represented as a list of key-value pairs. At least one field should be specified. If any of the fields are invalid, opening a browsing session does not succeed.

Only the fields explicitly asked for will be available for the [TagBrowseGetField](#) function. The only exception to this are the fields mentioned within the sort order since record sorting takes place on both the server and the client and sorting cannot be done on a field which is not available on the client.

## See Also

[The Browsing Session](#)

[Open a Browsing Session](#)

[Browsing Filter](#)

[Browsing Clusters](#)

[Specify a Sort Order](#)

## Specify a Sort Order

You can optionally include a preferred sort order for the fields returned in the browsing session by including A (ascending) or D (descending). For example, "TYPE:D".

By default tag browsing records are sorted by the tag primary key which is 'Cluster.TagName', which is implicitly appended to the list of sorting fields since the other fields may end up not being unique.

Tag records are sorted on the server and arrive at the client in the order specified by the sort order parameter, or the default sorting order.

## Link Tags to an External Data Source

Linking is an I/O device specific operation. When you add an I/O device to Plant SCADA, you can choose to link it to an external data source (see [Link an I/O Device to an External Data Source](#)).

The external data source is where the tag data was saved when the actual I/O device was programmed. If you link to the external data source, Plant SCADA automatically creates variable tag records for every tag in the I/O device.

These variable tag records are dynamically linked to the tags in the external data source. Plant SCADA can update whenever one of the external tags is changed.

For example, if you change the address of a tag using a third party I/O device programming package, the external data source is changed. Then, when you compile your project in Plant SCADA, the change is copied from the external database to Plant SCADA's variable tags database.

If a tag is linked and you change a field, your change will not be overwritten when the link is next refreshed. Generally, however, any field which takes its value from the external data source is disabled.

---

**Note:** Some properties defined for the external tags will not be relevant to Plant SCADA. Also, some will not be in a format that Plant SCADA can read. Each I/O device has an associated format file in Plant SCADA. It is this file that determines what information is copied to Plant SCADA's variable tags database and how this information is to be converted. In most cases, you will not have to edit this file.

---

## Linked Unity Tags

Note the following for Plant SCADA tags linked to Unity tags:

1. The addition of a new tag on either side, will result in the addition of a new tag on the other side.
2. The deletion of an existing tag on either side, will result in the deletion of the corresponding tag on the other side.
3. The modification of an existing tag on either side, will result in the modification of the corresponding tag on the other side.
4. The delete operation in either Unity or Plant SCADA will take precedence over other operations (such as modify).
5. If there is some contention between the Unity database and the Plant SCADA database for the same tag, that is modifications are done from both databases at the same time, the Unity database item will take precedence over the Plant SCADA database item.
6. The linked I/O Device live update synchronization will be triggered in the following cases:
  - Unity configuration update.
  - Plant SCADA configuration update.
  - Manual refresh.

See [Unity Support Matrixes](#) for information about levels of support between Unity and Plant SCADA.

### Imported Tags

For Unity SpeedLink Dynamic and Static:

Unity PLCs	Unity Data Types	Plant SCADA Protocols	Support Status
QUANTUM	BOOL	Unite	Not Supported
	EBOOL	Modnet	Supported (Except BYTE type)
	BYTE	Modbus	Supported (Except BYTE type)
	WORD	MBPlus	Supported (Except BYTE type)
	DWORD	OPC	Not Supported
PREMIUM	INT	Unite	Supported
	DINT	Modnet	Supported (Except BYTE type)
	UINT	Modbus	Supported (Except BYTE type)
	UDINT	MBPlus	Supported (Except BYTE type)
	REAL	OPC	Not Supported
* Denotes supported by Unity SpeedLink Dynamic only.			

Unity PLCs	Unity Data Types	Plant SCADA Protocols	Support Status
	STRING		
M340	BOOL EBOOL BYTE WORD DWORD INT DINT UINT UDINT REAL TIME * DATE * TOD * DT * STRING	Unite  Modnet  Modbus  MBPlus  OPC	Not Supported  Supported (Except BYTE type)  Supported (Except BYTE type)  Not Supported  Not Supported

**Note:** Plant SCADA recommends that you use the Unity SpeedLink Dynamic driver when importing tags from Unity Pro into a Plant SCADA project.

**Note:** Arrays are supported for every data type except DATE, TOD, DT and STRING data types. For Unity data types marked with \*, Plant SCADA does not have data types that directly match the Unity types. Instead use supported data types and Cicode to convert and simulate those data types.

In addition, the following Unity data types are not supported:

- Structured data types.
- Arrays which are not zero-based.
- Multi-dimensional arrays.
- Arrays of Unity BOOL data type are not supported for all protocols except OPC and will be excluded from the import.

## Alarms

An alarm indicates that an abnormal condition has occurred within your Plant SCADA system. For example, you can configure an alarm to notify you if a piece of hardware is not responding to input commands, or if a variable tag value has moved beyond a specified limit.

Alarms are a fundamental component of a control system, as they indicate to an operator that the system requires attention. When you configure your Plant SCADA system, you should confirm that alarms will be reported to an operator in a way that allows them to respond in an appropriate manner.

### LOSS OF CONTROL

- Do not use Plant SCADA's alarming system as the primary alert mechanism for safety-related alarms or notifications (that is, those classified as critical to process safety, the protection of the plant and equipment, or the protection of human life).
- Do not use Plant SCADA's audible alarm functionality as a replacement for safety-related warning systems critical to process safety, the protection of the plant and equipment or the protection of human life.
- Safety-related alarms and notifications should be independent and separate from the process control system. They should be implemented in the form of a stand-alone physical alarm system driving individual discrete alarm annunciators.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

Plant SCADA supports two types of alarms:

- **Defined alarms**

Defined alarms are added to a project by a system engineer to report specific runtime conditions that require an operator's attention. Each alarm is associated with one or more tags, depending on the type of alarm that has been configured.

See [Defined Alarm Types](#).

- **Hardware alarms**

Plant SCADA regularly runs diagnostic routines to monitor the performance of internal operations associated with any connected peripheral equipment. If the system detects any abnormal conditions, such as an I/O device that is not responding to input commands, a hardware alarm is generated.

See [Hardware Alarms](#).

Plant SCADA monitors a system for the conditions that define an alarm. This is evaluated by an [alarm server process](#), which generates an alarm whenever it detects the conditions that define an alarm.

When the alarm server generates an alarm, it is reported to an operator via the runtime interface. If your project is based on a Plant SCADA starter project, alarms are reported in the following ways:

- The three most recent alarms are displayed on the alarm banner
- Alarm lists and alarm counts are displayed on specific alarm pages
- A historical list of alarms and events is displayed on the Sequence of Events page (see [Events](#)).

For more information, see [Viewing Alarms](#).

You can also add content to your graphics pages that are animated when specific alarm conditions occur (see [Using Alarm Properties as Tags](#)).

Information about alarms is provided in the following sections:

- [Manage Alarms](#)
- [Configure Alarms](#)
- [Action Alarms at Runtime](#)
- [Archive the Alarms History](#)
- [Customize Alarm Pages](#).

## Defined Alarm Types

The following table describes the types of defined alarms you can add to your Plant SCADA project. Within these types, two different processes are used to determine alarm conditions.

- With most alarm types, polling is used to monitor a system for the conditions that define an alarm. The system subscribes to the tags associated with each configured alarm, and polls them at a rate specified by the Citect.ini parameter [\[Alarm\]ScanTime](#).

When a change in value is detected, a notification is sent to the alarm server for processing. The alarm server evaluates each notification against the conditions that define each alarm, and generates an alarm if the conditions are met.

- For time stamped digital alarms, time stamped analog alarms, and double point status alarms, Plant SCADA supports the retrieval of time-stamped data directly from field devices. This is enabled via the Cicode function [AlarmNotifyVarChange](#), or via a set of specific drivers that support the Driver Runtime Interface (see [Retrieving Time-stamped Data from I/O Devices](#)).

---

**Note:** Different types of alarms, even those which are not designated as "timestamped", can retrieve timestamp information from different sources. To avoid any discrepancies in the reporting of alarms, it is recommended that your system uses an accurate clock synchronisation mechanism.

---

Alarm Type	Description
Digital alarms	<p>Digital alarms activate in response to the state of one or two digital variables.</p> <p>When you define the variable tags for a digital alarm, you can precede a tag name with the logical operator "NOT". This specifies that the OFF state (0) is the triggering condition for the variable tag.</p> <p><b>Example</b></p> <p>A digital alarm is configured to activate in response to the following variable tags:</p> <ul style="list-style-type: none"> <li>• Variable Tag A = RFP3_TOL</li> <li>• Variable Tag B = NOT MCOL3043</li> </ul> <p>In this scenario, the alarm is triggered when the state of both variables changes to the active state:</p> <ul style="list-style-type: none"> <li>• RFP3_TOL changes to ON (1)</li> <li>• MCOL304 changes to OFF (0).</li> </ul> <p>You can specify a delay for a digital alarm, which means the alarm only becomes active when the triggering condition spans the duration of the specified delay period.</p> <p>See <a href="#">Add a Digital Alarm</a>.</p>
Time stamped alarms	<p>Time stamped alarms are similar to digital alarms, except that a counter variable is used to provide an external time stamp of when a triggering condition occurs, rather than the poll time. Time stamped alarms can only be associated with a single digital variable.</p> <p>See <a href="#">Add a Time Stamped Alarm</a>.</p>
Analog alarms	<p>Analog alarms are triggered when an analog variable changes beyond one or more specified limits. Each alarm can be configured as any combination of the following types:</p> <ul style="list-style-type: none"> <li>• <b>High</b> and <b>high high</b> alarms - where the value reaches an atypical high</li> <li>• <b>Low</b> and <b>low low</b> alarms - where the value reaches an atypical low</li> <li>• <b>Deviation</b> alarm - where the values move away from a predefined set point</li> </ul>

Alarm Type	Description
	<ul style="list-style-type: none"> <li>• <b>Rate of change</b> alarm - where a dramatic value change occurs within a specified period of time.</li> </ul> <p>See <a href="#">Add an Analog Alarm</a>.</p>
Advanced alarms	<p>An advanced alarm activates when the result of an associated expression changes to true.</p> <p>See <a href="#">Add an Advanced Alarm</a>.</p>
Multi-digital alarms	<p>Multi-digital alarms use the output for up to three digital variables to define eight states. These states represent different combination of true and false values. You can specify which of these states will trigger an alarm.</p> <p>The following eight states represent the possible tag value combinations. The tags are represented in the order tag C, tag B, tag A.</p> <ul style="list-style-type: none"> <li>• State 000 - all 3 tags are false.</li> <li>• State 00A - tags C and B are false, tag A is true.</li> <li>• State 0B0 - tags C and A are false, tag B is true.</li> <li>• State 0BA - tag C is false, tags B and A are true.</li> <li>• State C00 - tag C is true, and tags B and A are false.</li> <li>• State COA - tags C and A are true, tag B is false.</li> <li>• State CB0 - tags C and B are true, tag A is false.</li> <li>• State CBA - all 3 tags are true.</li> </ul> <p>You can indicate whether a particular state will trigger an alarm by applying a value of 1 (indicates an alarm state) or 0 (indicates no alarm will be triggered).</p> <p>See <a href="#">Add a Multi-Digital Alarm</a>.</p>
Time stamped digital alarms	<p>Time stamped digital alarms operate via a process where the alarm server is notified if a value changes to a specified digital variable using the Cicode function <a href="#">AlarmNotifyVarChange</a>.</p> <p>The alarm server uses this information to update alarms that monitor the variable, allowing an accurate time stamp to be associated with an alarm condition.</p> <p>Time stamped digital alarms activate in response to the state of one or two digital variable tags. When you specify the variable tags, you can precede a tag name</p>

Alarm Type	Description
	<p>with the logical operator "NOT". This specifies that the OFF state (0) is the triggering condition.</p> <p>Events trends can be used in conjunction with time stamped digital alarms to provide millisecond accuracy for both trend and alarm data. See the <a href="#">TrnEventSetTable</a> and <a href="#">TrnEventSetTableMS</a> Cicode functions.</p> <p>See <a href="#">Add a Time Stamped Digital Alarm</a>.</p> <p><b>Note:</b> When a time stamped alarm is used in conjunction with some protocols (such as OPC, OFSOPC and DNP3), a time stamp will be pushed from a tag into an alarm without the need to use <code>AlarmNotifyVarChange</code>. See <a href="#">Retrieving Time-stamped Data from I/O Devices</a>.</p>
Time stamped analog alarms	<p>Time stamped analog alarms operate via a process where the alarm server is notified of any value changes to a specified variable using the Cicode function <code>AlarmNotifyVarChange</code>.</p> <p>The alarm server uses this information to update the alarms that monitor the variable, allowing an accurate time stamp to be associated with an alarm condition.</p> <p>Time stamped analog alarms are triggered when an analog variable changes beyond one or more specific limits. Each alarm can be configured as any combination of the following types:</p> <ul style="list-style-type: none"> <li>• <b>High</b> and <b>high high</b> alarms - where the value reaches an atypical high</li> <li>• <b>Low</b> and <b>low low</b> alarms - where the value reaches an atypical low</li> <li>• <b>Deviation</b> alarm - where the values moves away from a predefined set point</li> <li>• <b>Rate of change</b> alarm - where a dramatic value change occurs within a specified period of time.</li> </ul> <p>Events trends can be used in conjunction with time stamped analog alarms to provide millisecond accuracy for both trend and alarm data. See the <a href="#">TrnEventSetTable</a> and <a href="#">TrnEventSetTableMS</a> Cicode functions.</p> <p>See <a href="#">Add a Time Stamped Analog Alarm</a>.</p> <p><b>Note:</b> When a time stamped alarm is used in conjunction with some protocols (such as OPC,</p>

Alarm Type	Description
	OFSOPC and DNP3), a time stamp will be pushed from a tag into an alarm without the need to use AlarmNotifyVarChange. See <a href="#">Retrieving Time-stamped Data from I/O Devices</a> .
Double point status alarms	<p>A double point status alarm responds to eight states in a field device that are represented in Plant SCADA as a single integer tag.</p> <p>For each of the eight states you can specify the following:</p> <ul style="list-style-type: none"> <li>• <b>State Name &lt;n&gt;</b> — a name that identifies the condition that the state represents.</li> <li>• <b>State Type &lt;n&gt;</b> — the action that occurs when the device transitions to a defined state.</li> </ul> <p>See <a href="#">Add a Double Point Status Alarm</a>.</p> <p><b>Note:</b> When a double point status alarm is used in conjunction with some protocols (such as OPC UA, IEC870IP or DNP3), a time stamp will be pushed from a tag into an alarm (see <a href="#">Retrieving Time-stamped Data from I/O Devices</a>). Alternatively, you can trigger a double point status alarm using the Cicode function <a href="#">AlarmNotifyVarChange</a>.</p>

For more information on adding defined alarms to a Plant SCADA project, see [Configure Alarms](#).

## Hardware Alarms

Hardware alarms notify an operator of circumstances such as:

- Interrupted communication to a device
- An inoperative server
- Cicode not executing.

Hardware alarms are fully integrated in Plant SCADA, which means there is no need to manually configure them in a project. However, you need to carefully consider how they are reported to an operator.

If your project is based on one of the Plant SCADA starter projects, a hardware alarm count can be viewed on the alarm banner, and a list is displayed on the dedicated hardware alarms page.

---

**Note:** Do not allow your system to have any recurring hardware alarms.

There are two hardware alarm fields that are not always shown on the hardware alarms pages. ERRPAGE will display the name of the page that was displayed when the error was detected. This is useful for finding errors caused by improperly programmed animations. ERRDESC provides information that is specific to the type of the alarm. For example, if the alarm is an I/O Device error, ERRDESC shows the name of the device.

---

**Note:** A timeout applies on hardware alarms, so that old hardware alarms will be inactive as per [\[Alarm\]HardHoldTime](#) parameter. Unlike configured alarms, all inactive hardware alarms will be removed immediately.

---

## Hardware Alarms for Certificates

The Hardware Alarms page displays hardware alarms when a secure connection cannot be established due to certificates. Some scenarios where a hardware alarm may be generated include the following.

- The binding certificate is inaccessible because of incorrect permissions.
- The chain of trust to the binding certificate is not valid.
- A client cannot trust the certificate with which a server's connections is signed.
- A certificate's common name check is unsuccessful or other policy errors are encountered.

To rectify these alarms, check the error logs and if required contact your network administrator. See [Troubleshooting Certificate Error Messages](#).

## Alarm Server Process

An alarm server process is responsible for evaluating the conditions that define an alarm.

The I/O server sends a notification to the alarm server process each time the value changes for a variable tag that is associated with an alarm. If a notification results in an alarm condition occurring, the alarm server process will generate an alarm.

An alarm server process evaluates the notifications it receives from an I/O server at a rate that is double that used by the I/O server to poll the variable tags (that is, the rate set by the Citect.ini parameter [\[Alarm\]ScanTime](#)).

For information on how to add an alarm server process to a project, see the topic [Add an Alarm Server Process](#).

A Plant SCADA system can have more than one alarm server process. Multiple alarm server processes may be required in the following circumstances:

- Redundant systems – alarm servers can be paired and synchronized so alarm data remains online if a primary server becomes inactive (see [Alarm Server Redundancy](#) in the chapter on [Redundancy](#))
- Clustered systems – multiple alarm servers can be added to a distributed system that includes multiple clusters (see [Clusters](#)).

If required, you can also configure an alarm server to operate in **Extended Memory** mode. This allows the alarm server process to utilize memory beyond a 4GB limit. It does this by running the process in 64 bit.

---

**Note:** When operating in Extended Memory mode, an alarm server process does not support the following:

- ActiveX objects
  - Calls from CitectVBA
  - Cicode functions or alarm expressions that call a DLL compiled in 32 bit.
- 

Extended Memory mode enables efficient query handling under the following circumstances:

- On systems with a large archive of historical alarm data
- On high-capacity systems that can generate a large number of alarms.

To enable this mode of operation, you need to set the alarm server's **Extended Memory** property to TRUE (see [Add an Alarm Server Process](#)). You also need to recompile your project and restart the runtime system for the change to take effect.

## See Also

[Manage Alarms](#)

## Viewing Alarms

If you create a project using one of Plant SCADA's starter projects, the following components will be available to monitor alarms at runtime.

- [Alarm Pages](#)
- [Alarm Banner](#)
- [Alarm Equipment Tree](#).

These components are automatically added to a project as they are included in the templates on which a starter project is based. This is the case for both the Tab Style Templates and the SxW Style Templates.

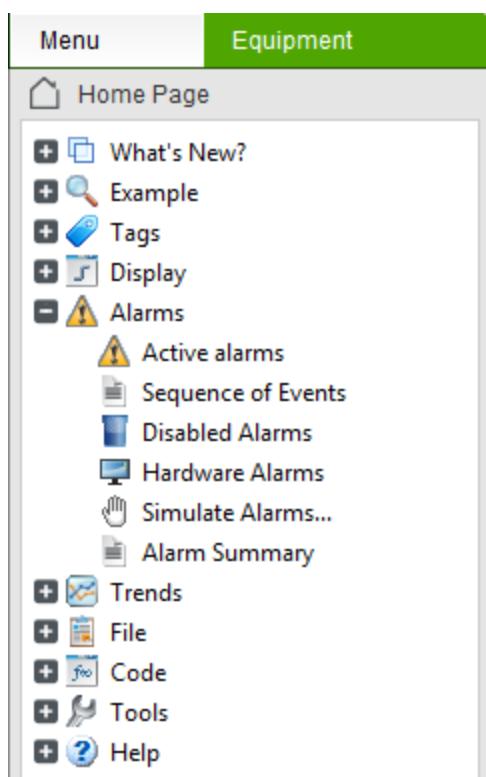

## Alarm Pages

Alarm pages present a list of alarms to an operator. There are different types of alarm pages, each designed to suit a specific purpose. For example, an alarm page may only display alarms that are currently active, or it may include a historical summary of all alarms that have occurred.

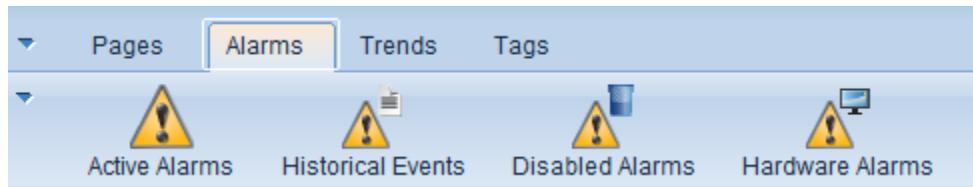

---

**Note:** For information about the alarm pages that are available in a project based on a Situational Awareness Starter Project, see the topic [Default Alarm Pages](#).

Viewing alarm pages at runtime varies according to the templates used to create the alarm pages. For example, if your project uses the SxW templates the Alarm pages are automatically included in the runtime system available from the list of alarm pages in the **Menu** panel.

If your project is based on a Tab Style starter project, you can access the Alarms page at runtime via the **Alarms** tab.

The following alarm pages will be available at runtime:

## Active Alarms Page

The Active Alarms page displays all alarms that are unacknowledged, or acknowledged and still in an alarm state. The active state of a digital alarm is ON, while the active state of an analog alarm varies, depending on how the alarm is configured. For example, the alarm state could be HIGH, LOW, or so on.

By default, the following columns are displayed:

- **Date** — the day on which the alarm occurred
- **Time** — the time at which the alarm occurred
- **Tag** — the tag associated with the alarm (if applicable)
- **Name** — the name of the tag associated with the alarm (if applicable)
- **State** — the current state of the tag associated with the alarm
- **User Comment** — a comment attached to the alarm at runtime (see [Add a Comment to the SOE Page](#)).

You can also include additional columns that display information such as specific alarm property values or quality

flags (see [Add a Column to an Alarms List](#)).

When an alarm is selected, you can perform the following actions:

- **Acknowledge** the alarm (see [Acknowledge Alarms](#))
- **Disable** the alarm (see [Disable Alarms](#))
- **Disable for** a specified number of hours (see [Shelve Alarms](#))
- **Disable until** a specified date and time (see [Shelve Alarms](#))
- View **Information** about the alarm.

## Hardware Alarms Page

The Hardware Alarms page displays a list of any hardware alarms that are unacknowledged, or acknowledged and still in alarm state.

The following columns are displayed:

- **Tag** — the tag associated with the alarm (if applicable)
- **Name** — the name of the tag associated with the alarm (if applicable)
- **Description** — a description of the hardware alarm
- **Source** — a description of the location where the error originated . For example, it could be the name of a page or a Cicode function.
- **Error Details** — Additional information that is specific to the error.

When a hardware alarm is selected, you can perform the following actions:

- **Acknowledge** the alarm (see [Acknowledge Alarms](#)).

## Disabled Alarms Page

The Disabled Alarms page displays a list of alarms that are disabled in the system for reasons such as a maintenance shutdown.

By default, the following columns are displayed:

- **Date** — the day on which the alarm occurred
- **Time** — the time at which the alarm occurred
- **Tag** — the tag associated with the alarm (if applicable)
- **Name** — the name of the tag associated with the alarm (if applicable)
- **State** — the current state of the tag associated with the alarm
- **User Comment** — a comment attached to the alarm at runtime (see [Add a Comment to the SOE Page](#)).

You can also include additional columns that display information such as specific alarm property values or quality flags (see [Add a Column to an Alarms List](#)).

When an alarm is selected, you can perform the following actions:

- **Enable** the alarm (see [Disable Alarms](#))

- View [Information](#) about the alarm.

## Alarm Summary Page

The Alarm Summary page displays a historical log of alarms that you can use for long term analysis and troubleshooting. It displays the date and time each alarm reached ON state and OFF state.

**Note:** The alarm summary includes historical data, which means you should manually refresh the page to view the latest events before you analyze the data it includes.

By default, the following columns are displayed:

- **Tag** — the tag associated with the alarm (if applicable)
- **Name** — the name of the tag associated with the alarm (if applicable)
- **On Date** — the day on which the alarm reached an ON state
- **On Time** — the time at which the alarm reached an ON state
- **Off Date** — the day on which the alarm reached an OFF state
- **Off Time** — the time at which the alarm reached an OFF state
- **Delta Time** — the difference between OFF time and ON time
- **Sum State** — the state of the tag associated with the alarm when it occurred
- **User Comment** — a comment attached to the alarm at runtime (see [Add a Comment to the SOE Page](#)).

You can also include additional columns that display information such as specific alarm property values or quality flags (see [Add a Column to an Alarms List](#)).

When an alarm is selected, you can perform the following actions:

- **Acknowledge** the alarm (see [Acknowledge Alarms](#))
- Add a **Comment**
- **Disable** the alarm (see [Disable Alarms](#))
- **Disable for** a specified number of hours (see [Shelve Alarms](#))
- **Disable until** a specified date and time (see [Shelve Alarms](#))
- **Enable** a disabled alarm (see [Enable a Disabled Alarm](#))
- View [Information](#) about the alarm.

## Sequence of Events (SOE) Page

The Sequence of Events (SOE) page displays a historical view of all system events that have occurred. In the case of alarms, an event is logged when an alarm changes state, or when an alarm is enabled or disabled.

By default, the following columns are displayed:

- **Date** — the day on which the event occurred
- **Time** — the time at which the event occurred
- **Tag** — the tag associated with the event (if applicable)
- **Name** — the name of the tag associated with the event (if applicable)

- **Message** — a message describing the event
- **State** — the current state of the tag associated with the event
- **Classification** — the type of event (see Events)
- **User Name** — the name of the user that initiated the event (including "System")
- **User Location** — the IP address or computer name of the client computer that generated the event.

You can also include additional columns that display information such as specific alarm property values or quality flags (see Add a Column to an Alarms List).

**Note:** You can only use the **Date**, **Time** and **Milliseconds** columns to sort the SOE page (see [Sort Alarms](#)).

When an event is selected, you can perform the following actions:

- Manually add an event (see Add an Event to the SOE page)
- Add a comment to an event (see Add a Comment to the SOE page)
- View **Information** about the alarm.

Information included on the alarm pages is presented in a table. This allows you to make simple runtime changes to the page, as you can adjust, rearrange and remove columns (see [Add a Column to an Alarms List](#)).

Each alarm page supports a variety of built in features that an operator can use at runtime. For example, if you used a starter project an operator will be able to perform the following tasks:

- Acknowledge alarms
- Enable and disable alarms
- Shelve alarms
- Filter an alarms list
- Sort an alarms list
- Change the fields displayed in an alarms list
- View a count of the active and disabled alarm on all pages
- Add user events to a sequence of events.

For more information, see [Action Alarms at Runtime](#).

## See Also

[Alarm Banner](#)

[Alarm Equipment Tree](#)

### Alarm Banner

An alarm banner is a reduced version of the active alarms page that displays three alarms. If you use a starter project as the foundation of your Plant SCADA project, the alarm banner is displayed at the top of the runtime view for the system.

	10/04/2014 04:30:00 PM PLT_LINE1_PM800\MSSTAT1\MaxW	Plant Mixer Peak Demand N...
	10/04/2014 04:30:00 PM PLT_LINE2_PM800\MSSTAT1\MaxW	Plant Bottler Peak Demand N...
	10/04/2014 04:25:46 PM PLT_LINE2_PM800\PDT_MSSTAT1\AvW	Plant Bottler Predicted Peak...

The alarm banner that is included in the starter project based on the SxW templates.

This means the alarm banner appears as a permanent feature of the runtime interface, allowing an operator to be alerted to alarm conditions even if an alarm page is not displayed.

The alarm banner also includes alarm counts that summarize the current activity for a number of alarm types including active alarms, unacknowledged alarms and disabled alarms. Alarm counts are created using the Cicode function `AlarmCount`.

	20	22/04/2014 03:27:50 PM PLT_LINE2_PM800\PDT_MSSTAT1\AvW
	25	11/04/2014 02:15:00 PM PLT_LINE1_PM800\MSSTAT1\MaxW
	3	22/04/2014 03:28:50 PM Entry_Fault_Multi

Alarm counts.

The Alarm Banner allows an operator to perform the following actions at runtime:

- Acknowledge an alarm
- Disable an alarm
- Display information about an alarm.

For more information, see [Action Alarms at Runtime](#).

## See Also

[Alarm Pages](#)

[Alarm Equipment Tree](#)

## Alarm Equipment Tree

If you use a starter project as the foundation of your Plant SCADA project, an alarms equipment tree will automatically be included on the following alarm pages:

- Active Alarms
- Sequence of Events
- Disabled Alarms
- Alarms Summary.

The equipment tree displays in a panel to the left of these alarm page. It allows you to locate the alarms listed on the current page within the system's equipment hierarchy.

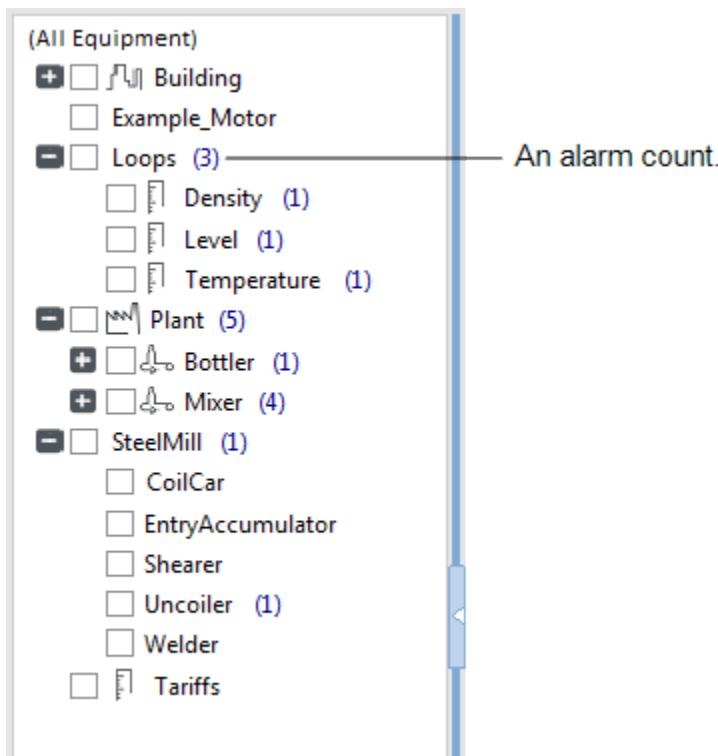

On the Active Alarms and Disabled Alarms pages, an alarm count is applied to each branch of the equipment

tree. If a value appears next to a branch, it indicates the number of alarms from the current list that are included within the branch.

If you would like the alarm count to include alarms defined for the equipment and the equipment it references set the Including Reference.parameter to 1 when configuring the AlarmCountEquipment Cicode function.

**Note:** The Alarm Summary page will not list the alarms belonging to referenced equipment.

The example below shows the equipment tree on the Active Alarms page.

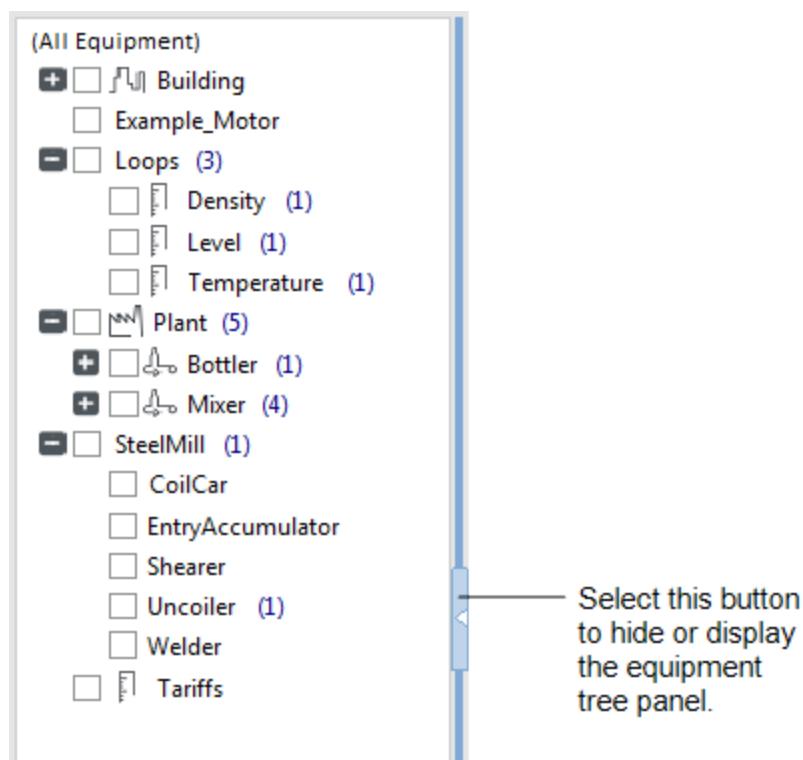

Observe that the alarm count on the "Loops" branch is displaying the value "3", which represents the total number of the alarms included within the branch.

**Note:** The Alarm Summary and Sequence of Events pages will not include alarm count information on the equipment tree as they present historical data.

You can create your own alarm counts using the Cicode function AlarmCount.

The alarm equipment tree allows an operator to perform the following actions at runtime:

- Filter the alarms list by selecting the check boxes to the left of each branch
- Hide and display the equipment tree panel.

Select this button  
to hide or display  
the equipment  
tree panel.

[Alarm Pages](#)

[Alarm Banner](#)

## Events

Events provide notification of occurrences within a Plant SCADA system that do not require any action to be taken. Examples of such occurrences could include a particular user logging on, or an alarm being acknowledged.

The events that are generated by a Plant SCADA system are grouped according to the following classifications:

- **Action** — events that log an action performed on an alarm by an operator
- **<Alarm Type>** — events associated with a particular type of alarm (for example, ON, OFF and ACK transitions)
- **System** — events that represent an occurrence that affects the entire system, such as the server being stopped and restarted
- **Configuration** — events that occur when configuration changes are loaded (for example, alarm tags being added or removed)
- **Comment** — events that indicate when a user adds a comment to the sequence of events (see [Add a Comment to the SOE Page](#))
- **Interface Events** — events that indicate when a user adds an event to the sequence of events (see [Add an Event to the SOE Page](#)).

Events can be viewed at runtime via the Sequence of Events (SOE) page (see [Alarm Pages](#)).

---

**Note:** Plant SCADA also supports triggering events that allow you to initiate a particular action when a specified set of circumstances occurs. For more information on this type of event, see [Triggering Events](#).

---

## Manage Alarms

You should carefully consider alarm management when you configure a Plant SCADA project, as it could determine if an operator is able to respond to all the alarms that a system generates.

When an operator receives an alarm notification, there are several actions they may need to perform. These include:

- Acknowledge the alarm
- Navigate to the relevant system data
- Analyze the data
- Perform the required actions
- Confirm that the alarm condition is resolved.

If a system generates alarm notifications at a rate that does not allow the operator enough time to perform these tasks, it raises the possibility of alarms being missed.

There are guidelines on the number of alarms which can be successfully managed by an operator. For example, the ISA 18.2 Alarm Management standard provides metrics regarding manageable average alarm rates. It suggests that an average of one alarm per ten minutes is very likely to be acceptable, with a maximum manageable level of two alarms per ten minutes.

The following topics include information you can use to keep the alarms in your system at a manageable level:

- [Prioritize Alarms](#)
- [Categorize Alarms](#)
- [Provide Cause and Response Information to Operators](#)
- [Use Alarm Indicators](#)
- [Set the Alarm Scan Rate](#).

If required, you can also configure an alarm server to operate in **Extended Memory** mode. This allows the alarm server process to utilize memory beyond a 4GB limit. For more information, see [Alarm Server Process](#).

### Prioritize Alarms

During periods of high activity, a control system can generate a large number of alarms within a short period of time. If you prioritize the alarms in your Plant SCADA system, you can indicate to an operator which alarms they should address first.

There are two things to consider when you plan alarm priorities:

- The severity of the consequence that could occur if the operator does not take the appropriate corrective action to the alarm
- The amount of time that the operator has available, compared to the amount of time that it would take to perform a corrective action.

Alarm management standards provide guidelines on how to effectively prioritize alarms in a control system. For example, the EEUMA 191 standard recommends that three alarm priorities should be used within one alarm display.

However, if your control system incorporates more than one alarm system (for example, if your site includes a separate fire or gas alarm panel), it is recommended that the alarm priorities you use are consistent with any existing systems.

Alarm priorities are managed in Plant SCADA through alarm categories. Each alarm category can be assigned a priority value (from 1 to 255), which can be used to determine the order in which alarms are displayed, acknowledged and enabled.

If required, you can configure optional display properties for an alarm priority that will allow you to:

- Specify a name for a priority value to provide a meaningful representation of its purpose.
- Define background and foreground colors that provide a visual representation of priority on a graphics page.
- Associate Genies with a priority that you can use as an alarm flag or icon.

These additional properties are configured in the **Setup** activity (see [Configure Display Properties for an Alarm Priority](#)).

You can also [Create Priority and State Symbols for an Alarms List](#).

## See Also

[Categorize Alarms](#)

### Categorize Alarms

Alarm categories allow you to group the alarms in your Plant SCADA system. They are a key part of an alarm management strategy, as the priorities that are applied to alarms are implemented through the alarm categories you create (see [Prioritize Alarms](#)).

When you create an alarm category, you can define the following settings for all the alarms that are added to the category:

- The priority applied to an alarm
- The font that is used when an alarm displays
- The formatting that is used when an alarm displays
- The action that is triggered (via a Cicode expression) when an alarm reaches a specified status (on, off or acknowledged)
- The logging that occurs for an alarm.

Alarms can also be filtered and sorted based on their category.

A Plant SCADA project can support up to 16376 alarm categories. Each individual alarm category is represented by a numeric value. There are three special cases:

- Category 0 is reserved as a default category
- Category 254 is reserved for user-created alarm summary entries
- Category 255 is reserved for hardware alarms.

You can also create a label to refer to an alarm category. This allows you use a meaningful name to identify the category instead of a numeric value. When you define a label for an alarm category, the label's **Expression** field should include the numeric value associated with the category you would like the label to represent. For more information, see [Define a Label](#).

## See Also

[Add an Alarm Category](#)

## Provide Cause and Response Information to Operators

Plant SCADA allows you to associate cause and response information with an alarm tag. This means you can describe the circumstances that are likely to cause an alarm, and the appropriate course of action required to address the alarm. This information can then be presented to an operator at runtime.

The properties you can associate with an alarm tag include:

- **Cause** — a description of the cause of an alarm.
- **Response** — a description of the appropriate response to an alarm.
- **Response Time** — the period of time in which the specified response needs to be acted upon.
- **Consequence** — a description of the likely outcome if the suggested response is not acted upon within the specified response time.

You can configure up to eight sets of cause and response properties for each alarm tag.

This information is presented to an operator at runtime using the following Cicode functions:

- [AlarmGetDsp](#)
- [AlarmGetFieldRec](#)
- [AlmBrowseGetField](#).

For example, you could use the following Cicode to retrieve cause and response information from a displayed alarm list:

```
// Example of getting alarm responses from an Animation Number of a displayed alarm list
FUNCTION GetAlarmResponsesForAN(INT AN)
    INT i;
    STRING cause, response, time, consequence;
    INT Count = AlarmGetDsp(AN, "ResponseNum");
    FOR i = 1 to Count DO
        cause = AlarmGetDsp(AN, "Cause" + IntToStr(i));
        response = AlarmGetDsp(AN, "Response" + IntToStr(i));
        time = AlarmGetDsp(AN, "RespTime" + IntToStr(i));
        consequence = AlarmGetDsp(AN, "Consequence" + IntToStr(i));
        // DO something with the retrieved fields
        // ...
    END
END
```

If your project is based on the SxW or Tab Style templates, you can also view cause and response information at runtime via the Cause and Response dialog. See [Display Cause and Response Information](#).

To specify cause and response information for an alarm tag, you need to use the **Alarming** view in the **Setup** activity. See [Add Cause and Response Information to Alarms](#).

## Use Alarm Indicators

Alarm indicators consist of a border and flag that appear around the extent of an object group or Genie. You can use them to provide a prominent visual indication of alarm occurrences at runtime.

### Alarm border

An alarm border will appear around an object group or Genie when an associated alarm state occurs.

### Alarm flag

An alarm flag provides additional information about an alarm by presenting:

- a flag color
- a flag shape
- a flag code that can indicate the alarm priority or the alarm type.

The example below shows the shape, color and flag codes that are used to indicate emergency alarms, high priority alarms and low priority alarms in a project created from the Situational Awareness Starter Project.

If you need to configure your own alarm flags, see [Create a Custom Flag for an Alarm Indicator](#).

As well as using color to indicate the priority of an alarm, the appearance of an alarm indicator can be used to determine the current state of an alarm. For example, if an alarm is unacknowledged, the indicator will flash. For more information, see [Alarm States](#).

You can position an alarm flag at a number of locations around the outside of an object's alarm border. To indicate a specific alarm state, an alarm indicator may flash or display a lighter version of a color.

To configure an alarm indicator for an object group or Genie, you need to perform the following tasks:

1. Confirm that the required alarm priorities are assigned to an alarm category. See [Categorize Alarms](#).
2. Define the display properties for the alarm priorities that an indicator will represent. See [Configure Display Properties for an Alarm Priority](#).

3. For each object group or Genie, define the Alarm Indicator properties in Graphics Builder. See [Alarm Indicator](#).

## See Also

[Prioritize Alarms](#)

## Alarm States

Five alarm states can be represented by an alarm indicator:

1. **Normal** — no alarms are active.
2. **On Unacknowledged** — an active alarm has not been acknowledged.
3. **On Acknowledged** — an active alarm has been acknowledged.
4. **Off Unacknowledged** — the object has gone in and out of an alarm state without being acknowledged.
5. **Shelved** — the alarm is currently shelved (which means it is disabled for a specified period of time).

These five state are demonstrated in the following table. The examples show the default appearance of emergency priority alarms in a project based on the Situational Awareness Starter Project. For other priorities, the color and flag shape would be different (see [Use Alarm Indicators](#)).

State	Example	Behavior
Normal		<ul style="list-style-type: none"><li>• No alarms are active.</li></ul>
On Unacknowledged		<ul style="list-style-type: none"><li>• The alarm border and flag are shown around the object.</li><li>• The border and flag both flash between colored and white fill.</li></ul>
On Acknowledged		<ul style="list-style-type: none"><li>• The alarm border remains around the object, but is filled with half-intensity color.</li><li>• The alarm flag retains its usual appearance.</li><li>• There is no flashing for either element.</li><li>• If the alarm condition clears, the object returns to normal state.</li></ul>

State	Example	Behavior
Off Unacknowledged		<ul style="list-style-type: none"> <li>The alarm border appears around the object filled with half-intensity color.</li> <li>The alarm flag retains its usual appearance.</li> <li>The alarm flag flashes.</li> <li>The alarm border does not flash.</li> </ul>
Shelved		<ul style="list-style-type: none"> <li>A white alarm border is shown with a generic alarm flag symbol; this is shown while alarms are shelved for the object (that is, temporarily disabled).</li> </ul>

## See Also

[Create a Custom Flag for an Alarm Indicator](#)

### Create a Custom Flag for an Alarm Indicator

An [Use Alarm Indicators](#) includes a flag that can be used to reflect the priority and current state of the most critical active alarm.

By default, this flag is constructed from the following set of Genies:

- One Genie for each alarm priority that is flagged
- One Genie for the Disabled/Shelved alarm mode.

To create a custom flag for an alarm indicator, you need to create the required Genies and assign them to the associated alarm priority or alarm mode.

#### Create a Genie to use as a flag

The Genie requires a root level object named "Shape".

- In Graphics Builder, create a new Genie.
- Add the object you would like use as an alarm flag.
- Display the Properties dialog for the object.
- On the **Appearance | General** tab, select **Filled**.

**Note:** If you are configuring a Genie for the Disabled/Shelved alarm mode, set the fill color you would like to use on the **Appearance | General** tab. You can then skip step 5 as the Genie will not need to change color.

5. On the **Fill | Color** tab, configure the following:
  - Set the **Type** to **Array**.
  - Enter the following **Array Expression**:

```
 dspAnGetMetaData(dspGetAnCur(), "State")
```
  - Specify the **Array Colors** you want to use for 1 – 3, based to the following states:
    - 1 = On and Unacknowledged
    - 2 = Off and Unacknowledged
    - 3 = On and AcknowledgedYou can configure flashing colors via the [Edit Favorite Colors Dialog Box](#), which is accessible via the **Edit** button on the Color Picker.
6. On the **Access | General** tab, enter the **Name** "Shape".
7. On the **Metadata | General** tab, enter the following items:
  - Name: Equipment; Value: <blank>
  - Name: Label; Value: <blank>
  - Name: State; Value: 0

---

**Note:** If you are configuring a Genie for the Disabled/Shelved alarm mode, replace "Name: State; Value: 0" with "Name: Priority; Value: <blank>".
8. Click **OK**.

Alarm flag Genies use functionality provided by the Cicode function DspSym. You need to perform the remaining steps to enable DspSym support for the Genie.

1. Display the Page Properties for the Genie. To do this:

On the **File** menu, select **Properties**.

Or:

Right-click on the Genie background and select **Page Properties**.

2. On the Page Properties dialog, select **I want to use this Genie with the Cicode function DspSym**.
  3. Click **OK**.
  4. Save the Genie to a library.
- 

**Note:** When saving an alarm flag Genie, use a name that is unique across all included projects that share the same primary project.

## Add a text label

The Genie can also include an optional text label. The procedure described below adds a text label that displays the **Short Name** specified for an Alarm Priority.

1. Add a text object to an alarm flag Genie.
2. Display the Text Properties dialog.
3. On the **Appearance | Display Value** tab, configure the following:
  - Set the **Type** to **Numeric**. This will allow you to specify the number of characters used for the text label.
  - Select the required **Format** for the label.

This should reflect the number of characters used for the **Short Name** specified in the Alarm Priority properties.

- Enter the following **Numeric Expression**:

```
dspGetMetaDataFromName( ".Shape", "Label" )
```

4. On the **Fill|Color** tab, configure the following:

- Set the **Type** to **Array**.

- Enter the following **Array Expression**:

```
dspGetMetaDataFromName( ".Shape", "State" )
```

- Specify the **Array Colors** you want to use for 1 – 3, based to the following states:

1 = On and Unacknowledged

2 = Off and Unacknowledged

3 = On and Acknowledged

5. Click **OK**.

6. Save the Genie.

### Associate a Genie with an alarm priority

1. In Plant SCADA Studio's **Setup** activity, select **Alarming**.
2. On the menu below the Command Bar, select **Alarm Priorities**.
3. Locate the Alarm Priority you would like to associate with a Genie.
4. In the **Genie Name** field, enter the name of the Genie you would like to associate with the alarm priority.
5. In the **Library Name** field, enter the name of the library that includes the Genie.
6. Click **Save**.

### Associate a Genie with the Shelved/Disabled alarm mode

1. In Plant SCADA Studio's **Setup** activity, select **Alarming**.
2. On the menu below the Command Bar, select **Alarm Modes**.
3. Locate the Shelved/Disabled mode in the **Display Name** column.
4. In the **Genie Name** field, enter the name of the Genie you would like to associate with the alarm mode.
5. In the **Library Name** field, enter the name of the library that includes the Genie.
6. Click **Save**.

### Example

The default alarm flag Genies that are provided with Plant SCADA are located in the SA\_Include project in a library called "sa\_priorities". They are named as follows:

- Priority 1 – "sa\_p1\_normal"
- Priority 2 – "sa\_p2\_normal"
- Priority 3 – sa\_p3\_normal"
- Disabled/Shelved – "sa\_disabled\_normal".

## See Also

[Use Alarm Indicators](#)

## Set the Alarm Scan Rate

You can use the Citect.ini parameter [\[Alarm\]ScanTime](#) to adjust the rate at which the alarm server receives updates from the I/O server. By default, the rate is set to 500 ms. This means the minimum time between alarm transitions will be 500 ms.

If you increase the scan time setting, it reduces the subscription rate used to poll tags that are associated with alarms. This may reduce the load on the I/O server. Be aware, however, that this will only work if no other servers have subscribed to a device at a higher rate.

## See Also

[Alarm Server Process](#)

## Configure Alarms

You can add alarms to a project that allow specific conditions to be brought to an operator's attention at runtime (see [Alarms](#)).

There are two ways to add configured alarms to a Plant SCADA project:

- Use Equipment Editor to generate alarms that are a part of the hierarchical architecture defined for the equipment in your system (see [Use Equipment Editor to Configure Alarms](#))
- Using the System Model activity in Plant SCADA Studio to add defined alarms (see [Use Plant SCADA Studio to Configure Alarms](#)).

## See Also

[Using Alarm Properties as Tags](#)

## Use Equipment Editor to Configure Alarms

Alarms can be added to a Plant SCADA system using the [Equipment Editor](#). This will incorporate the alarms you create into the hierarchical architecture defined for the equipment in your system.

When you define an equipment type in Equipment Editor, you can associate alarms with the items it includes. These alarms are passed through to each instance of the equipment type, and the required alarm tags are generated when an equipment update is run. Any changes to an equipment type can also be instantiated across all existing instances of the associated equipment.

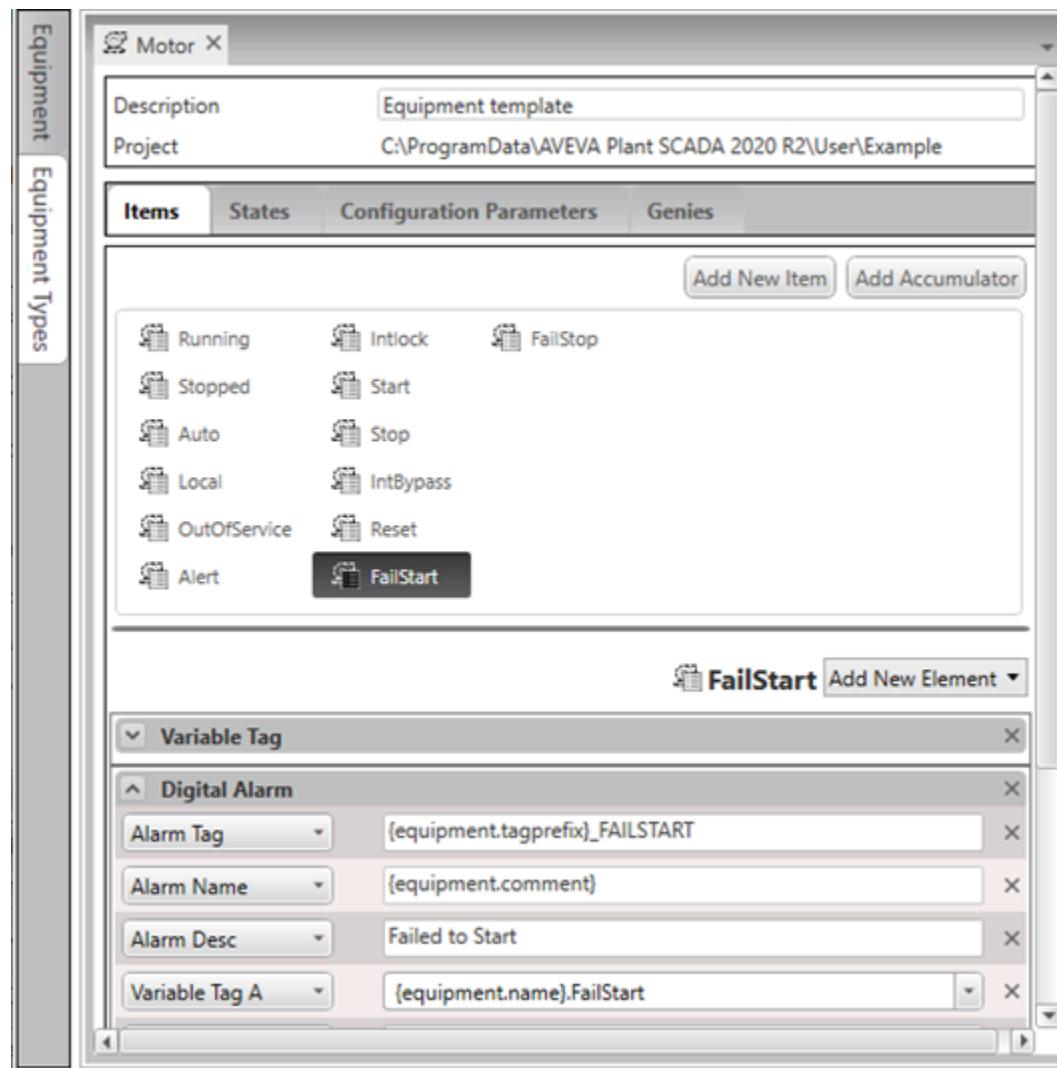

**UNINTENDED EQUIPMENT OPERATION**

On updating the Equipment Name or Equipment Item for an alarm, the update will not be reflected on the client side until the alarm servers have been restarted. The reload procedure will indicate a reload error on Runtime Manager. Reloadlog.dat and Syslog.dat of the server process will show the details of the unsupported changes. You can use this information to revert the changes, or restart all servers after deploying your updated project.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

## Example

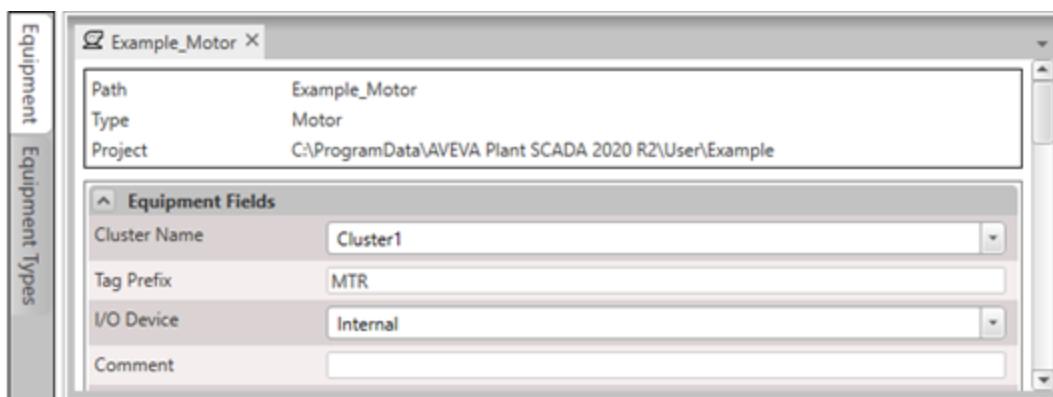

The following example shows the Equipment Editor displaying the configuration for an equipment type named "Motor".

The "FailStart" item includes a digital alarm as one of its elements, and the **Alarm Tag** property is defined as follows:

{equipment.tagprefix}\_FAILSTART

An instance of this equipment type named "Example\_Motor" is created.

The **Tag Prefix** property (which is referenced by the **Alarm Name** property in the associated equipment type) is defined as "MTR". This means a digital alarm called "MTR\_FAILSTART" will be generated when an equipment update is run.

The Digital Alarms grid will display the corresponding alarm record.

System Model		Equipment	Variables	Alarms	Trends	Accumulators	SPC	
		Save	Discard	Copy	Paste	Delete Row(s)	Export All	Import All
<b>Digital Alarms</b>								
Row	Equipment	Item Name	Alarm Tag	Alarm Name	Cluster Name			
71	Plant.Bottler.Filler	Fault	Bottler_Filler_FAULT	Bottler Filler Fault	Cluster1			
72	Plant.Bottler.Capper	Fault	Bottler_Cap_FAULT	Bottler Capper Fault	Cluster1			
73	Plant.Bottler.Labeller	Fault	Bottler_Label_FAULT	Bottler Labelller Fa	Cluster1			
74	Example_Motor	FailStart	MTR_FAILSTART		Cluster1			
75	Example_Motor	FailStop	MTR_FAILSTOP		Cluster1			

Alarm properties generated by the Equipment Editor that are read-only appear as gray text, which indicates that they cannot be manually updated in Plant SCADA Studio.

**Note:** You can also associate defined alarms with equipment using Plant SCADA Studio. See [Associate an Alarm with Equipment](#).

## Use Plant SCADA Studio to Configure Alarms

You can use the System Model activity in Plant SCADA Studio to add alarms to your project. Each alarm record is added using a properties form that reflects a particular alarm type (see [Alarms](#)).

There are properties that are common to all alarm types. These include:

- Alarm Tag (see [Name an Alarm Tag](#))
- Alarm Name (see [Use an Alarm Name to Describe an Alarm Tag](#))
- Category (see [Assign an Alarm to an Alarm Category](#))
- Cluster Name (see [Assign an Alarm to a Cluster](#))
- Equipment properties (see [Associate an Alarm with Equipment](#)).

Each configured alarm type also includes specific properties. For more information, see:

- [Add a Digital Alarm](#)
- [Add a Time Stamped Alarm](#)
- [Add an Analog Alarm](#)
- [Add an Advanced Alarm](#)
- [Add a Multi-Digital Alarm](#)
- [Add a Time Stamped Digital Alarm](#)
- [Add a Time Stamped Analog Alarm](#)
- [Add a Double Point Status Alarm](#)

## See Also

[Use Alarm Delay](#)

[Using Alarm Properties as Tags](#)

### Name an Alarm Tag

When configuring an alarm, you use the **Alarm Tag** property to specify a name for the alarm tag. The name you use needs to meet the following requirements:

1. The tag name needs to use [Tag Name Syntax](#).
2. The tag name needs to be unique within a cluster (see [Assign an Alarm to a Cluster](#)).

If the tag name does not meet these requirements, it may not be recognized.

---

**Note:** If your project has a large number of tags, use a naming convention to easily find and debug your tags (see [Structured Tag Names](#)).

---

#### To name an alarm tag:

1. In the **System Model** activity, select **Alarms**.
2. On the menu below the Command Bar, select the required alarm type. The alarms list will display in the Grid Editor.
3. If you would like to update an existing alarm, locate the required record.
4. In the **Alarm Tag** field displayed in the Property Grid, enter an appropriate name for the alarm tag.
5. Click **Save**.

For more information on how to configure a particular alarm type, select one of the following topics:

- [Add a Digital Alarm](#)
- [Add a Time Stamped Alarm](#)
- [Add an Analog Alarm](#)
- [Add an Advanced Alarm](#)
- [Add a Multi-Digital Alarm](#)

- Add a Time Stamped Digital Alarm
- Add a Time Stamped Analog Alarm

## See Also

[Use an Alarm Name to Describe an Alarm Tag](#)

### Use an Alarm Name to Describe an Alarm Tag

When configuring an alarm, you can use the **Alarm Name** property to include a description of the alarm. For example, you may include the name of the physical device with which the alarm is associated.

The name you enter can be used to identify an alarm when it is displayed on screen or logged to a device.

#### To add an Alarm Name to an alarm tag:

1. In the **System Model** activity, select **Alarms**.
2. On the menu below the Command Bar, select the required alarm type. The alarms list will display in the Grid Editor.
3. If you would like to update an existing alarm, locate the required record.
4. In the **Alarm Name** field displayed in the Property Grid, enter a name that describes the alarm tag.
5. Click **Save**.

For more information on how to configure a particular alarm type, select one of the following topics:

- Add a Digital Alarm
- Add a Time Stamped Alarm
- Add an Analog Alarm
- Add an Advanced Alarm
- Add a Multi-Digital Alarm
- Add a Time Stamped Digital Alarm
- Add a Time Stamped Analog Alarm

## See Also

[Assign an Alarm to an Alarm Category](#)

### Assign an Alarm to an Alarm Category

To assign a configured alarm to an alarm category, you use the **Alarm Category** property (see [Categorize Alarms](#)).

To do this, you would typically enter a numeric value that represents one of the categories defined in your project. However, you can also enter a label (if one has been associated with a particular category).

If a value is not specified in the **Alarm Category** field, the default category zero (0) will be used.

**To assign an alarm to an alarm category:**

1. In the **System Model** activity, select **Alarms**.
2. On the menu below the Command Bar, select the required alarm type. The alarms list will display in the Grid Editor.
3. If you would like to update an existing alarm, locate the required record.
4. In the **Alarm Category** field in the Property Grid, enter a number or label that represents one of the categories defined in your project.
5. Click **Save**.

For more information on how to configure a particular alarm type, select one of the following topics:

- [Add a Digital Alarm](#)
- [Add a Time Stamped Alarm](#)
- [Add an Analog Alarm](#)
- [Add an Advanced Alarm](#)
- [Add a Multi-Digital Alarm](#)
- [Add a Time Stamped Digital Alarm](#)
- [Add a Time Stamped Analog Alarm](#)

**See Also**

[Assign an Alarm to a Cluster](#)

**Assign an Alarm to a Cluster**

When you assign an alarm to a cluster you specify the cluster that will run the alarm. To assign an alarm to a cluster, you use the **Cluster Name** property.

---

**Note:** If your system has more than one cluster, you need to specify a cluster for each alarm.

---

**To assign an alarm to a cluster:**

1. In the **System Model** activity, select **Alarms**.
2. On the menu below the Command Bar, select the required alarm type. The alarms list will display in the Grid Editor.
3. If you would like to update an existing alarm, locate the required record.
4. In the **Cluster Name** field displayed in the Property Grid, enter the name of the cluster that will run the alarm. You can select an existing cluster from the drop-down menu to the right of the field.
5. Click **Save**.

For more information on how to configure a particular alarm type, select one of the following topics:

- [Add a Digital Alarm](#)
- [Add a Time Stamped Alarm](#)
- [Add an Analog Alarm](#)

- Add an Advanced Alarm
- Add a Multi-Digital Alarm
- Add a Time Stamped Digital Alarm
- Add a Time Stamped Analog Alarm

## See Also

[Associate an Alarm with Equipment](#)

### Associate an Alarm with Equipment

To associate an alarm with equipment in Plant SCADA Studio, you use the **Equipment** and **Item Name** properties:

- The **Equipment** property defines the equipment association that you can use to reference the alarm
- The **Item Name** property is associate the alarm with a particular attribute of the equipment.

**Note:** The steps described here are recommended if you are associating an existing alarm tag with equipment. If you are creating new alarm tags, you should use Equipment Editor to manage your equipment associations. For more information, see [Use Equipment Editor to Configure Alarms](#).

#### **WARNING**

##### **UNINTENDED EQUIPMENT OPERATION**

On updating the Equipment Name or Equipment Item for an alarm, the update will not be reflected on the client side until the alarm servers have been restarted. The reload procedure will indicate a reload error on Runtime Manager. Reloadlog.dat and Syslog.dat of the server process will show the details of the unsupported changes. You can use this information to revert the changes, or restart all servers after deploying your updated project.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

### To associate an alarm with equipment:

1. In the **System Model** activity, select **Alarms**.
2. On the menu below the Command Bar, select the required alarm type. The alarms list will display in the Grid Editor.
3. Locate the alarm record you would like to update.
4. In the **Equipment** field displayed in the Property Grid, enter the name of the equipment with which you would like to associate the alarm. You can select an existing equipment definition from the drop-down menu to the right of the field.
5. If required, specify an **Item Name** for the alarm.
6. Click **Save** to save the changes to the selected alarm record.

For more information on how to configure a particular alarm type, select one of the following topics:

- [Add a Digital Alarm](#)

- Add a Time Stamped Alarm
- Add an Analog Alarm
- Add an Advanced Alarm
- Add a Multi-Digital Alarm
- Add a Time Stamped Digital Alarm
- Add a Time Stamped Analog Alarm
- Add a Double Point Status Alarm.

### Add a Digital Alarm

Digital alarms activate in response to the state of one or two digital variables. The alarm becomes active when the triggering condition spans the duration of a specified delay period.

#### To add a digital alarm:

1. In the **System Model** activity, select **Alarms**.
2. On the menu below the Command Bar, select **Digital Alarms**.
3. Add a row to the Grid Editor.
4. Type the required information in each column, or in the Property Grid (see below for a description of the properties).
5. Click **Save**.

**Note:** Configure the [\[Alarm\]UseConfigLimits](#) parameter to force the Plant SCADA alarms server to use digital alarm property values from the RDB, rather than using the values which may be stored in the database file.

### Digital Alarms Properties

**Note:** If an alarm was generated by the Equipment Editor, a number of fields on the properties form will be shaded. To configure these fields, you will need to use Equipment Editor (see [Use Equipment Editor to Configure Alarms](#)).

#### Equipment Properties

Property	Description
<b>Equipment</b>	The name of the equipment associated with the digital alarm. Select a name from the drop-down list of existing equipment definitions, or enter a name. There is a limit of 254 characters across the Equipment and <b>Item Name</b> fields, including any separating periods (.).
<b>Item Name</b>	The name of the item with which the alarm is associated. Items form part of an equipment hierarchy. They can be used to associate tags, alarms and trends with a particular attribute of a physical piece of equipment

Property	Description
	<p>(see <a href="#">Items</a>).</p> <p>There is a limit of 254 characters across the <b>Equipment</b> and Item Name, including any separating periods (.).</p> <p>If you leave this field blank, the last 63 characters of the <b>Alarm Tag</b> field will be used for the Item Name. Be aware that the Alarm Tag allows 79 characters, while Tag Item has a maximum of 63 characters. This may result in compiler errors if the combination of '&lt;Equipment&gt;.&lt;TagItem&gt;' is not unique.</p> <p><b>Note:</b> When defining an item name, avoid using the <a href="#">Reserved Words</a>. If you use any of these, an error message will display when you compile your project.</p>

### General Properties

Property	Description
<b>Alarm Tag</b>	<p>The name of the alarm tag. The name needs to be unique to the cluster and adhere to <a href="#">Tag Name Syntax</a> rules.</p> <p>If your project includes a large number of tags, a naming convention can be helpful when searching and debugging tags (see <a href="#">Structured Tag Names</a>).</p>
<b>Alarm Name</b>	<p>A meaningful description of the alarm, for example, a name that includes the physical device associated with the alarm. The name is used when details of the alarm are displayed on the screen or logged to a device. This field does not support variable data.</p>
<b>Cluster Name</b>	<p>The name of the cluster that runs the alarm. This field needs to be defined if your project has more than one cluster.</p> <p>You can leave this field blank in a multi-cluster system if cluster replication is enabled (see the parameter <a href="#">[General]ClusterReplication</a>).</p>
<b>Category</b>	<p>The alarm category to which the alarm is assigned, defined as either a category number or a label (see <a href="#">Categorize Alarms</a>).</p> <p>If not specified, the category defaults to category 0.</p>
<b>Alarm Desc</b>	<p>A meaningful description of the alarm condition. This description is used when details of the alarm are displayed on screen or logged to a device.</p>

Property	Description
	<p>This field can support variable data (by enclosing an expression in braces). For example:</p> <p>Line Broken Alarm at Line Speed {LineSpeed1}</p> <p>See <a href="#">Add Variable Data to Alarm Messages</a>.</p>
<b>Delay</b>	<p>The alarm delay period (see <a href="#">Use Alarm Delay</a>).</p> <p>A digital alarm becomes active when the state of the triggering condition remains true for the duration of the delay period.</p> <p>The delay period needs to be entered in the following format:</p> <p>HH:MM:SS (Hours:Minutes:Seconds).</p> <p>The value needs to be between 0 seconds (00:00:00) and 24 hours (24:00:00).</p>
<b>Help</b>	<p>The name of the graphics page that displays when the <code>AlarmHelp()</code> function is called by a user-defined command. If not specified, no action occurs when the <code>AlarmHelp()</code> function is called.</p>
<b>Comment</b>	<p>Any useful comment.</p>

#### Source Properties

Property	Description
<b>Variable Tag A / Variable Tag B</b>	<p>Configure digital alarms to activate based on the state of a single or multiple digital variable tags. For a single variable tag use field Var Tag A. For multiple variable tags use fields Var Tag A and Var Tag B.</p> <p>See <a href="#">Alarms</a> for more information on digital alarms.</p>

#### Custom Properties

Property	Description
<b>Custom 1 to Custom 8</b>	<p>A user-defined string for filtering active alarms (maximum 64 characters).</p> <p>Used in a custom Cicode query function as search criteria, the custom alarm filter enables operators to identify and display a subset of active alarms.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>• Custom filters are visible only when the Digital Alarms form is open in Extended mode.</li> <li>• The fields are not case-sensitive and can contain</li> </ul>

Property	Description
	'A'..'Z', 'a'..'z', '0' .. '9', and the underscore '_'. • A custom filter cannot start with a digit.

**Paging Properties**

Property	Description
<b>Paging</b>	A read/write property that indicates whether the alarm will be paged. When the value is 1 (TRUE) the alarm will be paged. The default value is 0 (FALSE). This property can be read using alarm tag browsing and read or modified when tag properties are enabled using the tag name "myCluster.myAlarm.paging".
<b>Paging Group</b>	A read only text string that indicates the paging group to which the alarm belongs. Maximum length is 80 characters. See your third-party paging system documentation for information on how to use this Paging Group string. This property can be read using alarm tag browsing or when tag properties are enabled read using the tagname "myCluster.myAlarm.paginggroup". For example, assign the value of PagingGroup to a variable: <code>myString = myCluster.Alarm_1.paginggroup</code>

**Security Properties**

Field	Description
<b>Area</b>	The Area to which the alarm belongs. If an operator does not have access to an area, the alarm is not visible on the alarm display. For example, if you enter <b>Area 1</b> here, operator need to have access to Area 1 (plus any necessary privileges) to acknowledge or disable this alarm.  The area and privilege fields defined here needs to be designed to work in conjunction. A privilege defined on a button (say) will ignore the alarm defined area.
<b>Privilege</b>	Privilege necessary by an operator to acknowledge or disable the alarm.  If you assign an acknowledgment privilege to an alarm, you should also check the privilege that is assigned to the command(s) that acknowledge the

Field	Description
	alarm. If you assign a different privilege to the commands, an operator needs to have both privileges to acknowledge the command. More importantly, the area defined here may be ignored.

**Historian Properties**

Property	Description
<b>Historize</b>	This field enables you to automatically historize and publish the specified digital alarm in CitectHistorian. If you set this field to "TRUE", the variable will be included in an automated configuration process within the Historian environment. If you set the field to "FALSE" (or leave it blank), the variable will not be included.  See <a href="#">Integration with Historian</a> .

**Project Properties**

Property	Description
<b>Project</b>	The project in which the alarm is configured.

**See Also**[Alarms](#)**Add a Time Stamped Alarm**

Time stamped alarms use a counter to provide an accurate time stamp of when a triggering condition occurred, rather than the time the variable was polled. They can be associated with a single digital variable.

See [Alarms](#) for more information on time stamped alarms.

**To add a time stamped alarm:**

1. In the **System Model** activity, select **Alarms**.
2. On the menu below the Command Bar, select **Time Stamped Alarms**.
3. Add a row to the Grid Editor.
4. Type the required information in each column, or in the Property Grid (see below for a description of the properties).
5. Click **Save**.

**Note:** Configure the [\[Alarm\]UseConfigLimits](#) parameter to force the Plant SCADA alarms server to use digital

---

alarm property values from the RDB, rather than using the values which may be stored in the database file.

---

## Time Stamped Alarms Properties

**Note:** If an alarm was generated by the Equipment Editor, a number of fields on the properties form will be shaded. To configure these fields, you will need to use Equipment Editor (see [Use Equipment Editor to Configure Alarms](#)).

---

### Equipment Properties

Property	Description
<b>Equipment</b>	The name of the equipment associated with the time stamped alarm. Select a name from the drop-down list of existing equipment definitions, or enter a name. There is a limit of 254 characters across the <b>Equipment</b> and <b>Item Name</b> fields, including any separating periods (.).
<b>Item Name</b>	The name of the item with which the alarm is associated. Items form part of an equipment hierarchy. They can be used to associate tags, alarms and trends with a particular attribute of a physical piece of equipment (see <a href="#">Items</a> ). There is a limit of 254 characters across the <b>Equipment</b> and Item Name, including any separating periods (.). If you leave this field blank, the last 63 characters of the <b>Alarm Tag</b> field will be used for the Item Name. Be aware that the Alarm Tag allows 79 characters, while Tag Item has a maximum of 63 characters. This may result in compiler errors if the combination of '<Equipment>.<TagItem>' is not unique. <b>Note:</b> When defining an item name, avoid using the reserved words. If you use any of these, an error message will display when you compile your project.

### General Properties

Property	Description
<b>Alarm Tag</b>	<p>The name of the alarm tag. The name needs to be unique to the cluster and adhere to <a href="#">Tag Name Syntax</a> rules.</p> <p>If your project includes a large number of tags, a naming convention can be helpful when searching and debugging tags (see <a href="#">Structured Tag Names</a>).</p>
<b>Alarm Name</b>	<p>A meaningful description of the alarm, for example, a name that includes the physical device associated with the alarm. The name is used when details of the alarm are displayed on the screen or logged to a device. This field does not support variable data.</p>
<b>Cluster Name</b>	<p>The name of the cluster that runs the alarm. This field needs to be defined if your project has more than one cluster.</p> <p>You can leave this field blank in a multi-cluster system if cluster replication is enabled (see the parameter <a href="#">[General]ClusterReplication</a>).</p>
<b>Category</b>	<p>The alarm category to which the alarm is assigned, defined as either a category number or a label (see <a href="#">Categorize Alarms</a>).</p> <p>If not specified, the category defaults to category 0.</p>
<b>Alarm Desc</b>	<p>A meaningful description of the alarm condition. This description is used when details of the alarm are displayed on screen or logged to a device.</p> <p>This field can support variable data (by enclosing an expression in braces). For example:</p> <p>Line Broken Alarm at Line Speed {LineSpeed1}</p> <p>See <a href="#">Add Variable Data to Alarm Messages</a>.</p>
<b>Timer Expr.</b>	<p>The variable tag or Cicode expression that represents the counter (or millisecond timer) configured in the I/O Device. The counter needs to be configured and maintained by the program in the I/O Device; it is read only when the alarm is triggered.</p> <p>You can use one of three types of counter or timer to record the triggering of time-stamped alarms:</p> <p><b>Continuous counter</b> - A continuous counter is read in the unit to determine the sequence in which the alarms are triggered. The alarms are sorted based on the value of the counter when the alarm was triggered (the exact time is not recorded). Program the counter</p>

Property	Description
	<p>(in the unit) to count continually to its limit, reset, and again count to its limit.</p> <p><b>Millisecond counter</b> - If your unit supports a millisecond counter, program a counter (in the unit) to count (in milliseconds) for 24 hours, and then reset (at midnight). The value of this timer variable (in the unit) is read to determine the exact time when the alarm was triggered.</p> <p><b>LONGBCB timer</b> - Using a LONGBCD timer, you can log the exact time when a Time-stamped alarm becomes active. This variable is read, along with the alarm tag when the alarm activates. You need to program the LONGBCD variable in the following format with the range specified as hexadecimal numbers, excluding numbers containing alphabetic characters:</p> <ul style="list-style-type: none"> <li>1st BYTE - Hours - 00-23 (most significant byte)</li> <li>2nd BYTE - Minutes - 00-59</li> <li>3rd BYTE - Seconds - 00-59</li> <li>4th BYTE - 100th/sec - 00-99 (least significant byte)</li> </ul> <p>Use 'Timer' to handshake with the PLC code: The PLC is informed that it has read the timer register and now the PLC can overwrite the last value. For example, with the following code saved in a Cicode file:</p> <pre> INT FUNCTION AlarmTimerReset(INT iTimer, STRING sTimerTrigger) TagWrite(sTimerTrigger, 0); //Reset the trigger RETURN iTimer; //Return the timer value to the alarm system END </pre> <p><b>Example:</b></p> <p>Where:</p> <p><b>Variable Tag is AlmTrigger1 AND Timer is AlarmTimerReset(AlmTimer1, "AlmTrigger1")</b></p> <p>In this example <b>AlmTimer1</b> is the PLC register that stores the alarm time, and <b>AlmTrigger1</b> is the alarm trigger bit.</p> <p>When AlmTrigger1 is set to 1, the alarm is triggered, and the Cicode function is called. On calling the function, the AlmTimer1 register is read. The function resets the trigger bit (handshaking), and the value of</p>

Property	Description
	<p>AlmTimer1 is returned.</p> <p><b>Note:</b> <code>AlarmTimerReset()</code> is a user function that does not exist in Plant SCADA.</p>
<b>Timer Group</b>	<p>This field is only applicable if the parameter <code>[Alarm]HresType</code> is set to 1 (continuous counter).</p> <p>It allows you to group alarms so that the alarm server can keep track of the counter sequence for each group independently. This may be useful if your system requires multiple alarm count sequences (to support multiple devices).</p>
<b>Help (Optional)</b>	The name of the graphics page that displays when the <code>AlarmHelp()</code> function is called by a user-defined command. If not specified no action occurs when the <code>AlarmHelp()</code> function is called.
<b>Comment</b>	Any useful comment.

**Source Properties**

Property	Description
<b>Variable Tag</b>	The variable tag that triggers the alarm.

**Custom Properties**

Property	Description
<b>Custom 1 to Custom 8</b>	<p>A user-defined string for filtering active alarms (maximum 64 characters).</p> <p>Used in a custom Cicode query function as search criteria, the custom alarm filter enables operators to identify and display a subset of active alarms.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>Custom filters are visible only when the MultiDigital Alarm form is open in Extended mode.</li> <li>The fields are not case-sensitive and can contain 'A'..'Z', 'a'..'z', '0'..'9', and the underscore '_'.</li> <li>A custom filter cannot start with a digit.</li> </ul>

**Paging Properties**

Property	Description
<b>Paging</b>	A read/write property that indicates whether the alarm will be paged. When the value is 1 (TRUE) the alarm will be paged. The default value is 0 (FALSE).

Property	Description
	This property can be read using alarm tag browsing and read or modified when tag properties are enabled using the tag name "myCluster.myAlarm.paging".
<b>Paging Group</b>	<p>A read only text string that indicates the paging group to which the alarm belongs. Maximum length is 80 characters. See your third-party paging system documentation for information on how to use this Paging Group string. This property can be read using alarm tag browsing or when tag properties are enabled read using the tagname "myCluster.myAlarm.paginggroup". For example, assign the value of PagingGroup to a variable:</p> <pre>myString = myCluster.Alarm_1.paginggroup</pre>

### Security Properties

Property	Description
<b>Area</b>	<p>The area to which the alarm belongs. If an operator does not have access to an area, the alarm is not visible on the alarm display. For example, if you enter <b>Area 1</b> here, operator need to have access to Area 1 (plus any necessary privileges) to acknowledge or disable this alarm.</p> <p>The area and privilege fields defined here needs to be designed to work in conjunction. A privilege defined on a button (say) will ignore the alarm defined area.</p>
<b>Privilege</b>	<p>Privilege necessary by an operator to acknowledge or disable the alarm.</p> <p>If you assign an acknowledgment privilege to an alarm, you should also check the privilege that is assigned to the command(s) that acknowledge the alarm. If you assign a different privilege to the commands, an operator needs to have both privileges to acknowledge the command. More importantly, the area defined here may be ignored.</p>

### Historian Properties

Property	Description
<b>Historize</b>	<p>This field enables you to automatically historize and publish the specified time-stamped alarm in CitectHistorian.</p> <p>If you set this field to "TRUE", the variable will be</p>

Property	Description
	<p>included in an automated configuration process within the Historian environment. If you set the field to "FALSE" (or leave it blank), the variable will not be included.</p> <p>See <a href="#">Integration with Historian</a>.</p>

**Project Properties**

Property	Description
<b>Project</b>	The project in which the alarm is configured.

**See Also**[Alarms](#)**Add an Analog Alarm**

Analog alarms are triggered when an analog variable changes beyond one or more specific limits.

To configure an alarm that triggers when the associated tag value reaches a specified limit, you use the following properties:

- High
- High High
- Low
- Low Low

To configure an alarm that triggers when the tag value moves away from a predefined set point, you use:

- Setpoint
- Deviation

To configure an alarm that monitors the rate of change for a tag value across a set period of time, you use:

- Rate

For more information on analog alarms, see [Alarms](#).

**To add an analog alarm:**

1. In the **System Model** activity, select **Alarms**.
2. On the menu below the Command Bar, select **Analog Alarms**.
3. Add a row to the Grid Editor.
4. Complete the properties (see below for a description of the properties).

For a description of the properties, see below.

5. Click **Save**.

**Note:** Configure the [\[Alarm\]UseConfigLimits](#) parameter to force the Plant SCADA Alarm Server to use digital alarm property values from the RDB, rather than using the values which may be stored in the database file.

## Analog Alarms Properties

**Note:** If an alarm was generated by the Equipment Editor, a number of fields on the properties form will be shaded. To configure these fields, you will need to use Equipment Editor (see [Use Equipment Editor to Configure Alarms](#)).

### Equipment Properties

Property	Description
<b>Equipment</b>	The name of the equipment associated with the analog alarm. Select a name from the drop-down list of existing equipment definitions, or enter a name. There is a limit of 254 characters across the Equipment and <b>Item Name</b> fields, including any separating periods (.).
<b>Item Name</b>	The name of the item with which the alarm is associated. Items form part of an equipment hierarchy. They can be used to associate tags, alarms and trends with a particular attribute of a physical piece of equipment (see <a href="#">Items</a> ). There is a limit of 254 characters across the <b>Equipment</b> and Item Name, including any separating periods (.). If you leave this field blank, the last 63 characters of the <b>Alarm Tag</b> field will be used for the Item Name. Be aware that the Alarm Tag allows 79 characters, while Tag Item has a maximum of 63 characters. This may result in compiler errors if the combination of '<Equipment>.<TagItem>' is not unique. <b>Note:</b> When defining an item name, avoid using the <a href="#">Reserved Words</a> . If you use any of these, an error message will display when you compile your project.

### General Properties

Property	Description
<b>Alarm Tag</b>	The name of the alarm tag. The name needs to be unique to the cluster and adhere to <a href="#">Tag Name Syntax</a> rules. If your project includes a large number of tags, a

Property	Description
	naming convention can be helpful when searching and debugging tags (see <a href="#">Structured Tag Names</a> ).
<b>Alarm Name</b>	A meaningful description of the alarm, for example, a name that includes the physical device associated with the alarm. The name is used when details of the alarm are displayed on the screen or logged to a device. This field does not support variable data.
<b>Cluster Name</b>	<p>The name of the cluster that runs the alarm. This field needs to be defined if your project has more than one cluster.</p> <p>You can leave this field blank in a multi-cluster system if cluster replication is enabled (see the parameter [General]ClusterReplication).</p>
<b>Category</b>	<p>The alarm category to which the alarm is assigned, defined as either a category number or a label (see <a href="#">Categorize Alarms</a>).</p> <p>If not specified, the category defaults to category 0.</p>
<b>Setpoint</b>	<p>An analog variable tag, expression or base value that determines if a deviation alarm is to be triggered. This property is optional. If a setpoint is not specified, it will default to 0 (zero).</p> <p><b>Note:</b> If set to an analog variable tag, it needs to be a different tag to the Variable Tag property of the alarm.</p>
<b>High High Delay</b>	<p>Delay period for High High Alarms. Alarm will activate if its triggering condition is met for the duration of the delay period (see <a href="#">Use Alarm Delay</a>).</p> <p>If no value is set, the high high alarm will be activated as soon as the tag exceeds the high high value.</p> <p><b>Note:</b> The delay period needs to be entered in the format HH:MM:SS (hours:minutes:seconds). The value needs to be between 0 seconds (00:00:00) and 24 hours (24:00:00).</p>
<b>High Delay</b>	<p>The delay period for high alarms. Alarm will activate if its triggering condition is met for the duration of this period. If no value is set, the high alarm will be activated as soon as the tag exceeds the high value.</p> <p><b>Note:</b> The delay period needs to be entered in the format HH:MM:SS (hours:minutes:seconds). The value needs to be between 0 seconds (00:00:00) and 24 hours (24:00:00).</p>

Property	Description
	<p>When a tag value increases from high to high high within the high delay period, the delay timer is reset. The high high alarm is only activated if the value remains in the high high range for the delay period.</p> <p>When the value increases from high to high high after the high delay period has expired, a high alarm is activated and then the delay period for the high high alarm begins.</p> <p>If the tag value exceeds the high high value and then falls below it before the high high delay period expires, at the time it falls, the high alarm is triggered immediately.</p> <p>It has an ON time of when the tag value exceeded the high high value. These points also apply to tag values traveling between Low and Low Low ranges.</p>
<b>Low Delay</b>	<p>The delay period for Low Alarms. The alarm will only activate if its triggering condition is met for the duration of this period. This property is optional. If no value is set, the Low Alarm is activated as soon as the tag drops below the Low value.</p> <p><b>Note:</b> The delay period needs to be entered in the format HH:MM:SS (Hours:Minutes:Seconds). The value needs to be between 0 seconds (00:00:00) and 24 hours (24:00:00).</p>
<b>Low Low Delay</b>	<p>The delay period for Low Low Alarms. The alarm will only activate if its triggering condition is met for the duration of this period. If no value is set, the Low Low Alarm is activated as soon as the tag drops below the Low Low value.</p> <p><b>Note:</b> The delay period needs to be entered in the format HH:MM:SS (Hours:Minutes:Seconds). The value needs to be between 0 seconds (00:00:00) and 24 hours (24:00:00).</p>
<b>Variable Tag</b>	<p>The analog variable (tag) or expression that triggers the alarm.</p>
<b>Deviation</b>	<p>The value used as the triggering condition for a Deviation Alarm. A Deviation Alarm is activated when the value of the Variable Tag remains outside the deviation range (determined by the Setpoint) for the duration of the Deviation Delay period. This property is optional. If a deviation is not specified, no Deviation Alarm is activated.</p>

Property	Description
<b>Deviation Delay</b>	<p>The delay period for Deviation Alarms. The alarm will only activate if its triggering condition is met for the duration of this period. If no value is set, the Deviation Alarm is activated as soon as the Variable Tag falls outside the deviation range.</p> <p><b>Note:</b> The delay period needs to be entered in the format HH:MM:SS (Hours:Minutes:Seconds). The value needs to be between 0 seconds (00:00:00) and 24 hours (24:00:00).</p>
<b>Rate</b>	<p>By dividing this value by the alarm period, the "maximum rate" at which the value of the variable tag can change is determined. At each Scan Time, the value of the tag is checked. If its rate of change is greater than the maximum rate, a Rate of Change Alarm is triggered.</p> <p>For example, to verify that a tank does not fill too quickly, you might configure a rate of change alarm, using a Rate of <b>300</b> liters, an <b>[Alarm]Period of 60 seconds</b>, and an <b>[Alarm]ScanTime of 1 second</b>. This means that the maximum allowable rate of change for the tank level is <b>5 l/sec</b> (300 liters / 60 seconds). The actual rate of change at each <b>ScanTime</b> is calculated. That is, every second, it checks the current level of the tank and compares it to the level recorded a second earlier. If the actual rate of change is, say, <b>8 l/sec</b>, a Rate of Change Alarm is triggered immediately.</p> <p>The variable tags deadband % needs to be less than the alarms rate divided by the engineering scale of the variable tag. Otherwise, the rate of change alarm will only go off when the change in the variable tag exceeds the deadband value. If no value is set, no Rate of Change Alarm is activated.</p>
<b>Deadband</b>	Value the Variable Tag needs to return to before the Alarm becomes inactive.
<b>Format</b>	The display format of the value (of the variable) when it is displayed on a graphics page, written to a file or passed to a function (that expects a string). If a format is not specified, the format defaults to the format specified for Variable tag.
<b>Help</b>	The name of the graphics page that displays when the <b>AlarmHelp()</b> function is called by a user-defined command. If not specified no action occurs when the

Property	Description
	AlarmHelp() function is called.
Comment	Any useful comment.

**Source Properties**

Property	Description
Variable Tag	The analog variable (tag) or expression that triggers the alarm.

**Limits Properties**

Property	Description
<b>High High</b>	<p>Value used as the triggering condition for a high high alarm. If the value of the variable tag exceeds this value for the duration of the high high delay period the alarm will be triggered. The active alarm will have an ON time of when the tag exceeded the high high value. Because a high alarm needs to precede a high high alarm, when the high high alarm is triggered it replaces the high alarm.</p> <p>To display more than one state on the alarm page at the same time, configure a separate alarm for each state. (Each alarm would monitor the same tag.)</p>
<b>High</b>	The value used as the triggering condition for a high alarm. The high alarm becomes active when the value of the variable tag exceeds this value for the duration of the high delay period. The active alarm has an ON time of when the tag exceeded the high value.
<b>Low</b>	The value used as the triggering condition for a Low Alarm. Alarm becomes active when the value of the Variable Tag drops below this value and remains there for the duration of the Low Delay period. The active alarm has an ON time of when the tag fell below the Low value.
<b>Low Low</b>	<p>The value used as the triggering condition for a Low Low Alarm. A Low Low Alarm becomes active when the value of the Variable Tag drops below this value and remains there for the duration of the Low Low Delay period. The active alarm has an ON time of when the tag fell below the Low Low value.</p> <p>Because a Low Alarm needs to precede a Low Low Alarm, when the Low Low Alarm is triggered it</p>

Property	Description
	replaces the Low Alarm. If you want an analog alarm to display more than one state on the alarm page at the same time, configure a separate alarm for each state. (Each alarm would monitor the same tag.)

**Custom Properties**

Property	Description
<b>Custom 1 to Custom 8</b>	<p>A user-defined string for filtering active alarms (maximum 64 characters).</p> <p>Used in a custom Cicode query function as search criteria, the custom alarm filter enables operators to identify and display a subset of active alarms.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>• Custom filters are visible only when the Digital Alarms form is open in Extended mode.</li> <li>• The fields are not case-sensitive and can contain 'A'..'Z', 'a'..'z', '0'..'9', and the underscore '_'.</li> <li>• A custom filter cannot start with a digit.</li> </ul>

**Paging Properties**

Property	Description
<b>Paging</b>	A read/write property that indicates whether the alarm will be paged. When the value is 1 (TRUE) the alarm will be paged. The default value is 0 (FALSE). This property can be read using alarm tag browsing and read or modified when tag properties are enabled using the tag name "myCluster.myAlarm.paging".
<b>Paging Group</b>	A read only text string that indicates the paging group to which the alarm belongs. Maximum length is 80 characters. See your third-party paging system documentation for information on how to use this Paging Group string. This property can be read using alarm tag browsing or when tag properties are enabled read using the tagname "myCluster.myAlarm.paginggroup". For example, assign the value of PagingGroup to a variable: <code>myString = myCluster.Alarm_1.paginggroup</code>

**Security Properties**

Field	Description
<b>Area</b>	The Area to which the alarm belongs. If an operator

Field	Description
	<p>does not have access to an area, the alarm is not visible on the alarm display. For example, if you enter <b>Area 1</b> here, operator need to have access to Area 1 (plus any necessary privileges) to acknowledge or disable this alarm.</p> <p>The area and privilege fields defined here needs to be designed to work in conjunction. A privilege defined on a button (say) will ignore the alarm defined area.</p>
<b>Privilege</b>	<p>Privilege necessary by an operator to acknowledge or disable the alarm.</p> <p>If you assign an acknowledgment privilege to an alarm, you should also check the privilege that is also assigned to the command(s) that acknowledge the alarm. If you assign a different privilege to the commands, an operator needs to have both privileges to acknowledge the command. More importantly, the area defined here may be ignored.</p>

### Historian Properties

Field	Description
<b>Historize</b>	<p>This field enables you to automatically historize and publish the specified analog alarm in Citect Historian.</p> <p>If you set this field to "TRUE", the variable will be included in an automated configuration process within the Historian environment. If you set the field to "FALSE" (or leave it blank), the variable will not be included.</p> <p>See <a href="#">Integration with Historian</a>.</p>

### Project Properties

Property	Description
<b>Project</b>	The project in which the alarm is configured.

## See Also

[Alarms](#)

### Add an Advanced Alarm

Advanced alarms trigger when the result of an expression changes to true. To achieve this, you enter the required Cicode expression in the alarm's **Expression** property.

**To add an advanced alarm:**

1. In the **System Model** activity, select **Alarms**.
2. On the menu below the Command Bar, select **Advanced Alarms**.
3. Add a row to the Grid Editor.
4. Complete the property information in each column, or in the fields in the Property Grid (see below for a description of the properties).
5. Click **Save**.

**Note:** Configure the [\[Alarm\]UseConfigLimits](#) parameter to force the Plant SCADA alarms server to use digital alarm property values from the RDB, rather than using the values which may be stored in the database file.

## Advanced Alarms Properties

**Note:** If an alarm was generated by the Equipment Editor, a number of fields on the properties form will be shaded. To configure these fields, you will need to use Equipment Editor (see [Use Equipment Editor to Configure Alarms](#)).

### Equipment Properties

Property	Description
<b>Equipment</b>	The name of the equipment associated with the alarm. Select a name from the drop-down list of existing equipment definitions, or enter a name. There is a limit of 254 characters across the <b>Equipment</b> and <b>Item Name</b> fields, including any separating periods (.).
<b>Item Name</b>	The name of the item with which the alarm is associated. Items form part of an equipment hierarchy. They can be used to associate tags, alarms and trends with a particular attribute of a physical piece of equipment (see <a href="#">Items</a> ). There is a limit of 254 characters across the <b>Equipment</b> and Item Name, including any separating periods (.). If you leave this field blank, the last 63 characters of the <b>Alarm Tag</b> field will be used for the Item Name. Be aware that the Alarm Tag allows 79 characters, while Tag Item has a maximum of 63 characters. This may result in compiler errors if the combination of '<Equipment>.<TagItem>' is not unique. <b>Note:</b> When defining an item name, avoid using the reserved words. If you use any of these, an error message will display when you compile your project.

**General Properties**

Property	Description
<b>Alarm Tag</b>	<p>The name of the alarm tag. The name needs to be unique to the cluster and adhere to <a href="#">Tag Name Syntax</a> rules.</p> <p>If your project includes a large number of tags, a naming convention can be helpful when searching and debugging tags (see <a href="#">Structured Tag Names</a>).</p>
<b>Alarm Name</b>	<p>A meaningful description of the alarm, for example, a name that includes the physical device associated with the alarm. The name is used when details of the alarm are displayed on the screen or logged to a device. This field does not support variable data.</p>
<b>Cluster Name</b>	<p>The name of the cluster that runs the alarm. This field needs to be defined if your project has more than one cluster.</p> <p>You can leave this field blank in a multi-cluster system if cluster replication is enabled (see the parameter <a href="#">[General]ClusterReplication</a>.</p>
<b>Category</b>	<p>The alarm category to which the alarm is assigned, defined as either a category number or a label (see <a href="#">Categorize Alarms</a>).</p> <p>If not specified, the category defaults to category 0.</p>
<b>Alarm Desc</b>	<p>A meaningful description of the alarm condition. This description is used when details of the alarm are displayed on screen or logged to a device.</p> <p>This field can support variable data (by enclosing an expression in braces). For example:</p> <p>"Line Broken Alarm at Line Speed {LineSpeed1}"</p> <p>See <a href="#">Add Variable Data to Alarm Messages</a>.</p>
<b>Delay</b>	<p>The alarm delay period (see <a href="#">Use Alarm Delay</a>).</p> <p>An alarm becomes active when the state of the triggering condition remains true for the duration of the delay period. The active alarm has an ON time of when the state became true. If not specified the alarm is active as soon as it is triggered by the digital tag(s).</p> <p>The delay period needs to be entered in the format HH:MM:SS (Hours:Minutes:Seconds).</p> <p>The value needs to be between 0 seconds (00:00:00) and 24 hours (24:00:00).</p>

Property	Description
<b>Help</b>	The name of the graphics page that displays when the AlarmHelp() function is called by a user-defined command. If not specified no action occurs when the AlarmHelp() function is called.
<b>Comment</b>	Any useful comment.

**Source Properties**

Property	Description
<b>Expression</b>	The Cicode expression that triggers the alarm. Whenever the result of the expression changes to TRUE, the alarm is triggered.

**Custom Properties**

Property	Description
<b>Custom 1 to Custom 8</b>	<p>A user-defined string for filtering active alarms (maximum 64 characters).</p> <p>Used in a custom Cicode query function as search criteria, the custom alarm filter enables operators to identify and display a subset of active alarms.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>Custom filters are visible only when the Advanced Alarms form is open in Extended mode.</li> <li>The fields are not case-sensitive and can contain 'A'..'Z', 'a'..'z', '0'..'9', and the underscore '_'.</li> <li>A custom filter cannot start with a digit.</li> </ul>

**Paging Properties**

Property	Description
<b>Paging</b>	A read/write property that indicates whether the alarm will be paged. When the value is 1 (TRUE) the alarm will be paged. The default value is 0 (FALSE). This property can be read using alarm tag browsing and read or modified when tag properties are enabled using the tag name "myCluster.myAlarm.paging".
<b>Paging Group</b>	A read only text string that indicates the paging group to which the alarm belongs. Maximum length is 80 characters. See your third-party paging system documentation for information on how to use this Paging Group string. This property can be read using alarm tag browsing or when tag properties are

Property	Description
	enabled read using the tagname "myCluster.myAlarm.paginggroup". For example, assign the value of PagingGroup to a variable: <code>myString = myCluster.Alarm_1.paginggroup</code>

**Security Properties**

Property	Description
<b>Area</b>	Area the alarm belongs to. If an operator does not have access to an area, the alarm is not visible on the alarm display. For example, if you enter <b>Area 1</b> here, operator need to have access to Area 1 (plus any necessary privileges) to acknowledge or disable this alarm.  The area and privilege fields defined here needs to be designed to work in conjunction. A privilege defined on a button (say) will ignore the alarm defined area.
<b>Privilege</b>	Privilege necessary by an operator to acknowledge or disable the alarm.  If you assign an acknowledgment privilege to an alarm, you should check the privilege that is assigned to the command(s) that acknowledge the alarm. If you assign a different privilege to the commands, an operator needs to have both privileges to acknowledge the command. More importantly, the area defined here may be ignored.

**Historian Properties**

Property	Description
<b>Historize</b>	This field enables you to automatically historize and publish the specified advanced alarm in CitectHistorian.  If you set this field to "TRUE", the variable will be included in an automated configuration process within the Historian environment. If you set the field to "FALSE" (or leave it blank), the variable will not be included.  See <a href="#">Integration with Historian</a> .

**Project Properties**

Property	Description
<b>Project</b>	The project in which the alarm is configured.

## See Also

[Alarms](#)

### Add a Multi-Digital Alarm

Multi-digital alarms use the output from three digital variables to define eight states. These states represent every possible combination of true and false values. You can then specify which of these states will trigger an alarm.

See [Alarms](#) for more information on multi-digital alarms.

**To add a multi-digital alarm:**

1. In the **System Model** activity, select **Alarms**.
2. On the menu below the Command Bar, select **Multi-Digital Alarms**.
3. Add a row to the Grid Editor.
4. Type the required information in each column, or in the fields in the Property Grid (see below for a description of the fields).
5. Click **Save**.

**Note:** Configure the [\[Alarm\]UseConfigLimits](#) parameter to force the Plant SCADA alarms server to use digital alarm property values from the RDB, rather than using the values which may be stored in the database file.

## Multi-digital Alarms Properties

### WARNING

#### UNINTENDED EQUIPMENT OPERATION

Do not put a blocking Cicode function in the ON Function or OFF Function fields. A blocking function will affect the polling of alarms, and may result in slow or delayed alarm processing.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** If an alarm was generated by the Equipment Editor, a number of fields on the properties form will be shaded. To configure these fields, you will need to use Equipment Editor (see [Use Equipment Editor to Configure Alarms](#)).

#### Equipment Properties

Field	Description
<b>Equipment</b>	The name of the equipment associated with the multi-digital alarm. Select a name from the drop-down list of existing equipment definitions, or enter a name.  There is a limit of 254 characters across the Equipment and <b>Item Name</b> fields, including any separating periods (.).
<b>Item Name</b>	The name of the item with which the alarm is associated.  Items form part of an equipment hierarchy. They can be used to associate tags, alarms and trends with a particular attribute of a physical piece of equipment (see <a href="#">Items</a> ).  There is a limit of 254 characters across the <b>Equipment</b> and Item Name, including any separating periods (.).  If you leave this field blank, the last 63 characters of the <b>Alarm Tag</b> field will be used for the Item Name. Be aware that the Alarm Tag allows 79 characters, while Tag Item has a maximum of 63 characters. This may result in compiler errors if the combination of '<Equipment>.<TagItem>' is not unique.  <b>Note:</b> When defining an item name, avoid using the reserved words. If you use any of these, an error message will display when you compile your project.

**General Properties**

Field	Description
<b>Alarm Tag</b>	The name of the alarm tag. The name needs to be unique to the cluster and adhere to <a href="#">Tag Name Syntax</a> rules.  If your project includes a large number of tags, a naming convention can be helpful when searching and debugging tags (see <a href="#">Structured Tag Names</a> ).
<b>Alarm Name</b>	A meaningful description of the alarm, for example, a name that includes the physical device associated with the alarm. The name is used when details of the alarm are displayed on the screen or logged to a device. This field does not support variable data.
<b>Cluster Name</b>	The name of the cluster that runs the alarm. This field needs to be defined if your project has more than one cluster.

Field	Description
	You can leave this field blank in a multi-cluster system if cluster replication is enabled (see the parameter [General]ClusterReplication).
<b>Category</b>	<p>The alarm category to which the alarm is assigned, defined as either a category number or a label (see <a href="#">Categorize Alarms</a>).</p> <p>If not specified, the category defaults to category 0.</p>
<b>Alarm Desc</b>	<p>A meaningful description of the alarm condition. This description is used when details of the alarm are displayed on screen or logged to a device.</p> <p>This field can support variable data (by enclosing an expression in braces). For example:</p> <p>"Line Broken Alarm at Line Speed {LineSpeed1}"</p> <p>See <a href="#">Add Variable Data to Alarm Messages</a>.</p>
<b>On function</b> (254 chars)	<p>A Cicode function that is executed when the Multi-Digital Alarm becomes active, for example:</p> <p><b>ON Function</b> is <b>STOP_PROCESS = 1;</b></p> <p>In this example the digital variable STOP_PROCESS is set to ON when the alarm is triggered.</p> <p><b>Note:</b> Do not put a blocking Cicode function in this field. The alarm system executes ON or OFF actions within the polling loop. A blocking function will affect the polling of alarms, and may result in slow or delayed alarm processing.</p> <p>A special case of this command occurs when the Alarm ON Function is self-referring, for example:</p> <p>TAG1 = TAG1 + 1.</p> <p>This command will not work properly since tags are not read again before processing the Alarm On function (for performance reasons). Therefore this particular command will initially set the value of TAG1 to 1 rather than incrementing it.</p> <p>To correctly run a command of this type in the Alarm ON Function, use TaskNew() to run your own Cicode function to perform the tag command:</p> <p><b>ON function</b> is <b>TaskNew("MyFunc","Data",5);</b></p>
<b>OFF function</b> (254 chars)	<p>A Cicode function that is executed when a Multi-Digital Alarm becomes inactive. For example:</p> <p><b>OFF Function</b> is <b>ENABLE_PROCESS = 1;</b></p>

Field	Description
	<p>In this example the digital variable ENABLE_PROCESS is set to ON when an alarm in this category is reset.</p> <p><b>Note:</b> Do not put a blocking Cicode function in this field. The alarm system executes ON or OFF actions within the polling loop. A blocking function will affect the polling of alarms, and may result in slow or delayed alarm processing.</p>
Help	The name of the graphics page that displays when the AlarmHelp() function is called by a user-defined command. If not specified, no action occurs when the AlarmHelp() function is called.
Comment	Any useful comment.

**Source Properties**

Field	Description
Variable Tag A	
Variable Tag B	
Variable Tag C	The three digital variables used to define eight states. Each state represents a different combination of tag values for these three variables.

**States Properties**

Field	Description
States and Descriptions	<p>The following eight states represent any possible tag value combinations. The variable tags are presented in the order tag C, tag B, tag A.</p> <ul style="list-style-type: none"> <li>• State 000 - all 3 tags are false.</li> <li>• State 00A - tags C and B are false, tag A is true.</li> <li>• State 0B0 - tags C and A are false, tag B is true.</li> <li>• State 0BA - tag C is false, tags B and A are true.</li> <li>• State C00 - tag C is true, and tags B and A are false.</li> <li>• State C0A - tags C and A are true, tag B is false.</li> <li>• State CB0 - tags C and B are true, tag A is false.</li> <li>• State CBA - all 3 tags are true.</li> </ul> <p>For each state, there are two fields you can configure. In the first field enter a description (for example, "Healthy" or "Stopped") with a maximum of eight characters.</p> <p>In the second field, indicate whether the state will trigger an alarm. A value of 1 indicates an alarm state, and a 0 indicates no alarm will be triggered.</p>

**Suppression Properties**

Field	Description
<b>Suppression</b>	<p>The number of the Suppression Group to which the alarm belongs.</p> <p>Integer value between 0–32767.</p> <p>Alarms in the same group display the same value in this field. Use in conjunction with Suppression Level.</p> <p><b>Note:</b> To assign a name to a Suppression Group, define the name as a label with an integer value.</p>
<b>Level</b>	<p>The level of an alarm within its Suppression Group (integer value). This is a value between 0 and 255, where a lower level represents a higher priority.</p> <p>This property enables an active alarm which is in an ON state (irrespective of whether it is acknowledged or not) to suppress lower priority alarms within the same Suppression Group. When this occurs, only the higher priority (lower level) alarms are displayed.</p> <p>Alarms with lower priorities (higher levels) will only activate and display when the higher priority (lower level) alarms become inactive.</p>

**Custom Properties**

Field	Description
<b>Custom 1 to Custom 8</b>	<p>A user-defined string for filtering active alarms (maximum 64 characters).</p> <p>Used in a custom Cicode query function as search criteria, the custom alarm filter enables operators to identify and display a subset of active alarms.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>• Custom filters are visible only when the MultiDigital Alarm form is open in Extended mode.</li> <li>• The fields are not case-sensitive and can contain 'A'..'Z', 'a'..'z', '0'..'9', and the underscore '_'.</li> <li>• A custom filter cannot start with a digit.</li> </ul>

**Paging Properties**

Field	Description
<b>Paging</b>	A read/write property that indicates whether the alarm will be paged. When the value is 1 (TRUE) the alarm will be paged. The default value is 0 (FALSE). This property can be read using alarm tag browsing and read or modified when tag properties are enabled using the tag name "myCluster.myAlarm.paging".
<b>Paging Group</b>	A read only text string that indicates the paging group to which the alarm belongs. Maximum length is 80 characters. See your third-party paging system documentation for information on how to use this Paging Group string. This property can be read using alarm tag browsing or when tag properties are enabled read using the tagname "myCluster.myAlarm.paginggroup". For example, assign the value of PagingGroup to a variable: <code>myString = myCluster.Alarm_1.paginggroup</code>

**Security Properties**

Field	Description
<b>Area</b>	The Area to which the alarm belongs. If an operator does not have access to an area, the alarm is not visible on the alarm display. For example, if you enter <b>Area 1</b> here, operator need to have access to Area 1 (plus any necessary privileges) to acknowledge or disable this alarm.  The area and privilege fields defined here needs to be designed to work in conjunction. A privilege defined on a button (say) will ignore the alarm defined area.
<b>Privilege</b>	Privilege necessary by an operator to acknowledge or disable the alarm.  If you assign an acknowledgment privilege to an alarm, you should also check the privilege that is assigned to the command(s) that acknowledge the alarm. If you assign a different privilege to the commands, an operator needs to have both privileges to acknowledge the command. More importantly, the area defined here may be ignored.

**Historian Properties**

Field	Description
<b>Historize</b>	This field enables you to automatically historize and publish the specified multi-digital alarm in

Field	Description
	<p>CitectHistorian.</p> <p>If you set this field to "TRUE", the variable will be included in an automated configuration process within the Historian environment. If you set the field to "FALSE" (or leave it blank), the variable will not be included.</p> <p>See <a href="#">Integration with Historian</a>.</p>

**Project Properties**

Field	Description
Project	The project in which the alarm is configured.

**See Also**[Alarms](#)**Add a Time Stamped Digital Alarm**

Time stamped digital alarms use notifications from the alarm server to determine when an alarm is triggered. This provides an accurate time stamp of when an alarm condition occurs.

**Note:** Time stamped digital alarms are timestamp based and designed to work with the Driver Runtime Interface (DRI). For a list of supported drivers, see [Retrieving Time-stamped Data from I/O Devices](#). Alternatively, you can configure the Cicode function [AlarmNotifyVarChange](#), as it notifies the alarm server of any value changes for the associated variable. It also passes the timestamp with the notification message. The alarm server maintains a queue for notification messages and runs a separate task to check this queue.

A time stamped digital alarm activates in response to the state of one or two digital variables (specified in the alarm's **Variable Tag A** and **Variable Tag B** properties). When you define the variable tags, you can precede a tag name with the logical operator "NOT". This specifies that the OFF state (0) is the triggering condition for the variable tag.

The alarm becomes active when the triggering condition spans the amount of time specified in the **Delay** property.

**To add a time stamped digital alarm:**

1. In the **System Model** activity, select **Alarms**.
2. On the menu below the Command Bar, select **Time Stamped Digital Alarms**.
3. Add a row to the Grid Editor.
4. Type the required information in each column, or in the fields in the Property Grid (see below for a description of the fields).
5. Click **Save**.

**Note:** Configure the [\[Alarm\]UseConfigLimits](#) parameter to force the Plant SCADA alarms server to use digital alarm property values from the RDB, rather than using the values which may be stored in the database file.

## Time-stamped Digital Alarms Properties

**Note:** If an alarm was generated by the Equipment Editor, a number of fields on the properties form will be shaded. To configure these fields, you will need to use Equipment Editor (see [Use Equipment Editor to Configure Alarms](#)).

### Equipment Properties

Field	Description
<b>Equipment</b>	The name of the equipment associated with the digital alarm. Select a name from the drop-down list of existing equipment definitions, or enter a name. There is a limit of 254 characters across the Equipment and <b>Item Name</b> fields, including any separating periods (.).
<b>Item Name</b>	The name of the item with which the alarm is associated. Items form part of an equipment hierarchy. They can be used to associate tags, alarms and trends with a particular attribute of a physical piece of equipment (see <a href="#">Items</a> ). There is a limit of 254 characters across the <b>Equipment</b> and Item Name, including any separating periods (.). If you leave this field blank, the last 63 characters of the <b>Alarm Tag</b> field will be used for the Item Name. Be aware that the Alarm Tag allows 79 characters, while Tag Item has a maximum of 63 characters. This may result in compiler message if the combination of '<Equipment>.<TagItem>' is not unique. <b>Note:</b> When defining an item name, avoid using the reserved words. If you use any of these, an error message will display when you compile your project.

### General Properties

Field	Description
<b>Alarm Tag</b>	The name of the alarm tag. The name needs to be unique to the cluster and adhere to <a href="#">Tag Name Syntax</a> rules. If your project includes a large number of tags, a naming convention can be helpful when searching and debugging tags (see <a href="#">Structured Tag Names</a> ).
<b>Alarm Name</b>	A meaningful description of the alarm, for example, a name that includes the physical device associated with

Field	Description
	the alarm. The name is used when details of the alarm are displayed on the screen or logged to a device. This field does not support variable data.
<b>Cluster Name</b>	The name of the cluster that runs the alarm. This field needs to be defined if your project has more than one cluster.  You can leave this field blank in a multi-cluster system if cluster replication is enabled (see the parameter <a href="#">[General]ClusterReplication</a> ).
<b>Category</b>	The alarm category to which the alarm is assigned, defined as either a category number or a label (see <a href="#">Categorize Alarms</a> ).  If not specified, the category defaults to category 0.
<b>Alarm Desc</b>	A meaningful description of the alarm condition. This description is used when details of the alarm are displayed on screen or logged to a device.  This field can support variable data (by enclosing an expression in braces). For example:  Line Broken Alarm at Line Speed {LineSpeed1} See <a href="#">Add Variable Data to Alarm Messages</a> .
<b>Delay</b>	The alarm delay period (see <a href="#">Using Alarm Delay</a> ).  A time stamped digital alarm becomes active when the state of the triggering condition remains true for the duration of the delay period.  The delay period needs to be entered in the following format:  HH:MM:SS (Hours:Minutes:Seconds).  The value needs to be between 0 seconds (00:00:00) and 24 hours (24:00:00).
<b>Help</b>	The name of the graphics page that displays when the <code>AlarmHelp()</code> function is called by a user-defined command. If not specified no action occurs when the <code>AlarmHelp()</code> function is called.
<b>Comment</b>	Any useful comment.

**Source Properties**

Field	Description
<b>Variable Tag A /</b>	Configure time stamped digital alarms to activate

Field	Description
<b>Variable Tag B</b>	based on the state of a single or multiple digital variable tags. For a single variable tag use field Var Tag A. For multiple variable tags use fields Var Tag A and Var Tag B.  See <a href="#">Alarms</a> for more information on time stamped digital alarms.

**Custom Properties**

Field	Description
<b>Custom 1 to Custom 8</b>	A user-defined string for filtering active alarms (maximum 64 characters).  Used in a custom Cicode query function as search criteria, the custom alarm filter enables operators to identify and display a subset of active alarms.  <b>Note:</b> <ul style="list-style-type: none"> <li>The fields are not case-sensitive and can contain 'A'..'Z', 'a'..'z', '0'..'9', and the underscore '_'. </li> <li>A custom filter cannot start with a digit.</li> </ul>

**Paging Properties**

Field	Description
<b>Paging</b>	A read/write property that indicates whether the alarm will be paged. When the value is 1 (TRUE) the alarm will be paged. The default value is 0 (FALSE). This property can be read using alarm tag browsing and read or modified when tag properties are enabled using the tag name "myCluster.myAlarm.paging".
<b>Paging Group</b>	A read only text string that indicates the paging group to which the alarm belongs. Maximum length is 80 characters. See your third-party paging system documentation for information on how to use this Paging Group string. This property can be read using alarm tag browsing or when tag properties are enabled read using the tagname "myCluster.myAlarm.paginggroup". For example, assign the value of PagingGroup to a variable:  myString = myCluster.Alarm_1.paginggroup

**Security Properties**

Field	Description
<b>Area</b>	The Area to which the alarm belongs. If an operator

Field	Description
	<p>does not have access to an area, the alarm is not visible on the alarm display. For example, if you enter <b>Area 1</b> here, operator need to have access to Area 1 (plus any necessary privileges) to acknowledge or disable this alarm.</p> <p>The area and privilege fields defined here needs to be designed to work in conjunction. A privilege defined on a button (say) will ignore the alarm defined area.</p>
<b>Privilege</b>	<p>Privilege necessary by an operator to acknowledge or disable the alarm.</p> <p>If you assign an acknowledgment privilege to an alarm, there is no need to assign a privilege to the command(s) that acknowledge the alarm. If you assign a different privilege to the commands, an operator needs to have both privileges to acknowledge the command. More importantly, the area defined here may be ignored.</p>

**Historian Properties**

Field	Description
<b>Historize</b>	<p>This field enables you to automatically historize and publish the specified digital alarm in CitectHistorian.</p> <p>If you set this field to "TRUE", the variable will be included in an automated configuration process within the Historian environment. If you set the field to "FALSE" (or leave it blank), the variable will not be included.</p> <p>See <a href="#">Integration with Historian</a>.</p>

**Project Properties**

Property	Description
<b>Project</b>	The project in which the time-stamped digital alarm is configured.

**See Also**

[Alarms](#)

**Add a Time Stamped Analog Alarm**

Time stamped analog alarms use notifications from the alarm server to determine when an alarm is triggered.

This provides an accurate time stamp of when an alarm condition occurs.

**Note:** Time stamped analog alarms are timestamp based and designed to work with the Driver Runtime Interface (DRI). For a list of supported drivers, see [Retrieving Time-stamped Data from I/O Devices](#). Alternatively, you can configure the Cicode function [AlarmNotifyVarChange](#), as it notifies the alarm server of any value changes for the associated variable. It also passes the timestamp with the notification message. The alarm server maintains a queue for notification messages and runs a separate task to check this queue.

To configure an alarm that triggers when the associated tag value reaches a specified limit, you use the following properties:

- High
- High High
- Low
- Low Low

To configure an alarm that triggers when the tag value moves away from a predefined set point, you use:

- Setpoint
- Deviation

To configure an alarm that monitors the rate of change for a tag value across a set period of time, you use:

- Rate

#### To add a time stamped analog alarm:

1. In the **System Model** activity, select **Alarms**.
2. On the menu below the Command Bar, select **Time Stamped Analog Alarms**.
3. Add a row to the Grid Editor.
4. Type the required information in each column, or in the fields in the Property Grid.  
For a description of the properties, see below.
5. Click **Save**.

**Note:** Configure the [\[Alarm\]UseConfigLimits](#) parameter to force the Plant SCADA alarms server to use digital alarm property values from the RDB, rather than using the values which may be stored in the database file.

## Time Stamped Analog Alarms Properties

**Note:** If an alarm was generated by the Equipment Editor, a number of fields on the properties form will be shaded. To configure these fields, you will need to use Equipment Editor (see [Use Equipment Editor to Configure Alarms](#)).

### Equipment Properties

Field	Description
Equipment	The name of the equipment associated with the digital alarm. Select a name from the drop-down list

Field	Description
	<p>of existing equipment definitions, or enter a name. There is a limit of 254 characters across the Equipment and <b>Item Name</b> fields, including any separating periods (.).</p>
Item Name	<p>The name of the item with which the alarm is associated.</p> <p>Items form part of an equipment hierarchy. They can be used to associate tags, alarms and trends with a particular attribute of a physical piece of equipment (see <a href="#">Items</a>).</p> <p>There is a limit of 254 characters across the <b>Equipment</b> and Item Name, including any separating periods (.).</p> <p>If you leave this field blank, the last 63 characters of the <b>Alarm Tag</b> field will be used for the Item Name. Be aware that the Alarm Tag allows 79 characters, while Tag Item has a maximum of 63 characters. This may result in compiler errors if the combination of '&lt;Equipment&gt;.&lt;TagItem&gt;' is not unique.</p> <p><b>Note:</b> When defining an item name, avoid using the <a href="#">Reserved Words</a>. If you use any of these, an error message will display when you compile your project.</p>

### General Properties

Field	Description
Alarm Tag	<p>The name of the alarm tag. The name needs to be unique to the cluster and adhere to <a href="#">Tag Name Syntax</a> rules.</p> <p>If your project includes a large number of tags, a naming convention can be helpful when searching and debugging tags (see <a href="#">Structured Tag Names</a>).</p>
Alarm Name	<p>A meaningful description of the alarm, for example, a name that includes the physical device associated with the alarm. The name is used when details of the alarm are displayed on the screen or logged to a device. This field does not support variable data.</p>
Cluster Name	<p>The name of the cluster that runs the alarm. This field needs to be defined if your project has more than one cluster.</p> <p>You can leave this field blank in a multi-cluster system if cluster replication is enabled (see the parameter</p>

Field	Description
	<a href="#">[General]</a> <a href="#">ClusterReplication</a> ).
Category	<p>The alarm category to which the alarm is assigned, defined as either a category number or a label (see <a href="#">Categorize Alarms</a>).</p> <p>If not specified, the category defaults to category 0.</p>
Setpoint	<p>An analog variable tag that determines if a deviation alarm is to be triggered. This property is optional. If no value is set, it will default to 0 (zero).</p> <p><b>Note:</b> If set to an analog variable tag, it needs to a different tag to the Variable Tag property of the alarm.</p>
High High Delay	<p>Delay period for High High Alarms. Alarm will activate if its triggering condition is met for the duration of the delay period (see <a href="#">Use Alarm Delay</a>).</p> <p>If no value is set, the high high alarm will be activated as soon as the tag exceeds the high high value.</p> <p><b>Note:</b> The delay period needs to be entered in the format HH:MM:SS (hours:minutes:seconds). The value needs to be between 0 seconds (00:00:00) and 24 hours (24:00:00).</p>
High Delay	<p>The delay period for high alarms. Alarm will activate if its triggering condition is met for the duration of this period. If no value is set, the high alarm will be activated as soon as the tag exceeds the high value.</p> <p><b>Note:</b> The delay period needs to be entered in the format HH:MM:SS (hours:minutes:seconds). The value needs to be between 0 seconds (00:00:00) and 24 hours (24:00:00).</p> <p>When a tag value increases from high to high high within the high delay period, the delay timer is reset. The high high alarm is only activated if the value remains in the high high range for the delay period.</p> <p>When the value increases from high to high high after the high delay period has expired, a high alarm is activated and then the delay period for the high high alarm begins.</p> <p>If the tag value exceeds the high high value and then falls below it before the high high delay period expires, at the time it falls, the high alarm is triggered immediately.</p> <p>It has an ON time of when the tag value exceeded the high high value. These points also apply to tag values</p>

Field	Description
	traveling between Low and Low Low ranges.
Low Delay	<p>The delay period for Low Alarms. The alarm will only activate if its triggering condition is met for the duration of this period. This property is optional. If no value is set, the Low Alarm is activated as soon as the tag drops below the Low value.</p> <p><b>Note:</b> The delay period needs to be entered in the format HH:MM:SS (Hours:Minutes:Seconds). The value needs to be between 0 seconds (00:00:00) and 24 hours (24:00:00).</p>
Low Low Delay	<p>The delay period for Low Low Alarms. The alarm will only activate if its triggering condition is met for the duration of this period. If no value is set, the Low Low Alarm is activated as soon as the tag drops below the Low Low value.</p> <p><b>Note:</b> The delay period needs to be entered in the format HH:MM:SS (Hours:Minutes:Seconds). The value needs to be between 0 seconds (00:00:00) and 24 hours (24:00:00).</p>
Deviation	<p>The value used as the triggering condition for a Deviation Alarm. A Deviation Alarm is activated when the value of the Variable Tag remains outside the deviation range (determined by the Setpoint) for the duration of the Deviation Delay period. This property is optional. If no deviation is set, no Deviation Alarm is activated.</p>
Deviation Delay	<p>The delay period for Deviation Alarms. The alarm will only activate if its triggering condition is met for the duration of this period. If no value is set, the Deviation Alarm is activated as soon as the Variable Tag falls outside the deviation range.</p> <p><b>Note:</b> The delay period needs to be entered in the format HH:MM:SS (Hours:Minutes:Seconds). The value needs to be between 0 seconds (00:00:00) and 24 hours (24:00:00).</p>
Rate	<p>By dividing this value by the alarm period, the "maximum rate" at which the value of the variable tag can change is determined. At each Scan Time, the value of the tag is checked. If its rate of change is greater than the maximum rate, a Rate of Change Alarm is triggered.</p>

Field	Description
	<p>For example, to verify that a tank does not fill too quickly, you might configure a rate of change alarm, using a Rate of <b>300</b> liters, an <b>[Alarm]Period of 60 seconds</b>, and an <b>[Alarm]ScanTime of 1 second</b>. This means that the maximum allowable rate of change for the tank level is <b>5 l/sec</b> (300 liters / 60 seconds). The actual rate of change at each <b>ScanTime</b> is calculated. That is, every second, it checks the current level of the tank and compares it to the level recorded a second earlier. If the actual rate of change is, say, <b>8 l/sec</b>, a Rate of Change Alarm is triggered immediately.</p> <p>The variable tags deadband % needs to be less than the alarms rate divided by the engineering scale of the variable tag. Otherwise, the rate of change alarm will only go off when the change in the variable tag exceeds the deadband value. If no value is set, no Rate of Change Alarm is activated.</p>
Deadband	Value the variable tag needs to return to before the alarm becomes inactive.
Format	The display format of the value (of the variable) when it is displayed on a graphics page, written to a file or passed to a function (that expects a string). If no format is specified, it defaults to the format specified for variable tag.
Help	The name of the graphics page that displays when the <b>AlarmHelp()</b> function is called by a user-defined command. If not specified no action occurs when the <b>Alarm()</b> function is called.
Comment	Any useful comment.

**Source Properties**

Field	Description
Variable Tag	The analog variable tag that triggers the alarm.

**Limits Properties**

Field	Description
High High	The value used as the triggering condition for a high high alarm. The high high alarm becomes active when the value of the variable tag exceeds this value for the duration of the high high delay period. The active

Field	Description
	<p>alarm has an ON time of when the tag exceeded the high high value.</p> <p>Because a high alarm needs to precede a high high alarm, when the high high alarm is triggered it replaces the high alarm. If you want an analog alarm to display more than one state on the alarm page at the same time, configure a separate alarm for each state. (Each alarm would monitor the same tag.)</p>
High	<p>The value used as the triggering condition for a high alarm. The high alarm becomes active when the value of the variable tag exceeds this value for the duration of the high delay period. The active alarm has an ON time of when the tag exceeded the high value.</p>
Low	<p>The value used as the triggering condition for a Low Alarm. Alarm becomes active when the value of the Variable Tag drops below this value and remains there for the duration of the Low Delay period. The active alarm has an ON time of when the tag fell below the Low value.</p>
Low Low	<p>The value used as the triggering condition for a Low Low Alarm. A Low Low Alarm becomes active when the value of the Variable Tag drops below this value and remains there for the duration of the Low Low Delay period. The active alarm has an ON time of when the tag fell below the Low Low value.</p> <p>Because a Low Alarm needs to precede a Low Low Alarm, when the Low Low Alarm is triggered it replaces the Low Alarm. If you want an analog alarm to display more than one state on the alarm page at the same time, configure a separate alarm for each state. (Each alarm would monitor the same tag.)</p>

#### Custom Properties

Field	Description
Custom 1 to Custom 8	<p>A user-defined string for filtering active alarms (maximum 64 characters).</p> <p>Used in a custom Cicode query function as search criteria, the custom alarm filter enables operators to identify and display a subset of active alarms.</p> <p><b>Note:</b></p>

Field	Description
	<ul style="list-style-type: none"> <li>The fields are not case-sensitive and can contain 'A'..'Z', 'a'..'z', '0'..'9', and the underscore '_'. </li> <li>A custom filter cannot start with a digit.</li> </ul>

**Paging Properties**

Field	Description
Paging	A read/write property that indicates whether the alarm will be paged. When the value is 1 (TRUE) the alarm will be paged. The default value is 0 (FALSE). This property can be read using alarm tag browsing and read or modified when tag properties are enabled using the tag name "myCluster.myAlarm.paging".
Paging Group	A read only text string that indicates the paging group to which the alarm belongs. Maximum length is 80 characters. See your third-party paging system documentation for information on how to use this Paging Group string. This property can be read using alarm tag browsing or when tag properties are enabled read using the tagname "myCluster.myAlarm.paginggroup". For example, assign the value of PagingGroup to a variable: <code>myString = myCluster.Alarm_1.paginggroup</code>

**Security Properties**

Field	Description
Area	The Area the alarm belongs to. If an operator does not have access to an area, the alarm is not visible on the alarm display. For example, if you enter <b>Area 1</b> here, operator need to have access to Area 1 (plus any necessary privileges) to acknowledge or disable this alarm.  The area and privilege fields defined here needs to be designed to work in conjunction. A privilege defined on a button (say) will ignore the alarm defined area.
Privilege	Privilege necessary by an operator to acknowledge or disable the alarm.  If you assign an acknowledgment privilege to an alarm, there is no need to assign a privilege to the command(s) that acknowledge the alarm. If you assign a different privilege to the commands, an operator

Field	Description
	needs to have both privileges to acknowledge the command. More importantly, the area defined here may be ignored.

**Historian Properties**

Field	Description
Historize	This field enables you to automatically historize and publish the specified analog alarm in CitectHistorian. If you set this field to "TRUE", the variable will be included in an automated configuration process within the Historian environment. If you set the field to "FALSE" (or leave it blank), the variable will not be included.  See <a href="#">Integration with Historian</a> .

**Project Properties**

Property	Description
Project	The project in which the time-stamped analog alarm is configured.

**See Also**[Alarms](#)**Add a Double Point Status Alarm**

A double point status alarm responds to eight states in a field device that are represented in Plant SCADA as a single integer tag.

For each of the eight states you can specify the following properties:

- **State Name <n>** — a name that identifies the condition that the state represents.
- **State Type <n>** — the action that occurs when the device transitions to the defined state. The options are:
  - "Alarm" - an alarm is added to the Active Alarms page and an event is logged to the SOE page. The **State Name** will appear in the **State** field.
  - "Event" - indicates an OFF state has occurred. An event is logged on the SOE page, even if an alarm state transition did not occur. The **State Name** will appear in the **State** field.
  - "None" - indicates an OFF state has occurred. The **State Name** will appear in the **State** field on both the SOE and Active Alarms pages when an alarm transition occurs.

**Note:** If an alarm is currently in an "Event" or "None" state, a further transition to a "None" state will not be reported.

This means when the value of the integer tag is 0, the alarm will go into "State Name 0". When the value of the tag is 1, it will go into "State Name 1", and so on. Out of range values will be ignored.

**Note:** Double point status alarms are timestamp based and designed to work with the Driver Runtime Interface (DRI). For a list of supported drivers, see [Retrieving Time-stamped Data from I/O Devices](#). Alternatively, you can trigger a double point status alarm using the Cicode function `AlarmNotifyVarChange` as it notifies the alarm server of any value changes for the associated variable. It also passes the timestamp with the notification message.

### Example

The following table demonstrates the configuration of a double point status alarm associated with a single integer tag that represents four states.

Tag Value	Alarm Property	Value	Alarm	Event
0	State Name 0	Unknown	Yes	No
	State Type 0	Alarm		
1	State Name 1	Open	No	Yes
	State Type 1	Event		
2	State Name 2	Closed	No	Yes
	State Type 2	Event		
3	State Name 3	Jammed	Yes	No
	State Type 3	Alarm		

This configuration will result in following:

- An alarm will be triggered whenever the device transitions to an "Unknown" or "Jammed" state. This is determined by the **State Type <n>** property, which is set to "Alarm" for these two states. When an alarm occurs, the associated **State Name <n>** value will display in the State field on the Active Alarms page and the SOE page.
- If a transition occurs between two states that both have **State Type <n>** set to "Event" (for example, a transition from "Open" to "Closed"), this will be recorded on the SOE page without an alarm being raised.
- If the alarm transitions between two states that both have **State Type <n>** set to "Alarm", the state of the alarm will change to reflect the new state, and the time of the alarm will be updated.
- If an alarm transitions from "Alarm" state to an "Event" state, the alarm will be moved to an OFF state on the Active Alarms page and an event will be logged on the SOE page.

### To add a double point status alarm:

- In the **System Model** activity, select **Alarms**.
- On the menu below the Command Bar, select **Double Point Status Alarms**.
- Add a row to the Grid Editor.
- Type the required information in each column, or in the fields in the Property Grid.  
For a description of the properties, see below.
- Click **Save**.

**Note:** Configure the [\[Alarm\]UseConfigLimits](#) parameter to force the Plant SCADA alarms server to use double point alarm property values from the RDB, rather than using the values which may be stored in the database file.

## Double Point Status Alarm Properties

**Note:** If an alarm was generated by the Equipment Editor, a number of fields on the properties form will be shaded. To configure these fields, you will need to use Equipment Editor (see [Use Equipment Editor to Configure Alarms](#)).

### Equipment Properties

Field	Description
Equipment	<p>The name of the equipment associated with the double point status alarm. Select a name from the drop-down list of existing equipment definitions, or enter a name.</p> <p>There is a limit of 254 characters across the <b>Equipment</b> and <b>Item Name</b> fields, including any separating periods (.).</p>
Item Name	<p>The name of the item with which the alarm is associated.</p> <p>Items form part of an equipment hierarchy. They can be used to associate tags, alarms and trends with a particular attribute of a physical piece of equipment (see <a href="#">Items</a>).</p> <p>There is a limit of 254 characters across the <b>Equipment</b> and Item Name, including any separating periods (.).</p> <p>If you leave this field blank, the last 63 characters of the <b>Alarm Tag</b> field will be used for the Item Name. Be aware that the Alarm Tag allows 79 characters, while Tag Item has a maximum of 63 characters. This may result in compiler errors if the combination of '&lt;Equipment&gt;.&lt;TagItem&gt;' is not unique.</p> <p><b>Note:</b> When defining an item name, avoid using the <a href="#">Reserved Words</a>. If you use any of these, an error message will display when you compile your project.</p>

### General Properties

Field	Description
Alarm Tag	<p>The name of the alarm tag. The name needs to be unique to the cluster and adhere to <a href="#">Tag Name Syntax</a> rules.</p> <p>If your project includes a large number of tags, a</p>

Field	Description
	naming convention can be helpful when searching and debugging tags (see <a href="#">Structured Tag Names</a> ).
Alarm Name	A meaningful description of the alarm, for example, a name that includes the physical device associated with the alarm. The name is used when details of the alarm are displayed on the screen or logged to a device. This field does not support variable data.
Cluster Name	<p>The name of the cluster that runs the alarm. This field needs to be defined if your project has more than one cluster.</p> <p>You can leave this field blank in a multi-cluster system if cluster replication is enabled (see the parameter <a href="#">[General]ClusterReplication</a>).</p>
Category	<p>The alarm category to which the alarm is assigned, defined as either a category number or a label (see <a href="#">Categorize Alarms</a>).</p> <p>If not specified, the category defaults to category 0.</p>
Alarm Desc	<p>A meaningful description of the alarm condition. This description is used when details of the alarm are displayed on screen or logged to a device.</p> <p>This field can support variable data (by enclosing an expression in braces).</p> <p>For example:</p> <p>"Line Broken Alarm at Line Speed {LineSpeed1}"</p> <p>See <a href="#">Add Variable Data to Alarm Messages</a>.</p>
Delay	<p>The alarm delay period (see <a href="#">Use Alarm Delay</a>).</p> <p>An alarm becomes active when the state of the triggering condition remains true for the duration of the delay period.</p> <p>The delay period needs to be entered in the following format:</p> <p>HH:MM:SS (Hours:Minutes:Seconds).</p> <p>The value needs to be between 0 seconds (00:00:00) and 24 hours (24:00:00).</p>
Help	The name of the graphics page that displays when the <code>AlarmHelp()</code> function is called by a user-defined command. If not specified no action occurs when the <code>Alarm()</code> function is called.

Field	Description
Comment	Any useful comment.

**Source Properties**

Field	Description
Variable Tag	An integer tag that represents up to eight different states in a field device.

**State Properties**

Field	Description
State Name <1> to State Name <7>	Enter a name that describes the associated state. If an alarm or event is triggered for this state, this name will appear in the <b>State</b> field of the Active Alarms page and/or the SOE page.
State Type <1> to State Type <7>	<p>Determines the action that occurs when the device transitions to the defined state. The options are:</p> <ul style="list-style-type: none"> <li>• <b>Alarm</b> - an alarm is added to the Active Alarms page and an event is logged to the SOE page. The <b>State Name</b> will appear in the <b>State</b> field.</li> <li>• <b>Event</b> - indicates an OFF state has occurred. An event is logged on the SOE page, even if an alarm state transition did not occur. The <b>State Name</b> will appear in the <b>State</b> field.</li> <li>• <b>None</b> - indicates an OFF state has occurred. The <b>State Name</b> will appear in the <b>State</b> field on both the SOE and Active Alarms pages when an alarm transition occurs.</li> </ul> <p><b>Note:</b> If an alarm is currently in an "Event" or "None" state, a further transition to a "None" state will not be reported.</p>

**Note:** The **State Type** is stored as a numeric value in the alarms database. In some circumstances, you will need to use a numeric value to represent a particular State Type. This will include:

- When using **Equipment Editor** to associate a double point status alarm with an Equipment Type item.
- When using the **Project DBF Add-in** to manually edit the alarms database.
- When using filtering in Plant SCADA Studio.
- When using the **Export All / Import All** feature in the Alarms activity.

When a numeric value is required, use one of the following: 0 = None; 1 = Event; 2 = Alarm.

**Custom Properties**

Field	Description
Custom 1 to Custom 8	<p>A user-defined string for filtering active alarms (maximum 64 characters). Used in a custom Cicode query function as search criteria, the custom alarm filter enables operators to identify and display a subset of active alarms.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>The fields are not case-sensitive and can contain 'A'..'Z', 'a'..'z', '0'..'9', and the underscore '_'.</li> <li>A custom filter cannot start with a digit.</li> </ul>

**Paging Properties**

Field	Description
Paging	<p>A read/write property that indicates whether the alarm will be paged. When the value is 1 (TRUE) the alarm will be paged. The default value is 0 (FALSE). This property can be read using alarm tag browsing and read or modified when tag properties are enabled using the tag name "myCluster.myAlarm.paging".</p>
Paging Group	<p>A read only text string that indicates the paging group to which the alarm belongs. Maximum length is 80 characters. See your third-party paging system documentation for information on how to use this Paging Group string. This property can be read using alarm tag browsing or when tag properties are enabled read using the tagname "myCluster.myAlarm.paginggroup". For example, assign the value of PagingGroup to a variable:</p> <pre>myString = myCluster.Alarm_1.paginggroup</pre>

**Security Properties**

Field	Description
Area	<p>The Area the alarm belongs to. If an operator does not have access to an area, the alarm is not visible on the alarm display. For example, if you enter <b>Area 1</b> here, operator need to have access to Area 1 (plus any necessary privileges) to acknowledge or disable this alarm.</p>

Field	Description
	The area and privilege fields defined here needs to be designed to work in conjunction. A privilege defined on a button (say) will ignore the alarm defined area.
Privilege	<p>Privilege necessary by an operator to acknowledge or disable the alarm.</p> <p>If you assign an acknowledgment privilege to an alarm, there is no need to assign a privilege to the command(s) that acknowledge the alarm. If you assign a different privilege to the commands, an operator needs to have both privileges to acknowledge the command. More importantly, the area defined here may be ignored.</p>

### Historian Properties

Field	Description
Historize	<p>This field enables you to automatically historize and publish the specified analog alarm in CitectHistorian. If you set this field to "TRUE", the variable will be included in an automated configuration process within the Historian environment. If you set the field to "FALSE" (or leave it blank), the variable will not be included.</p> <p>See <a href="#">Integration with Historian</a>.</p>

### Project Properties

Property	Description
Project	The project in which the time-stamped digital alarm is configured.

### See Also

[Alarms](#)

### Add an Alarm Category

You can use alarm categories to group the alarms in your Plant SCADA system (see [Categorize Alarms](#)). Up to 16376 alarm categories can be created.

#### To add an alarm category to a project:

1. In the **Setup** activity, select **Alarming**.

2. On the menu below the Command Bar, select **Alarm Categories**.
3. Type the required information in each column, or in the fields in the Property Grid (see below for a description of the fields).
4. Click **Save**.

You will now be able to assign alarms to the category you have created in the System Model activity (see [Assign an Alarm to an Alarm Category](#)).

## **WARNING**

### **UNINTENDED EQUIPMENT OPERATION**

When configuring an alarm category, do not use a blocking Cicode function in the following fields:

- ON Action
- OFF Action
- ACK Action.

A blocking function or a lengthy operation will affect the polling of alarms, and may result in slow or delayed alarm processing. Therefore, do not configure long running functions in these fields but keep the functions simple or they may not be executed correctly. To execute complicated functions, it is recommended to use TaskNew() function to initiate a new task which performs the required function in a separate task.

If the configuration of these fields is updated and reloaded by the alarm server, the new actions will be executed. However, the updated configuration can not call any new or updated user functions which did not exist before reloading, even if a new task is used to run it. If used, nothing will happen until the alarm server is restarted. Hence, confirm that the updated actions do not refer to brand new or updated functions or tasks prior to reloading the alarm server.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

## **Alarm Category Properties**

### **General Properties**

Field	Description
<b>Category</b>	The alarm category as a numeric value (0-16375). The following category numbers are reserved: <ul style="list-style-type: none"><li>• Category 0 is reserved for selecting all the alarms with all categories.</li><li>• Category 254 is reserved for user-created alarm summary entries.</li><li>• Category 255 is reserved for hardware alarms.</li></ul> This field supports up to 16 characters.
<b>Priority</b>	The priority applied to alarms assigned to this alarm

Field	Description
	<p>category (0- 255). Alarm priority determines the order in which alarms are displayed, acknowledged, enabled and so on.</p> <p>Priority 1 is the highest priority, and priority 255 is the lowest. For example, if alarms with priorities 1 to 8 were displayed, priority 1 alarms would be displayed first in their time/date order, then priority 2 alarms, then priority 3, and so on up to priority 8.</p> <p>Priority 0 is the default priority. It is reserved for selecting alarms of all priorities when referencing priorities. For example, if you use the Cicode function <a href="#">AlarmSetInfo</a> to change an alarms list so that alarms of all priorities are displayed, you would use the following settings:</p> <p><i>Type = 7, Value = 0.</i></p> <p><b>Note:</b> When priority 0 is used to display alarms of priorities, priority 0 only alarms will display first, followed by priority 1 alarms, then priority 2, and so on. You can also customize the order in which alarms are displayed on an alarm summary page using the SummarySort and SummarySortMode parameters. (This order will override the alarm category priority order.)</p>
<b>Show on Active</b>	<p>Determines if alarms assigned to this category display on active alarms pages.</p> <p>You can set this field to TRUE or FALSE. The default value is TRUE.</p> <p><b>Note:</b> For Situational Awareness projects, <b>Show On Active</b> must be blank (TRUE) for associated alarm counts to appear on the Page Navigation Zone and Tree Views.</p>
<b>Show on Summary</b>	<p>Determines if alarms assigned to this category display on alarm summary pages.</p> <p>You can set this field to TRUE or FALSE. The default value is TRUE.</p>
<b>Comment</b>	Any useful comment.

**Font Properties**

Field	Description
<b>UnAck On Font</b>	Defines the font used to display alarms that are unacknowledged and active.

Field	Description
	<p>This property is optional. If no font is specified, the font defaults to 10pt YELLOW.</p> <p>This field supports up to 16 characters.</p>
<b>UnAck Off Font</b>	<p>Defines the font used to display alarms that are unacknowledged and no longer active.</p> <p>This property is optional. If no font is specified, the font defaults to 10pt BROWN.</p> <p>This field supports up to 16 characters.</p>
<b>Ack On Font</b>	<p>Defines the font used to display alarms that have been acknowledged and are still active.</p> <p>This property is optional. If no font is specified, the font defaults to 10pt CYAN.</p> <p>This field supports up to 16 characters.</p>
<b>Ack Off Font</b>	<p>Defines the font used to display alarms that have been acknowledged and are no longer active.</p> <p>This property is optional. If no font is specified, the font defaults to 10pt WHITE.</p> <p>This field supports up to 16 characters.</p>
<b>Disabled Font</b>	<p>Defines the font used to display disabled alarms.</p> <p>This property is optional. If no font is specified, the font defaults to 10pt WHITE.</p> <p>This field supports up to 16 characters.</p>

### Format Properties

Field	Description
<b>Alarm Format</b>	<p>Defines the screen display format used on active alarm pages for alarms in this category.</p> <p><b>Note:</b> Alarm pages based on the tab-style templates will not consider individual formats for each category. The screen display format used for an alarm page is set by the first available of the following definitions:</p> <ul style="list-style-type: none"> <li>• [Format]Alarm parameter</li> <li>• The Alarm Format specified for category 0</li> <li>• The default alarm display format.</li> </ul> <p>When applied to pages based on a standard template, Alarm Format specifies how the data for alarms in this category are displayed on alarms pages (on the screen only). Each alarm displays on the alarms page in a single line, for example:</p>

Field	Description
	<p>2:32:21RFP3 Raw Feed pump 3 Overload</p> <p>When alarms are displayed using variable width fonts (such as Arial or Helvetica), the alarm fields may not align properly across different rows. This can be avoided by using a field separator in the alarm format configuration instead of just a space.</p> <p>Tab characters, denoted by either "<code>^t</code>" (horizontal tab) or "<code>^v</code>" (vertical tab), between the alarm fields will act as alignment points in your alarm display.</p> <p>If you leave the Alarm Format field blank, the format defaults to:</p> <p><b>{Time,12} {Tag,10} {Name,20} {Desc,32}</b></p> <p>You can change this default setting with the parameter <b>[Alarm]DefDspFmt</b>.</p> <p>See <a href="#">Alarm Format Fields</a> for details about each field type.</p> <p><b>Note:</b> If an alarm value is longer than the field it is to be displayed in, it will be truncated or replaced with the #OVR ("overflow of format width") alert message. When the alarm is logged to a device (i.e. printed or written to a file or database), the format specified for the logging device overrides the display format.</p>
<b>Summary Format</b>	<p>Defines the screen display format used on alarm summary pages for alarms in this category.</p> <p><b>Note:</b> Alarm summary pages based on the tab-style templates will not consider individual formats for each category. The screen display format used for an alarm summary page is set by the first available of the following definitions:</p> <ul style="list-style-type: none"> <li>• [Format]Alarm parameter</li> <li>• The Alarm format specified for category 0</li> <li>• Default Alarm display format.</li> </ul> <p>When applied to pages based on a standard template, Summary Format is defined the same way as <b>Alarm Format</b> (see above). However, you can also use additional data fields.</p> <p>See <a href="#">Alarm Format Fields</a> for details about each field type.</p> <p>If you leave the Summary Format field blank, the format defaults to:</p> <p><b>{Name,20} {OnTime,8} {OffTime,8} {DeltaTime,8} {Comment,22}</b></p>

Field	Description
	<p>You can change this default setting with the parameter <a href="#">[Alarm]DefSumFmt</a>.</p> <p><b>Note:</b> When an alarm is logged to a summary device (i.e. printed or written to a file or database), the format specified for the logging device overrides the display format.</p>
<b>SOE Format</b>	<p>Defines the screen display format used on sequence of event (SOE) pages for alarms in this category.</p> <p><b>Note:</b> SOE pages based on the tab-style templates will not consider individual formats for each category. The screen display format used for an SOE page is set by the first available of the following definitions:</p> <ul style="list-style-type: none"> <li>• <a href="#">[Format]Alarm</a> parameter</li> <li>• The Alarm format specified for category 0</li> <li>• Default Alarm display format.</li> </ul> <p>When applied to pages based on a standard template, SOE Format is defined the same way as <b>Alarm Format</b> (see above). However, you can also use additional data fields.</p> <p>See <a href="#">Alarm Format Fields</a> for details about each field type.</p> <p>If you leave the SOE Format field blank, the format defaults to:</p> <pre>{DATE,16} {TIME,16} {TAG,10} {NAME,15} {MESSAGE,64} {STATE,16} {CLASSIFICATION,13} {USERNAME,16} {USERLOCATION,16}</pre> <p>You can change this default setting with the parameter <a href="#">[Alarm]DefSOEFmt</a>.</p>

### Actions Properties

Field	Description
<b>ON Action</b>	<p>Specifies a Cicode command that is executed when an alarm of this Category becomes active (ON).</p> <p><b>Example:</b> Where <b>ON Action</b> is <b>STOP_PROCESS = 1;</b> In this example the digital variable STOP_PROCESS is set to ON when an alarm in this category is triggered.</p> <p><b>Note:</b> Do not put a blocking Cicode function in this field. The alarm system executes ON, OFF, or ACK actions within the polling loop. A blocking function will affect the polling of alarms, and may result in slow</p>

Field	Description
	<p>or delayed alarm processing.</p> <p>A special case of this command occurs when the ON Action is self-referring, with a form such as TAG1 = TAG1 + 1. This command will not work properly since tags are not reread before processing the ON action (for performance reasons). This particular command will therefore initially set the value of TAG1 to 1 rather than incrementing it.</p> <p>To correctly run a command of this type in the ON Action, use TaskNew() to run your own Cicode function to perform the tag command. For example: ON Action is TaskNew("MyFunc","Data",5);</p>
<b>OFF Action</b>	<p>Specifies a Cicode command that is executed when an alarm of this Category is reset (OFF).</p> <p><b>Example:</b> Where <b>OFF Action</b> is <b>ENABLE_PROCESS = 1;</b> In this example the digital variable <b>ENABLE_PROCESS</b> is set to ON when an alarm in this category is reset.</p> <p><b>Note:</b> Do not put a blocking Cicode function in this field. The alarm system executes ON, OFF, or ACK actions within the polling loop. A blocking function will affect the polling of alarms, and may result in slow or delayed alarm processing.</p>
<b>ACK Action</b>	<p>A Cicode command that is executed when an alarm of this Category is acknowledged.</p> <p><b>Note:</b> Do not put a blocking Cicode function in this field. The alarm system executes ON, OFF, or ACK actions within the polling loop. A blocking function will affect the polling of alarms, and may result in slow or delayed alarm processing.</p>

### Storage Properties

Field	Description
<b>Alarm Acquisition Error</b>	<p>Acquisition error is an error related to acquiring data from I/O sub-system for the underlying tag and/or expression, for example, Device Offline, Tag Unknown, etc. (Integer length 6).</p> <p>All acquisition errors are stored for each alarm record separately within the alarm server as a new AcqError field. They are not logged and no hardware alarm is raised from them.</p>

Field	Description
	The AcqError field stores the error as the Plant SCADA error code (for example, NO ERROR). This field is made accessible through the alarm browse functionality. If there are multiple acquisition errors for a single alarm record, then the first of these is stored within the system.
<b>Summary Device</b>	Specified the device to which the alarm summary is sent.  The format specified in the device is used instead the display format. If not specified, alarm summaries are not logged.
<b>Log Device</b>	Specifies the device to which alarm state changes are logged. An alarm entry is made in the log device each time an alarm assigned to the category changes state (on, off, acknowledged, enabled, or disabled).  When the alarm is printed, or written to a file or device, the format specified in the device overrides the display format.  If not specified, alarm state changes are not logged.
<b>Log Transitions: ON</b>	Determines if the alarm details are logged when an alarm assigned to this category becomes active.  You can set this field to TRUE or FALSE. The default value is TRUE.
<b>Log Transitions: OFF</b>	Determines if the alarm details are logged when an alarm assigned to this category becomes inactive.  You can set this field to TRUE or FALSE. The default value is TRUE.
<b>Log Transitions: ACK</b>	Determines if the alarm details are logged when an alarm assigned to this category is acknowledged.  You can set this field to TRUE or FALSE. The default value is TRUE.

**Project Properties**

Property	Description
<b>Project</b>	The project in which the specified alarm category is included.

[Prioritize Alarms](#)

### Use Alarm Delay

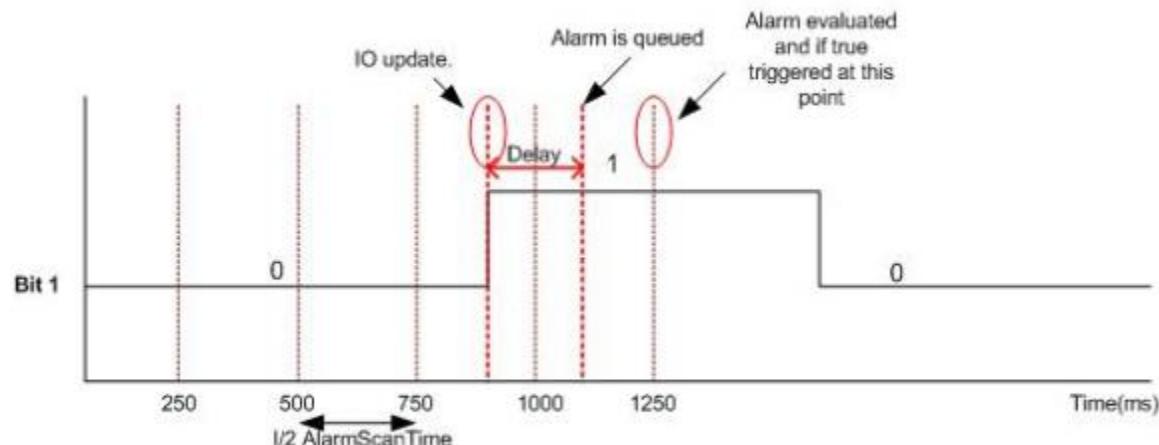

The **Alarm Delay** property allows you to configure digital, analog, and advanced alarms so that they will not be activated unless their triggering conditions remain true for a specified period.

For analog alarms, this means the analog variable needs to fall within a specified range for the duration of the alarm delay period before an alarm will activate. In the case of digital and advanced alarms, the triggering condition of the digital variable or Cicode expression need to remain true for the delay period.

#### Example

An alarm delay could be useful in monitoring temperature. By setting a delay period, you can filter out momentary alarms caused by a temperature moving in and out of different ranges.

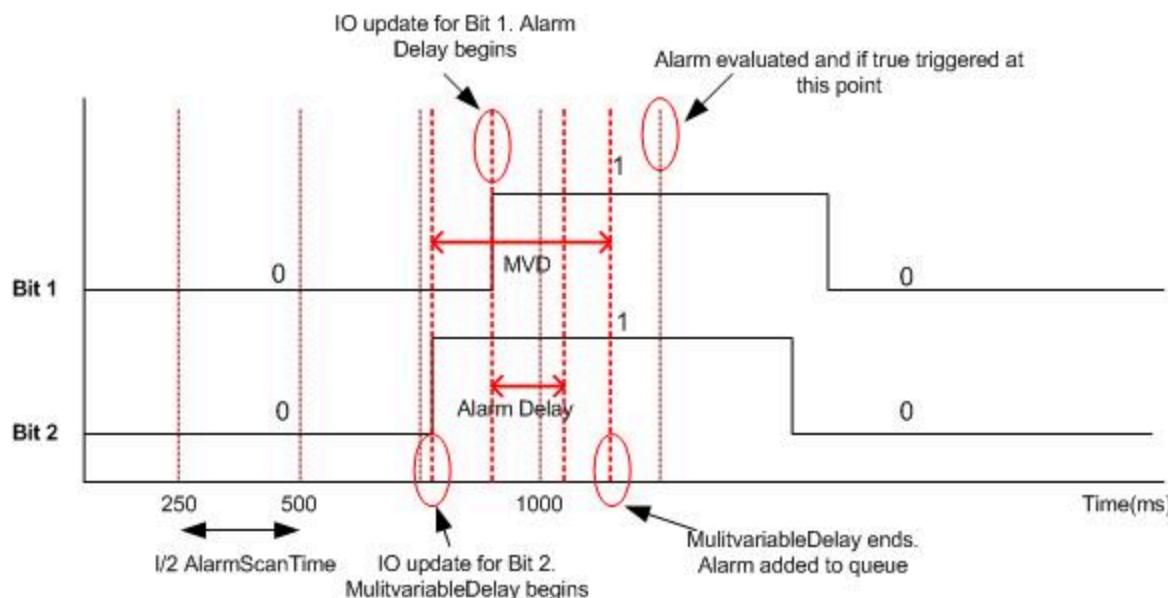

If 'Bit 1 = 1' then raise an alarm

When IO update occurs, alarm delay period will start. Once complete the alarm is queued.

For alarms with multiple variables configured, if you use the **Alarm Delay** property the delay period will start when the most recent I/O update has occurred. This delay can run concurrently with the internal multi-variable delay (MVD) which starts at the first IO update. The alarm will not be added to the queue until the period of the longest delay setting has elapsed. The alarm will then be triggered at the following 1/2 alarm scan time.

If 'Bit 1 AND Bit 2 = 1' then raise an alarm

Alarm delay starts after the most recent IO update has occurred and can run concurrently with the internal Multivariable delay (MVD), which starts at the first IO update has occurred. The alarm will not be added to the queue until the time of the longest delay setting has elapsed.

[Add an Advanced Alarm](#)

## Customize Alarm Pages

The Plant SCADA starter projects generate a set of alarm pages that are designed to support the requirements of a typical control system. This section of the help describes the different ways you can customize these pages to suit the requirements of a particular project.

If required, you can add additional alarm pages to a Plant SCADA project in Graphics Builder. For instructions on how to add a new page to a project, see [Create a Graphics Page](#).

---

**Note:** To display a custom alarm page (with a non-standard name), use the [PageDisplay](#) function to display the page, followed by the [AlarmSetInfo](#) function. You can create a keyboard command or a button to call the page, or add a touch command to an existing screen object.

---

If your project includes multiple clusters, you may want to visually indicate to an operator the status of alarm data across all clusters (see [Confirm that Alarms are Updated for All Clusters](#)).

You can also customize alarm pages in the following ways:

- Adjust the way alarms display on an alarms list (see [Format an Alarm Display](#))
- Customize fonts (see [Fonts](#))

- Adjust the default sort order (see [Alarms List Default Sort Order](#)).

It is also possible to define keywords for your alarm tags that allow you to perform customized queries on your alarm data (see [Using Custom Alarm Filters](#)).

## Confirm that Alarms are Updated for All Clusters

In a multi-cluster system, alarm data may appear on a display client in different time frames due to the proximity of the alarm server associated with each cluster.

For example, an alarm page may retrieve alarm data for one cluster from a local alarm server, while the alarm server for another cluster may be located remotely on a slow network. This could cause moments where alarm data is only partially retrieved for an alarms list, an SOE list or alarm summary.

If this situation is a possibility, you can use the Cicode function [AlarmGetInfo](#) to provide a visual indication of the status of your alarm data across all clusters. By calling this function from an animation object on a page, you can indicate the following to an operator:

- If data has been retrieved for no clusters, some clusters or all clusters
- If data has been retrieved for a specific cluster
- If any timeouts have occurred.

To do this:

1. Determine where you would like to implement AlarmGetInfo. You should use the Cicode function in a way that will indicate to an operator how alarm data retrieval is progressing for all clusters (see the example below).
2. Specify the **AN** associated with the alarms list that you would like the function to monitor.
3. Specify a **Type** of 13, 14 or 16, where:
  - 13 - the return value is used to indicate if data has been retrieved for all, some, or no clusters
  - 14 - the return value is used to indicate if data has been updated for a particular cluster (specified using the ClusterName argument)
  - 16 - the return value is used to indicate if a timeout occurred.

## Example

The following call of AlarmGetInfo() could be used to determine if the alarm data for the list at AN 21 has been retrieved for all clusters.

`AlarmGetInfo(21,13)`

- If zero (0) is returned, it would indicate that data is not ready for any clusters.
- If 1 is returned, it would indicate that data is ready for only some clusters.
- If 2 is returned, it would indicate that data is now ready for all clusters.

These return values could be implemented on a graphics page to indicate the completeness of the alarms list. For example, you could create an object that represents a traffic light, where "0" displays red, "1" displays amber, and "2" displays green.

## Format an Alarm Display

You can adjust the way alarms display on an alarms list.

The display format specifies how alarms are displayed on screen for the alarms.

The way you format the appearance of your alarms lists depends on the template used to create the pages in your project.

- [Format Alarm Pages in a Starter Project](#)
- [Format Alarms in a Standard Project](#)

### See also

[Create Priority and State Symbols for an Alarms List](#)

### Format Alarm Pages in a Starter Project

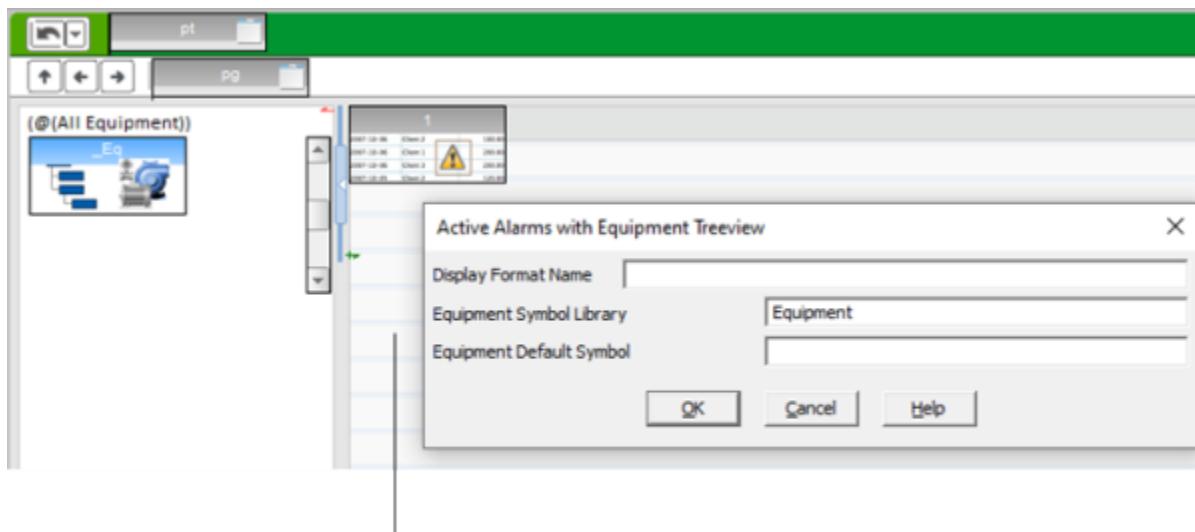

If you would like to customize the content included in each of the table columns on an alarm page, you can configure a new display format using [Alarm Format Fields](#).

To do this, you use the parameter `[Format]FormatName`. This parameter allows you to create and name a customized alarm display format that you can then associate with an alarm page.

**Note:** If you create a customized alarm display format for a page, be aware that the arrangement of columns may only be temporary. An operator will be able to rearrange the columns at runtime, and their changes will be restored each time they log in.

### To associate a customized alarm display format with an alarm page:

1. Use the `[Format]FormatName` parameter to create a customized alarm display format.
2. In Graphics Builder, open the alarm page that you would like to customize.
3. Double-click on the page. A dialog will appear displaying the page parameters.

4. In the **Display Format Name** field, enter the name of the alarm display format you created.
5. Click **OK** and **Save** the alarm page.

**Note:** The Hardware Alarm page does not display alarms in a table. To modify the alarm display format for a Hardware Alarms page, use the techniques described in the topic [Format Alarms in a Standard Project](#).

You can also use the following parameters to globally customize the alarm pages in a starter project:

- [Tab\\_Style Template Parameters](#)
- [Alarm Heading Parameters](#)

Advanced users may also use the [\[TabAlarm.Custom\] Parameters](#) to set a function that returns the value of a specified alarm field.

## See Also

[Format Alarms in a Standard Project](#)

### Format Alarms in a Standard Project

This topic describes how to format alarms in a standard project. The display format specifies how alarms are displayed on screen for the Active Alarms and Alarm Summary pages.

### Include System Data in an Alarm Field

Include data in an alarm display by specifying the field name and width for each field to display. You need to enclose each field in braces {} and use the following syntax:

{<field name>, [width[, justification]]}

For example:

Format	{Tag,8} {Name,32}
--------	-------------------

In this case, data displays in two fields: Tag, with 8 characters; and Name, with 32 characters. The width specifier is optional; if it is not used, the width of the field is determined by the number of characters between the braces.

Format	Name of Alarm:{Name }
--------	-----------------------

In this case, Name is followed by four spaces; the data {Name} displays with 8 characters.

**Note:** The screen resolution of your computer determines the total number of characters (and therefore the number of fields) that can be displayed on the alarms page.

### Include Fixed Text in an Alarm Field

You can include fixed text by specifying the text exactly as it will display; for example:

Format	Name of Alarm:
--------	----------------

Any spaces that you use in a text string are also included in the display.

## Set the Text Justification in an Alarm Field.

To set the justification of the text in each field, use a justification specifier. You can use three justification characters, L (Left), R (Right), and N (None); for example:

Format	Name of Alarm:{Name,32,R} {Tag,8,L}
--------	-------------------------------------

The justification specifier is optional; if it is omitted, the field is left justified. If you use a justification specifier, you need to also use the width specifier.

To display field text in columns, use the tab character (^t); for example:

Format	{Tag,8}^t{Name,32}^t{Desc,8}
--------	------------------------------

This format aligns the tag, name and description fields of the alarm when using a proportional font to display the alarms.

### See Also

[Alarm Format Fields](#)

### Alarm Format Fields

Alarm format fields define syntax you can use to customize the way alarms appear in an alarms list.

In a standard project, you would typically apply the syntax to the **Alarm Format** and **Summary Format** fields in the Alarm Category Properties (see [Add an Alarm Category](#)) to define how the alarms associated with a particular category will display (category zero (0) being the default for all categories).

In projects based on a starter project, some parameters allow you to use alarm format fields to customize an alarms list. For example, [\[Format\]FormatName](#).

The syntax associated with the alarm format fields are described in the following topics:

- [Alarm Display Fields](#)
- [Alarm SOE Fields](#)
- [Alarm Summary Fields](#).

### See Also

[Format an Alarm Display](#)

## Alarm Display Fields

You can use any of the fields listed below, or the [Alarm Summary Fields](#), to format an alarm display and an alarm log device (see [Format an Alarm Display](#)).

Field Name	Description
{AcqDesc,n}	Textual representation of Alarm Acquisition Error.
{AcqError, n}	Numeric representation of Alarm Acquisition Error.

Field Name	Description
{AlarmType,n}	Alarm type (string), not localized. Values are: Digital, Analog, Advanced, Multi-Digital, Time Stamped, Time Stamped Digital, Time Stamped Analog.
{AlmComment,n}	The text entered into the Comment field of the alarm properties dialog.
{Area,n}	Area <b>Note:</b> Set the value of this field between 0 and 255.
{Category,n}	Alarm Category
{Cluster,n}	Cluster Name
{CUSTOM1,n} {CUSTOM2,n} {CUSTOM3,n} {CUSTOM4,n} {CUSTOM5,n} {CUSTOM6,n} {CUSTOM7,n} {CUSTOM8,n}	Alarm custom fields as configured.
{Date,n}	The date on which the alarm changed state (dd:mm:yyyy). Be aware that you can change the format used via the parameter <a href="#">[Alarm]ExtendedDate</a> .
{DateExt,n}	The date on which the alarm changed state in extended format.
{Deadband,n}	Deadband
{Desc,n}	Alarm description
{Deviation,n}	Deviation alarm trigger value
{DisableEndTime,n}	Indicates when a shelved alarm will no longer be disabled.  This can be in 12 hour format (for example, h:mm:ss tt), or 24 hour format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.
{ErrDesc,n}	Text string associated with a protocol (communication) error. This field is only associated with hardware errors and contains extra information associated with whatever error is detected (for example if the error is associated with a device, the

Field Name	Description
	device name is returned; if the error is associated with a Cicode function, the function name is returned; if the error is associated with an I/O Device, the I/O Device's alert message is returned).
{ErrPage,n}	The page, device, etc. associated with the alarm.
{Format,n}	Display format of the Variable Tag
{Help,n}	Help Page
{High,n}	High Alarm trigger value
{HighHigh,n}	High High Alarm trigger value
{LocalTimeDate,n}	Alarm date and time in the form: "yyyy-mm-dd hh:mm:ss[.ttt]"
{LogState,n}	The last state that the alarm passed through. (This is useful when logging alarms to a device.)
{Low,n}	Low Alarm trigger value
{LowLow,n}	Low Low Alarm trigger value
{Name,n}	<p>Alarm Name</p> <p><b>Note:</b> If the <b>Name</b> field is configured to support long names (up to 79 characters), it might cause overlap in an alarm display. Use a smaller display font if long names are expected.</p>
{Native_Desc,n}	Alarm Description in the native language
{Native_Name,n}	<p>Alarm Name in the expression</p> <p><b>Note:</b> If the <b>Native_Name</b> field is configured to support long names (up to 79 characters), it might cause overlap in an alarm display. Use a smaller display font if long names are expected.</p>
{Paging,n}	Indicates whether the alarm has to be paged. When the value is TRUE the alarm will be paged. The default value is FALSE.
{PagingGroup, n}	Indicates the paging group to which the alarm belongs. Maximum length is 80 characters.
{Priority,n}	Alarm category's priority
{Priv,n}	Privilege

Field Name	Description
{Rate,n}	Rate of change trigger value
{State,n}	<p>The current state of the alarm. This field may be used for</p> <p>Alarm Display Only. It is not applicable to Alarm Summary.</p> <p>ON OFF DEVIATION RATE LOW LOWLOW HIGH HIGHHIGH ON State 2 ON State 3 ON State 4 ON State 5 ON State 6 ON State 7 CLEARED</p>
{State_desc, n}	The configured description (for example healthy or stopped) of a particular state. This description is entered when configuring the Multi-Digital Alarm Properties
{Tag,n}	<p>Alarm Tag</p> <p><b>Note:</b> If the <b>Tag</b> field is configured to support long names (up to 79 characters), it might cause overlap in an alarm display. Use a smaller display font if long names are expected.</p>
{TagEx,n}	<p>Alarm Tag with Cluster Name prefix</p> <p><b>Note:</b> If the <b>TagEx</b> field is configured to support long names (up to 79 characters), it might cause overlap in an alarm display. Use a smaller display font if long names are expected.</p>
{Time,n}	<p>The time at which the alarm changed state. This can be in 12 hour format (for example, h:mm:ss tt) or 24 hour format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.</p> <p>Set the <a href="#">[Alarm]SetTimeOnAck</a> parameter to use this field for the time the alarm is acknowledged.</p>

Field Name	Description
{Type,n}	The type of alarm or condition: ACKNOWLEDGED Cleared Disabled Unacknowledged
{TypeNum,n}	Alarm type number (use AlarmType to get string value instead). Values are: -1 Invalid 0 Digital 1 Analog 2 Advanced 3 Multi-Digital 4 ArgAna 5 User Event 6 timestamped 7 hardware 8 timestamped digital 9 timestamped analog
{Value,n}	The current value of the analog variable
{Classification,n}	The class of the event. For example: - "Action" - "Comment" - "Configuration" - "System" - "<alarm type>"
{Equipment,n}	The name of the equipment the alarm is associated with.
{Message,n}	The event message.
{Millisecond,n}	Adds milliseconds to the {Time,n} field
{RecordId,n}	String that uniquely identifies SOE records within the cluster. On the Alarm Summary table, this field references the associated SOE record.
{State,n}	State of the event. The value of this field indicates the action that triggers the event, similar to the value returned by the existing LogState field.
{UserLocation,n}	The IP of the machine which last raised, or performed an action on alarm.

Where n specifies the display field size.

**Note:**

- Any of the above fields can be displayed for any type of alarm. Where not applicable for a particular alarm type, zero or an empty string will be displayed.
- If an alarm value is longer than the field it is to be displayed in (n), it will be truncated or replaced with the #OVR ("overflow of format width") alert message.
- For summary pages use {SumState}. To log the state to a device, use {LogState}. State is the current state of the alarm, SumState is the state of the alarm when it occurred, and Log State is the state of the alarm at the transition.

**See Also**[Alarm Summary Fields](#)

## Alarm SOE Fields

You can use any fields listed below (or a combination) to format an alarm SOE display. Those fields specific to the event journal can be archived.

Format the alarm SOE for an entire category of alarms by specifying field names in the **SOE Format** field of the Alarm Category Properties dialog box.

**Note:** To change the font and format of the system events on the SOE page, use alarm category 0 (zero).

You can also use the [\[Alarm\]DefSOEFmt](#) parameter to format the alarm SOE, particularly if your alarm SOE formats are to be the same.

Field Name	Description	Archived
{AcqDesc,n}	Textual representation of Alarm Acquisition Error.	No
{AcqError,n}	Acquisition error. Separate event (error code) in SOE.	No
{AlarmType,n}	Alarm type (text). "Digital", "Analog", "Advanced", "Multi-Digital", "Time Stamped", "Time Stamped Digital", "Time Stamped Analog"	No
{AlmComment,n}	Alarm comment	No
{Area,n}	Alarm area. Numeric value (integer)	No
{Category,n}	Alarm category. Numeric value (integer)	No
{Classification,n}	The class of the event. For example: Action — The event was logged due to an action being performed. An	Yes

Field Name	Description	Archived
	<p>action can be triggered manually by an operator, or automatically.</p> <p>Comment — The event was logged due to a comment being created.</p> <p>Configuration — The event was logged due to configuration changes being made (for example, a new item being created, the configuration of an existing item being modified, an item being renamed or deleted from the database).</p> <p>System — The event has been logged due to an occurrence that affects the entire system, such as the server being stopped and restarted. The System category is also used for miscellaneous events that are not suited to the other categories.</p> <p>Alarm type - Type of Alarm (for example, digital, multi-digital etc.)</p>	
{Cluster,n}	The cluster to which the tag belongs.	No
{CUSTOM1,n} {CUSTOM2,n} {CUSTOM3,n} {CUSTOM4,n} {CUSTOM5,n} {CUSTOM6,n} {CUSTOM7,n} {CUSTOM8,n}	Alarm custom fields from 1 to 8	No
{Date,n}	Part of event record time in event journal.	Yes
{DateExt,n}	Part of event record time in event journal.	Yes
{DeadBand,n}	Alarm deadband. For Analog, and Timestamped Analog alarms: Numeric value (real).	No
{Deviation,n}	Alarm deviation. For Analog, and	No

Field Name	Description	Archived
	Timestamped Analog alarms: Numeric value (real).	
{Desc,n}	Alarm Description	Yes
{Equipment,n}	The name of the equipment the alarm is associated with.	No
{FullName,n}	The full name of the user (Full Name) who was logged on and performed some action on the alarm (for example acknowledging the alarm or disabling the alarm, etc.). When the alarm is first activated, the full name is set to "system" (because the operator did not trip the alarm). This field is not localized.	No
{Group,n}	Alarm group. For Argyle Digital (Multi-digital) alarms: Numeric value.	No
{Help,n}	Alarm help. The name of the help page.	No
{High,n}	High Alarm trigger value	No
{HighHigh,n}	High High Alarm trigger value	No
{LocalTimeDate,n}	Alarm date and time in the form: "yyyy-mm-dd hh:mm:ss[.sss]"	Yes
{LogState,n}	The last state that the alarm passed through. (This is useful when logging alarms to a device.)	Yes
{Low,n}	Low Alarm trigger value	No
{LowLow,n}	Low Low Alarm trigger value	No
{Message,n}	The event message.	Yes
{MilliSec,n}	Alarm milliseconds. Numeric value (integer)	Yes
{Name,n}	Alarm Name	No
{Native_SumDesc,n}	A description of the alarm	No

Field Name	Description	Archived
	summary, in the native language.	
{Paging,n}	Alarm paged flag. A flag to indicate that the alarm is going to be paged. Values are 1 (TRUE) or 0 (FALSE).	No
{PagingGroup,n}	Paging group for alarm. A free form text field indicating the sequence of people to notify in the event the alarm occurred.	No
{Priority,n}	Alarm category priority. Numeric value (integer)	No
{Priv,n}	Alarm privilege. Numeric value (integer)	No
{Quality, n}	The I/O server will pass the quality of the tag to the Alarm server when a tag's value is changed. If the changed tag value causes a state transition the alarm server will pass the quality to the database. This field displays the raw value (2 bytes numeric). The field TSQuality relates to this field and displays high byte of the 2 byte value in a string.	No
{Rate,n}	Alarm rate. For Analog, and Timestamped Analog alarms: Numeric value (real)	No
{ReceiptDate,n}	Date the master station received the event. For example, Date the RTU received the event.	
{ReceiptLocalDateTime,n}	This field displays the alarm's occurrence time (if known), otherwise it displays the receipt time of the alarm.	
{ReceiptTime,n}	Time the event was logged into the database. This can be in 12 hour format (for example, h:mm:ss tt) or 24 hour format (for example, H:mm:ss) depending on the regional date and time settings on	No

Field Name	Description	Archived
	the local computer.	
{State,n}	Current state of alarm.	Yes
{State_Desc,n}	The configured description (for example healthy or stopped) of a particular state. This description is entered when configuring the Multi-Digital Alarm Properties.	No
{State_Desc0,n} {State_Desc1,n} {State_Desc2,n} {State_Desc3,n} {State_Desc4,n} {State_Desc5,n} {State_Desc6,n} {State_Desc7,n}	Argyle state 0-7. For Argyle Digital (Multi-digital) alarms: "OFF". For others: "INVALID"	No
{SumDesc,n}	Alarm description text. Analog alarm - Alarm state text. Otherwise - Configured event [or alarm in case event not defined] description.	No
{SumState,n}	Describes the state of the alarm when it occurred.	No
{Tag,n}	Alarm Tag <b>Note:</b> If the Tag field is configured to support long names (up to 79 characters), it might cause overlap in an alarm display. Use a smaller display font if long names are expected.	Yes
{TagItem,n}	Alarm Tag with Cluster Name prefix <b>Note:</b> If the TagEx field is configured to support long names (up to 79 characters), it might cause overlap in an alarm display. Use a smaller display font if long names are expected.	No
{TagEx,n}	Alarm source	Yes
{Time,n}	This can be in 12 hour format (for example, h:mm:ss tt) or 24 hour format (for example, H:mm:ss)	Yes

Field Name	Description	Archived
	<p>depending on the regional date and time settings on the local computer.</p> <p><b>Note:</b> This works between UTC time 1/1/1980 - UTC time 31/12/2037, otherwise "".</p>	
{TimeDate,n}	<p>Special SQL formatted time. HH:MM:SS.</p> <p><b>Note:</b> The format can be configured in the Citect.ini file by specifying TimeDate under the section [Alarm].</p>	Yes
{TSQuality,n}	<p>The IO server will pass the quality of the tag to the Alarm server when a tag's value is changed. If the changed tag value causes a state transition the alarm server will pass the quality to the database. The field displays high byte of the 2 byte value (available under the Quality field) in a string . Expected Timestamp Quality strings are: Time Good, Time Uncertain, Clock Not Synchronized, or empty string if no match is found.</p>	Yes
{Type,n}	<p>The type of alarm or condition: ACKNOWLEDGED, DISABLED, UNACKNOWLEDGED</p>	Yes
{TypeNum,n}	<p>Alarm type number (use AlarmType to get string value instead). Values are: -1 Invalid, 0 Digital 1, Analog 2, Advanced 3, Multi-Digital 4, ArgAna 5, User Event 6, timestamped 7, hardware 8, timestamped digital 9, timestamped analog</p>	No
{UserLocation,n}	<p>The IP address where the event was triggered.</p>	Yes
{UserName,n}	<p>The name of the user (User Name) who was logged on and performed some action on the alarm (for example acknowledging the alarm or disabling the alarm, etc.). When</p>	Yes

Field Name	Description	Archived
	the alarm is first activated, the user name is set to "system" (because the operator did not trip the alarm).	

Where "n" specifies the display field size.

## Alarm Summary Fields

You can use any fields listed below (or a combination) to format an alarm summary display and an alarm summary device.

Format the alarm summary for an entire category of alarms by specifying field names in the **Summary Format** field of the Alarm Category Properties dialog box (category zero (0) being the default for all categories).

You can also use the [\[Alarm\]DefSumFmt](#) parameter to format the alarm summary, particularly if your alarm summary formats are to be the same.

Field Name	Description
{AckDate,n}	The date when the alarm was acknowledged.
{AckDateExt,n}	The date (in extended format) when the alarm was acknowledged (dd/mm/yyyy).
{AckTime,n}	The time when the alarm was acknowledged. This can be in 12 hour format (for example, h:mm:ss tt) or 24 hour format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.
{DeltaMilli,n}	Adds milliseconds precision to the DeltaTime.
{DeltaTime,n}	The time difference between OnDate/OnTime and OffDate/OffTime, in seconds.
{FullName,n}	The full name of the user (Full Name) who was logged on and performed some action on the alarm (for example acknowledging the alarm or disabling the alarm, etc.). When the alarm is first activated, the full name is set to "system" (because the operator did not trip the alarm).
{Native_SumDesc,n}	A description of the alarm summary, in the native language.

Field Name	Description
{OffDate,n}	The date when the alarm returned to its normal state.
{OffDateExt,n}	The date (in extended format) when the alarm returned to its normal state (dd/mm/yyyy).
{OffMilli,n}	Adds milliseconds to the time the alarm returned to its normal state.
{OffTime,n}	The time when the alarm returned to its normal state. This can be in 12 hour format (for example, h:mm:ss tt) or 24 hour format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.
{OnDate,n}	The date when alarm was activated.
{OnDateExt,n}	The date (in extended format) when the alarm was activated (dd/mm/yyyy).
{OnMilli,n}	Adds milliseconds to the time the alarm was activated.
{OnTime,n}	The time when the alarm was activated. This can be in 12 hour format (for example, h:mm:ss tt) or 24 hour format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.
{SumDesc,n}	A description of the alarm summary.
{SumState,n}	Describes the state of the alarm when it occurred.
{SumType,n}	Type of alarm summary (similar to alarm "Type"). Values are ACKNOWLEDGED, DISABLED, UNACKNOWLEDGED.
{UserDesc,n}	The text related to the user event. If you specify an asterisk '*' as the first letter of the tag argument in AlarmSumAppend, the field value is the text following the asterisk '*' in the tag argument.
{UserLocation,n}	The IP of the machine which last raised, performed an action on or modified the alarm. Note: If the last action performed is from a System machine, the IP will not over ride the last user machine IP address.
{UserName,n}	The name of the user (User Name) who was logged on and performed some action on the alarm (for example, acknowledging the alarm, disabling the alarm, and so on). When the alarm is first activated,

Field Name	Description
	the user name is set to "system" (because the operator did not trip the alarm).
{Value,n}	Formatted alarm value.

Where n specifies the display field size

**Note:** You can also include in your Alarm Summary any alarm display field other than **State**.

### Create Priority and State Symbols for an Alarms List

Plant SCADA allows you to add dynamic symbols to an alarms list that indicates the priority and state of an alarm.

Date	Time	Name	Priority	State
21/11/2017	02:28:34 PM	Drive1_V_Feedback_H_P3	3	HIGH
21/11/2017	02:28:34 PM	Drive1_OP_TRK_H_P2	2	HIGH
21/11/2017	02:28:34 PM	Drive1_V_OP_HH_P1	1	HIGH HIGH
8/11/2017	11:29:03 AM	Drive1_Running_False_P1	1	ON
Priority and State				

To achieve this, you need to perform the following tasks.

#### Create a Genie for each alarm priority that you want highlight with a symbol

The Genie requires a root level object named "Shape".

1. In Graphics Builder, create a new Genie.
2. Add the object you would like use as a symbol.  
A small, simple shape that supports a fill color is recommended.
3. Display the Properties dialog for the object.
4. On the **Appearance | General** tab, select **Filled**.
5. On the **Fill | Color** tab, configure the following:
  - Set the **Type** to **Array**.
  - Enter the following **Array Expression**:
 

```
dspAnGetMetaData(dspGetAnCur(), "State")
```
  - Specify the **Array Colors** you want to use for 6 – 9, based to the following states:
    - 6 = On and Unacknowledged
    - 7 = Off and Unacknowledged

8 = On and Acknowledged

9 = Disabled/Shelved.

If required, you can configure flashing colors for a state via the [Edit Favorite Colors Dialog Box](#), which is accessible via the **Edit** button on the drop-down Color Picker.

**Note:** Array colors 1 - 4 are reserved for use with the flag on an Alarm Indicator.

6. On the **Access | General** tab, enter the **Name** "Shape".
7. On the **Metadata | General** tab, enter the following items:
  - Name: Equipment; Value: <blank>
  - Name: Label; Value: <blank>
  - Name: State; Value: 0
8. Click **OK**.

Alarm flag Genies use functionality provided by the Cicode function DspSym. You need to perform the remaining steps to enable DspSym support for the Genie.

1. Display the Page Properties for the Genie. To do this:

On the **File** menu, select **Properties**.

Or:

Right-click on the Genie background and select **Page Properties**.

2. On the Page Properties dialog, select **I want to use this Genie with the Cicode function DspSym**.
3. Click **OK**.
4. **Save** the Genie to a library.

**Note:** When saving an alarm flag Genie, use a name that is unique across all included projects that share the same primary project.

## Associate a Genie with an alarm priority

1. In Plant SCADA Studio's **Setup** activity, select **Alarming**.
2. On the menu below the Command Bar, select **Alarm Priorities**.
3. Locate the Alarm Priority you would like to associate with a Genie.
4. In the **Small Genie Name** field, enter the name of the Genie you would like to associate with the alarm priority.
5. In the **Library Name** field, enter the name of the library that includes the Genie.
6. Click **Save**.

## Add a Priority and State column to an alarms list

To add a Priority and State column to an alarms list, you need to add the display field "{PriorityAndState}" to the alarm format used by the list.

For example, in a project created from a Situational Awareness Starter Project, the parameter [\[Format\]FormatName](#) is used as a project database parameter to define the following alarm formats:

Format Name	Display Fields
Alarm	{PriorityAndState,50}{Date,80}{Time,90}{Name,250}{Cluster,100}{State,40}{Type,70}{UserName,100}{Tag,250}{AlmComment,250}{Priority,60}{Quality,60}
Top5Alarm	{PriorityAndState,24}{Date,90}{Time,90}{Name,220}{Desc,300}{State,50}
SOE	{PriorityAndState,50}{Date,160}{Time,160}{Tag,100}{Message,640}{State,160}{Classification,130}{UserName,160}{UserLocation,160}
TopActiveAlarms_UHD4K	{PriorityAndState,24}{Date,120}{Time,130}{Name,190}{Desc,180}{State,50}
InfoAlarm_HD1080	{PriorityandState,24}{Time,90}{Item,160}{Name,180}

This places the Priority and State symbol in the first column of these alarm lists.

You can edit the alarm formats for a Situational Awareness project in the **Setup** activity (see [Project Database Parameters](#)).

For other projects, see [Format an Alarm Display](#).

A default set of priority and state symbols are provided in the SA\_Include project in a library called "sa\_priorities" (see [Alarms](#)). They represent the top three alarm priorities, and are named as follows:

- Priority 1 – "sa\_p1\_small"
- Priority 2 – "sa\_p2\_small"
- Priority 3 – "sa\_p3\_small".

---

**Note:** The Genie "sa\_p4\_small" is provided in the "sapriorities" library of the SA\_Controls project to represent alarms in the fourth-highest priority. If you would like to use this additional Genie, you need to correctly configure the fourth alarm priority. See [Configure Display Properties for a Fourth Alarm Priority](#).

[Configure Display Properties for an Alarm Priority](#)

## Add Variable Data to Alarm Messages

The **Alarm Desc** field of digital, advanced and time-stamped alarms can be used to display variable data. An expression (variable tag, function etc.) can be embedded into the text of the **Alarm Desc** field. This expression is evaluated when the alarm goes ON/OFF, returning the instant value of any associated variable tags.

Enclosing the expression in braces separates the variable data from the static text. For example:

Alarm Desc	Line Broken Alarm at Line Speed {LineSpeed1}
------------	--

When *LineSpeed1* is a variable tag, this expression will produce the following output on the alarm display or

alarm log:

Line Broken Alarm at Line Speed 1234

The following alarm entry uses an expression instead of a tag:

Alarm Desc	High Level at Total Capacity {Tank1+Tank2+Offset()}
------------	---

When *Tank1* and *Tank2* are variable tags, and *Offset* is a Cicode function, this expression produces the following output:

**High Level at Total Capacity 4985 liters**

**Note:** The result is formatted according to the formatting specified for the first variable tag in the expression. Standard variable formatting specifiers can be used to define the format for the numeric variable, over-riding the default format specified in Variable Tags.

[Alarm Display Fields](#)

### Alarms List Default Sort Order

The default sort order for an alarms list depends on the type of alarm page and the [\[Alarm\]SortMode](#) parameter. In the case of the Alarm Summary page, the equivalent parameter is [\[Alarm\]SummarySortMode](#).

Type of view	[Alarm] SummarySortMode	Default sorting order
Sequence of events	0	{TIME,Descending}
Sequence of events	1	{TIME,Ascending}
Alarm Summary	0	{Ack,Ascending}{Active,Descending} {TIME,Descending}
Alarm Summary	1	{Ack,Ascending}{Active,Descending} {TIME,Ascending}

Whatever sort order you specify, the system will append the following default set of order by fields:

Alarm list display	Appended default sort order
Sequence of events	RecordTime (ASC or DESC, depending on [Alarm]SortMode) SeqNo (DESC) Cluster (ASC) CommentNo (ASC)
Alarm Summary	As per [Alarm]SummarySort and [Alarm]SummarySortMode
Active, Disabled, Acknowledged, Off, On, Unacknowledged	(ASC) Active (DESC) As per [Alarm]Sort and [Alarm]SortMode

Alarm list display	Appended default sort order
Configuration (non-hardware alarms in system)	Tag (ASC)

### Example

According to the order you specified, if two records result in being equal, the records will adhere to the default sort orders above. In the example where tags have no equipment specified (and therefore are ordered equally) the alarms will be ordered according to Ack, Active, Time.

If you specify Active (ASC), then the resultant order on the active page will be:

Active (ASC), Acknowledged (ASC), [Alarm]Sort / [Alarm]SortMode.

You can customize the order in which alarms are displayed on the alarm summary page by using the SummarySort and SummarySortMode parameters.

The SummarySort parameter allows you to display alarms according to OnTime, OffTime, and AckTime. SummarySortMode determines if the alarms will be arranged in ascending or descending order. (The order set using these parameters will override the alarm category priority order.)

## Action Alarms at Runtime

An operator can perform the following actions on an alarm page at runtime.

- [Acknowledge Alarms](#)
- [Disable Alarms](#)
- [Enable a Disabled Alarm](#)
- [Shelve Alarms](#)
- [Display Cause and Response Information](#)
- [Filter Alarms](#)
- [Sort Alarms](#)
- [Add a Column to an Alarms List](#)
- [Save and Restore an Alarms List View](#)
- [Export an Alarms List](#)
- [Print an Alarms List](#)
- [Add a Comment to the SOE Page](#)
- [Add an Event to the SOE Page.](#)

### Acknowledge Alarms

When an operator acknowledges an alarm, it indicates that they have viewed the alarm and accepted responsibility for resolving it. The appearance of the font used to describe the alarm will change to let others know that the alarm is already being investigated.

### Acknowledge alarms in a Situational Awareness project

Alarms can be acknowledged during runtime in the following locations:

- Active Alarms page (see Default Alarm Pages)
- Hardware Alarms page (see Default Alarm Pages)
- Active Alarms Zone (UHD4K projects only)
- Top 5 Active Alarm list on the Header Bar
- Information Zone Alarms tab.

#### To acknowledge a selected alarm:

1. In an alarms list, right-click the alarm that you would like to acknowledge.
2. Select **Acknowledge** from the menu that appears.

	On Date	On Time	Name	State	Cluster
◇	2/5/2021	05:17:57 PM	TS03 Flavoured Milk Temperature Hi...	OFF	Cluster1
◇	2/5/2021	04:48:01 PM	TS02 Skim Milk Temperature High Hi...	OFF	Cluster1
◇	2/5/2021	04:42:57 PM	TS01 Milk Temperature Low Hi...	High	Cluster1
△	2/5/2021	05:29:14 PM	AC01 Compressor 1 Pressure Low	ON	Cluster1
△	2/5/2021	05:29:14 PM	AC01 Compressor 1 Pressure Low	ON	Cluster1
△	2/5/2021	05:26:52 PM	TS01 Milk Temperature Low Low	Low	Cluster1
△	2/5/2021	05:26:39 PM	CM01 Compressor 1 Motor Current	High	Cluster1
△	2/5/2021	05:26:39 PM	CM01 Compressor 1 Motor Current	OFF	Cluster1

A context menu is displayed over the third row of the table, listing options: Navigate, Find In Model, Acknowledge, Shelve for..., and Shelve until... The 'Acknowledge' option is highlighted with a blue background.

#### Acknowledge alarms in a project based on the SxW templates

Alarms can be acknowledged during runtime on the following alarm pages:

- Active Alarms
- Hardware Alarms.

#### To acknowledge selected alarms:

1. On the Active Alarms or Hardware Alarms page, right-click the alarm(s) that you would like to acknowledge.
2. Select **Acknowledge** from the menu that appears.

The screenshot shows the 'Active Alarms' page with a list of alarms. A context menu is open over the 5th alarm in the list, which has the following options:

- Acknowledge
- Disable
- Disable for ...
- Disable until ...
- Information
- Cause and Response

Date	Time	Tag	Name
2/5/2021	05:37:58 PM	TopMilk_TS03_PV...	TS03 Flavoured Mil
2/5/2021	05:37:51 PM	TopMilk_TS01_PV_H	TS01 Full Milk Terr
2/5/2021	05:37:46 PM	TopMilk_TS03_PV_H	TS03 Flavoured Mil
2/5/2021	05:29:14 PM	TopMilk_AC01_PV_L	AC01 Flavoured Mil
2/5/2021	05:29:14 PM	TopMilk_AC01_PV_L	AC01 Flavoured Mil
2/5/2021	05:29:14 PM	TopMilk_AC01_PV_L	AC01 Flavoured Mil
2/5/2021	05:36:59 PM	TopMilk_TS01_PV_H	TS01 Full Milk Terr
2/5/2021	05:36:57 PM	TopMilk_TS03_PV_H	TS03 Flavoured Mil
2/5/2021	05:36:49 PM	TopMilk_TS03_PV_H	TS03 Full Milk Terr

### To acknowledge all alarms on a page:

1. Select **Acknowledge Page** on the page Command Bar. You can just click on the Command Bar button, or select the command from the button's drop-down menu.

The screenshot shows the 'Active Alarms' page with a list of alarms. A context menu is open over the 5th alarm in the list, with the following options:

- Acknowledge page
- Disable Page
- Disable page for ...
- Disable page until ...

Date	Time	Tag	Name
2/5/2021	05:29:14 PM	TopMilk_AC01_PV_L	AC01 Flavoured Mil
2/5/2021	05:29:14 PM	TopMilk_AC01_PV_L	AC01 Flavoured Mil
2/5/2021	05:29:14 PM	TopMilk_AC01_PV_L	AC01 Flavoured Mil
2/5/2021	05:38:27 PM	TopMilk_TS01_PV_H	TS01 Full Milk Terr
2/5/2021	05:38:24 PM	TopMilk_TS03_PV_H	TS03 Flavoured Mil
2/5/2021	05:38:14 PM	TopMilk_TS03_PV_H	TS03 Flavoured Mil
2/5/2021	05:36:59 PM	TopMilk_TS01_PV_L	TS01 Full Milk Terr

### Acknowledge alarms in a project based on the Tab Style templates

Alarms can be acknowledged during runtime on the following alarm pages:

- Active Alarms
- Hardware Alarms.

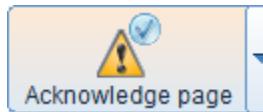

**To acknowledge selected alarms:**

1. On the Active Alarms or Hardware Alarms page, right-click the alarm(s) that you would like to acknowledge.
2. Select **Acknowledge** from the menu that appears.

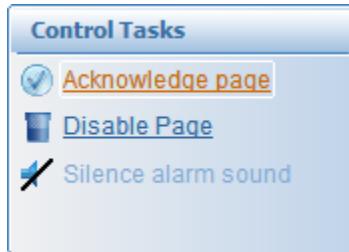

Date	Time	Tag	Name
2/5/2021	05:16:14 PM	TopMilk_TS02_PV_L	TS02 Skim Milk Temp
2/5/2021	05:01:58 PM	TopMilk_AC01_PV_L	AC01 Full Milk Level
2/5/2021	05:01:58 PM	TopMilk_AC01_PV_L	AC01 Full Milk Level
2/5/2021	05:01:58 PM	TopMilk_AC02_PV_L	AC02 Skim Milk Level
2/5/2021	05:01:58 PM	TopMilk_AC02_PV_L	AC02 Skim Milk Level
2/5/2021	05:15:26 PM	TopMilk_TS03_PV_L	TS03 Flavoured Milk Temp
2/5/2021	05:15:23 PM	TopMilk_TS03_PV_L	TS03 Flavoured Milk Temp
2/5/2021	05:15:20 PM	TopMilk_TS03_PV_L	TS03 Flavoured Milk Temp
2/5/2021	05:11:36 PM	TopMilk_TS03_PV_L	TS03 Flavoured Milk Temp
2/5/2021	05:06:55 PM	TopMilk_TS03_PV_L	TS03 Flavoured Milk Temp
2/5/2021	05:02:00 PM	TopMilk_TS03_PV_L	TS03 Flavoured Milk Temp

**To acknowledge all alarms on a page:**

1. Go to the **Action** tab and click on the **Acknowledge Page** button.

If the Action tab is not available, it means the page was created using an early version of the alarm page template. If this is the case, the **Acknowledge Page** command will available via the **Control Tasks** panel.

**Acknowledge alarms in a project based on a standard template**

Alarms can be acknowledged during runtime on the following alarm pages:

- Active Alarms

- Hardware Alarms.

**To acknowledge an alarm:**

1. Place the cursor over an alarm and press the **Enter** key.

**To acknowledge all alarms on a page:**

1. You can acknowledge every alarm on a page by clicking on the **Acknowledge All Alarms** button.

---

**Note:** In projects based on the SxW or Tab Style templates, the ability to acknowledge alarms may be restricted by the privilege level set in the parameter [Privilege]AckAlarms.

---

**Disable Alarms**

If an alarm does not appear to be operating as designed, or is determined to be unnecessary, an operator can disable it. A disabled alarms is ignored by the alarm system until it is returned to an enabled state (see [Enable a Disabled Alarm](#)).

---

**Note:** If the parameter [\[Alarm\]DisplayDisable](#) is set to 1, the system will continue to process state changes for alarms that are disabled. This means any state changes can continue to be displayed at runtime, for example, on the SOE and Disabled Alarms page. They will not display on the Active Alarms page.

---

If your project uses the SxW or Tab Style templates (accessible via a starter project), you can disable alarms during runtime from the Active Alarms page. Be aware that this may be restricted by the privilege level set in the parameter [\[Privilege\]DisableAlarms](#).

In a standard project, you need to define a command that uses the [AlarmDisable](#) function to disable alarms.

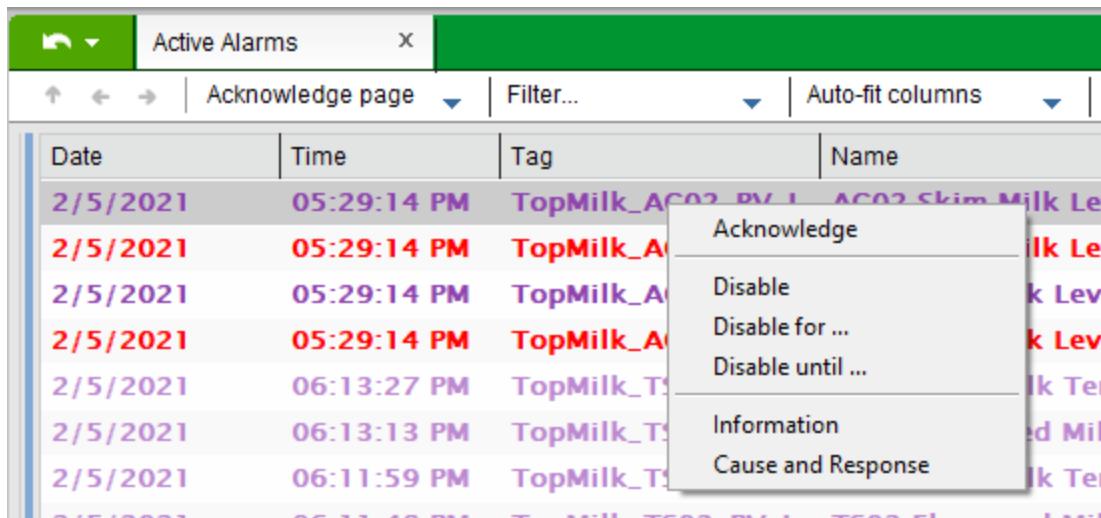

---

**Note:** You can also "shelve" an alarm, which will temporarily disable it for a specified period of time. In a Situational Awareness project, only shelving is supported. You are not able to permanently disable an alarm. See [Shelf Alarms](#).

---

**Disable alarms in a project based on the SxW templates****To disable selected alarms:**

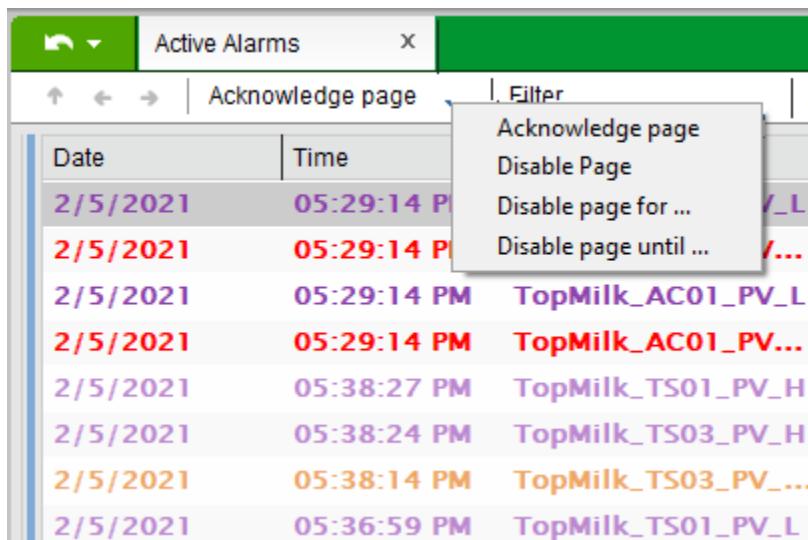

1. On the Active Alarms page, right-click on the alarm(s) that you would like to disable.
2. Select **Disable** from the menu that appears.

The selected alarm(s) will be removed from the Active Alarms page.

#### To disable all alarms on the Active Alarms page:

1. Display the drop-down menu for the **Acknowledge Page** Command Bar button.
2. Select **Disable Page** from the menu that appears.

#### Disable alarms in a project based on the Tab Style templates

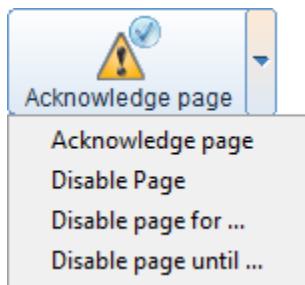

##### To disable selected alarms:

1. On the Active Alarms page, right-click the alarm(s) that you would like to disable.
2. Select **Disable** from the menu that appears.

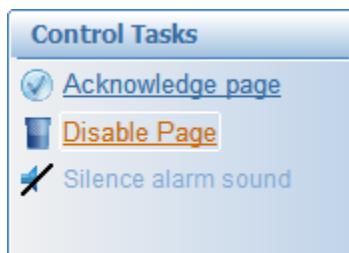

Date	Time	Tag	Name

### To disable all alarms on a page:

1. Go to the Action tab and display the drop-down menu for the **Acknowledge Page** button.
2. Select **Disable Page** from the menu that appears.

If the Action tab is not available, it means the page was created using an early version of the alarm page template. If this is the case, the **Disable Page** command will available via the **Control Tasks** panel.

**Note:** If Plant SCADA is installed on an English operating system and you want to provide a comment about a disabled alarm using a Unicode language (such as Korean, Russian or Chinese), you will need to change the Windows™ Region setting for the runtime computer. To do this, go to Windows Control Panel and open the Region dialog box. On the Administrative tab, use the Change system locale button to select the required system locale. Be aware that you will have to restart your computer. When you launch Plant SCADA runtime, select the

matching language on the login form. Your runtime comments will be recorded using the specified language characters.

## Enable a Disabled Alarm

The Disabled Alarms page displays a list of the alarms that have been disabled by an operator (see [Disable Alarms](#)).

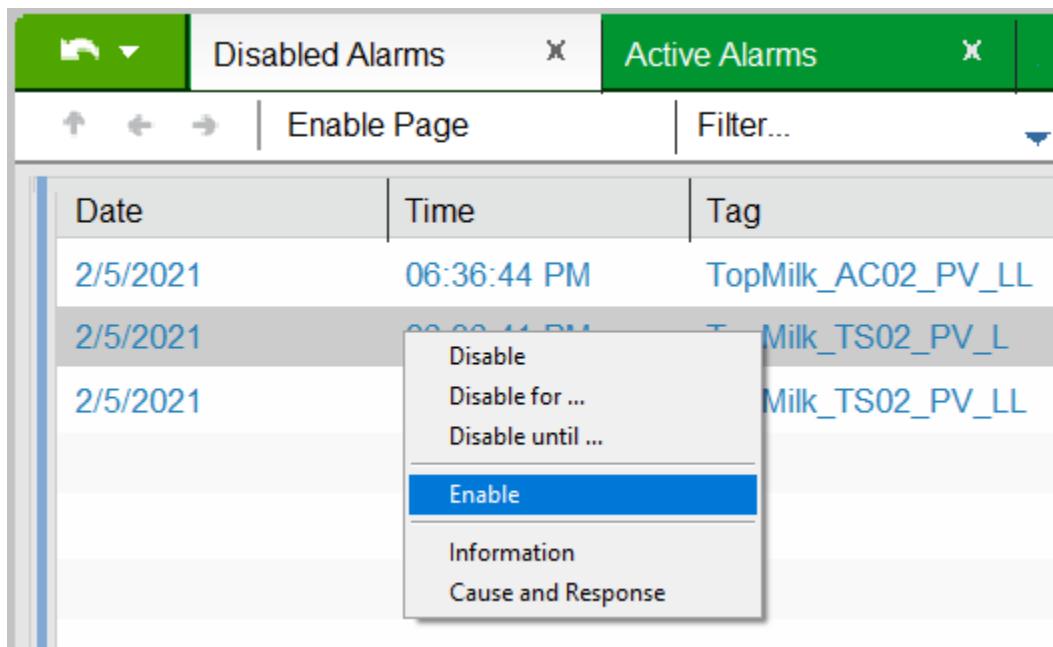

If your project uses the SxW or Tab Style templates (accessible via a starter project), you can re-enable an alarm using commands that are accessible via the Disabled Alarms page.

To enable an alarm in a standard project, you need to define a command that uses the [AlarmEnable](#) Cicode function.

## Enable alarms in a project based on SxW templates

### To enable an alarm:

1. On the Disabled Alarms page, right-click the alarm that you would like to enable.
2. Select **Enable** from the menu that appears.

The selected alarm will be removed from the Disabled Alarms page.

### To enable all alarms on the Disabled Alarms page:

1. In a project based on the SxW templates, select **Enable Page** on the page Command Bar.

## Enable alarms in a project based on the Tab Style templates

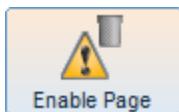

### To enable an alarm:

1. On the Disabled Alarms page, right-click the alarm that you would like to enable.
2. Select **Enable** from the menu that appears.

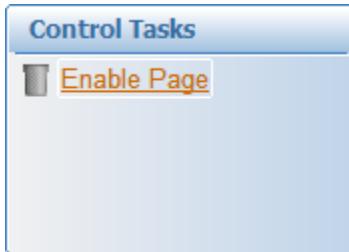

The selected alarm will be removed from the Disabled Alarms page.

### To enable all alarms on the Disabled Alarms page:

1. Go to the **Action** tab and select **Enable Page**.

If the Action tab is not available, it means the page was created using an early version of the disabled alarm page template. If this is the case, the **Enable Page** command will available via the **Control Tasks** panel.

**Note:** In projects based on the SxW or Tab Style templates, the ability to enable alarms may be restricted by the privilege level set in the parameter [\[Privilege\]DisableAlarms](#).

## Shelve Alarms

Alarm shelving allows an operator to temporarily disable nuisance or low value alarms that are causing an unnecessary distraction.

With Plant SCADA, you can shelve alarms by setting the *EndTime* argument for the following Cicode functions:

- [AlarmDisable](#)
- [AlarmDisableRec](#)
- [AlarmDisableTag](#)
- [AlmBrowseDisable](#)
- [AlmSummaryDisable](#)
- [AlmTagsDisable](#).

When the specified *EndTime* is reached, the alarm is automatically enabled and normal operation is resumed.

If you apply a new *EndTime* value to an alarm that is already shelved, the current setting will be overwritten; the values will not accumulate.

**Note:**

- 
- If the parameter [\[Alarm\]DisplayDisable](#) is set to 1, the system will continue to process state changes for alarms that are disabled or shelved. This means any state changes can continue to be displayed at runtime, for example, on the SOE and Disabled Alarms page.
  - If [\[Alarm\]DisplayDisable](#) is set to 1, the User Name and User Location recorded at the time an alarm was disabled will be maintained, despite any subsequent state changes; these properties will not be overwritten by the System User account.
  - If you would like an alarm list to display "Shelve End Time" in the header row instead of the default alarm field name "DisableEndTime", you can use the parameter [\[AlarmHeading\]AlarmField](#).
- 

You can also shelve alarms using the default runtime interface for the following projects.

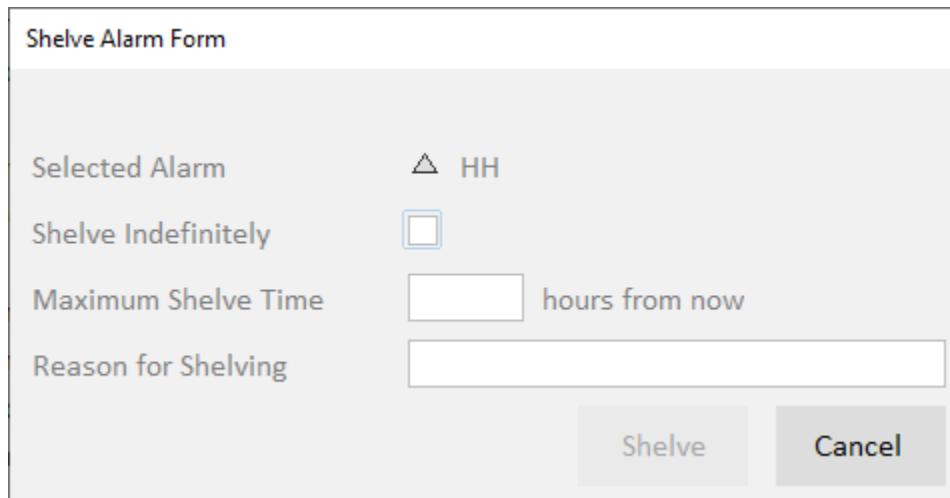

## Shelve alarms in a Situational Awareness project

Alarms can be shelved during runtime in the following locations:

- Active Alarms page (see [Default Alarm Pages](#))
- Shelved Alarms page (see [Default Alarm Pages](#))
- Active Alarms Zone (UHD4K projects only)
- Top 5 Active Alarm list on the Header Bar
- Information Zone **Alarms** tab.

### To shelve a selected alarm:

1. In an alarms list, right-click the alarm that you would like to shelve.
2. On the menu that appears, select one of the following options:
  - **Shelf for ...** — opens a dialog that allows you to **Shelf Indefinitely** or set a **Maximum Shelf Time**. You can also provide a **Reason For Shelving**.

- **Shelf until ...** — opens a dialog that allows you to set a **Shelf Until Date** and **Shelf Until Time**. You can also provide a **Reason for Shelving**.

Shelve Alarm Until Form

Selected Alarm	△ HH
Shelve Until Date	5 ▾ 2 ▾ 2021 ▾ DD/MM/YYYY
Shelve Until Time	HH:mm
Reason for Shelving	<input type="text"/>
Shelve Cancel	

**Note:** To extend the shelved period, repeat these steps on the Shelved Alarms page.

#### To restore a shelved alarm:

1. Go to the Shelved Alarms page.
2. Right-click on the alarm you want to restore.
3. On the menu that appears, select **Restore**.

### Shelve alarms in a project based on the SxW templates

If your project is based on the SxW templates, you can shelve alarms at runtime from the following alarm pages:

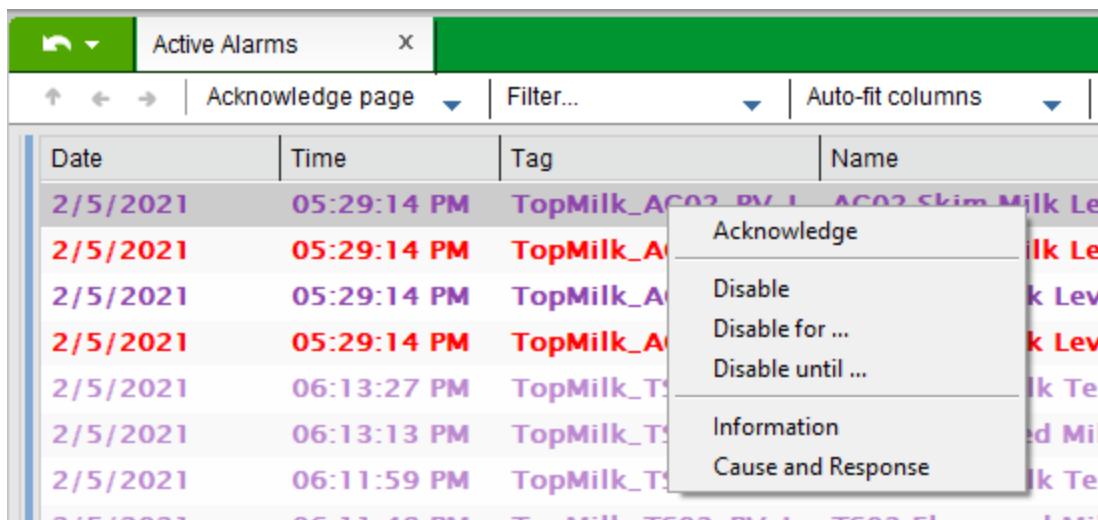

- Active Alarms
- Alarm Summary
- Disabled Alarms.

These pages provide commands that disable an alarm for a specified period of time, or until a specified time is reached.

**Note:** In projects based on the SxW templates, the ability to disable alarms may be restricted by the privilege level set in the parameter [\[Privilege\]DisableAlarms](#).

#### To shelve alarms:

1. On an alarms page, select the alarm(s) you would like to shelve.
2. Right-click on the selected alarms.

The screenshot shows a table titled "Active Alarms" with columns: Date, Time, Tag, and Name. A context menu is open over the last row of the table, listing options: Acknowledge, Disable, Disable for ..., Disable until ..., Information, and Cause and Response.

Date	Time	Tag	Name
2/5/2021	05:29:14 PM	TopMilk_AC02_PV_L	TopMilk_A...
2/5/2021	05:29:14 PM	TopMilk_A...	Acknowledge
2/5/2021	05:29:14 PM	TopMilk_A...	Disable
2/5/2021	05:29:14 PM	TopMilk_A...	Disable for ...
2/5/2021	06:13:27 PM	TopMilk_TS...	Disable until ...
2/5/2021	06:13:13 PM	TopMilk_TS...	Information
2/5/2021	06:11:59 PM	TopMilk_TS...	Cause and Response

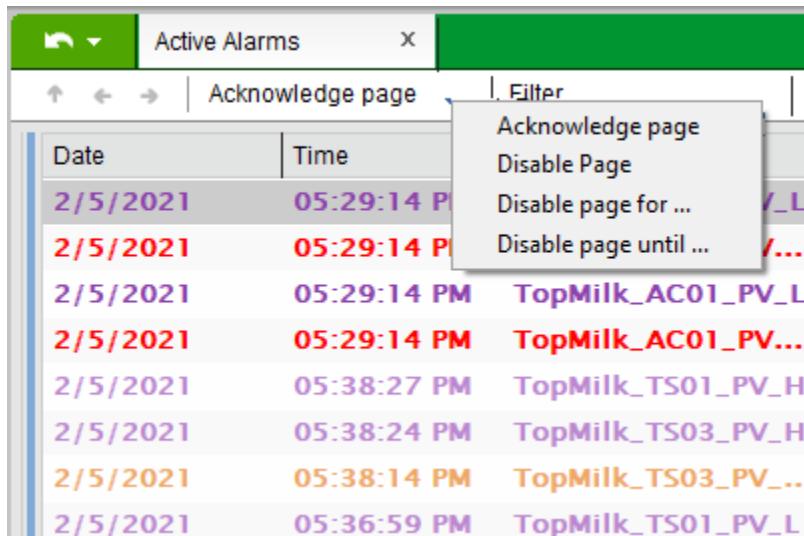

3. On the menu that appears, select one of the following options:

- **Disable for ...** — opens a dialog that allows you to disable an alarm for a specified number of hours.
- **Disable until ...** — opens a dialog that allows you to disable an alarm until a specified date and time.

In both cases, you can add a comment that describes why the alarm has been disabled.

#### To shelve all alarms on a page:

1. Display the drop-down menu for the **Acknowledge Page** Command Bar button.

The screenshot shows a table titled "Active Alarms" with columns: Date, Time, Tag, and Name. A context menu is open over the last row of the table, listing options: Filter, Acknowledge page, Disable Page, Disable page for ..., and Disable page until ...

Date	Time	Tag	Name
2/5/2021	05:29:14 P...	TopMilk_AC01_PV_L	TopMilk_AC01_PV...
2/5/2021	05:29:14 P...	TopMilk_AC01_PV_H	TopMilk_AC01_PV...
2/5/2021	05:38:27 PM	TopMilk_TS01_PV_H	TopMilk_TS01_PV...
2/5/2021	05:38:24 PM	TopMilk_TS03_PV_H	TopMilk_TS03_PV...
2/5/2021	05:38:14 PM	TopMilk_TS03_PV_L	TopMilk_TS03_PV...
2/5/2021	05:36:59 PM	TopMilk_TS01_PV_L	TopMilk_TS01_PV...

- Select **Disable page for ...** to disable all alarms for a specified number of hours.
- Select **Disable page until ...** to disable all alarms until a specified date and time.

#### Shelve alarms in a project based on the Tab Style templates

If your project is based on the Tab Style templates, you can shelve alarms at runtime from the following alarm pages:

- Active Alarms

- Alarm Summary
- Disabled Alarms.

These pages provide commands that disable an alarm for a specified period of time, or until a specified time is reached.

**Note:** In projects based on the Tab Style templates, the ability to disable alarms may be restricted by the privilege level set in the parameter [Privilege]DisableAlarms.

#### To shelve alarms:

1. On an alarms page, select the alarm(s) you would like to shelve.
2. Right-click on the selected alarms.

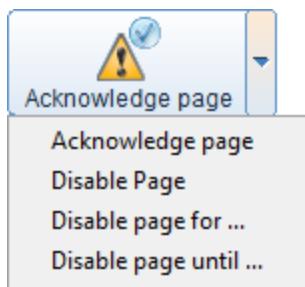

Date	Time	Tag	Name
2/5/2021	05:16:14 PM	TopMilk_TS02_PV_L	TS02 Skim Milk Temp
2/5/2021	05:01:58 PM	TopMilk_AC01_PV_L	AC01 Full Milk Level
2/5/2021	05:01:58 PM	TopMilk_AC01_PV_L	AC01 Full Milk Level
2/5/2021	05:01:58 PM	TopMilk_AC02_PV_L	AC02 Skim Milk Level
2/5/2021	05:01:58 PM	TopMilk_TS03_PV_L	TS03 Flavoured Milk Temp
2/5/2021	05:15:26 PM	TopMilk_TS03_PV_L	TS03 Flavoured Milk Temp
2/5/2021	05:15:23 PM	TopMilk_TS03_PV_L	TS03 Flavoured Milk Temp
2/5/2021	05:15:20 PM	TopMilk_TS03_PV_L	TS03 Flavoured Milk Temp
2/5/2021	05:11:36 PM	TopMilk_TS03_PV_L	TS03 Flavoured Milk Temp
2/5/2021	05:06:55 PM	TopMilk_TS03_PV_L	TS03 Flavoured Milk Temp
2/5/2021	05:02:00 PM	TopMilk_TS03_PV_L	TS03 Flavoured Milk Temp

3. On the menu that appears, select one of the following options:
  - **Disable for ...** — opens a dialog that allows you to disable an alarm for a specified number of hours.
  - **Disable until ...** — opens a dialog that allows you to disable an alarm until a specified date and time.

In both cases, you can add a comment that describes why the alarm has been disabled.

#### To shelve all alarms on a page:

1. Go to the **Action** tab, and display the drop-down menu for the **Acknowledge Page** button.

- Select **Disable page for ...** to disable all alarms for a specified number of hours.
- Select **Disable page until ...** to disable all alarms until a specified date and time.

---

**Note:** If Plant SCADA is installed on an English operating system and you want to add a comment or reason for shelving an alarm using a Unicode language (such as Korean, Russian or Chinese), you will need to change the Windows™ Region setting for the runtime computer. To do this, go to Windows **Control Panel** and open the **Region** dialog box. On the **Administrative** tab, use the **Change system locale** button to select the required system locale. Be aware that you will have to restart your computer. When you launch Plant SCADA runtime, select the matching language on the login form. Your runtime comments will be recorded using the specified language characters.

---

[Enable a Disabled Alarm](#)

## Display Cause and Response Information

Plant SCADA allows you to associate cause and response information with an alarm tag (see [Provide Cause and Response Information to Operators](#)).

In a **Situational Awareness** project, cause and response information is presented on the Default Alarm Pages and the **Alarms** tab in the Information Zone.

If your project is based on the **SxW** or **Tab Style** templates, you can view this information at runtime via the Cause and Response dialog. If multiple alarm responses have been configured for an alarm, this dialog will allow you to step through all of them.

You can launch the Cause and Response dialog from the following locations:

- Alarm Banner
- Active Alarms page
- Disabled Alarms page.

---

**Note:** If alarm response information has not been specified for an alarm, the menu items described in the procedure below will not be available.

---

### To display alarm response information for an alarm:

1. Select the alarm for which you would like to view cause and response information.
2. Right-click and select **Cause and Response**.

The Cause and Response dialog will appear. It includes the following information:

- Possible Alarm Cause — a description of the cause of an alarm.
  - Response — a description of the appropriate response to an alarm.
  - Response Time — the period of time in which the specified response needs to be acted upon.
  - Consequence — a description of the likely outcome if the appropriate response is not acted upon within the specified response time.
3. If multiple alarm responses have been configured for the selected alarm, click the **Next** button to step through the available cause and response information. When you have reached the last alarm response, the Next button will no longer be available.
  4. **Close** the dialog.

## See Also

[Add Cause and Response Information to Alarms](#)

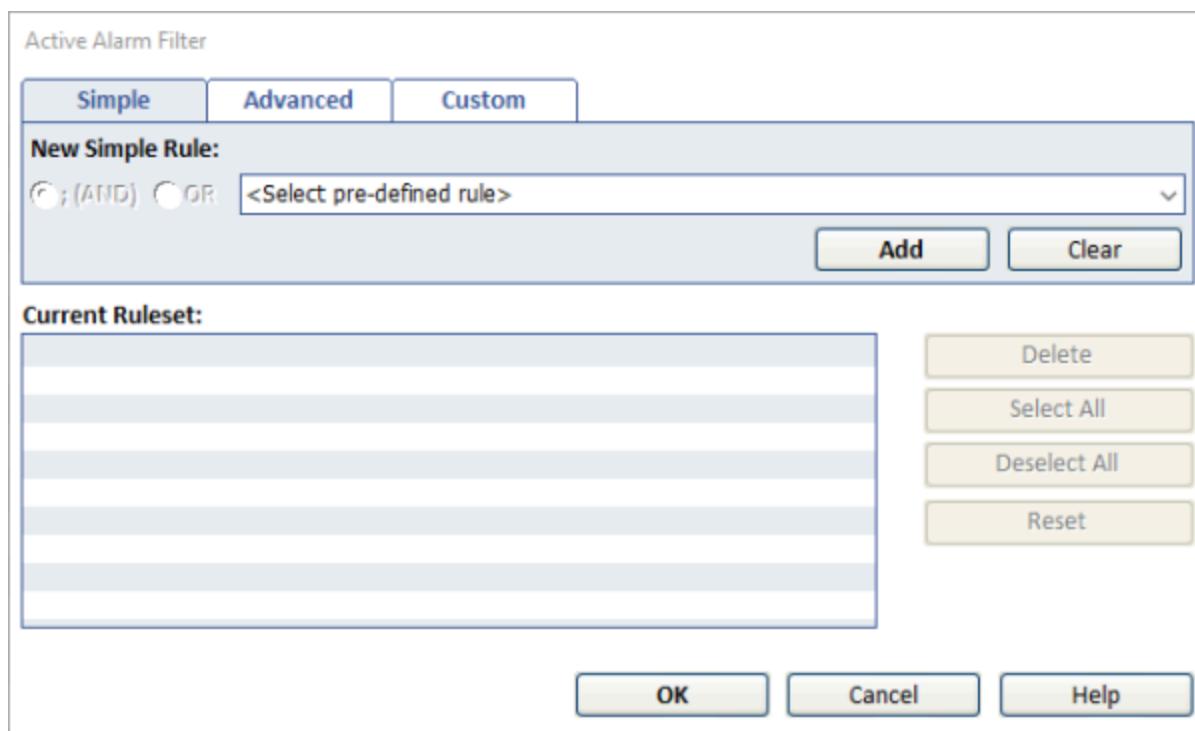

## Filter Alarms

In a **Situational Awareness** project, you can filter an alarms page at runtime using the following tools:

- the alarms list tree view
- the filters toolbar (directly above the alarms list)
- the Reference Equipment list.

These tools are available on the [Default Alarm Pages](#).

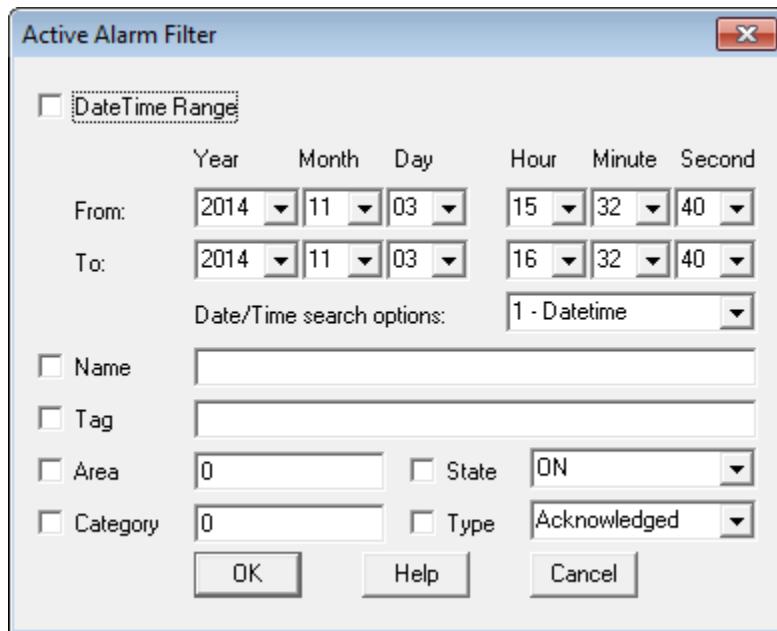

If your project uses the **SxW** or **Tab Style** templates (accessible via a starter project), you can use the Alarm Filter dialog to filter an alarms list.

This dialog is accessible from the following alarms pages:

- Active Alarms
- Disabled Alarms
- Sequence of Events
- Alarm Summary.

If your project uses standard page templates, you will have access to an earlier version of this dialog.

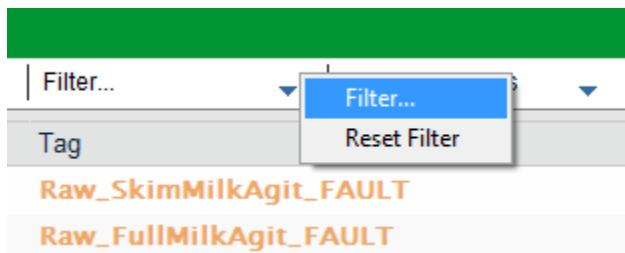

**Note:** Both versions of the Alarm Filter form are supported by their own documentation. For more information

on how to use a form to filter a list of alarms, refer to the documentation that is accessible from the **Help** button.

## View the alarm filter form in a project based on the SxW templates

### To view the alarm filter form:

- Select **Filter** on the Command Bar. You can click on the Command Bar button, or select **Filter** from the button's drop-down menu.

The Alarm Filter form will appear.

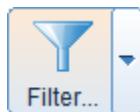

### To remove the filter that is applied to an alarms list:

- Select **Reset Filter** from the **Filter** drop-down menu.

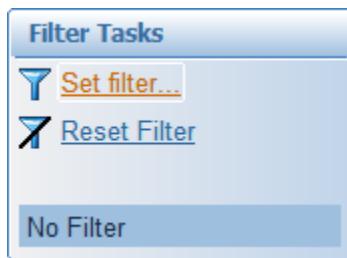

## View the alarm filter form in a project based on the Tab Style templates

### To view the alarm filter form:

- Go to the **Action** tab and select **Filter**. You can click on the button, or select **Filter** from the button's drop-down menu.

If the Action tab is not available, it means the page was created using an early version of the alarm page template. If this is the case, you can select **Set Filter** from the **Filter Tasks** panel.

### To remove the filter that is applied to an alarms list:

- Go to the **Action** tab and select **Reset Filter** from **Filter** button's drop-down menu.

If the Action tab is not available, you can select **Reset Filter** on the **Filter Tasks** panel.

## View the alarm filter form in a project based on standard templates

### To view the alarm filter form:

- You can view the Alarm Filter form by clicking on the **Display Alarm Filter Form** button.

The Alarm Filter form will appear.

### To remove the filter that is applied to an alarms list:

- Select the **Reset Alarm Filter** button.

## See Also

[Sort Alarms](#)

### Sort Alarms

If your project uses the SxW or Tab Style templates (accessible via a starter project), the alarm pages are presented using tables.

This means you can sort a list of alarms according to the values in a particular column by clicking in the header of the column.

Date	Time	Tag
31/10/2014	04:26:41	PM ALARM_1
31/10/2014	04:25:00	PM PLT_LINE1_PM800\MSSTA1\MaxW
31/10/2014	03:55:18	PM Raw_FullMilkAgit_FAULT
31/10/2014	03:23:09	PM Mixer_AgitatorFAULT

Click in the header row to sort an alarms list according to the

When you click a column header multiple times, the following will occur:

- The first click will sort the list in descending order
- The second click will sort the list in ascending order
- The third click will return the page to its default sort order.

A small blue arrow will appear in a selected column header to indicate if the current sort order is ascending or descending.

**Note:** You can only sort the Sequence of Events (SOE) page using the **Date**, **Time** and **Milliseconds** columns.

If you would like to adjust the default sort order for an alarm page, see the topic [Alarms List Default Sort Order](#).

## Add a Column to an Alarms List

If your project uses the **SxW** or **Tab Style** templates (accessible via a starter project), the following alarms pages are presented using tables:

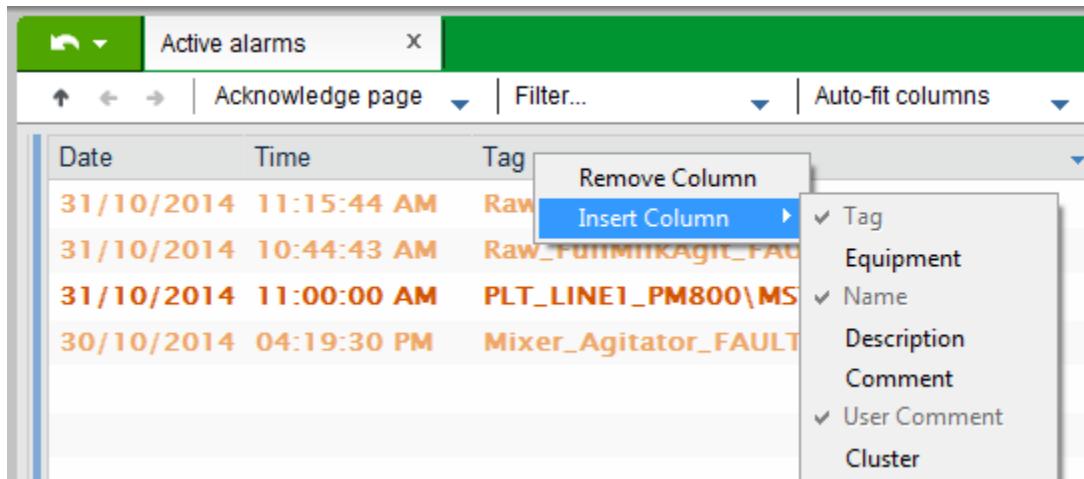

- Active Alarms
- Disabled Alarms
- Sequence of Events
- Alarm Summary.

The alarms list on each of these pages includes a default set of columns that are suited to the purpose of the page. If required, you can add columns to the lists to display additional information such as specific alarm property values or quality flags.

**Note:** The Hardware Alarms page includes a fixed set of columns and does not support any additional columns.

### To add a column to an alarms list:

1. While in runtime, open the alarm page to which you would like to add a column.
2. Right-click within the header row of the alarms list in the location where you would like to add the column.
3. In the menu that appears, hold the mouse over the **Insert Column** option. A further menu will appear displaying a list of column headings.

4. From this list, select the column you would like to add. (If a column has a check mark next to it, it means it is already displayed.)

The selected column will now appear in the list of alarms in the location where the right-click occurred. If required, you can click on the column header and drag it to a different location within the table.

**To remove a column from an alarms list:**

- Right-click within the header row of the column you would like to remove, and select **Remove Column** from the menu that appears.

The arrangement of columns is saved with your user profile and is restored each time you log in.

**See Also**

[Save and Restore an Alarms List View](#)

**Save and Restore an Alarms List View**

If your project uses the SxW or Tab Style templates (accessible via a starter project), the following alarms pages are presented using tables:

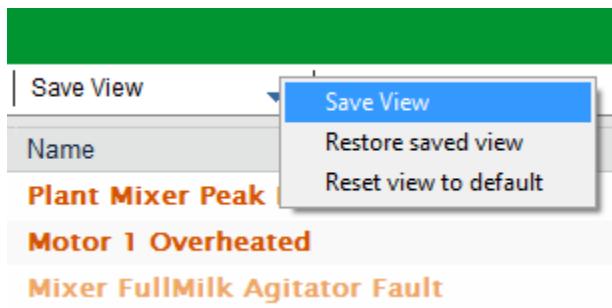

- Active Alarms
- Disabled Alarms
- Sequence of Events
- Alarm Summary.

This allows you to make simple runtime changes to an alarms list, as you can adjust, rearrange, add and remove columns.

If required, you can save the current arrangement of columns as a "view" that can be restored at a later point.

**Save an alarms list view in a project based on the SxW templates****To save the current arrangement of an alarms list as a view:**

- Select **Save View** on the Command Bar. You can click the Command Bar button, or select **Save View** from the button's drop-down menu.

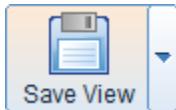

**To restore a saved view:**

- Select **Restored Saved View** from the **Save View** drop-down menu.

## Save an alarms list view in a project based on the Tab Style templates

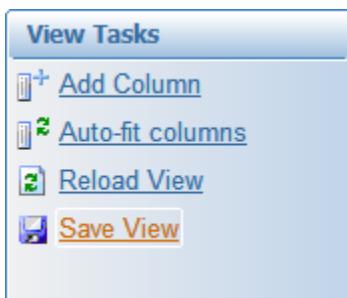

To save the current arrangement of an alarms list as a view:

- Go to the **Action** tab and select **Save View**.

You can just click on the button, or select **Save View** from the button's drop-down menu.

If the Action tab is not available, it means the page was created using an early version of the alarm page template. If this is the case, the **Save View** command will available via the **View Tasks** panel.

To restore a saved view:

- Go to the **Action** tab and select **Restored Saved View** from **Save View** drop-down menu.

If the Action tab is not available, you can select **Reload View** on the **View Tasks** panel.

---

**Note:** You can only save one view at a time. Each time you use the **Save View** command, the existing saved view will be replaced.

---

## Print an Alarms List

If your project uses the SxW or Tab Style templates (accessible via a starter project), you can print the list of alarms that is displayed on the following pages:

- Active Alarms
- Disabled Alarms
- Sequence of Events
- Alarm Summary.

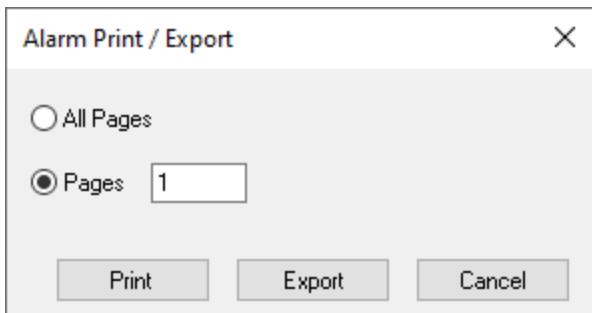

To print an alarms list:

- In a project based on the SxW templates, select **Print/Export** on the page Command Bar.

Or:

In a project based on the Tab Style templates, go to the **Action** tab and select **Print/Export**. If the Action tab is not available, you can select **Print/Export** on the **Page Tasks** panel.

The Alarm Print/Export dialog will appear.

2. Select **All Pages** to print the entire alarms list, or **Pages** to specify a subset of pages.
3. Click on the **Print** button to make the Print dialog appear.

## See Also

[Export an Alarms List](#)

### Export an Alarms List

If your project uses the SxW or Tab Style templates (accessible via a starter project), you can export a list of alarms as an HTML file. This feature is supported on the following pages:

- Active Alarms
- Disabled Alarms
- Sequence of Events
- Alarm Summary.

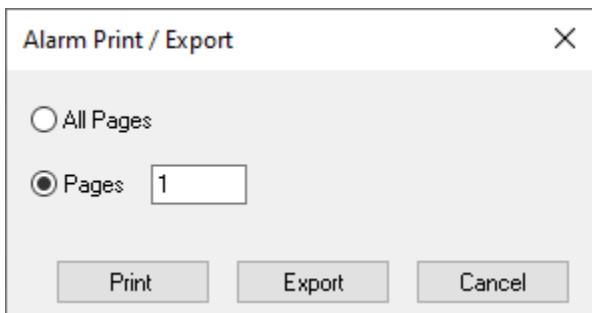

#### To export an alarms list:

1. In a project based on the SxW templates, select **Export All** on the page Command Bar.

Or:

In a project based on the Tab Style templates, go to the **Action** tab and select **Print/Export**. If the Action tab is not available, you can select **Print/Export** on the **Page Tasks** panel.

The Alarm Print/Export dialog will appear.

2. Select **All Pages** to export the entire alarms list, or **Pages** to specify a subset of pages.
3. Click on the **Export** button. The Alarm Export dialog will appear, allowing you to save the current alarms list as an HTML file.

## See Also

[Print an Alarms List](#)

### Add a Comment to the SOE Page

You can add a comment to an event listed on the Sequence of Events (SOE) page.

**Note:** You cannot modify or delete an existing comment for an event. You can only add a comment.

#### To add a comment to the SOE page:

1. Right-click on the relevant event and select **Comment**.

The Comment dialog will appear. The name of the associated alarm tag (if relevant to the selected event) displays in the dialog title bar (for example, "Comment [Alarm\_6]").

2. Enter your comment in the **Enter Comment** field.
3. Click **OK**.

The comment will display in the list on the Sequence of Events page next to the associated event.

You can also add comments to an event on the SOE page using the AlarmComment Cicode function. To add a message to the relevant event you can include the 'AN' as an additional parameter in the function.

For example:

```
AlarmComment ("Temperature discrepancies", 21)
```

To successfully add a comment to an event on the SOE page, the following rules need to be met:

- The event is not of "Comment" classification.
- A user should be logged on to the client process.
- If the event is associated with an alarm tag, the logged on user needs to have sufficient privileges for the alarm.
- If the event is not automatically generated by the system, the logged on user needs to match to the user associated with the event.
- If the event is automatically generated by the system, the logged on user needs to have full privileges (from 1 to 8).

**Note:** If you have installed Plant SCADA on an English operating system and want to add comments at runtime using a Unicode language (such as Korean, Russian or Chinese), you will need to change the Windows™ **Region** setting for the runtime computer. To do this, go to **Control Panel** and open the **Region** dialog box. On the **Administrative** tab, use the **Change system locale** button to select the required system locale. Be aware that you will have to restart your computer. When you launch runtime, select the matching **Language** on the login form. Your runtime comments will be recorded using the specified language characters.

## See Also

[Add an Event to the SOE Page](#)

## Add an Event to the SOE Page

You can add a new event to the Sequence of Events (SOE) page. If the new event is not associated with an alarm tag, it will be classified as a user event.

To add an event, you need to be logged on with a user account that has full privileges (that is, privileges from 1 to 8).

### To add an event to the SOE page:

1. Right-click on the relevant event and select **Add Event**.

The Message dialog will appear. The name of the associated alarm tag (if relevant to the selected event) displays in the dialog title bar (for example, "Message [Alarm\_6]").

2. Enter your message in the **Enter Message** field.
3. Click **OK**.

The new event will display in the list on the Sequence of Events page (see [Alarm Pages](#)).

You can also add events to the event journal page using the **SOEEventAdd** Cicode function.

---

**Note:** If you have installed Plant SCADA on an English operating system and want to add events messages at runtime using a Unicode language (such as Korean, Russian or Chinese), you will need to change the Windows™ Region setting for the runtime computer. To do this, go to **Control Panel** and open the **Region** dialog box. On the **Administrative** tab, use the **Change system locale** button to select the required system locale. Be aware that you will have to restart your computer. When you launch runtime, select the matching **Language** on the login form. Your event messages will be recorded using the specified language characters.

---

## See Also

[Add a Comment to the SOE Page](#)

## Archive the Alarms History

You can archive the alarms history stored on the alarm server to a variety of devices, including:

- Removable hard disk
- Removable flash memory
- CD-R and CD-RW
- DVD-R and DVD-RAM
- Network file share.

To archive events, you firstly need to confirm that the following parameters are configured correctly:

- [\[Alarm\]ArchiveAfter](#)
- [\[Alarm\]KeepOnlineFor](#)

For more information, see [Configure the Archiving Parameters](#).

To specify a destination for your archived events, you also need set the following alarm server properties:

- **Archive Path**
- **Archive Prefix** (optional)

For more information, see [Specify a Destination for Archived Events](#).

Once you have prepared your system, you can initiate archiving in the following ways:

- [Initiate Archiving with a Cicode Function](#)
- [Configure Automatic Archiving for an Alarm Server](#)
- [Using Scheduler to Trigger Archiving](#)

## See Also

[View Archived Event Data](#)

## Configure the Archiving Parameters

To archive events, you firstly need to confirm that the following parameters are configured correctly:

- [\[Alarm\]ArchiveAfter](#)

This parameter specifies how long event data is kept before it is marked for archiving. The default value is four weeks. After the specified period of time has passed, event data that is marked for archiving will remain in the database but will be read only. When the data becomes read only it is no longer writable. You are unable to make it writable.

- [\[Alarm\]KeepOnlineFor](#)

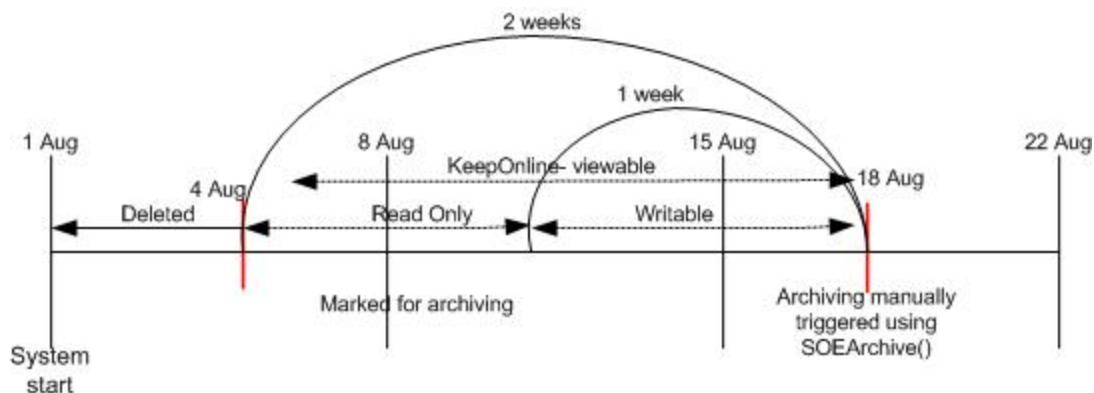

This parameter defines how long event data remains on the Alarm Summary or SOE pages. The default value is six weeks. After this time, the data will no longer appear.

The period of time set for the [Alarm]ArchiveAfter needs to be shorter than the time specified for [Alarm]KeepOnlineFor. If this is not the case, the value for ArchiveAfter will be automatically adjusted to equal the current value for KeepOnlineFor and an out-of-range hardware alarm will be raised.

## Example

The diagram below demonstrates the following scenario:

- "ArchiveAfter" is set to 1 week
- "KeepOnlineFor" is set to 2 weeks.

If archiving is manually triggered on Saturday 18 August 15:00:00, any data reported after midnight on Saturday 4 August will remain viewable via the Alarm Summary or SOE pages for two weeks. Any data reported before midnight on Saturday the 4th will be deleted.

Data that was reported between midnight on Saturday the 4th and midnight on Saturday the 11th is marked for archiving and is read only.

The data reported after midnight Saturday 11 August and the current time is unavailable for archiving as this data is still writable.

---

**Note:** The information available on your active and disabled alarm pages is classified as active data. For data integrity, [Alarm]ArchiveAfter needs to be configured to be longer than the lifetime of the active events.

---

[Specify a Destination for Archived Events](#)

### Specify a Destination for Archived Events

To specify a destination for your archived events, you need to set the following properties on the alarm server process that is managing the events (see [Add an Alarm Server Process](#)).

#### 1. Archive Path

This property specifies where your archived event data will be stored. The location should be accessible from the alarm server when an archiving operation is executed. When the volume is in place, Plant SCADA will mount the volume automatically (if required) prior to writing data.

**Note:**

- The media where the archived file is to be saved should be labeled. If this is not the case, archiving will not succeed and a message will display on the SOE page.
  - If you choose the Windows system drive (typically the "C:\\" drive) as the archive path destination, you may need to adjust Windows' UAC (User Access Control) settings to enable archiving to occur.
- 

#### 2. Archive Prefix

When archiving occurs, sub folders are created in the archive volume's destination directory. These folders are named using a timestamp (YYYYMMDD). This optional setting allows you to apply a prefix to the name of the folders that are created.

**Example**

An alarm server could be configured to use the following property values:

- Archive Path = D:\Data
- Archive Prefix = Archive

If archiving is executed on this server on 21 January 2021, the archive volume path would be:  
D:\Data\Archive20210121.

**Note:** If a redundant alarm server is configured, archiving should be enabled on both servers.

---

[Configure Automatic Archiving for an Alarm Server](#)  
[Using Scheduler to Trigger Archiving](#)

### Initiate Archiving with a Cicode Function

You can manually trigger event data archiving with the Cicode function [SOEArchive\(\)](#).

**Note:** You need to be logged in as a user that can run Cicode to initiate archiving with the SOEArchive() function.

When you call the function, archiving will commence according to the values defined for the "ArchiveAfter" and "KeepOnlineFor" parameters (see [Configure the Archiving Parameters](#)).

If required, you can use the function's **Path** attribute to specify a destination for the archived data. If no path is specified, the data will be archived to the location defined in the **Archive Path** property on the associated alarm server (see [Specify a Destination for Archived Events](#)).

**Note:** If you use this method to archive your event data, you will need to regularly call the SOEArchive() function to avoid data becoming inaccessible. For example, if the "ArchiveAfter" parameter is set to 1 week, and KeepOnlineFor is set to 2 weeks, you will need to manually trigger archiving after every eight days to confirm that all data is captured.

- [Configure Automatic Archiving for an Alarm Server](#)  
[View Archived Event Data](#)

### Configure Automatic Archiving for an Alarm Server

You can configure automatic event archiving for each alarm server in your system. This is achieved via the alarm server properties (see [Add an Alarm Server Process](#)).

**To configure automatic archiving for an alarm server:**

1. In the Topology activity, select **Edit**.
2. On the menu below the Command Bar, select **Alarm Servers**. All configured alarms servers are displayed.
3. Locate the record for the required alarm server.
4. In the **Archive Internal (Days)** field, enter the number of days after which archiving will automatically occur.
5. Confirm that **Archive Path** and **Archive Prefix** fields are correctly configured (see [Specify a Destination for Archived Events](#)).

6. Click **Save**.

**Note:** In order for archiving succeed, the "KeepOnlineFor" and "ArchiveAfter" parameters need to be configured correctly (see [Configure the Archiving Parameters](#)).

## See Also

[View Archived Event Data](#)

### Using Scheduler to Trigger Archiving

You can use Scheduler to trigger event archiving. However, the steps needed to complete this task will differ if the system you are running is in single process or multi-process mode.

If you attempt to trigger archiving in multi-process mode, Scheduler needs to invoke a custom Cicode function that includes the following:

```
Login (Username, Password);  
SOEArchive()
```

Follow the instructions outlined in [Configure Equipment for Scheduling](#) to define new Equipment. The Equipment name can be any name specified by the user.

Follow the instructions outlined in [Define Equipment States in Plant SCADA Studio](#) to define the 'Trigger' and 'OFF' states for the newly added equipment.

#### To trigger archiving in single process mode:

**Note:** For archiving to succeed in single process mode you need to log in to a display client in Runtime.

1. Open the 'Trigger' Equipment State form.
2. In the **Entry Action** field enter the function SOEArchive(). Click **OK** to save.
3. Start runtime and log in to the display client.
4. Open Scheduler. The Archive Equipment branch should be displayed in the equipment hierarchy.
5. Following the instructions outlined in [Add a Schedule Entry](#), schedule the state 'trigger' to occur.

When the time transitions for this scheduled task, SOEArchive() will be called and archiving will be triggered.

#### To trigger archiving in Multi Process Mode:

1. In the Cicode Editor create a custom Cicode function and save it. This Cicode function needs to include login information. For example:

```
FUNCTION  
ArchiveMyData()  
Login("ConfigUsers", "SCADA");  
SOEArchive();  
END
```
2. Open the 'Trigger' Equipment State form.
3. In the **Entry Action** field enter the name of the custom Cicode function. e.g. ArchiveMyData(). Click **OK** to save.
4. Open Scheduler. The Archive Equipment branch should be displayed in the equipment hierarchy.

5. Following the instructions outlined in [Add a Schedule Entry](#), schedule the state 'trigger' to occur.

[Initiate Archiving with a Cicode Function](#)  
[Configure Automatic Archiving for an Alarm Server](#)

## View Archived Event Data

Archived data that is no longer available online for viewing can be accessed using the [SOEMount](#) Cicode function.

In mounting the volume, you are directing the server to where the archived data is stored. You are not restoring the data, merely making the data available for viewing via the SOE page. To view the data on the mounted volume you need to query the data using the filter options available on the SOE page. To view data, including data on the mounted volume, use 'page down' to query the data and bring it into the SOE page.

When mounting a volume, you should pass the volume path when calling SOEMount() Cicode function. For example, the path should be the following:

C:\Data\Archive20120121

rather than:

C:\Data\Archive20120121\EventJournal

If you need to copy or move archived data to another directory (for example, from "C:\Data\Archive20120121" to "D:\Data"), you will need to copy or move the entire "EventJournal" folder to the new directory. You can then invoke SOEMount("D:\Data") to restore the data from the new location.

If you no longer need to view the data on the mounted volume, you can call use the [SOEDismount](#) Cicode function.

**Note:** To call SOEMount() or SOEDismount(), you need to be logged on as a user that has full privileges.

## Using Custom Alarm Filters

You can define keywords for your alarm tags that you can then use to perform customized queries on your alarm data.

The Alarm Properties dialog allows you to define up to eight custom filters for each of the alarms in your system, allowing you to generate queries that filter your alarm data for specific information.

For example, you will want to prioritize any alarms that monitor equipment and conditions with the potential to cause a fire. You could set Custom Filter 1 for each relevant tag to "fire hazard". You could then call a Cicode function that requests alarms with a "custom filter 1" field equal to "fire hazard". The end result would be a list of alarms notifying an operator of any potentially flammable circumstances.

You could also set aside Custom Filter 2 to define the type of equipment the alarm is associated with, and label each alarm accordingly (for example "pump", "conveyor", and so on). Queries could then be created to list the alarms related to a particular type of machinery; for example, alarms associated with pumps.

## See Also

[Implementing Queries that Use Custom Alarm Filters](#)

[Named Filters](#)[Implementing Alarm Filters Using Cicode](#)[Converting Legacy AlarmSetQuery\(\) Functions](#)

## Implementing Queries that Use Custom Alarm Filters

To implement a query that creates a custom alarm filter, you need to use the following Cicode functions:

- [AlarmFilterEditOpen](#)
- [AlarmFilterEditAppend](#)
- [AlarmFilterEditSet](#)
- [AlarmFilterEditCommit](#)
- [AlarmFilterEditFirst](#)
- [AlarmFilterEditLast](#)
- [AlarmFilterEditNext](#)
- [AlarmFilterEditClose](#)

The alarms within any query function can also be filtered via [AlarmSetInfo](#) set to Type=12 and a named filter (see [Named Filters](#)).

---

**Note:** If a requested filter is too complex (for example, it contains too many conditions or too many nested brackets), the filter is cleared (no filter is used). If this occurs, the hardware alarm "Too many alarms in filters" is generated on the client components, and a tracelog error message is logged.

---

## Example

You may want to create a query that calls the current alarms for the conveyors in your plant. This could be drawn from the alarm tags you have identified as being associated with a conveyor by applying the keyword "conveyor" to the field **Custom Filter 1**.

The AlarmFilterEditSet (hdl, "Custom1=conveyor") followed by the AlarmFilterEditCommit(hndl) function will filter your alarm data for "conveyor" information.

The query function you would create would be as follows:

```
! This query function called FilterCustom1()
! filters alarms by the requested Custom filter 1.
! Only alarms with the requested Custom Filter 1 are displayed.
INT
FUNCTION
    FilterCustom1(STRING sValue)
        INT iResult=-1, INT iHndl=-1,
        STRING sFilter="";
        sFilter = "Custom1=" + "^" + sValue + "^"; iHndl= AlarmFilterEditOpen(21);
        IF iHndl <> -1 THEN
            iResult = AlarmFilterEditSet(iHndl,sFilter)
            IF iResult = 0 THEN
                iResult = AlarmFilterEditCommit(iHndl)
            END
            AlarmFilterEditClose(iHndl)
```

```
END
RETURN iResult;
END
```

Say you then want to create a button on a graphics page that lists current conveyor alarms. You would implement this by applying the custom function to the button.

```
FilterCustom1("conveyer");
```

You could also create a reset button that clears the current displayed list by canceling the query:

```
hSession = AlarmFilterEditOpen(21);
AlarmFilterEditSet(hSession, "");
AlarmFilterEditCommit(hSession);
AlarmFilterEditClose(hSession);
```

You have the choice of calling a specific Cicode function, for example, "Customfield1", with the argument "pumpcontrol", or using a more generic approach with the function "Checkfield" with argument "CUSTOM1=pumpcontrol". In this case, the Cicode function filters the passed string and checks the field specified.

## See Also

[Implementing Alarm Filters Using Cicode](#)

## Named Filters

You can create a named filter and use it across multiple alarm lists.

A named filter can be used to filter an alarm list or an alarm count only if that alarm list or alarm count is associated to the named filter. It is not used to directly filter alarms. Instead it is used to update the active filter of multiple alarm lists or alarm counts. Once you create the named filter you then edit it to add the filter criteria you want the named filter to query.

To associate an alarm list to a named filter, you need to call [AlarmSetInfo](#)(AN, 12, "Named Filter"), where AN is the animation number of the associated alarms list, 12 is the mode for associating the named filter to the alarms list, and "NamedFilter" is the name of the filter that was created by calling the function [AlarmFilterOpen](#).

To disassociate the named filter from an alarm list set "NamedFilter" to empty text, for example, [AlarmSetInfo](#)(AN, 12, ""). This will remove the association from the named filter, but the disassociated alarm list will not be refreshed, hence the filter query will still be in place until a new filter is applied.

In order to associate an alarm count to a named filter, you need to call [AlarmCount](#)(Type, "NamedFilter", KeepAliveSeconds, CacheMode), where Type, KeepAliveSeconds and CacheMode are documented in the [AlarmCount](#) function, and "NamedFilter" is the named filter that was previously opened by calling [AlarmFilterOpen](#).

In each of these cases, editing the filter criteria belonging to the named filter will update all associated alarm lists or alarm counts.

---

**Note:** If a requested filter is too complex (for example, it contains too many conditions or too many nested brackets), the filter is cleared (no filter is used). If this occurs, the hardware alarm "Too many alarms in filters" is generated on the client components, and a tracelog error message is logged.

### Example

The following examples show how to open, edit (add filter criteria), associate, disassociate and close a named filter called "MyFilter".

```
// The following examples show how to open, edit, associate, disassociate and close
// a named filter (e.g. "MyFilter").
// These are fictional examples for demonstration purposes only.
// The prompt message is displayed in prompt-line for increasing clarity.
// This function returns zero when all examples are successful,
// otherwise error is returned.
INT
FUNCTION
AlarmNamedFilterExamples()
    INT iError, iHndl;
    INT iAN=21; // Animation Number
    INT iOpenModeNew = 1;
    INT iCloseModeManual = 0;
    INT iAlarmCounted=0, IAlarmDisplayed=0;
    STRING sName, sEmptyString="", sNamedFilter, sLinkedFilter;
    ! Open the new filter named "MyFilter"
    sNamedFilter = "MyFilter";
    iError = AlarmFilterOpen(sNamedFilter, iOpenModeNew, iCloseModeManual);
    IF iError <> 0 THEN
        Prompt ("MyFilter open error!");
        RETURN iError;
    END;
    ! Edit this filter by selecting alarms of Category 1 and Area 0
    iHndl = AlarmFilterEditOpen(sNamedFilter);
    IF iHndl <> -1 THEN;
        iError = AlarmFilterEditSet(iHndl,"Category=1;Area=0;");
        IF iError = 0 THEN
            iError = AlarmFilterEditCommit(iHndl);
            IF iError = 0 THEN
                iError = AlarmFilterEditClose(iHndl);
            END
        END
    END
    IF iError <> 0 THEN
        Prompt ("MyFilter edit error!");
        RETURN iError;
    END
    ELSE
        Prompt ("MyFilter hndl-edit error!");
        RETURN iHndl;
    END;
    ! Associate this filter to the specified AN of Alarm page.
    ! Other alarm pages can be linked in similar way.
    PageDisplay("Alarm");
    iError = AlarmSetInfo(iAN, 12, sNamedFilter);
    IF iError <> 0 THEN
        Prompt ("MyFilter link error!");
        RETURN iError;
    END
    ! Retrieve associated filter name. Verify associated filter.
    sLinkedFilter = AlarmGetFilterName(iAN); // "MyFilter"
    IF sLinkedFilter <> sNamedFilter THEN
        Prompt ("MyFilter get-name error!");
        RETURN iError;
    END;
    ! Count active alarms of this filter and verify against displayed alarms
    iAlarmCounted = AlarmCount(0, sNamedFilter, 1,0);
```

```
iAlarmDisplayed = AlarmCountList(iAN);
IF iAlarmCounted <> iAlarmDisplayed THEN
    Prompt ("Count verification error!");
    RETURN iError;
END;
! disassociate "MyFilter"
iError = AlarmSetInfo(iAN, 12, "");
IF iError <> 0 THEN
    Prompt ("MyFilter unlink error!");
    RETURN iError;
END;
! Verify disassociate action.
sName = AlarmGetFilterName(iAN); // ""
IF sName <> sEmptyString THEN
    Prompt ("MyFilter unlink error!");
    RETURN iError;
END;
! Close this filter
iError = AlarmFilterClose(sNamedFilter);
IF iError <> 0 THEN
    Prompt ("MyFilter Close error!");
END;
RETURN iError;
END
```

[Implementing Queries that Use Custom Alarm Filters](#)

[Implementing Alarm Filters Using Cicode](#)

## Implementing Alarm Filters Using Cicode

For historical event lists, you can define and apply a filter (the filter is not shared between lists). The filter is a combination of conditions on the different fields which define the set of rows to display. These conditions may become large, with Cicode only permitting a string of 254 characters. The set / append functions allows you to separate the filter into smaller pieces without verification of the syntax on the sub parts. The whole filter (e.g. concatenation of the pieces) is validated and applied later by the commit function.

Multiple Cicode tasks can access the same filter and modify it, with the filter browsing and modification part of a session. This follows the principles used in tag browsing.

## Filter Syntax

The filter expression may contain a field, comparison operator and a value e.g. Tag=A. The field can be any name listed in the Browse Field Reference, with comparison operators being < <= > >= <>, and value being either a String, Integer, Date Time, and Boolean. Tag Value pairs can be connected by logical operators AND OR Eqv NOT Xor.

A filter may contain multiple expressions separated by a semi colon.

The syntax of the filter can be verified against the following:

---

**Note:**

- 
- (1) The ";" between <filter\_expr> is interpreted as AND
  - (2) The parenthesis are optional but recommended to obtain the right evaluation order. If they are present they need to match.
  - (7) The "\*" is standard wild card. it can be used only once per <string\_value>
- 

1. <filter> ::= <filter\_expr> { ";" <filter\_expr> }
  2. <filter\_expr> ::= { "(" <filter\_expr> ")" } <logical\_binary\_op> { "(" <filter\_expr> ")" }
  3. | <comparison>
  4. | "NOT" "(" <filter\_expr> ")"
  5. <comparison> ::= <field> <comparison\_op> <value>
  6. <comparison\_op> ::= "=" | ">" | "<" | ">=" | "<="
  7. <logical\_binary\_op> ::= "AND" | "OR"
  8. <value> ::= <string\_value> | <boolean\_value> | <DateTime\_value> | <int\_value>
  9. <string\_value> ::= <singleword> ["\*"]
  10. | " " <singleword> { {"<space>"} <singleword> ["\*"] } " "
  11. <singleword> ::= {any character but space}
  12. <boolean\_value> ::= "0" | "1"
  13. <int\_value> ::= ["-"]{numeric char}["." numeric char]
  14. <DateTime\_value> ::= string of number of sec.  
as returned by IntToStr( TimestampToInt(..)) in UTC
  15. <field> ::= valid Plant SCADA field name (case insensitive).
- 

**Note:** If a requested filter is too complex (for example, it contains too many conditions or too many nested brackets), the filter is cleared (no filter is used). If this occurs, the hardware alarm "Too many alarms in filters" is generated on the client components, and a tracelog error message is logged.

---

## Valid filters examples:

- Tag=A
- (Tag=A) OR (TAG=B)
- (Tag=A) OR (TAG=B) ; Name=C
- Time > IntToStr(TimestampToInt(yesterday))
- Tag=Dig\*
- Message="quoted sentence with blanks"
- (((Tag=A) OR (TAG=B)) AND (category=1))

When using the alarm filter Cicode functions first open a session (AlmFilterOpen) and then use this session to browse the different parts (AlmFilterFirst/Next/Prev) of the filter and to update (AlmFilterSet / Append / Commit) the filter. The browse session will be available until closed (AlmFilterClose).

Multiple sessions can be used on the same list. For multiple sessions modify the same filter then the current applied filter is the result of the last commit.

[Implementing Queries that Use Custom Alarm Filters](#)

### Converting Legacy AlarmSetQuery() Functions

With the release of Plant SCADA 7.30, the AlarmSetQuery() and Query() Cicode functions were replaced with a set of alarm filter functions. If your project uses AlarmSetQuery(), you will need to review and manually replace each instance with the alarm filter edit functions (see [Implementing Queries that Use Custom Alarm Filters](#)).

Below are examples of v7.20 Cicode and what the v7.30 Cicode may look like with the new alarm filter edit functions.

### Conversion examples from v7.20 to v7.30:

#### v7.20 code:

```
.....
INT resultAlarmsetQuery=0;
// e.g. fieldName = Category, fieldValue = 10
// or fieldName = Tag, fieldValue = DigitalAlarm1
resultAlarmsetQuery =
AlarmsetQuery(21,"AlarmFilter","^"+fieldName+"^",^"+filterValue+"^"); //Obsolete in
v7.30
.....
PUBLIC
INT
FUNCTION AlarmFilter
    (INT iRecId,
    INT iInst,
    STRING fieldName,
    STRING filterValue)
    INT resultFilter=0;
    STRING getValue="";
    getValue = AlarmGetFieldRec(iRecId, fieldName, iInst);
    IF filterValue = getValue THEN
        resultFilter = TRUE;
    ELSE
        // when "*" entered -> all values are accepted
        IF filterValue = "*" THEN
            resultFilter = TRUE;
        ELSE
            resultFilter = FALSE;
        END
    END;
    RETURN resultFilter;
END
```

#### v7.30 code:

```
.....
INT resultAlarmsetQuery=0;
//AlarmsetQuery(21,"AlarmFilter30","^"+fieldName+"^",^"+filterValue+"^");Obsolete in
7.30
//replace the above by direct call
```

```
resultAlarmSetQuery = AlarmFilter730(fieldName,filterValue);
.....
PUBLIC
INT
FUNCTION AlarmFilter730
    (STRING fieldName,
     STRING filterValue)
    INT hndl=-1, resultFilter=-1;
    TRING sFilter="";
    sFilter = fieldName + "=" + filterValue;
    hndl= AlarmFilterEditOpen(21);
    IF hndl <> -1 THEN
        resultFilter = AlarmFilterEditSet(hndl,sFilter)
    IF resultFilter = 0 THEN
        resultFilter = AlarmFilterEditCommit(hndl)
    END
    AlarmFilterEditClose(hndl)
END
RETURN resultFilter;
END
```

Another example of how this function could be returned:

```
PUBLIC
INT
FUNCTION AlarmFilter730
    (STRING fieldName,
     STRING filterValue)
    INT hndl;
    INT resultFilter=-1;
    hndl = AlarmFilterEditOpen(21);
    IF hndl <> -1 THEN
        resultFilter = AlarmFilterEditSet(hndl, fieldName)
        IF resultFilter = 0 THEN
            resultFilter = AlarmFilterEditAppend(hndl, "=^""")
        END
        IF resultFilter = 0 THEN
            resultFilter = AlarmFilterEditAppend(hndl, filterValue)
        END
        IF resultFilter = 0 THEN
            resultFilter = AlarmFilterEditAppend(hndl, "^^")
        END
        IF resultFilter = 0 THEN
            resultFilter = AlarmFilterEditCommit(hndl)
        END
        AlarmFilterEditClose(hndl)
    END
    RETURN resultFilter;
END
```

## Using Alarm Properties as Tags

Alarm properties can be used wherever variable tags can be used (except in alarm descriptions). For example, you can provide the operator with a visual indication when the alarm **CV110\_ERROR** is active:

- **CV110\_ERROR.On** will be TRUE when the alarm is active

- **CV110\_ERROR.On** will be FALSE when it is inactive.

This means **CV110\_ERROR.On** could be entered as the fill color expression in a graphics object. When the conveyor becomes inoperative, the graphics object will change color.

**Note:**

- Using alarm properties as tags is not supported by an OPC UA Server or an Industrial Graphics Server
- If you want to use time-stamped digital or time-stamped analog alarm properties as variable tags, you will need to verify that they are configured correctly with the necessary data being pushed to the relevant variables via the Cicode function [AlarmNotifyVarChange](#). See the topic [Alarms](#) for more details on how Time Stamped Digital Alarms and Time Stamped Analog Alarms operate.

## Alarm reference syntax

You can reference alarm tags in the following ways:

- Refer to an alarm property by tag name
- Refer to an alarm using an 'equipment.item' reference

### Refer to an alarm property by tag name

You can refer to an alarm's properties (and an optional tag extension) using the following syntax:

[Cluster.]Alarm.AlarmProperty[.ExtItem]

Where:

Cluster	The cluster name (optional).
Alarm	The alarm tag name.
AlarmProperty	The alarm property name. This part of the reference is not optional as it is for variable tags. There are different available properties for different categories of alarms. See <a href="#">Supported Alarm Properties</a> .
ExtItem	<p>The tag extension item name (optional). Available items are the same as for tags:</p> <ul style="list-style-type: none"><li>• Value = V</li><li>• Value Timestamp = VT</li><li>• Quality = Q</li><li>• Quality Timestamp = QT</li><li>• Overall Timestamp = T</li></ul> <p>See <a href="#">Tag Extensions</a>.</p> <p>If the item name is not specified, the value of the alarm property is referenced.</p>

For example, "Alarm1.On" will enable you to see and control alarm states. If you want to know the timestamp of the On state, you can use the tag extension "T" (for example, "Alarm1.On.T").

Such references can appear in Cicode and on graphic pages.

### Refer to an alarm using an 'equipment.item' reference

You can use "equipment.item" instead of an alarm tag name to refer to an alarm's properties. To do this, use the following syntax:

[Cluster.]Equipment.Item.AlarmProperty[ .ExtItem]

Where:

Cluster	The cluster name (optional).
Equipment.Item	A substitution for a tag name using an "equipment.item" reference. See <a href="#">Items</a> .
AlarmProperty	The alarm property name. This part of the reference is not optional as it is for variable tags. There are different available properties for different categories of alarms. See <a href="#">Supported Alarm Properties</a> .
ExtItem	The tag extension item name (optional). See <a href="#">Tag Extensions</a> . If the item name is not specified, the value of the alarm property is referenced.

This syntax means you can:

- Use equipment.item in place of an alarm tag name in expression fields in graphic pages.
- Use equipment.item to reference alarms in Genie and Super Genie substitutions.
- Use equipment.item in the value field to represent an alarm when associating Super Genie substitutions via metadata.
- Pass equipment.item to Cicode functions in which an alarm tag name is an argument.

## See Also

[Writing to Alarm Properties](#)

[Setting Up Alarm Properties](#)

## Supported Alarm Properties

The following properties can be used for every alarm type. Remember, the return value relates to the description. For example, for a digital, if 1 is returned, that means the description is TRUE, whereas 0 (zero) means it is FALSE.

Property	Description	Return Type
.On	Alarm active  The .On property for analog alarms is true if any alarms associated with the alarm tag are active.	Digital
.Ack	Alarm acknowledged	Digital
.AcqErr	Data acquisition error	Integer
.Category	Alarm category	Integer
.ComBreak	For Multi-Digital alarms, the property is set to 1 if the device cannot read data from the underlying tag at start-up for a time greater than [Alarm]ArgyleTagValueTimeout value. The property is set to 0 and re-alarms the corresponding alarm, when the alarm server receives valid data from the device.  For every Disabled and Display Disabled alarms (except Time Stamped Digital and Time Stamped Analog alarms) the property is set to 1, when they are being Enabled. The property is set to 0 and re-alarms the corresponding alarm, when the alarm server receives valid data from the device.	Digital
.Custom1 .Custom2 .Custom3 .Custom4 .Custom5 .Custom6 .Custom7 .Custom8	Custom Field.	String(64 bytes)
.Disabled	Alarm disabled (see note below)	Digital
.Historian	Alarm can be historized and published in CitectHistorian.	Digital
.Item	The name of the item with which the alarm is associated.	String

Property	Description	Return Type
.Millisec	The milliseconds part of the time the alarm was triggered	Long
.Name	Alarm name	String (80 bytes)
.OnTime	The time the alarm was triggered.	Long
.Paging	Alarm paged	Boolean
.PagingGroup	Paging group alarm belongs to.	String (80 bytes)
.Priority	Alarm priority	Integer
.State	<p>An alarm's state value. An alarm state value is a combination of state enumeration and action bit masks described below.</p> <p><b>State enumerations</b></p> <p>0 – Alarm OFF state or state 000 for Multi-Digital alarm</p> <p>1 – Alarm ON state or state 00A for Multi-Digital alarm</p> <p>2 – State 0B0 for Multi-Digital alarm</p> <p>3 – State 0BA for Multi-Digital alarm</p> <p>4 – State C00 for Multi-Digital alarm</p> <p>5 – State C0A for Multi-Digital alarm</p> <p>6 – State CB0 for Multi-Digital alarm</p> <p>7 – State CBA for Multi-Digital alarm</p> <p>8 – Analog deviation from set point High</p> <p>9 – Analog deviation from set point low</p> <p>10 – Analog rate of change alarm state</p> <p>11 – Analog low limit alarm state</p> <p>12 – Analog high limit alarm state</p> <p>13 – Analog low low limit alarm state</p> <p>14 – Analog High High limit alarm</p>	Short

Property	Description	Return Type
	<p>state</p> <p><b>Alarm action masks</b></p> <ul style="list-style-type: none"> <li>32 – Unable to get the status of underlying tag at start-up</li> <li>64 – Alarm cleared bit mask</li> <li>128 – Alarm acknowledged but held</li> <li>256 – Alarm unacknowledged bit mask</li> <li>512 – Alarm disabled bit mask</li> <li>1024 – Argyle type alarm bit mask</li> <li>2048 – Argyle type alarm ON bit mask</li> <li>4096 – Analog alarm threshold value changed</li> <li>8192 – User generated event</li> <li>16384 – Event already logged</li> <li>32768 – Disable the alarm display</li> </ul> <p><b>Example:</b></p> <p>A digital alarm called "AlmDigital1" that is ON and unacknowledged, the value of the state property will be:</p> <p>AlmDigital1.State = 1 (ON state) + 256 (Unacknowledged alarm) = 257</p>	
.Tag	Alarm tag	String (80 bytes)
.Time	<p>The time at which the alarm changed state (hh:mm:ss).</p> <p>You can use the following parameters to change this default behavior:</p> <ul style="list-style-type: none"> <li>• <a href="#">[Alarm]SetTimeOnAck</a> — sets the property to the time the alarm is acknowledged.</li> <li>• <a href="#">[Alarm]SetTimeOnOff</a> — sets the property to the time the alarm becomes inactive.</li> </ul>	Long

**Note:** Once an alarm is disabled, it cannot be re-enabled unless you use the function [AlarmEnable](#) or [AlarmEnableRec](#).

For digital alarms, time stamped alarms, time stamped digital alarms, multi digital alarms, advanced alarms and double point status alarms, the following property can also be used.

Property	Description	Return Type
.Desc	Alarm description	String (128 bytes)

**Note:** Desc exists for every alarm type but will not return meaningful data for analog or time-stamped analog alarms.

For digital alarms, time-stamped digital alarms, advanced alarms and double point status alarms, the following property can also be used.

Property	Description	Return Type
.Delay	Alarm delay	Long

For analog alarms and time-stamped analog alarms, the following properties can also be used.

Property	Description	Return Type
.DevDelay	Deviation delay	Long
.DeadBand	Deadband	Real
.Deviation	Deviation	Real
.HighHigh	High High	Real
.High	High	Real
.LowLow	Low Low	Real
.Low	Low	Real
.HHDelay	High High delay	Long
.HDelay	High delay	Long
.LDelay	Low delay	Long
.LLDelay	Low Low delay	Long
.Rate	Rate	Real
.Setpoint	Setpoint	Real
.Value	Alarm tag Value	Real

For the digital properties below, only one can be true at any point in time for each alarm. They are arranged in order of priority, from lowest to highest.

.DVL	Deviation alarm triggered (Low)	Digital
.DVH	Deviation alarm triggered (High)	Digital

.R	Rate of Change alarm triggered	Digital
.L	Low alarm triggered	Digital
.H	High alarm triggered	Digital
.LL	Low Low alarm triggered	Digital
.HH	High High alarm triggered	Digital

**Note:** DVL and DVH are only evaluated if Deviation > 0. R is only evaluated if Rate > 0.

Some alarm properties return configuration data. If the user has not defined this information, the following defaults are provided:

Property	Default
.Setpoint	0
.HighHigh	3.4e+38
.High	3.4e+38
.LowLow	-3.4e+38
.Low	-3.4e+38
.Rate	0
.Deviation	0
.Deadband	0
.Category	0
.Priority	0

## Writing to Alarm Properties

If you have the necessary access rights, you can write to the following alarm properties. (Remember, the value you write to the property relates to the description. For example, if you set a digital alarm property to 1, you are making the description TRUE. If you set it to 0 (zero), you are making it FALSE.)

Property	Description	Input Type
.Ack	Alarm acknowledged (once)	Digital

Property	Description	Input Type
	acknowledged cannot be "unacknowledged")	
.Category	Alarm category	Integer
.Deadband	Alarm deadband	Real
.Delay	Alarm delay	Long
.Deviation	Deviation from setpoint	Real
.Disabled	Alarm disabled	Digital
.HighHigh	High High	Real
.High	High	Real
.LowLow	Low Low	Real
.Low	Low	Real
.HHDelay	High High delay	Long
.HDelay	High delay	Long
.LDelay	Low delay	Long
.LLDelay	Low Low delay	Long
.DevDelay	Deviation delay	Long
.Custom1 .Custom2 .Custom3 .Custom4 .Custom5 .Custom6 .Custom7 .Custom8	Custom field	String
.Paging	Alarm paged	Boolean
.PagingGroup	The paging group the alarm belongs to.	String
.Rate	Rate of change	Real

Analog alarm thresholds can also be changed using the [AlarmSetThreshold](#) function.

Note the following:

- The alarm tag needs to be unique.
- The alarms databases in the included projects on the alarm servers and the control client computer need to be identical.

[Setting Up Alarm Properties](#)

### Setting Up Alarm Properties

To use alarm properties, you need to enable them on the Alarm Server.

1. In the **Topology** activity, select **Edit | Alarm Servers**.
2. Locate the alarm server you wish to update.
3. Specify the port that the Alarm Server will listen on using the Grid Editor or the Property Grid.

**Note:** You are not required to specify the port if using the default settings for ports.

## Trends

The trend system can help you better understand your plant and equipment's performance. Trending can be used for dynamic visual analysis (trend and SPC graphs), production records, or for regularly recording the status of equipment for efficiency and preventive maintenance.

Using trend tags, you can specify the data you want to collect from your I/O device variables. This information can be logged at regular intervals (periodic trend), or only when an event occurs (event trend). Event trends are used for trending data that is not time-based, for example, for a product as it comes off an assembly line. Trend data is usually saved on disk for analysis or displayed on a trend graph or in [Process Analyst](#).

The trend system is based on real-time samples. The trend system expects a return of one data point each time it samples the data. Although gaps in the data can be filled, you will want to verify that your field device can return data values at the rate you specify (especially if you are using sample periods of less than 100 ms).

Any amount of data can be collected and stored. The only restriction on the amount of data that you can store is the size of the hard disk on your computer (an efficient data storage method is used to optimize the use of storage space on your computer's hard disk).

By default, Plant SCADA stores trend files in the [DATA] directory (defined by the parameter [\[CtEdit\]Data](#)) on the hard disk where installation occurred. However, you can use the **File Name** property to specify a different directory for a particular trend file.

For example, if your system includes a large number of trend tags (in excess of 1000), Plant SCADA will perform more efficiently if you distribute the associated trend files across a number of directories. To enable this, you could set the **File Name** property for a trend tag to the following:

[DATA]:Area1\TANK131

This would store the trend file in a subdirectory (named "Area1") within the [DATA] directory.

For long term storage, you can archive the data to disk or a removable drive (without disrupting your runtime system).

---

**Note:** If you are trending data across a network, it is recommended that you enable time synchronization using the [Time Synchronization](#) configuration application.

---

This section covers the following information:

- [View Trends](#)
- [Configure Trends](#)
- [Debugging Trending](#)

## View Trends

Trend data is presented in trend graphs that visually represent past and current activity of plant-floor data, building a picture over time of how a variable (such as product output, level, temperature, and so on) changes or how a device or process is performing. You can monitor current activity as it happens and scroll back through time to view trend history.

---

**Note:** The Process Analyst (a built-in trend visualization tool) superseded the functionality of trend graphs. However, trend graphs are still supported. Be aware that SPC is not supported by the Process Analyst. To view SPC trends you need to use trend graphs. For details, see [Process Analyst](#)

---

## Trend Graphs

Trend graphs visually represent past and current activity of plant-floor data. As the values of variables change over time or as events happen, the graph moves across the page. The latest values are displayed by default. You can scroll back through historical data to display past values of the variable (or process).

You can trend any single variable or Cicode expression. You can display any number of trends on the screen simultaneously, even if they have different sample periods. You can also display up to eight trend tags (pens) in any trend window.

A trend graph can only communicate with one cluster, therefore you cannot mix trends from multiple clusters on a single trend graph. To graph trends from multiple clusters you will need to use multiple trend graphs, or, use the Process Analyst which has no such restrictions.

Historical data collection continues even when the display is not active. You can switch between pages without affecting trend graphs. Trend data acquisition and storage of data (in trend history files) continues even when the display is not active.

You can use the following standard trends:

- A single full page trend, where one trend window displays on a graphics page.
- A double full page trend, where two trend windows display on a graphics page.
- A zoom trend with two trend windows and added functionality for zooming.
- A pop-up trend that you can 'pop up' anywhere (in a separate window) on your computer screen.
- User-defined trends that you can position anywhere on any graphics page.

---

**Note:** Variable tags can also be visually trended using an SPC Control Chart. Statistical Process Control (SPC) is a facility that enables you to control the quality of materials, manufactured products, services, etc. This quality control is achieved by collecting, arranging, analyzing, and testing sampled data in a manner that detects lack of uniformity or quality.

## See Also

[Configure Trends](#)

[Create Pages for Trend Graphs](#)

## Configure Trends

Before you can view trends, the following configuration tasks need to be completed:

- [Add a Trend Tag](#)
- [Create Pages for Trend Graphs](#)
- [Define Trend Interpolation](#).

---

**Note:** If a variable tag is associated with a driver that supports the Driver Runtime Interface (see [Retrieving Time-stamped Data from I/O Devices](#)), you can define a trend tag as a pure-event trend. See [Configure Event Trends for a DRI Driver](#).

---

## Add a Trend Tag

Trend tags allow you to collect data from your I/O device variables for analysis and/or trend graphing.

### To add a trend tag:

1. In the **System Model** activity, select **Trends**.
2. Add a row to the Grid Editor.
3. Type the required information in each column, or in the fields in the Property Grid.  
For a description of the properties, see below.
4. Click **Save**.

## Trend Tag Properties

**Note:** If a trend tag was generated by the Equipment Editor, a number of fields on the properties form will be shaded. To configure these fields, you will need to use [Equipment Editor](#).

### Equipment Properties

Property	Description
<b>Equipment</b>	The name of the equipment associated with the trend tag. Select a name from the drop-down list of existing equipment definitions, or enter a name. There is a limit of 254 characters across the <b>Equipment</b> and <b>Item Name</b> fields, including any separating periods (.).
<b>Item Name</b>	The name of the item with which the trend tag is associated. Items form part of an equipment hierarchy. They can be used to associate tags, alarms and trends with a particular attribute of a physical piece of equipment (see <a href="#">Items</a> ). There is a limit of 254 characters across the <b>Equipment</b> and Item Name, including any separating periods (.). <b>Note:</b> When defining an item name, avoid using the <a href="#">Reserved Words</a> . If you use any of these, an error message will display when you compile your project.

### General Properties

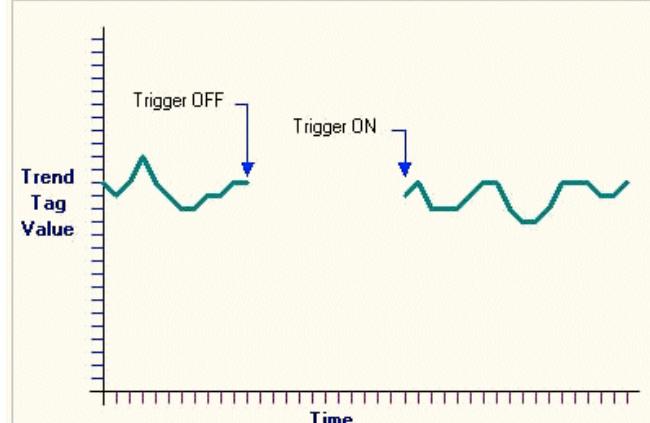

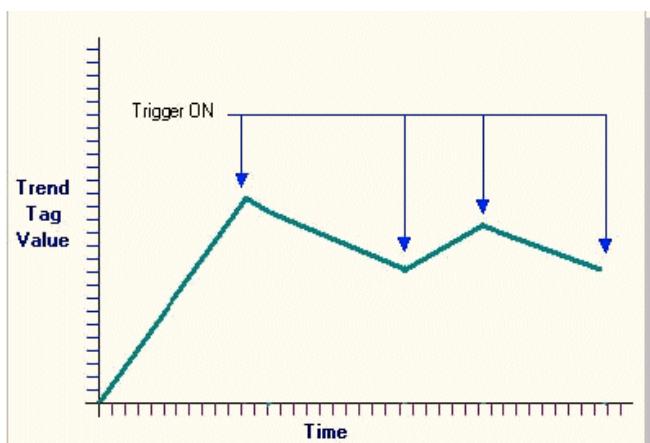

#### UNINTENDED EQUIPMENT OPERATION

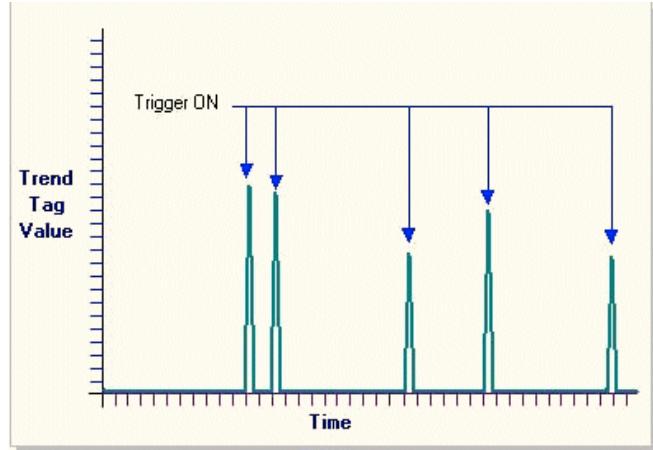

If using the **File Name** property, ensure that each trend tag uses a unique file name. Two tags accessing the

same file can result in system errors which may include lost or corrupted trend/SPC data.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

Field	Description
<b>Tag Name</b>	<p>The name assigned to the trend data (79 characters maximum). If the trend tag is logging a particular variable, use a 16-character name that resembles the 32-character name of the related variable tag. This will mean an association between the two is easily recognizable. The name needs to be unique to the cluster. Trend Tag names need to adhere to the <a href="#">Tag Name Syntax</a>. If the name is not unique or is not syntactically correct it may not be recognized. If you have many tags, use a naming convention (see <a href="#">Structured Tag Names</a>). This makes it easier to find and debug your tags.</p> <p><b>Note:</b> Where Cluster Name is left blank, the name needs to be unique to every defined cluster.</p> <p><b>Note:</b> Trend tag names have to be unique and not identical to any SPC tag names within the cluster(s) that run this trend. Two tags accessing the same file can result in system errors which may include lost or corrupted trend/SPC data.</p>
<b>Cluster Name</b>	<p>The name of the cluster that runs the trend tag. This field needs to be defined if your project has more than one cluster.</p> <p>You can leave this field blank in a multi-cluster system if cluster replication is enabled (see the parameter <a href="#">[General]ClusterReplication</a>).</p>
<b>Type</b>	<p>The type of trend (32 characters maximum):</p> <p><b>TRN_PERIODIC</b> - A trend that is sampled continuously at a specified period. You can also define a trigger to stop and start the trend (when a specified condition occurs in the plant).</p>

Field	Description
	 <p>The graph illustrates a trend tag value plotted against time. Two specific points on the curve are highlighted with vertical arrows and labeled "Trigger OFF" and "Trigger ON". The curve shows a continuous trend between these discrete trigger events.</p>
	<p><b>TRN_EVENT</b> - A trend that is sampled once each time the value of the trigger changes from FALSE to TRUE. Interpolation occurs between each data point to create a continuous graph.</p>  <p>The graph illustrates a trend tag value plotted against time. Three distinct vertical spikes are shown, each labeled "Trigger ON". The trend line connects these spikes at specific intervals, indicating no interpolation between the data points.</p> <p><b>Note:</b> If a variable tag is associated with a driver that supports the Driver Runtime Interface, you can define a trend tag as a pure-event trend. See <a href="#">Configure Event Trends for a DRI Driver</a>.</p> <p><b>TRN_PERIODIC_EVENT</b> - A trend that is sampled once each time the value of the trigger changes from FALSE to TRUE. No interpolation occurs between these points, thus providing a graph which spikes at each data point.</p>

Field	Description
	
<b>Expression</b>	<p>The logged value of the trend tag (254 characters maximum). You can log individual variables by using a variable tag. For example:</p> <p>Expression: LT131</p> <p>Comment: Logs the Variable Tag LT131</p> <p>The value of the process variable LT131 is logged.</p> <p>You can also log any Cicode expression or function, for example:</p> <p>Expression: LT131/COUNTER</p> <p>Comment: Logs Variable Tag LT131 divided by the Variable Tag COUNTER</p> <p><b>Note:</b> When a variable tag is used in the expression field of a trend tag property, the <b>Eng Zero Scale</b> and <b>Eng Full Scale</b> fields of that variable tag needs to be set appropriately, or data may be lost because the trend logs negative values are invalid.</p> <p>If a variable tag is associated with a driver that supports the Driver Runtime Interface, you can enter a variable tag in this field. See <a href="#">Configure Event Trends for a DRI Driver</a>.</p>
<b>Trigger</b>	<p>The Cicode expression (or variable tag) that triggers data logging (254 characters maximum). For example:</p> <p>Trigger: LT131&lt;50</p> <p>In this example, logging occurs when the value of the variable tag (LT131) falls below 50.</p> <p>For a periodic trend, data is logged only while the value of the trigger is TRUE. (The trend graph will still scroll, but will display &lt;GATED&gt; where the trigger is FALSE.) In the above example, data is logged</p>

Field	Description
	<p>continuously while the value of LT131 remains less than 50. Logging ceases when the value rises to (or above) 50. Logging does not occur again until the value of LT131 falls below 50.</p> <p>You do not have to specify a trigger for a periodic trend. If you do not specify a trigger for a periodic trend, logging occurs continuously.</p> <p>For an event trend, data is logged once when the value of the trigger changes from FALSE to TRUE. In the above example, one sample is logged when the value of LT131 first becomes less than 50. Another sample is not logged until the value of LT131 rises to (or above 50) and again falls below 50.</p> <p><b>Note:</b> If a variable tag is associated with a driver that supports the Driver Runtime Interface, you should leave this field blank as the trend sample updates are controlled by the driver. See <a href="#">Configure Event Trends for a DRI Driver</a>.</p>
<b>Sample Period</b>	<p>The sampling period of the data. You can either enter a period of your own, or choose one from the menu.</p> <p>Enter sampling periods of greater than one second in hh:mm:ss (hours:minutes:seconds) format. If you enter a single digit, without the colon (:), it will be considered a second. For example, if you enter 2, it will be interpreted as 2 seconds.</p> <p>Sampling periods of less than one second needs to be entered as decimals. For example, to enter a period of 200 milliseconds, you would enter 0.2.</p> <p>If the sample period is less than one second, then one second needs to be divisible by the period (to give an integer). For example, a sample period of 0.05 is valid, because <math>1/0.05 = 20</math>, whereas a sample period of 0.3 is not valid because <math>1/0.3 = 3.333\dots</math>.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>Your I/O Device needs to be capable of providing data at the specified rate, otherwise gaps will appear in the trend data and/or the hardware alarm <b>Trend has missed samples</b> will be evoked. You can fill gaps in the file and graph using the <a href="#">[Trend]GapFillTime</a> parameter. Gaps in the graph only can be filled using the <a href="#">TrnSetDisplayMode()</a> function.</li> <li>If trends with a sample period of less than a second are shared by several clients across a network (distributed processing), enable time synchronization</li> </ul>

Field	Description
	<p>using the <a href="#">Time Synchronization</a> configuration application. This verifies that trends are synchronized with each other.</p> <p>The Trigger is checked each sample period. If the Trigger is TRUE (or has just changed from FALSE to TRUE, in the case of event trends), the value of the Expression is logged.</p> <p><b>Examples</b></p> <ul style="list-style-type: none"> <li>Sample Period: 30 - Logs data every 30 seconds</li> <li>Sample Period: 10:00 - Logs data every 10 minutes</li> <li>Sample Period: 10:00:00 - Logs data every 10 hours</li> <li>Sample Period: 2:30:00 - Logs data every 2 and a half hours</li> </ul> <p>The sampling period of the fastest trend on the page is taken as the default value for the display period of the page.</p> <p>This property is optional. If you do not specify a sample period, the sampling period defaults to 10 seconds.</p> <p><b>Note:</b> If you edit this property in an existing project, delete the associated trend files before running the new runtime system.</p>
<b>Eng Units</b>	The engineering units of the variable/expression being logged (8 characters maximum). The engineering units are used by the trend scales and trend cursor displays.
<b>Format</b>	<p>The format of the variable/expression being logged (11 characters maximum). The format is used by the trend scales and trend cursor displays.</p> <p>This property is optional. If you do not specify a format, the format defined for the associated variable will be used. If the associated variable does not have a format defined, it will default to #####.##.</p> <p><b>Note:</b> If multiple variable tags are defined in the trend expression and a trend format is not specified, the format will be indeterminate. Under these circumstances, it is recommended that you use this field to specify a trend format.</p>
<b>Deadband</b>	A deadband allows the value of a variable tag to fluctuate within a defined threshold without updates being sent through to the trend tag. This may be useful if a tag produces many small, insignificant value

Field	Description
	<p>changes. The threshold is represented as a percentage of the tag's engineering range. The default value is 0 (zero), which captures every value change.</p> <p>For example, if a tag has an engineering range of zero to 10000, a deadband of 1 would mean a change in value would have to be greater than 100 (or 1 percent of the range) to be recognized. If the current value was 5600, the tag in the PLC would have to change to a value greater than 5700 or less than 5500 before an update would be sent to the trend tag.</p> <p>If an associated variable tag has a deadband setting, it will not automatically apply to a related trend tag. The trend tag deadband should be configured independently.</p> <p><b>Note:</b> If a variable tag is associated with a driver that supports the Driver Runtime Interface, you can define a trend tag as a pure-event trend (see <a href="#">Configure Event Trends for a DRI Driver</a>). Under this configuration, the trend sample updates are controlled by the driver and the <b>Deadband</b> setting will be based on what is defined in the variable tag instead of the trend tag.</p>
Comment	Any useful comment (254 characters maximum).

### Storage Properties

#### UNINTENDED EQUIPMENT OPERATION

If using the **File Name** property, ensure that each trend tag uses a unique file name. Two tags accessing the same file can result in system errors which may include lost or corrupted trend/SPC data.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

Field	Description
<b>File Name</b>	<p>The file where the data is to be stored (253 characters maximum). Specify the complete path or use a path substitution (see <a href="#">Use a Path Substitution</a>).</p> <p>When data is collected from your plant floor, it is stored in a file on the hard disk of your computer and used to display a trend or SPC graph (a separate file is used for each trend tag).</p> <p>The File Name property is optional. If you leave this field blank, the trend file is stored in the [DATA] directory (defined by the parameter <a href="#">[CtEdit]Data</a>) on</p>

Field	Description
	<p>the hard disk where installation occurred. The default name of the file is the trend tag name.</p> <p>If required, you can use this field to specify an alternate file name like the following:</p> <p>File Name: [DATA] : TANK131</p> <p>In this case, [DATA] specifies the disk and path for the data (as defined by [CtEdit]Data) and "TANK131" is the name specified for the trend file.</p> <p>To specify an alternate directory for the trend file, use a file name like the following:</p> <p>File Name: [DATA] : Area1\TANK311</p> <p>This would store the trend file in a subdirectory (named "Area1") within the [DATA] directory.</p> <p>Be aware that you will need to manually configure the access control list for a new folder location so that it matches the permissions that were applied to the default location during installation. See <a href="#">Configure Directory Security for Modified Folder Locations</a>.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"><li>• If you use the File Name property, confirm that no other SPC tags or trend tags use the same file name. A compile error message (E2172) will be raised if duplicate file names are detected.</li><li>• Duplicated file names can occur if your path substitutions are not configured correctly, for example, if [TREND1] and [TREND2] incorrectly point to the same location. If this occurs, an error will be logged to the syslog.dat file, and a hardware error will be raised.</li><li>• If a path with invalid characters (such as '*' or '?') is detected at runtime, an error will be logged to the syslog.dat file, and a hardware error will be raised.</li><li>• The trend system will buffer the acquired data before saving it to a file. The [Trend]CacheSize parameter determines the buffer sizes for returned data.</li><li>• A file extension should not be used when specifying a file name. If you edit this property (change the file name or path) in an existing project, existing trend data is ignored.</li></ul>

Field	Description
	<ul style="list-style-type: none"> <li>You can no longer store trend files in the 'Bin', 'Runtime', 'Backup' or 'User' directories, or any subdirectories of these. If this is attempted, an error will be logged to the syslog.dat file, and a hardware error will be raised. If you have existing Version 3.xx or 4.xx projects that use these directories to store trend files, the path for these will have to be changed to the 'Data' directory.</li> </ul>
<b>No. Files</b>	<p>The number of history files stored on your hard disk (for this tag) (4 characters maximum). The maximum number of files you can specify per trend tag is 999. Performance and storage will be severely impacted by having a large number of history files per trend.</p> <p>By default, 2 history files are stored on your hard disk.</p>
<b>Period</b>	<p>The period of the history file, in hh:mm:ss (32 characters maximum). Alternatively, you can:</p> <ul style="list-style-type: none"> <li>Specify a weekly period by entering the day of the week on which to start the history file, for example Monday, Tuesday, Wednesday, etc.</li> <li>Specify a monthly period by entering the day of the month on which to start the history file, for example 1st, 2nd, 3rd, 4th, 5th, etc.</li> <li>Specify a yearly period by entering the day and the month on which to start the history file, for example 1st January, 25th February, etc. The day and month needs to be separated by a space.</li> </ul> <p>If you do not specify a period, the period defaults to Sunday (weekly).</p> <p>When deciding on a period setting, be aware that the performance of a trend viewer (be it the existing Plant SCADA or Process Analyst) may be impacted by the size of a trend file. This is particularly true when displaying event-based trend data.</p> <p><b>Note:</b> If you edit this property in an existing project, delete or move the associated trend files before you run the new runtime system. (For location of the trend files, see the <b>File Name</b> property.)</p>
<b>Time</b>	<p>The time of day to synchronize the beginning of the</p>

Field	Description
	<p>history file, in hh:mm:ss (32 characters maximum). If you do not specify a time, the file is synchronized at 0:00:00 (i.e. midnight). The time needs to be specified in Greenwich Mean Time, not the local time zone.</p> <p><b>Note:</b> If you edit this property in an existing project, you will need to delete the associated trend files before you run the new runtime system. Otherwise, the trend history files will continue to roll over at the previously specified time.</p> <p>For the location of the trend files, see the <b>File Name</b> property.</p>
<b>Storage Method</b>	<p>Select <b>Scaled</b> or <b>Floating Point</b> (64 characters).</p> <p><b>Scaled</b> is a 2-byte data storage method; floating point uses 8 bytes.</p> <p>Trend records need to explicitly define their trend storage method. The compiler will raise an error if not defined.</p> <p><b>Floating point</b> storage has an expanded data range in comparison to scaled storage, allowing values to have far greater resolution. However, you need to consider that it also uses a lot more disk space.</p> <p>If you use scaled trends, then a loss of precision may occur when reading trend data via CtAPI applications. This occurs when the engineering range does not evenly divide into 32000. In this case, it is recommended that you use floating point (8-byte) trends.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>• Trend records need to explicitly define their trend storage method. The compiler will raise an error if not defined. In earlier versions, the default when not defined was "Scaled (2 byte)". When upgrading, customers should set the trend storage method for blank entries to match the default from the previous version.</li> <li>• If you edit this property in an existing project, you need to delete the associated trend files before you run the new runtime system. (For the location of the trend files, see the <b>File Name</b> property.)</li> </ul>

## Security Properties

Property	Description
Area	The area to which the trend data belongs.
Privilege	The privilege necessary by an operator to display the trend data on a trend.

**Historian Properties**

Property	Description
Historize	This field enables you to automatically historize and publish the specified trend tag in CitectHistorian. If you set this field to "TRUE", the variable will be included in an automated configuration process within the Historian environment. If you set the field to "FALSE" (or leave it blank), the variable will not be included.  See <a href="#">Integration with Historian</a> .

**Project Properties**

Property	Description
Project	The project in which the trend tag is configured.

**See Also**

[Create Pages for Trend Graphs](#)

**Configure Event Trends for a DRI Driver**

If a variable tag is associated with a driver that supports the Driver Runtime Interface (see [Retrieving Time-stamped Data from I/O Devices](#)), you can define a trend tag as pure-event trend.

This means each sample value and timestamp is automatically populated to the trend tag by the driver whenever the I/O value changes.

**To define a pure-event trend:**

1. Follow the procedure described in [Add a Trend Tag](#).
2. Set the trend **Type** to "TRN\_EVENT".
3. Set the **Expression** to a variable tag from an I/O device that uses a DRI driver.
4. Set the **Trigger** to blank.

Under this configuration, trend sample updates are controlled by the driver. The **Deadband** setting will be based on what is defined in the variable tag instead of the trend tag.

## See Also

[Trend Interpolation](#)

[Create Pages for Trend Graphs](#)

### Create Pages for Trend Graphs

You can use any of the predefined trend templates for your trend pages, or use a predefined template to produce your own trend templates. You can draw a trend background (such as grid lines) on your trends.

#### To configure a trend page:

1. Open Graphics Builder.
2. Click the **New Page** button on the Command Bar, or choose **File | New**.
3. On the New dialog box, select **Type: Page**.
4. Choose the **Resolution** (size) of the trend page.
5. Choose a trend **Template** for the trend page:
  - **Singletrend** - One trend on the page
  - **Doubletrend** - Two trends on the page
  - **Eventtrend** - One event trend on the page
  - **Zoomtrend** - Two trends on the page (one window for zooming)
  - **Poptrend** - A single trend on the page (for display in a pop-up window)
6. Click **OK**.

To create multiple trend pages, you can:

- Create a trend page for each set of trends to display in the runtime system.
- Create a single trend page and use the [PageTrend\(\)](#) function to display trends as necessary. With this function, you can display the trends in the system with a single trend page
- Create the trend page with the Graphics Builder, and set the pen names to blank. You then display that page by calling this function and passing the necessary trend tags (up to 8). Call the PageTrend() function from a menu of trend pages.

## See Also

[Trend Interpolation](#)

### Trend Interpolation

Trend interpolation is used to define the appearance of a trend graph when the incoming samples fall out of synchronization with the display period or when samples are missed.

For example, a particular trend might be sampled five times between each update of the trend graph. As only one value can be displayed for each update, a single value needs to be used that appropriately represents the five samples; and that could be the highest value, the lowest value, or an average.

To define how Plant SCADA calculates the value to use, you set a particular trend interpolator display method.

The following table shows the available interpolator display methods, grouped into *condense methods* (where the display period is longer than the sample period) and *stretch methods* (where the display period is less than or equal to the sample period).

Condense methods	Stretch methods
<b>Average</b> ( <i>default</i> ) - this displays the average of the samples within the previous display period	<b>Step</b> ( <i>default</i> ) - This method simply displays the value of the most recent sample.
<b>Minimum</b> - This displays the lowest value that occurred during the previous display period.	<b>Ratio</b> - This method uses the ratio of sample times and values immediately before and after the requested time to interpolate a "straight line" value.
<b>Maximum</b> - This displays the highest value that occurred during the previous display period.	<b>Raw Data</b> - This method displays the actual raw values.

The interpolation display method is set via `TrnSetDisplayMode()` function. You can also use the `[Trend]GapFillMode` parameter, but it will interpolate values within the actual trend file as well as on the trend graph.

## Print Trend Data

You can print trend data using the following functions:

Function	Purpose
<code>TrnPrint</code>	Prints a trend that is displayed on the screen.
<code>TrnPlot</code>	Prints a plot of one or more trend tags.
<code>TrnComparePlot</code>	Prints two trends (one overlaid on the other), each of up to four trend tags.
<code>WinPrint</code>	Prints the active window

The standard trend templates have buttons that call these functions to print data.

When you print using the `TrnPrint` function, the Plot Setup dialog box appears. Use this dialog box to:

- Specify the title of the trend.
- Add a comment which is displayed beneath the title.
- Specify whether the trend is going to print in black and white, or in color. The selection that you make here will become the setting for the `[General]PrinterColourMode` parameter.
- Define your printer setup. The printer that you select here will be set as the default printer at the `[General]TrnPrinter` parameter.
- Specify whether or not the form displays the next time the function is used. This check box sets the `[General]DisablePlotSetupForm` parameter.

## See Also

[Export Trend Data](#)

## Export Trend Data

You can export trend data to reports and databases with the following functions:

Function	Purpose
TrnGetTable	Retrieves trend information and stores it in a Cicode array
TrnExportClip	Copies trend data to the clipboard
TrnExportCSV	Copies trend data to a CSV file
TrnExportDBF	Copies trend data to a DBF file

The standard trend templates have buttons that call these functions to export data.

---

**Note:** You can also select part of your trend graph (click and drag) and copy the underlying values to the Windows clipboard. You can then paste them into an Excel spreadsheet. (If you are pasting millisecond values, you will need to create a custom format for the TIME column to display these values correctly. To do this, select the column and select **Format | Cells**. In the **Number** tab, select **Custom** for Category, and type **h:mm:ss.000 AM/PM.**)

---

## See Also

[Use Trend History Files](#)

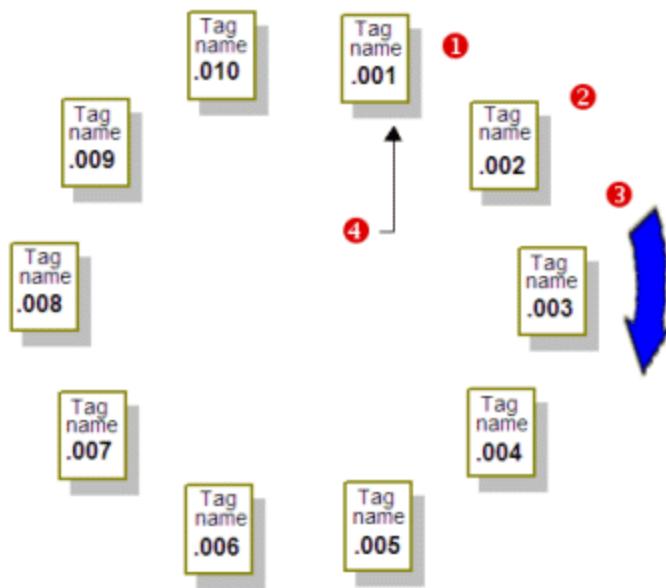

## Use Trend History Files

When Plant SCADA starts up for the first time, it creates the trend files necessary for each trend tag in the runtime system. You can change this default using the [\[Trend\]AllFiles](#) parameter.

A system of rotational history files is used to store the trend data. Data is stored in several files rather than in a single large file.

By default, there are 2 files for each trend tag. If required, you can specify the number of files to use via a trend tag's **No. Files** property (see [Add a Trend Tag](#)). For example:

No. Files	Comment
10	Use ten files for the data, as in the diagram below.

1. When Plant SCADA begins logging, data is written to the first file.
2. At midnight the following Sunday, Plant SCADA writes to the second file.
3. At midnight the following Sunday, Plant SCADA writes to the third file, and so on.
4. After week 10, the first file is overwritten with new data.

The maximum number of files you can specify per trend tag is 999.

You can also specify the period between files, i.e., when a new history file is used, for example:

Period	Comment
1:00:00	Use a new file each hour
6:00:00	Use a new file every six hours
72:00:00	Use a new file every three days
Monday	Use a new file each week beginning on Monday
15th	Use a new file every month beginning on the 15th of each month
25th June	Use a new file every year beginning on the 25th of June

You can also specify the time of day to synchronize the start of the history file; for example:

Time	Comment
6:00:00	Synchronize the file at 6:00 am
12:00:00	Synchronize the file at 12:00 midday

Time	Comment
18:30:00	Synchronize the file at 6:30 pm

## See Also

[Storage Method](#)

### Storage Method

You can select the storage method to use for trend tags and SPC tags. You are given a choice of either **Scaled** or **Floating Point**. Scaled represents a 2-byte data storage method; floating point uses 8 bytes.

Floating point storage has a dramatically expanded data range in comparison to scaled storage, allowing values to be more precise, but it also uses more disk space. Use scaled where compatibility with pre-V5.31 trend history files is necessary.

You can set the necessary storage method via the Trend Tag or SPC Tag properties. The storage method is set to Scaled by default.

#### Note:

- Trend records need to explicitly define their trend storage method. The compiler will raise an error if not defined. In previous versions, the default when not defined was "Scaled (2 byte)"8 byte. When upgrading, customers should set the trend storage method for blank entries to match the default from the previous version.
- If you edit this property in an existing project, you need to delete the associated trend files before you run the new runtime system. (For location of the trend files, see the **File Name** property for the trend tag.)

## See Also

[Calculating Disk Storage](#)

### Calculating Disk Storage

Equations allow you to calculate the total disk space necessary to store a trend across a specified period of time.

The storage method used for a trend (**Scaled** or **Floating Point**) affects the number of bytes necessary for each sample, so in order to calculate the disk space necessary correctly it is important to base your calculations on the appropriate formula. By default, the Scaled storage method is used.

### Floating point

Each data sample requires eight bytes of storage. This alters the equation to:

$$\text{Bytes necessary for each trend} = 704 \times \text{No. Files} + 160 + \left( \frac{\text{File Period (secs)} \times (\text{No. Files})}{\text{Sample Period (secs)}} \times 8 \right)$$

The number of bytes necessary then becomes:

$$\text{Bytes necessary} = 704 \times 5 + 160 + \left( \frac{(7 \times 24 \times 60 \times 60) \times 5 \times 8}{10} \right)$$

Bytes necessary = 2,422,976 bytes

## Scaled

Each data sample requires two bytes of storage. You can therefore calculate the total disk storage necessary for each trend by using the following formula:

$$\text{Bytes necessary for each trend} = 464 \times \text{No. Files} + 176 + \left( \frac{\text{File Period (secs)} \times (\text{No. Files}) \times 2}{\text{Sample Period (secs)}} \right)$$

For example, if a trend record produces one sample every ten seconds for one week, and you are using five data files (five weeks), the number of bytes necessary is:

$$\text{Bytes necessary} = 464 \times 5 + 176 + \left( \frac{(7 \times 24 \times 60 \times 60) \times 5 \times 2}{10} \right)$$

Bytes necessary = 607,296 bytes

---

**Note:** The calculations above do not take into account the space necessary to store the history file for each trend. This is because these files remain at a set size and therefore do not significantly impact the amount of disk space necessary.

---

**Note:** For efficient trends storage, use Windows file compression. By using this method you often can reduce your files to 10% of their original size; the actual amount of compression varies depending on the rate of change of the data.

---

## See Also

[Reconfiguring History Files](#)

### Reconfiguring History Files

If you change the configuration of your trend history files (in an existing project), or you change the configuration of a trend tag that affects the number, time, or period of the trend files, you need to delete the existing trend files - before you run the new system.

If you change the path of your trend history files (in an existing project), existing trend data is ignored.

---

**Note:** You need to not delete history files (that Plant SCADA creates) from your hard disk while your system is running, as the trend server will attempt to recreate the files and this may cause system performance issues.

---

## Use a Path Substitution

Instead of specifying the full path to data files in your system, you can use a path substitution.

With path substitution, you use a name that is a substitution for a full directory path. You can then use the substitution name in the following format:

File Name	[SUBSTITUTION]:<filename>
-----------	---------------------------

For example, if you decide to store a trend data file in the default data directory, you could specify the full path to the file:

File Name	%PROGRAMDATA%\AVEVA Plant SCADA 2023\Data\MYFILE
-----------	--

Or you could use a default path substitution and specify the following:

File Name	[DATA]:MYFILE
-----------	---------------

Path substitution provides greater control of data storage. You can change the location of data files by changing the definition of the data path - instead of locating and changing each occurrence of the data path.

A set of default path names are listed below. You can also define your own path substitutions using the parameter [\[Path\]<PathName>](#).

## Default Path Substitutions

Plant SCADA has the following pre-defined path substitutions:

Path Name	Default Directory
[Bin]	%PROGRAMFILES(x86)%\AVEVA Plant SCADA\Bin
[User]	%PROGRAMDATA%\AVEVA Plant SCADA <VersionNumber>\User
[Data]	%PROGRAMDATA%\AVEVA Plant SCADA <VersionNumber>\Data
[Run]	The current project directory.
[Copy]	The current copy project directory.
[Back]	The current backup project directory.

**Note:** You will need to manually configure the access control list for a folder specified in a path substitution so that it matches the permissions that were applied to the default location during installation. See [Configure Directory Security for Modified Folder Locations](#).

## See Also

[Add a Trend Tag](#)

## Debugging Trending

The [\[Trend\]TrendDebug](#) Citect.ini parameter is provided to help you while logging and trending data.

### Example:

```
[Trend]  
TrendDebug=n
```

Where *n* can be the combination of the following debug options:

- 1 - Logs the client, server, and redundancy message types and also the samples being written in the Trends Server from normal acquisition.
- 2 - Logs detailed information about the currently active backfill process, including the redundant samples written to the archive.
- 4 - Logs detailed information for the TrendSetTable functions.
- 7 - Logs trend activities.
- 8 - Logs the summary information only for the currently active backfill process.
- 16 - Logs to syslog.dat the client trend data.

These settings can be added together to have combinations of logging levels. For example:

```
[Trend]  
TrendDebug=6
```

logs the detailed backfill process and TrendSetTable functions.

These settings are read dynamically, meaning that you can change these settings while Plant SCADA is running and the changes will take effect from that point onwards.

[Trends - Frequently Asked Questions](#)

## Trends - Frequently Asked Questions

### Q: How do I get trend data into a dBASE database?

A: Display the trend on screen and select the File Save/As tool. This tool displays a Save/As dialog box for you to enter the name of the file, and calls the TrnExportDBF function to save the data. (For more complex procedures, call this function directly.)

### Q: How do I get trend data into Excel?

A: You can get data into Excel in three ways:

- Display the trend on the screen, select the Clipboard tool to copy the data, and use the Excel paste command to paste the data into Excel.
- Display the trend on the screen and select the File Save/As tool. Save the data in CSV format, and open the CSV file in Excel.
- Display the trend on the screen and select the File Save/As tool. Save the data in DBF format and open the DBF file in Excel.

(For other procedures, call the TrnExportCSV or TrnExportDBF function.)

**Q: How do I get trend data into MS Access?**

**A:** You can get data into Access in three ways:

- Display the trend on the screen, select the Clipboard tool to copy the data, and use the Access Paste command to paste the data into Access.
- Display the trend on the screen and select the File Save/As tool. Save the data in CSV format, and open the CSV file in Access.
- Display the trend on the screen and select the File Save/As tool. Save the data in DBF format and open the DBF file in Access.

(For other procedures, call the TrnExportCSV or TrnExportDBF function.)

**Q: How do I update trend data?**

**A:** Use the TrnSetTable function to write data back to the trend system.

**Q: How do I get trend data into a report?**

**A:** Use the TrnGetTable function.

## Accumulators

Accumulators track incremental runtime data, such as motor run hours, power consumption, and downtime. You set a trigger (for example, motor on) to increment three counters:

- The number of times the accumulator is triggered (for example the number of starts for the motor).
- The run time, in steps of 1 second.
- A totalizer value, by an increment you define.

The accumulated data is stored as variable tags in an I/O device. This allows easy access to these variables and, because they are saved in the I/O device, their values are retained if the project is shutdown.

Variable tags are read at startup and updated regularly while the trigger is active. You can monitor and display accumulated data by animating, trending, or logging the variable tags.

You can increase system performance by storing these variables in a disk I/O device. If you store these variables in an external I/O devices, communications bandwidth will be consumed updating the variables. If using a network, you can use a redundant disk I/O device to secure these variables.

---

**Note:** The accumulator server runs as a part of the report server. You need to add a report server to your project to make accumulators work. See [Add a Report Server Process](#).

---

If you have a redundant reports server, you need to use a primary/standby configuration to stop the accumulators running on both reports servers. Use the Setup Wizard to define the reports servers.

You can control (re-read or reset) any accumulator at runtime by using the [AccControl](#) Cicode function.

## See Also

[Add an Accumulator](#)

## Add an Accumulator

[Accumulators](#) track incremental runtime data.

### To add an accumulator:

1. In the **System Model** activity, select **Accumulators**.
2. Add a row to the Grid Editor.
3. Type the required information in each column, or in the fields in the Property Grid.  
For a description of the properties, see below.
4. Click **Save**.

## Accumulators Properties

### Equipment Properties

Field	Description
<b>Equipment</b>	The name of the equipment associated with the accumulator. Select a name from the drop-down list of existing equipment definitions, or enter a name. There is a limit of 254 characters across the <b>Equipment</b> and <b>Item Name</b> fields, including any separating periods (.).
<b>Item Name</b>	The name of the item with which the accumulator is associated. Items form part of an equipment hierarchy. They can be used to associate accumulators, tags, alarms and trends with a particular attribute of a physical piece of equipment (see <a href="#">Items</a> ). There is a limit of 254 characters across the <b>Equipment</b> and Item Name, including any separating periods (.). <b>Note:</b> When defining an item name, avoid using the <a href="#">Reserved Words</a> . If you use any of these, an error message will display when you compile your project.

### General Properties

Field	Description
<b>Name</b>	The name of the accumulator. Enter a value of 79 characters or less.
<b>Cluster Name</b>	The name of the cluster that runs the accumulator. This field needs to be defined if your project has more than one cluster.

Field	Description
	You can leave this field blank in a multi-cluster system if cluster replication is enabled (see the parameter <a href="#">[General]ClusterReplication</a> ).
<b>Trigger</b>	<p>The Cicode expression (or variable tag) to trigger the accumulator. If the result of the expression (in this field) is TRUE, accumulation starts. If the result of the expression (in this field) becomes FALSE, accumulation stops. Enter a value of 254 characters or less.</p> <p>The frequency with which the trigger is checked is controlled by the <a href="#">[Accumulator]WatchTime</a> parameter.</p>
<b>Totalizer Inc</b>	Any Cicode expression (or variable tag) to add to (increment) the <b>Totalizer</b> variable while the <b>Trigger</b> condition is TRUE. Enter a value of 254 characters or less.
<b>Totalizer</b>	<p>The variable (tag) that contains the totalized value. Enter a value of 254 characters or less.</p> <p>On startup, this value is read. Each time the trigger is checked and while the trigger is TRUE, the value in the <b>Totalizer Inc</b> field is added to the local copy of this <b>Totalizer</b> variable. The new <b>Totalizer</b> variable is written back to the I/O Device at a frequency determined by the <a href="#">[Accumulator]UpdateTime</a> parameter.</p> <p>For example, if you configure an accumulator for a motor, and <b>Totalizer Inc</b> is the current (amperage) used by the motor, then <b>Run Time</b> will contain the time (in seconds) that the motor has run, <b>No. of Starts</b> will contain the number of times the motor was started, and <b>Totalizer</b> will contain the total current used by the motor. The average current used by the motor is <b>Totalizer/Run Time</b>.</p>
<b>Run Time</b>	The variable (tag) that contains the run time (in seconds). Enter a value of 254 characters or less. On startup, this value is read. Then the local copy of this variable is incremented (while <b>Trigger</b> is TRUE) and the variable is written back to the I/O Device at a frequency determined by the <a href="#">[Accumulator]UpdateTime</a> parameter.
<b>No. of Starts</b>	The variable (tag) that contains the number of starts (that is, the number of times the trigger changes from FALSE to TRUE). Enter a value of 254 characters or less. On startup, this value is read. Then the local copy

Field	Description
	of this variable is incremented and the variable is written back to the I/O Device at a frequency determined by the [Accumulator]UpdateTime parameter.
<b>Comment</b>	Any useful comment. Enter a value of 48 characters or less.

**Security Properties**

Field	Description
<b>Area</b>	The area to which the accumulator belongs. Only users with access to this area (and any required privileges) will be able to perform operations on the accumulator. For example, if you enter Area 1 here, operators need to have access to Area 1 (plus any required privileges) to perform operations on the accumulator. Enter a value of 16 characters or less.
<b>Privilege</b>	The privilege needed by an operator to perform operations on the accumulator (by using accumulator functions). Enter a value of 16 characters or less.

**Project Properties**

Property	Description
<b>Project</b>	The project in which the accumulator is configured.

[Accumulators](#)

## Statistical Process Control (SPC)

Statistical Process Control (SPC) is the primary tool of statistical quality control and encompasses the collection, arrangement, and interpretation of process variables associated with a product, in regard to uniformity of quality.

**About Statistical Process Control**

Statistical quality control (SQC) helps track and improve product or service quality. Statistical process control (SPC) is the primary tool of SQC and encompasses the collection, arrangement, and interpretation of process variables associated with a product, in regard to uniformity of quality.

Every process is subject to variation and therefore there is always room to improve process consistency and quality. To respond to this, adopt a continuous improvement strategy. By repeating the following cycle, a strategy of prevention can be implemented. This is the key to using SPC effectively. Consider the following steps:

- Analyze the process
- What do we know about the variability of this process?
- Is this process statistically controllable (predictable)?
- Is the process capable of meeting the set requirements?
- What considerations are most important to meeting process quality criteria?
- Maintain (control) the process
- Improve the process

SPC encompasses the following concepts:

- Process Variation
- Statistical Control
- Process Capability

It typically uses the tools [XRS Control Charts](#), [Configure a Capability Chart](#), and [Pareto Charts](#).

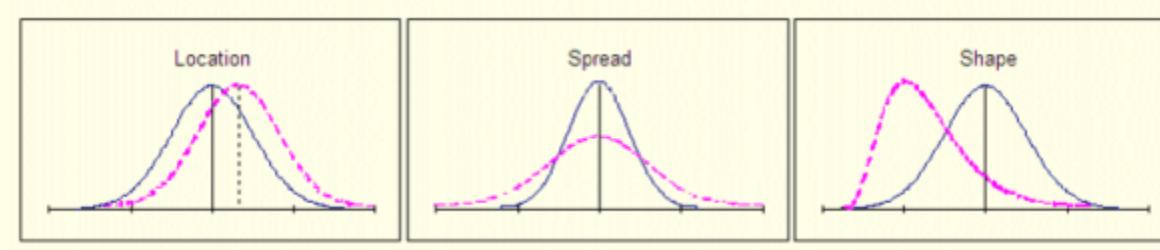

## See Also

[Using Statistical Process Control \(SPC\)](#)

## Process Variation

To use SPC effectively, understand the concept of *variation*. When a product characteristic is measured repeatedly, each measurement is likely to differ from the last. This is because the process contains sources of variability.

When the data is grouped into a frequency histogram, it will tend to form a pattern. The pattern is referred to as a probability distribution and is characterized in three ways:

---

**Note:** Most SPC techniques assume that the collected data has a normal distribution.

Variation is generally categorized into one of two types:

- **Common:** refers to variation that is predictable and repeatable over time. The distribution characteristics will be stable. Common variation could be due to consistent process inaccuracy or similar.  
Statistics indicate that common variations account for about 85% of departures from process quality requirements. Usually these departures require solution at the management level.
- **Special:** refers to variation that is not consistently present. When special variation occurs it will tend to change the distribution characteristics. The distribution is not stable over time.

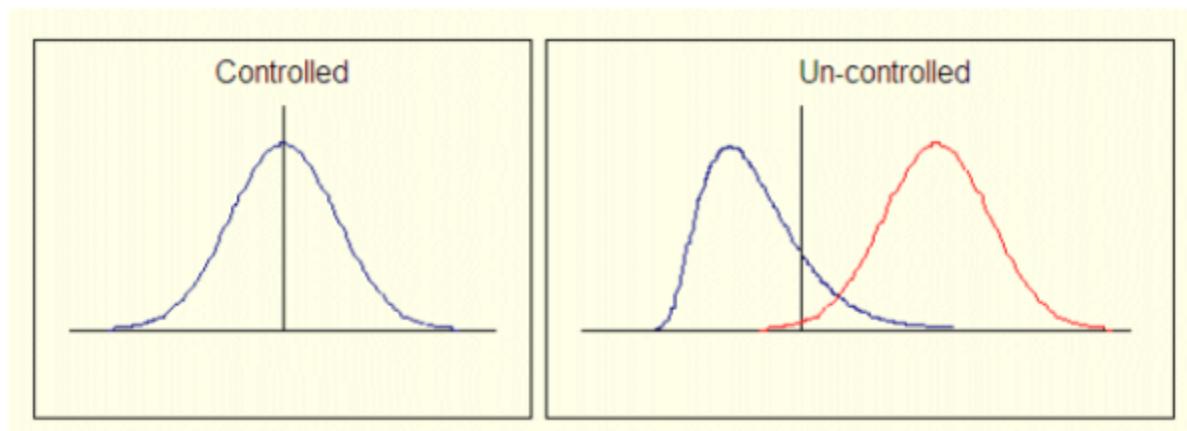

Statistics indicate that special variations account for about 15% of departures from process quality requirements. Typically these departures require local action (equipment repair and so on) for solution.

## See Also

[Process Capability](#)

## Statistical Control

A process is said to be in statistical control when the only sources of variation are from common causes. A statistically controllable process is desirable because it is predictable, while a statistically uncontrollable process will yield unpredictable distributions.

Even though a process might not be statistically controllable, it might still meet requirements. Conversely, a process which is controllable might not meet requirements. This issue is clarified by considering Process Capability.

## See Also

[Process Variation](#)

## Process Capability

A process is said to be capable when the percentage of samples outside the specification limits is less than a predefined value. The following assumptions need to also be true:

- The process is statistically stable (only common causes of variation exist)
- The individual measurements conform to a normal distribution
- Measurement variation (due to the measuring instrument) is small

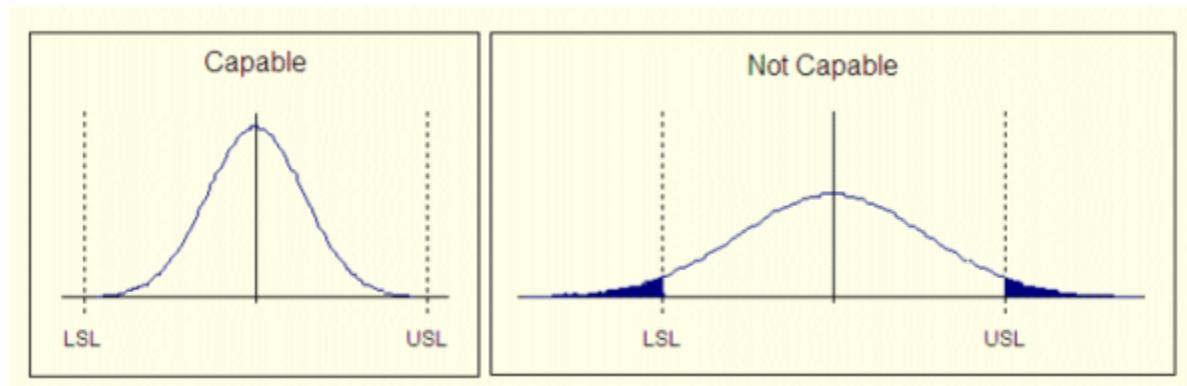

The specification limits are a reflection of the customers requirements and are selectable. The percentage of samples that need to lie within the specification limits is calculated from the standard deviation ("sigma") "3-sigmas" on either side of the mean.

**Note:** The "3-sigma" term refers to the boundaries which are located 3 standard deviations on either side of the

---

center. For a normal distribution 99.74% of the samples are expected to fall within this boundary.

Ultimately capability determines whether the process is statistically able to meet the specification or not. Reducing the effects of common variation will make your process more capable, as shown here:

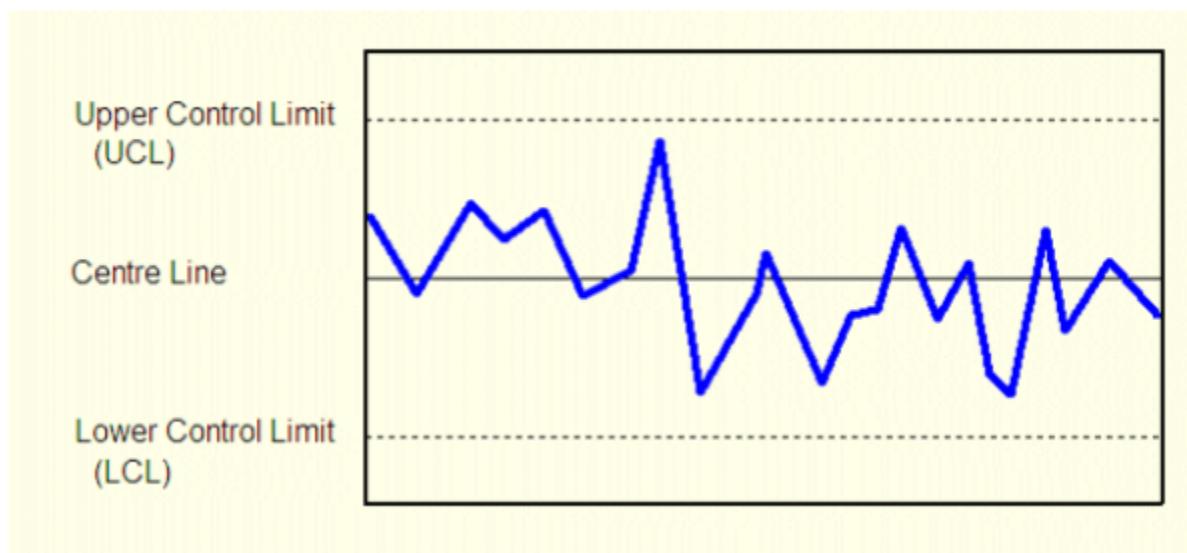

## See Also

[XRS Control Charts](#)

## XRS Control Charts

XRS charts are the primary tool of SPC and convey information about variation and control-ability. The charts are trend graphs that individually show mean ( $\bar{X}$  bar), range ( $R$ ), and standard deviation ( $s$  or  $\sigma$ ). Each point on the graph represents sub-grouped data, not individual samples.

Refer to the following for more information:

## CL, UCL, LCL

Each graph has center, upper control limit (UCL), and lower control limit (LCL) lines drawn. The control limits are estimates of where the "3-sigma" limits would lie for an approximately normal distribution. In practice the limits

are calculated from the measured X double bar, R bar, and s bar, and table values which are based on the size of the subgroup used.

These lines are used as a guide for analysis as they are based on the natural variability of the process. These limits are not specification limits.

## Interpreting the Chart

Control charts can provide valuable information about process variation. By watching for particular patterns and events, conclusions can be drawn as to how the process is controlling.

A (normal) process that is statistically under control will tend to distribute data according to a normal distribution. The data will appear randomly, but centered around the center line. Data that appears near the control limits may be infrequent but expected. Presence of data that appears outside of the control limits indicates the process is statistically uncontrolled and action should be taken to address the cause. Similarly, runs of constant data or patterns indicate instability.

The following list of patterns and events are considered to be cause for alarm:

- Points beyond the control limits
- Several consecutive points on only one side of the average
- Several consecutive points that are consistently increasing or decreasing
- Substantially more than 2/3 of plotted points lie close to the average
- Substantially less than 2/3 of plotted points lie close to the average

The presence of these types of patterns and events has different meanings, depending on which type of chart is being analyzed. By using each of the three control charts together (X bar, R and s) together, a better understanding of readings is gained.

## See Also

[Configure an XRS Control Chart](#)

## Capability Charts

The process capability chart is the frequency histogram and distribution of the process mean data and is used to analyze process capability. This chart is drawn with center line, lower specification limit and upper specification limit indicators in place. Interpreting capability charts is typically made with the Cp, Cpk, kurtosis and skewness indices.

Refer to the following for more information:

## Upper Specification Limit and Lower Specification Limit

Upper specification limit (USL) and lower specification limit (LSL) specify the requirements of the product, and so are customer driven. Make the target value the midpoint between USL and LSL.

## Cp Index

The inherent process capability ( $C_p$ ) is the ratio of tolerance to 6-sigma. Essentially this index indicates whether the distribution would fit inside the USL and LSL limits. Its meaning is defined as follows:

- $C_p > 1.0$  - Indicates the process variation will fit within the specified limits (USL and LSL) and therefore, is capable.
- $C_p < 1.0$  - Indicates the process is not capable.

## Cpk Index

The process capability based on the worst case ( $C_{pk}$ ) is similar  $C_p$ . This index, however, indicates where the mean lies in relation to the USL and LSL limits. It is used to mathematically clarify  $C_p$ . Its meaning is defined as follows:

- $C_{pk} < 0$  - Indicates the process mean is outside the specified limits (USL and LSL)
- $C_{pk} = 0$  - Indicates the process mean is equal to one of the specified limits.
- $C_{pk} > 0$  - Indicates the process mean is within the specified limits.
- $C_{pk} = 1.0$  - Indicates that one side of the 6-sigma limits falls on a specification limit.
- $C_{pk} > 1.0$  - Indicates that the 6-sigma limits fall completely within the specified limits.

## Pareto Charts

A Pareto chart is a tool which is used to analyze the relative frequency of deviations from specifications or success criteria. The Pareto chart is a frequency histogram which is ordered from highest to lowest. Unlike control and capability charts, this chart uses no statistical guides.

Pareto charts emphasize Pareto's empirical law that any assortment of events consists of a few major and many minor elements. In the context of SQC, it is important to select the few vital major opportunities for improvement from the many trivial minor ones. The Pareto chart is particularly useful for Cost-to-fix versus Deviation-frequency analysis.

In addition to the histogram, typically a cumulative percentage is also given. From top to bottom, the percentage represents the ratio of the sum of every value to this point, to the sum of every value in the chart.

## Using Statistical Process Control (SPC)

To implement Statistical Process Control (SPC) in a Plant SCADA system, there are two procedures to follow. They are:

- [Add an SPC Tag](#)
- [Configure an SPC Chart](#).

## See Also

- [SPC Alarms](#)
- [SPC Formulas and Constants](#)
- [Control Chart Line Constants](#)

## Add an SPC Tag

Statistical Process Control (SPC) tags specify data that is to be collected for use in SPC operations. Once data is defined it can be dynamically analyzed (as SPC graphs and alarms) at runtime.

SPC tags are similar to trend tags. Like trends, Plant SCADA can collect and store any amount of SPC data. The only restriction on the amount of data that you can store is the size of the hard disk on your computer. (Plant SCADA uses an efficient data storage method to optimize the use of storage space on your computer's hard disk.) For long-term storage, you can archive the data to disk or tape (without disrupting your runtime system). You can also log data at regular intervals (periodic trend), or only when an event occurs (event trend), in the same manner as Trend Tags.

---

**Note:** SPC does not support Periodic-Event trends, which is a combination of the properties of Periodic and Event trends. In addition, if you use event-based SPC tags, your display screen refresh rate may be slower than desired or practical for your application.

---

When you define an SPC tag you will want to be sure to fill in the upper specification limit (USL) and lower specification limit (LSL) if you intend to perform a capability analysis. These values have to accurately represent the users requirements, and the target value lie midway between the two. If these fields are left blank the capability analysis will be meaningless.

### To add an SPC tag:

1. On the **System Model** activity, select **SPC**.
2. Add a row to the Grid Editor.
3. Type the required information in each column, or in the fields in the Property Grid.  
For a description of the properties, see below.
4. Click **Save**.

## Statistical Process Control (SPC) Properties

---

**Note:** If an SPC tag was generated by the Equipment Editor, a number of fields on the properties form will be shaded. To configure these fields, you will need to use [Equipment Editor](#).

---

### Equipment Properties

Field	Description
<b>Equipment</b>	The name of the equipment associated with the SPC tag. Select a name from the drop-down list of existing equipment definitions, or enter a name. There is a limit of 254 characters across the <b>Equipment</b> and <b>Item Name</b> fields, including any

Field	Description
	separating periods (.).
<b>Item Name</b>	<p>The name of the item with which the SPC tag is associated.</p> <p>Items form part of an equipment hierarchy. They can be used to associate tags, alarms and trends with a particular attribute of a physical piece of equipment (see Items).</p> <p>There is a limit of 254 characters across the <b>Equipment</b> and Item Name, including any separating periods (.).</p> <p><b>Note:</b> When defining an item name, avoid using the reserved words. If you use any of these, an error message will display when you compile your project.</p>

**General Properties****⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

If using the File Name property, ensure that the SPC tag uses a unique name. Two tags accessing the same file can result in system errors which may include lost or corrupted trend/SPC data.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

Field	Description
<b>SPC Tag Name</b>	The name assigned to the SPC data. If you are logging a variable, use the same name for the SPC tag that you used for the variable tag.
<b>Cluster Name</b>	<p>The name of the cluster that runs the SPC tag. This field needs to be defined if your project has more than one cluster.</p> <p>You can leave this field blank in a multi-cluster system if cluster replication is enabled (see the parameter <a href="#">[General]ClusterReplication</a>).</p>
<b>Type</b>	<p>The type of SPC trend:</p> <ul style="list-style-type: none"> <li>• TRN_PERIODIC</li> <li>• TRN_EVENT</li> </ul> <p><b>Note:</b> SPC does not support Periodic-Event trends, which is a combination of the properties of Periodic and Event trends. In addition, if you use</p>

Field	Description
	event-based SPC tags, your display screen refresh rate may be slower than desired or practical for your application.
<b>Expression</b>	<p>The logged value of the SPC tag. Enter a value of 254 characters or less. You can log individual variables by using a Variable Tag, for example:</p> <p>Expression: PT104</p> <p>Comment: Logs the Variable Tag PT104</p> <p>The value of the process variable PT104 is logged. Variable PT104 has to be defined as a variable tag. You can also log any Cicode expression or function, for example:</p> <p>Expression: PT104/COUNTER</p> <p>Comment: Logs Variable Tag PT104 divided by the Variable Tag COUNTER</p>
<b>Trigger</b>	<p>The Cicode expression (or variable tag) that triggers data logging. Enter a value of 254 characters or less. For example:</p> <p>Trigger: PT104 &lt; 500</p> <p>In this example, logging occurs when the value of the variable tag (PT104) falls below 500.</p> <p>For a periodic SPC trend, data is logged only while the value of the trigger is TRUE. In the above example, data is logged continuously while the value of PT104 remains less than 500. Logging ceases when the value rises to (or above) 500. Logging does not occur again until the value of PT104 falls below 500.</p> <p>You do not have to specify a trigger for a periodic SPC trend. If you do not specify a trigger for a periodic SPC trend, then logging will occur continuously.</p> <p>For an event SPC trend, data is logged once when the value of the trigger changes from FALSE to TRUE. In the above example, one sample is logged when the value of PT104 first becomes less than 500. Another sample is not logged until the value of PT104 rises to (or above 500) and again falls below 500.</p>
<b>Subgroup Size</b>	The size of each subgroup. The default value for this value is 5. Valid values are 1 - 25 inclusive.
<b>Sample Period</b>	The sampling period of the data, in hh:mm:ss

Field	Description
	<p>(hours:minutes:seconds). Plant SCADA checks the <b>Trigger</b> each sample period. If the Trigger is TRUE (or has just changed from FALSE to TRUE, in the case of event SPC trends), Plant SCADA will log the value of the <b>Expression</b>.</p> <p>Examples</p> <p>Sample Period: 30 - Logs data every 30 seconds</p> <p>Sample Period: 10:00 - Logs data every 10 minutes</p> <p>Sample Period: 10:00:00 - Logs data every 10 hours</p> <p>Sample Period: 2:30:00 - Logs data every 2 and a half hours</p> <p>This property is optional. If you do not specify a sample period, the sampling period will default to 10 seconds.</p> <p><b>Note:</b> If you edit this property in an existing project, delete or move or move the associated trend files before you run the new runtime system.</p>
<b>Eng Units</b>	The engineering units of the variable/expression being logged. The engineering units are used by the SPC trend scales and SPC trend cursor displays.
<b>Format</b>	<p>The format of the variable/expression being logged. The format is used by the SPC trend scales and SPC trend cursor displays.</p> <p>This property is optional. If you do not specify a format, the format defaults to #####.#.</p>
<b>Deadband</b>	The value that <b>SPC Tag</b> needs to return to before the SPC data becomes inactive.
<b>Lower Spec Limit</b>	<p>The Lower Specification Limit (LSL). This value is used as the lower limit to determine process capability. When used in conjunction with the USL it provides a tolerance for your process.</p> <p>If you are unfamiliar with process capability and capability indices, ask for expert opinion. Rather than leave this blank (at least) attempt an estimate. Enter a value that you think is the lowest acceptable value of this tag. If you leave this field blank only your capability analysis will be affected.</p>
<b>Upper Spec Limit</b>	The Upper Specification Limit (USL). This value is used as the upper limit to determine process capability. When used in conjunction with the LSL it provides a

Field	Description
	<p>tolerance for your process.</p> <p>If you are unfamiliar with Process Capability and capability indices, ask for expert opinion. Rather than leave this blank (at least) attempt an estimate - Enter a value that you think is the highest acceptable value of this tag. If you do leave this field blank only your capability analysis will be affected.</p>
<b>x Double Bar</b>	<p>The calculation override for process mean (X double bar). If a value is specified here it will be used in every SPC calculation, instead of the value calculated by Plant SCADA. This will affect the calculation of control limits which are normally a function of the collected samples of data.</p> <p>You should not use this field unless you are experienced in SPC.</p>
<b>Range</b>	<p>The calculation override for process range (R bar). If a value is specified here it will be used in every SPC calculation, instead of the value calculated by Plant SCADA. This will affect the calculation of control limits which are normally a function of the collected samples of data.</p> <p>You should not use this field unless you are experienced in SPC.</p>
<b>St Deviation</b>	<p>The calculation override for process standard deviation (s bar). If a value is specified here it will be used in every SPC calculation, instead of the value calculated by Plant SCADA. This will affect the calculation of control limits which are normally a function of the collected samples of data.</p> <p>Do not use this field unless you are experienced in SPC.</p>
<b>Comment</b>	Any useful comment (254 characters).

#### Storage Properties

##### UNINTENDED EQUIPMENT OPERATION

If using the File Name property, ensure that each trend tag uses a unique file name. Two tags accessing the same file can result in system errors which may include lost or corrupted trend/SPC data.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

If you edit one of the following properties in an existing project, delete associated SPC trend files before placing the system back in service.

- No Files
- Period
- Time
- Storage Method

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

Field	Description
File Name	<p>The file where the data is to be stored. You need to specify the complete path or use path substitution (see <a href="#">Use a Path Substitution</a>).</p> <p>When Plant SCADA collects data from your plant floor, it stores the data in a file on the hard disk of your computer. When it subsequently uses the data to display an SPC trend, it reads the data from this file. (Plant SCADA uses a separate file for each SPC tag.)</p> <p>The File Name property is optional. If you do not specify a file name, the file name defaults to [DATA]:&lt;Name&gt; on the hard disk where you installed Plant SCADA. Where &lt;Name&gt; is the SPC Tag Name.</p> <p>You can also specify an alternate file name like this:</p> <p>File Name: [DATA]:TANK131</p> <p>Where [DATA] specifies the disk and path for the data. Use path substitution to make your project more 'portable'.</p> <p>Be aware that you will need to manually configure the access control list for a new folder location so that it matches the permissions that were applied to the default location during installation. See <a href="#">Configure Directory Security for Modified Folder Locations</a>.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"><li>• If you use the File Name property, confirm that no other SPC tags or trend tags use the same file name. A compile error message (E2172) will be raised if duplicate file names are detected.</li><li>• Duplicated file names can occur if your path</li></ul>

Field	Description
	<p>substitutions are not configured correctly, for example, if [TREND1] and [TREND2] incorrectly point to the same location. If this occurs, an error will be logged to the syslog.dat file, and a hardware error will be raised.</p> <ul style="list-style-type: none"> <li>If a path with invalid characters (such as '*' or '?') is detected at runtime, an error will be logged to the syslog.dat file, and a hardware error will be raised.</li> <li>A file extension should not be used when specifying a file name. If you edit this property (change the file name or path) in an existing project, existing trend data is ignored.</li> <li>You can no longer store trend files in the 'Bin', 'Runtime', 'Backup' or 'User' directories, or any sub-directories of these. If this is attempted, an error will be logged to the syslog.dat file, and a hardware error will be raised. If you have existing Version 3.xx or 4.xx projects that use these directories to store trend files, the path for these will have to be changed to the 'Data' directory.</li> </ul>
<b>No. Files</b>	<p><b>Note:</b> If you edit this property in an existing project, delete associated SPC trend files before placing the system back in service.</p> <p>The number of history files stored on your hard disk (for this tag).</p> <p>By default, two history 2 history files are stored on your hard disk. The maximum number of files you can specify is 270.</p>
<b>Period</b>	<p><b>Note:</b> If you edit this property in an existing project, delete associated SPC trend files before placing the system back in service.</p> <p>The period of the history file, in hh:mm:ss (hours:minutes:seconds). Alternatively, you can:</p> <ul style="list-style-type: none"> <li>Specify a weekly period by entering the day of the week on which to start the history file, for example Monday, Tuesday, Wednesday, etc.</li> <li>Specify a monthly period by entering the day of the month on which to start the history file, for example 1st, 2nd, 3rd, 4th, 5th, etc.</li> </ul>

Field	Description
	<ul style="list-style-type: none"> <li>Specify a yearly period by entering the day and the month on which to start the history file, for example 1st January, 25th February, etc. The day and month needs to be separated by a space.</li> </ul> <p>If you do not specify a period, the period defaults to Sunday (weekly).</p>
<b>Time</b>	<p><b>Note:</b> If you edit this property in an existing project, delete associated SPC trend files before placing the system back in service.</p> <p>The time of day to synchronize the beginning of the history file, in hh:mm:ss (hours:minutes:seconds). If you do not specify a time, the file is synchronized at 0:00:00 (i.e. midnight).</p>
<b>Storage Method</b>	<p><b>Note:</b> If you edit this property in an existing project, delete associated SPC trend files before placing the system back in service.</p> <p>Select either <b>Scaled</b> or <b>Floating Point</b> as the storage method for the SPC data (64 characters). The key difference between these two options is that Scaled is a two-byte data storage method, whereas Floating Point uses eight bytes.</p> <p>Floating Point storage has a dramatically expanded data range in comparison to Scaled storage, allowing values to have far greater resolution. However, you need to consider that it also uses a lot more disk space. Scaled should be used where compatibility with pre-V5.31 trend history files is necessary.</p> <p>If you do not specify a storage method, it is set to <b>Scaled</b> by default.</p>

### Security Properties

Field	Description
<b>Area</b>	<p>The area to which the SPC data belongs. Only users with access to this area (and any necessary privileges) will be able to display the SPC data on an SPC page. For example, if you enter Area 1 here, operators need to have access to Area 1 (plus any necessary privileges) to display the SPC data.</p>
<b>Privilege</b>	<p>The privilege necessary by an operator to display the SPC data on an SPC page.</p>

## Historian Properties

Field	Description
Historize	This field enables you to automatically historize and publish the specified SPC tag in CitectHistorian. If you set this field to "TRUE", the variable will be included in an automated configuration process within the Historian environment. If you set the field to "FALSE" (or leave it blank), the variable will not be included.

## Project Properties

Property	Description
Project	The project in which the SPC tag is configured.

## See Also

[Configure an SPC Chart](#)

## Configure an SPC Chart

Plant SCADA displays Statistical Process Control information on three types of charts:

- XRS Control Chart
- Process Capability Chart
- Pareto Chart.

### To configure an SPC chart:

1. Open Graphics Builder.
  2. Click the **New Page** button on the Command Bar, or choose **File | New**.
  3. On the New dialog, select **Page**.
  4. Choose the **Resolution** (size) of the SPC page.
  5. Choose an SPC **Template** for the SPC page:
    - **SPCXRSChart** - An XRS control chart
    - **SPCCpk** - A capability (Cpk) chart combined with an Mean chart.
- 
- Note:** Pareto charts are configured slightly differently and hence, are not included here (see [Configure a Pareto Chart](#)).
6. Click **OK**.
  7. Double-click the graph display.
  8. Enter the variable tag in the Genie pop-up.
  9. Click **OK**.

10. Save the page.

## See Also

[SPC Control Charts](#)

### SPC Control Charts

Genies simplify the task of adding a new SPC page.

You can use Plant SCADA to configure the following types of control charts:

- [Configure an XRS Control Chart](#)
- [Configure a Capability Chart](#)
- [Configure a Pareto Chart.](#)

## See Also

[Control Chart Line Constants](#)

### Configure an XRS Control Chart

The XRS charts display trends of subgroup means (X bar), ranges (R) and standard deviations (s). The XRS chart operates similarly to a standard trend, but with additional SPC extra features. Each subgroup displays as a single node on the graph and consecutive nodes are linked by a line.

Each control chart has a central line and two control limits-upper and lower (UCL and LCL). Plant SCADA automatically calculates these SPC values at run-time. If you want to override the UCL and LCL you can do so by entering the Process Mean, Range, and Standard Deviation fields in SPC Tags.

#### To configure an XRS Control Chart:

1. Define the SPC Tags.
2. Create the page using an XRS template.

---

**Note:** If you want to develop your own XRS template, the method is to copy and modify an existing template.

---

## See Also

[Configure a Capability Chart](#)

### Configure a Capability Chart

The process capability chart is a frequency histogram and distribution of the sample data currently displayed (on the Mean chart). Plant SCADA automatically takes the data being trended, builds a distribution, adds the LSL and USL. It also calculates the Cp, Cpk, kurtosis, and skewness indices.

The process capability is defined in relation to the upper and lower specification limits (USL and LSL) for a given

SPC Tag. These values are defined in SPC Tags and accurately represent the users requirements.

#### To configure a capability chart:

1. Define the SPC Tags and specify the LSL and USL.
2. Create the page using a Capability (Cpk) template.

#### Configure a Pareto Chart

Pareto analysis is a technique used to identify the relative importance of problems and conditions. The Pareto chart is a frequency histogram ordered from highest to lowest (Plant SCADA automatically orders the bars at run-time). The data for each bar in the histogram represents one Plant SCADA variable - as defined in Variable Tags. Do not use SPC tags.

---

**Note:** Typically the frequency in a histogram is of integer type, though you can use floating point types if you want. Negative values are not valid.

---

#### To configure a Pareto Chart:

1. Define the Variable Tags (Pareto charts do not use SPC Tags).
2. Create the page using a Pareto template.

#### To configure a page using a Pareto chart:

1. In Graphics Builder click **New Page**, or choose **File | New**.
2. Select **Type: Page**.
3. Choose the **Resolution** (size) of the SPC page.
4. Choose the **SPCParetoTemplate** for the SPC chart.
5. Click **OK**.
6. Double-click the display (where prompted by the template).
7. Enter the variable tags in the **Tag Name** fields. (Use Variable tags here, not necessarily SPC tags.)
8. Enter the variable descriptions in the **Tag Description** boxes.
9. Click **OK**.
10. Save the page.

#### SPC Alarms

Plant SCADA automatically monitors several special kinds of conditions that are specific to SPC data. When specific patterns or events occur to an SPC tag, it will set the appropriate alarm. Typically these alarms are related to, and used in conjunction with, the XRS control charts.

SPC alarms are configured differently to standard digital alarms to provide for this extra functionality. SPC alarms needs to be configured using the Advanced Alarms form. You use the SPCAlarms Cicode function to check for the condition of the alarms:

---

**Note:** An SPC alarm can only be defined on an Alarm Server in the same cluster as the Trends Server that contains the SPC tag (though the variable tag referenced in the SPC tag can be on a different IOServer cluster).

---

Complete the **Advanced Alarm** settings as shown here:

Alarm Tag	Feed_Above_UCL
Alarm Desc	Un-controlled variation
Expression	SPCALarms("Feed_SPC", XAboveUCL)
Comment	Several samples are above UCL

The SPC (Trends) Server checks for any specified alarm conditions. When one is detected, it informs the Alarm Server that an alarm has occurred. Be aware of the number of subgroups displayed on your SPC charts, and the number used in SPC alarm calculations (as set by the [\[SPC\]AlarmBufferSize](#) parameter). If these two values differ, SPC alarms might not correlate with your SPC charts.

The following list shows the alarms types that are valid:

Name	Description
XFreak	Single point greatly differs (2 sigma) from the center line.
XOutsideCL	Process mean outside either of the control limits (UCL or LCL).
XAboveUCL	Process mean above the upper control limit (UCL).
XBelowLCL	Process mean below the lower control limit (LCL).
XOutsideWL	Process mean outside the alert limits which are 67% of the UCL and LCL.
XGradualUp	Process mean is gradually drifting up to a new level indicated by several consecutive points above the mean.
XGradualDown	Process mean is gradually drifting down to a new level indicated by several consecutive points below the mean.
XUpTrend	Several points continuously increasing in value.
XDownTrend	Several points continuously decreasing in value.
XErratic	Large fluctuations that are greater than the control limits.
XStratification	Artificial constancy. Several consecutive points are close to (within 1 sigma of) the center line.
XMixture	Several consecutive points are far from (outside 1 sigma of) the center line.
ROutsideCL	Process range outside either of the control limits (UCL or LCL).

Name	Description
RAboveUCL	Process range above the upper control limit (UCL).
RBelowLCL	Process range below the lower control limit (LCL).

**Note:** The above alarms rely on  $n$  number of consecutive points to generate the alarm. The value of  $n$  can be set for each type of alarm through [SPC Parameters](#).

## See Also

[SPC Formulas and Constants](#)

### SPC Formulas and Constants

The SPC calculations are based on the samples collected in subgroups. Each subgroup will have the same number of samples, typically 4. The subgroup size for each SPC tag is set at the **SPC Tags** properties form.

The number of samples in each subgroup can range from 1 to 25 inclusive.

### When the number of samples in each subgroup is 1

#### Subgroup Mean ( $\bar{X}_i$ ):

is the value of the single sample in the group, and is defined by:

$$\bar{X}_i = X_i$$

Where  $X_i$  is the single sample value in the subgroup.

#### Moving Range (MR):

is the difference between successive sample values, and is defined by:

$$MR_i = X_i - X_{i-1} \quad i \geq 2$$

Where  $X_i$  is the current sample value and  $X_{i-1}$  is the previous sample value. The number of moving ranges in the process is always one less than the number of subgroups.

#### Subgroup Standard Deviation (s):

is a measure of absolute variation or dispersion. It describes how much the sample values differ from their mean, and is estimated by:

$$s_i = \frac{MR_i}{D2} \quad i \geq 2$$

The number of subgroup standard deviations in the process is always one less than the number of subgroups.

#### Process Average ( $\bar{\bar{X}}$ ):

$$\bar{\bar{X}} = \frac{\bar{X}_1 + \bar{X}_2 + \dots + \bar{X}_m}{m}$$

Where  $\bar{X}_1$ ,  $\bar{X}_2$ , and  $\bar{X}_m$  are the subgroup means, and m is the total number of subgroups in the process.

**Process Range ( $\bar{R}$ ):**

$$\bar{R} = \frac{MR_2 + MR_3 + \dots + MR_m}{m - 1}$$

Where MR2, MR3, and MRm are the subgroup moving ranges, and m is the total number of subgroups in the process.

**Process Standard Deviation ( $s$ ):**

$$\bar{s} = \frac{\bar{R}}{D2}$$

## When the number of samples in each subgroup is greater than 1

**Subgroup Mean ( $\bar{X}$ ):**

is the average (not median or center) of the samples in the group, and is defined by:

$$\bar{X} = \frac{X_1 + X_2 + \dots + X_n}{n}$$

Where X1, X2, and Xn are the sample values in the subgroup, and n is the total number of samples in the subgroup.

**Subgroup Range (R):**

is the difference between the highest and lowest samples in the group, and is defined by:

$$R = X_{\max} - X_{\min}$$

Where Xmax is the maximum sample value and Xmin is the minimum sample value in the group.

**Subgroup Standard Deviation (s):**

is a measure of absolute variation or dispersion. It describes how much the sample values differ from their mean, and is defined by:

$$s = \sqrt{\frac{\sum (X_i - \bar{X})^2}{n - 1}}$$

Where X's are the sample values in the group,  $\bar{X}$  is the group average, and n is the number of samples in the group.

**Process Average ( $\bar{\bar{X}}$ ):**

$$\bar{\bar{X}} = \frac{\bar{X}_1 + \bar{X}_2 + \dots + \bar{X}_m}{m}$$

Where  $\bar{X}_1$ ,  $\bar{X}_2$ , and  $\bar{X}_m$  are the subgroup averages, and m is the total number of subgroups in the process.

**Process Range ( $\bar{R}$ ):**

$$\bar{R} = \frac{R_1 + R_2 + \dots + R_m}{m}$$

Where  $R_1$ ,  $R_2$ , and  $R_m$  are the subgroup ranges, and  $m$  is the total number of subgroups in the process.

**Process Standard Deviation ( $\bar{s}$ ):**

$$\bar{s} = \frac{s_1 + s_2 + \dots + s_m}{m}$$

Where  $s_1$ ,  $s_2$  and  $s_m$  are the group standard deviations, and  $m$  is the total number of groups in the process.

**Average Control Limits (UCL<sub>x</sub> and LCL<sub>x</sub>):**

Specify the approximated 3-sigma boundaries. For a normal distribution 99.74% of the samples will fall within this boundary.

$$UCL_x = \bar{\bar{X}} + A_2 * \bar{R}$$

$$LCL_x = \bar{\bar{X}} - A_2 * \bar{R}$$

Where  $\bar{R}$  is the Process Range and  $A_2$  is a constant (given in the Control Chart Line Constants table).

**Range Control Limits (UCLR and LCLR):**

Specify the approximated 3-sigma boundaries. For a normal distribution 99.74% of the samples will fall within this boundary.

$$UCL_R = D_4 * \bar{R}$$

$$LCL_R = D_3 * \bar{R}$$

Where  $\bar{R}$  is the Process Range and  $D_3$  and  $D_4$  are constants (given in the Control Chart Line Constants table).

**Standard Deviation Control Limits (UCLs and LCLs):**

Specify the approximated 3-sigma boundaries. For a normal distribution 99.74% of the samples will fall within this boundary.

$$UCL_s = B_4 * \bar{s}$$

$$LCL_s = B_3 * \bar{s}$$

Where  $\bar{s}$  is the Process Standard Deviation and  $B_3$  and  $B_4$  are constants given in the Control Chart Line Constants table).

**Process Capability (Cp):**

Is the capability of a process to meet a specific tolerance. A process is considered capable when the percentage of samples of a variable for that process that fall within the upper and lower specification limits is greater than a specified value.

The inherent process capability is defined as:

$$C_p = \frac{(USL - LSL)}{6s}$$

- $C_p > 1.0$  - Indicates the process variation is within the specified limits (USL and LSL) and therefore, is capable.
- $C_p < 1.0$  - Indicates the process is not capable.

The process capability based on worst case data is defined as:

$$C_{pk} = \frac{\min((USL - \bar{\bar{X}}, (\bar{\bar{X}} - LSL))}{3s}$$

- $C_{pk} < 0$  - Indicates the process mean is outside the specified limits (USL and LSL)
- $C_{pk} = 0$  - Indicates the process mean is equal to one of the specified limits.
- $C_{pk} > 0$  - Indicates the process mean is within the specified limits.
- $C_{pk} = 1.0$  - Indicates that one side of the 6-sigma limits falls on a specification limit.
- $C_{pk} > 1.0$  - Indicates that the 6-sigma limits fall completely within the specified limits.

#### **Skewness (Sk):**

Is the degree of asymmetry of a frequency distribution (usually in relation to a normal distribution).

$$Sk = \frac{\sum(X_i - \bar{\bar{X}})^3}{Ns}$$

where N is the number of samples for the entire process (i.e. Subgroup Size \* number of Subgroups).

- Skewness  $> 0$  - Indicates that the histogram's mean (and tail) is pushed to the right.
- Skewness  $< 0$  - Indicates that the histogram's mean (and tail) is pushed to the left.

#### **Kurtosis (Ku):**

Is the degree of peakedness of a frequency distribution (usually in relation to a normal distribution).

$$Ku = \frac{\sum(X_i - \bar{\bar{X}})^4}{Ns}$$

where N is the number of samples for the entire process (i.e. Subgroup Size \* number of Subgroups).

- Kurtosis  $< 3$  - Indicates a thin distribution with a relatively high peak.
- Kurtosis  $> 3$  - Indicates a distribution that is wide and flat topped.

## **Control Chart Line Constants**

The table below shows the control chart line constants:

	Averages	Ranges			Standard Deviations	
Samples in Group	A2	D2*	D3	D4	B3	B4
1	2.660	1.128	0	3.267	0	3.267
2	1.880		0	3.267	0	3.267
3	1.023		0	2.574	0	2.568
4	0.729		0	2.282	0	2.266
5	0.577		0	2.114	0	2.089
6	0.483		0	2.004	0.030	1.970
7	0.419		0.076	1.924	0.118	1.882
8	0.373		0.136	1.864	0.185	1.815
9	0.337		0.184	1.816	0.239	1.761
10	0.308		0.223	1.777	0.284	1.716
10	0.308		0.223	1.777	0.284	1.716
11	0.285		0.256	1.744	0.321	1.679
12	0.266		0.283	1.717	0.354	1.646
13	0.249		0.307	1.693	0.382	1.618
14	0.235		0.328	1.672	0.406	1.594
15	0.223		0.347	1.653	0.428	1.572
16	0.212		0.363	1.637	0.448	1.552
17	0.203		0.378	1.622	0.466	1.534
18	0.194		0.391	1.608	0.482	1.518
19	0.187		0.403	1.597	0.497	1.503
20	0.180		0.415	1.585	0.510	1.490
21	0.173		0.425	1.575	0.523	1.477
22	0.167		0.434	1.566	0.534	1.466
23	0.162		0.443	1.557	0.545	1.455

	Averages	Ranges			Standard Deviations	
24	0.157		0.451	1.548	0.555	1.445
25	0.153		0.459	1.541	0.565	1.435

\* D2 is only used for estimating standard deviation when there is one sample per subgroup.

#### Hints

Double-click the chart area on an SPC page to display the SPC Genie and change the SPC variables.

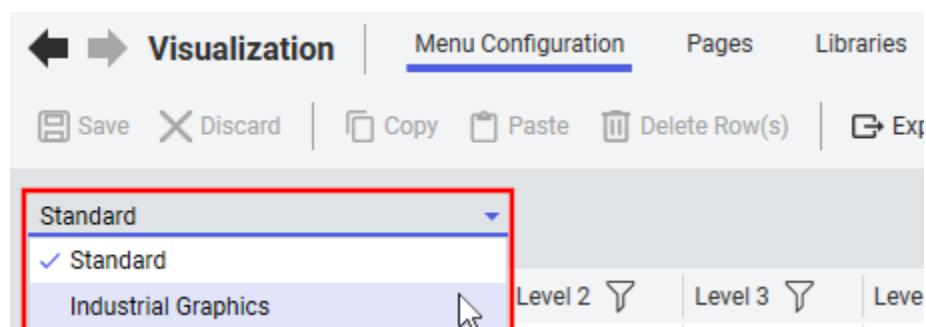

The tools and menu items in these procedures automatically open the Plant SCADA form for you. Move the cursor till it changes to a hand to find these tools or options.

## Visualization

The **Visualization** activity is used to manage the content that comprises the interface an operator uses to monitor and control a runtime system. It includes the following views:

- [Menu Configuration](#)
- [Pages](#)
- [Libraries](#)
- [Content Types](#)
- [Keyboard Commands](#)
- [Reports](#).

In some cases, a view will feature a drop-down menu below the command bar that allows you to choose the graphics between "Standard" and "Industrial Graphics."

- Standard graphics are designed to run on Plant SCADA display clients, typically running on network computers. They are created and edited using [Graphics Builder](#).
- Industrial Graphics are designed for delivery to web-based clients via an AVEVA™ Industrial Graphics Server. They are created and edited using the AVEVA Industrial Graphics Editor.

## See Also

[AVEVA Industrial Graphics](#)

## Menu Configuration

The **Menu Configuration** view in the **Visualization** activity allows you to define hierarchical menu items that can be used at runtime to provide navigational assistance to an operator.

Plant SCADA supports two types of menus:

- **Standard Menus**

Standard menus are used to navigate projects that are run on Plant SCADA display clients.

The way a standard menu is implemented is determined by the Starter Project upon which a project was based.

For example, in a project based on the SxW Starter Project, the menu is incorporated as a common feature across every page. In a project based on the Situational Awareness Starter Project, the menu you configure determines the layout of the Navigation Zone on the operator dashboard.

For more information, see [Configure a Standard Plant SCADA Menu](#).

- **Industrial Graphics Menus**

Industrial Graphics menu is designed to arrange the pages that are delivered to web-based clients via the AVEVA Web Server.

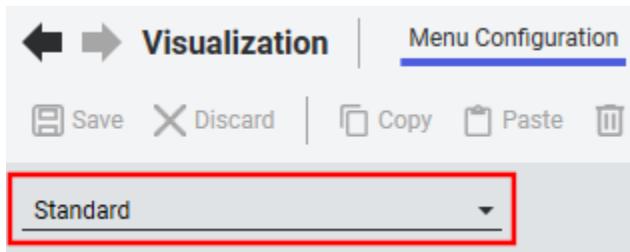

For more information, see [Configure a Menu for Industrial Graphics Pages](#).

## See Also

[Menu Functions](#)

## Configure a Standard Plant SCADA Menu

You can use the **Menu Configuration** view in Plant SCADA Studio's **Visualization** activity to configure a standard menu for your project's runtime system. To do this, firstly select **Standard** from the drop-down menu below the command bar.

**Note:** If you want to configure a menu for Industrial Graphics pages displayed on a Web Server, see [Configure a Menu for Industrial Graphics Pages](#).

The method you use to configure a standard menu is determined by the Starter Project that was used to create your project. For an appropriate description of the Menu Configuration Properties, select from the following

Starter Projects.

### Situational Awareness Starter Project

If your project is created from a Situational Awareness Starter Project, the menu configuration is used to build the following:

- The layout of buttons and tabs on the Navigation Zone on the operator dashboard (see [Prepare the Navigation Menu](#)).
- The tabs that appear across the Information Zone on the operator dashboard.
- The content of the workspace header bar.
- A set of custom tabs for the [Tab Bar Genie](#).

A Menu Configuration has the following properties:

#### General Properties

Property	Description
<b>Page</b>	<p>The Page property is used to give a name to the menu that will include the item.</p> <p>In a Situational Awareness project, the system expects the following menu names:</p> <ul style="list-style-type: none"><li>• <b>InformationZone</b> – used to define the tabs that appear across the Information Zone on the operator dashboard.</li><li>• <b>Headerbar</b> – used to define the content of the workspace header bar.</li><li>• <b>Navigation</b> – used to define the layout of buttons and tabs on the Navigation Zone on the operator dashboard.</li></ul> <p>A project based on the Situational Awareness Starter Project will include a set of default entries for the <b>InformationZone</b> and <b>Headerbar</b> menus.</p> <p>There are no default entries for the <b>Navigation</b> menu, as you will need to manually configure these to reflect the pages included in your project. See <a href="#">Prepare the Navigation Menu</a>.</p>
<b>Level 1-6</b>	<p>In a Situational Awareness project, the <b>Level 1-6</b> properties are used in the following ways, based on the three expected menus:</p> <ul style="list-style-type: none"><li>• <b>InformationZone</b> – this menu defines the tabs that appear across the Information Zone. Only a single sets of tabs is supported, which means only the <b>Level 1</b> field is used.</li></ul>

Property	Description
	<ul style="list-style-type: none"> <li>• <b>Headerbar</b> – this menu defines the content of the workspace header bar. The included buttons are specified by the <b>Level 1</b> field. The default "Login Menu" uses <b>Level 2</b> to add a "Log Out" option as a drop-down menu.</li> <li>• <b>Navigation</b> – this menu defines the layout of buttons and tabs on the Navigation Zone on the operator dashboard. <b>Level 1</b> of the menu sets the overall context for the workspace. The tabs along the navigation section header represent the menu's <b>Level 2</b> entries. The buttons on each tab represent up to 20 lower-level menu entries.</li> </ul> <p>In each case, the arrangement of menu entries is determined by the <b>Order</b> property.</p> <p><b>Note:</b> The greater-than character ( &gt; ) cannot be used within a menu name.</p>
<b>Menu Command</b>	<p>The Cicode expression to be executed when the menu item is selected. String of up to 254 characters.</p> <p>For Situational Awareness projects, use the "Navigation_ShowTargetPage" command to call a page.</p> <p>If you have the same page in HD1080 and UHD4K resolutions (to support a range of client screens), the variation of the page that displays at runtime will be determined by the context of the current workspace. This means you do not need to add the resolution suffix ("_HD1080" or "_UHD4K") to the end of the page name specified in the <b>Target Page</b> field.</p>
<b>Target Page</b>	<p>The page that is displayed when the menu item is executed. See the <b>Menu Command</b> property.</p>
<b>Comment</b>	<p>An optional comment (of up to 128 characters) about the menu entry.</p>
<b>Order</b>	<p>Defines the position of a menu entry in relation to the other menu entries in the same hierarchy level. The <b>Order</b> property functions in the following ways, based on the three expected menus:</p> <ul style="list-style-type: none"> <li>• <b>InformationZone</b> – the order defines how the tabs will appear across the top of Information Zone (from left to right).</li> </ul>

Property	Description
	<ul style="list-style-type: none"> <li>• <b>Headerbar</b> – the order defines how the command buttons will appear across the workspace header bar (from left to right).</li> <li>• <b>Navigation</b> – For <b>Level 1</b> entries, the order defines how the tabs will appear across the top of Navigation Zone (from left to right). For lower level entries, the order determines the layout of up to 20 buttons on each tab (four rows of five buttons, from left to right).</li> </ul> <p>If this field is left blank, it will take the default value of zero (0). If more than one entry of the same order exists, they are displayed in the same order as they are defined in the database. In the case of Navigation menu, the entry will fill the first available space in the layout of buttons.</p> <p>This property affects the order that the menu entries are returned through menu Cicode functions.</p>
<b>Hidden when</b>	A Cicode expression that determines when the menu entry is hidden on the page.
<b>Disabled when</b>	A Cicode expression that determine when the menu entry is disabled on the page.
<b>Disabled style</b>	<p>A number to indicate how the disabled entry is displayed in the menu. It is up to the user to decide what the numbers mean.</p> <p><b>Note:</b> By default, this property is not used by a Situational Awareness project.</p>
<b>Symbol</b>	If the menu entry is associated with a tab, this field allows you to display an icon on the tab. Enter the name of the graphic file you would like to display. You can use the <b>Custom 2</b> property (see below) to hide the symbol if required.
<b>Privilege</b>	The user privilege (0–8) that is necessary to select the menu entry.
<b>Area</b>	The user area (0–255) that is necessary to select the menu entry.
<b>Checked</b>	If the menu entry is associated with a tab, this field allows you to specify if the tab is pinned by default. Leaving the field blank will mean the tab is not pinned

Property	Description
	by default. Any other value will mean the tab is pinned by default.  This setting will only work if pinning is enabled for the tab bar. This is determined by the <b>Can Tabs Be Pinned?</b> parameter in the <a href="#">Tab Bar Genie</a> .
Width	The width of the menu entry on the page.  <b>Note:</b> By default, this property is not used by a Situational Awareness project.

**Equipment Properties**

Property	Description
Cluster	The name of the cluster associated with the menu item. The specified cluster should be configured otherwise a compile will not be successful.
Equipment	Name of equipment associated with the menu item. Select a name from the drop down list, or type a name. String limit of 254 characters, including separating periods (.)

**Custom Properties**

Property	Description
Custom 1	If the menu entry is associated with a tab, this property determines if the <b>Close</b> button will appear on the tab. If you leave this field blank, the Close button will appear. Any other value will hide the Close button.
Custom 2	If the menu entry is associated with a tab, this property determines if the icon identified in the <b>Symbol</b> field will appear on the tab. If you leave this field blank, the icon will appear. Any other value will hide the icon. .
Custom 3	If the menu entry is associated with a tab, this property determines if a label will appear on the tab. If you leave this field blank, the label will appear. Any other value will hide the label.
Custom 4-8	These custom properties are reserved for system use.

**Project Properties**

Property	Description
<b>Project</b>	The project in which the menu will be created.

### SxW Starter Project

If your project is created from a SxW starter project, some common menu items are already pre-configured in the menu configuration database (as part of the starter project). They will be displayed on the page automatically at runtime. To view additional pages in your project at runtime you will need to manually configure the menu items.

You can assign individual menu items to a particular page, or make them available to every page. Menu items configured in included projects will be merged with the ones configured in the main project, into a single menu tree structure when you compile your main project. This allows extra menu items to be automatically added to your project depending on what projects are included.

A Menu Configuration has the following properties:

#### General Properties

Property	Description
<b>Page</b>	The page on which this entry will exist. If blank, the entry exists on every page.
<b>Level 1-6</b>	Creates the menu hierarchy path of the entry. String length can be up to 64 characters.  Up to 6 levels of menu hierarchy are supported. Menu entries that have the same upper levels are considered to be under the same hierarchical branch.  Menu entries are not case sensitive.  <b>Note:</b> The greater-than character ( > ) cannot be used within a menu name.
<b>Menu Command</b>	The Cicode expression to be executed when the menu item is selected. String of up to 254 characters.
<b>Comment</b>	A comment about the menu entry. String of up to 128 characters.
<b>Order</b>	The position of a menu entry in relation to the other menu entries in the same hierarchy level.  This property affects the order that the menu entries are returned through the menu Cicode functions. If this field is left blank, it will take the default value of zero (0). The relevant menu entries will be returned at the start as a result. If more than one entry of the same order exists, they are displayed in the same order as they are defined in the database.
<b>Symbol</b>	The symbol to associate with the menu entry. The string length can be up to 128 characters. A symbol

Property	Description
	needs to be already defined in the project / included project, and specified in the format of <library name>.<symbol name>.
<b>Hidden when</b>	Cicode expression to determine when the menu entry is hidden on the page. String of up to 254 characters.
<b>Disabled when</b>	Cicode expression to determine when the menu entry is disabled on the page. String of up to 254 characters.
<b>Disabled style</b>	<p>By default, this property is not used by an SxW project. However, if you choose to implement your own menu system, you can retrieve the value of this field (or any other fields) via the Menu family of Cicode functions at runtime.</p> <p>For example, if you set a numeric value for the <b>Disable Style</b> field in a menu configuration, you can then use the Menu family of Cicode functions to retrieve the value:</p> <pre data-bbox="871 958 1519 1262">INT hMenuNode = MenuGetPageNode("Headerbar");  INT hItemNode = MenuGetNodeByPath(hMenuNode, "Login Menu.@(Log Out)");  INT nDisabledStyle = StrToInt(MenuNodeGetProperty(hItemNode, 4));  INT bIsDisabled = MenuNodIsDisabled(hItemNode);</pre> <p>Once you have retrieved the disabled style and disabled state, you can expose them as the return value of Cicode functions. You can then call the functions in page animations such as color fill, visibility, and so on.</p> <p><b>Note:</b> This property has no direct relation to the Disable Style property on the Disable tab for a graphic object. The latter is defined as part of the graphic object and cannot be altered via Cicode.</p>
<b>Width</b>	The width of the menu entry on the page. It is up to the user to decide what units to be used.
<b>Checked</b>	Determines if the menu entry is initialized with a checked status.
<b>Privilege</b>	The user privilege of (0-8) necessary to select the menu entry.

Property	Description
Area	<p>The user area (0-255) necessary to select the menu entry.</p> <p><b>Note:</b> At runtime, you can use the Menu family of Cicode functions to access the information entered in the Menu Configuration dialog.</p>

**Equipment Properties**

Property	Description
Cluster	The name of the cluster associated with the menu item. The specified cluster should be configured otherwise a compile will not be successful.
Equipment	Name of equipment associated with the menu item. Select a name from the drop down list, or type a name. String limit of 254 characters, including separating periods (.).

**Custom Properties**

Property	Description
Custom 1-8	User-defined strings that can be accessed by Cicode Functions <a href="#">MenuNodeGetProperty</a> and <a href="#">MenuNodeSetProperty</a> . Max length is 254 characters.

**Project Properties**

Property	Description
Project	The project in which the menu will be created.

To configure menus for SxW templates, see [Creating Custom Menus for SxW Templates](#).

**Tab Style Starter Project**

A set of page templates known as [Tab Style Templates](#) is provided with the product. These templates already contain a tabbed menu system.

If your pages are based on these templates, the menu items configured in the menu configuration database will be displayed on the page automatically at runtime. If no menu is defined in the project, a default menu will be created at runtime to provide access to pages in the project. The default menu functionality can be changed using [\[Page\]AddDefaultMenu](#).

A Menu Configuration has the following properties:

**General Properties**

Property	Description
Page	The page on which this entry will exist. If blank, the entry exists every page.

Property	Description
	The page name of "Template" is a keyword used in the Tab Style templates for defining custom pop-up menus.
<b>Level 1-6</b>	<p>Creates the menu hierarchy path of the entry. String length can be up to 64 characters.</p> <p>Up to 6 levels of menu hierarchy are supported. Menu entries that have the same upper levels are considered to be under the same hierarchical branch.</p> <p>Menu entries are not case sensitive.</p> <p><b>Note:</b> The greater-than character ( &gt; ) cannot be used within a menu name.</p> <p>In a Tab Style Project:</p> <ul style="list-style-type: none"> <li>• Level 1 represents the tabs on the tab bar.</li> <li>• Level 2 represents the buttons displayed under a particular tab.</li> <li>• Level 3 represents the menu items of the drop-down menu next to a particular button.</li> <li>• Level 4 represents the sub-menu items of a particular drop-down menu item.</li> </ul>
<b>Menu Command</b>	The Cicode expression to be executed when the menu item is selected. String of up to 254 characters.
<b>Comment</b>	A comment about the menu entry. String of up to 128 characters.
<b>Order</b>	<p>The relative display position of the tabs/buttons or menu items among themselves.</p> <p>For the tabs and buttons, it determines the display order from left to right. For the drop-down menu items, it determines the display order from the top to the bottom.</p> <p>If this field is left blank, it will take the default value of 0. The relevant entries will be displayed at the start as a result.</p> <p>If more than one entry of the same order exists, they are displayed in the same order as they are defined in the database.</p>
<b>Symbol</b>	The symbol to associate with the menu entry. The string length can be up to 128 characters. The format to use is <library name>.<symbol name>.

Property	Description
	<p>The template expects the symbol to be a certain size when it is configured against different menu types.</p> <ul style="list-style-type: none"> <li>For tabs, symbols are 16 x 16 pixels.</li> <li>For buttons, symbols are 32 x 32 pixels.</li> </ul> <p>Some common symbols can be found in the symbol libraries "icons_16x16" and "icons_32x32".</p> <p>The field is not applicable for menu and sub-menu items.</p>
<b>Hidden when</b>	<p>The tab menu bar on the template does not support visibility. When the expression defined in this field is true, the relevant menu entry is disabled instead.</p>
<b>Disabled when</b>	<p>Cicode expression to determine when the menu entry is disabled on the page. String of up to 254 characters.</p>
<b>Disabled style</b>	<p>By default, this property is not used by a Tab Style project. However, if you choose to implement your own menu system, you can retrieve the value of this field (or any other fields) via the Menu family of Cicode functions at runtime.</p> <p>For example, if you set a numeric value for the <b>Disable Style</b> field in a menu configuration, you can then use the Menu family of Cicode functions to retrieve the value:</p> <pre> INT hMenuNode = MenuGetPageNode("Headerbar");  INT hItemNode = MenugetNodeByPath(hMenuNode, "Login Menu.@(Log Out)");  INT nDisabledStyle = StrToInt(MenuNodeGetProperty(hItemNode, 4));  INT bIsDisabled = MenuNodIsDisabled(hItemNode); </pre> <p>Once you have retrieved the disabled style and disabled state, you can expose them as the return value of Cicode functions. You can then call the functions in page animations such as color fill, visibility, and so on.</p> <p><b>Note:</b> This property has no direct relation to the Disable Style property on the Disable tab for a graphic object. The latter is defined as part of the graphic object and cannot be altered via Cicode.</p>

Property	Description
<b>Width</b>	<p>The width (measured in pixels) of the item on the page. If this is not specified, the item is automatically sized to show the most content. This field only applies to the tabs and buttons.</p> <p>The objects used in the template are subjected to minimum widths:</p> <ul style="list-style-type: none"> <li>• Tab (Level 1) = 63 pixels.</li> <li>• Button(Level 2) = 61 pixels.</li> </ul>
<b>Checked</b>	<p>Determines if the menu entry is initialized with a checked status. This field only applies to the menu items and sub-menu items.</p>
<b>Privilege</b>	<p>The user privilege of (0-8) necessary to select the menu entry.</p>
<b>Area</b>	<p>The user area (0-255) necessary to select the menu entry.</p> <p><b>Note:</b> At runtime, you can use the Menu family of Cicode functions to access the information entered in the Menu Configuration dialog.</p>

### Equipment Properties

Property	Description
<b>Cluster</b>	<p>The name of the cluster associated with the menu item. The specified cluster should be configured otherwise a compile will not be successful.</p>
<b>Equipment</b>	<p>Name of equipment associated with the menu item. Select a name from the drop down list, or type a name. String limit of 254 characters, including separating periods (.).</p>

### Custom Properties

Property	Description
<b>Custom 1-8</b>	<p>User-defined strings that can be accessed by Cicode Functions <a href="#">MenuNodeGetProperty</a> and <a href="#">MenuNodeSetProperty</a>. Max length is 254 characters.</p>

### Project Properties

Property	Description
Project	The project in which the menu will be created.

To configure menus for Tab Style templates, see [Create Custom Tab Style Menus](#).

You can also create a custom menu system for your project through the combination of Cicode and graphical objects.

At runtime, three types of menu trees are created.

1. The first type of menu tree allows you to access the configured menu items for generic (all) pages or a specific page. You can access this menu tree using the Cicode function [MenuGetGenericNode](#) to get the page node for the generic pages, and [MenuGetPageNode](#) to get the menu items specific to a page.
2. The second menu tree automatically merges the menu items for the generic pages and the items specified for the current page. You can access this menu tree using the Cicode function [MenuGetWindowNode](#) to get to the root node.
3. The third type of menu tree exists as a virtual menu that is not associated with the generic pages. You can access this menu tree using the Cicode function [MenuGetWindowNode](#) to get to the root node.

**Note:** For existing users of the CSV\_Include project, the menu was defined in a file called Menu.dbf in your project folder. You can migrate the menu definition in this file to the built-in menu configuration database using the [Project Migration Tool](#). This step is useful if you plan to migrate your project from the CSV\_Include project to a newer set of templates.

## Configure a Menu for Industrial Graphics Pages

You can use the **Menu Configuration** view in Plant SCADA Studio's **Visualization** activity to configure a navigation menu for the Industrial Graphics pages delivered to web-based clients via the Web Server.

To do this, firstly select **Industrial Graphics** from the drop-down menu below the command bar.

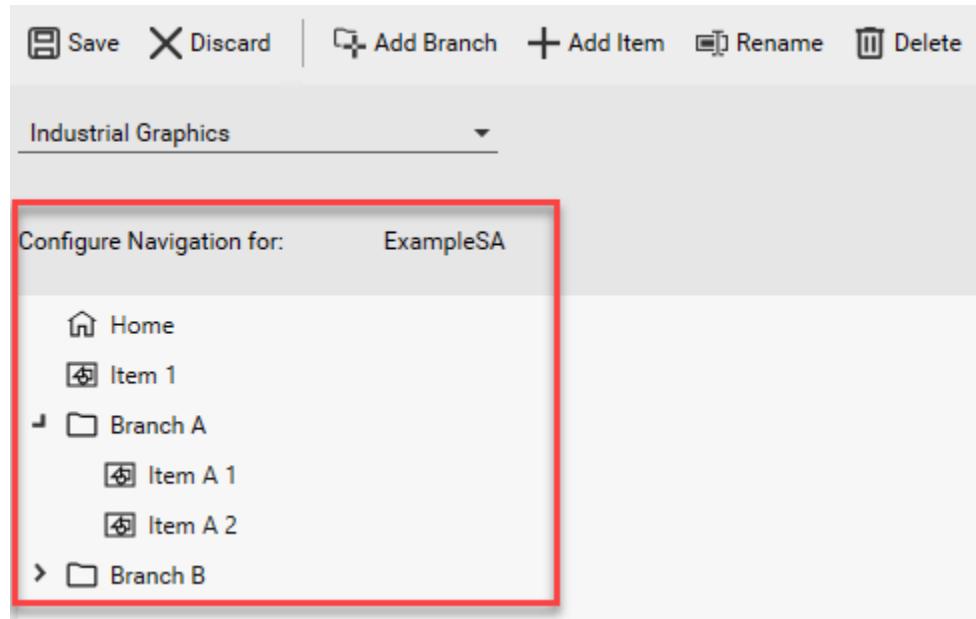

**Note:** If you want to configure a menu for standard project, see [Configure a Standard Plant SCADA Menu](#).

You can create one Industrial Graphics menu for each Plant SCADA project. At runtime, the menu configured in the primary active project will be applied to the Web Server; any menus configured in an included project will not be used.

A menu can include the following:

 Home	Home represents the top-level of the menu tree. It cannot be moved, renamed or deleted.  You can link to a page at this level of the tree. The page you choose will display when the Web Client is launched at runtime.
 Branch	A branch creates the entry point for a new level within the menu tree. You can: <ul style="list-style-type: none"><li>• Add items to a branch</li><li>• Add additional branches within a branch (up to 10 levels).</li></ul> You cannot link a branch to a page.
 Item	Items provide the links to the Industrial Graphics pages within your project. The name you give to an item should represent the page that will display when it is selected at runtime.

To build a menu, use the tree to the left of the Menu Configuration view.

If a menu item has a page linked to it, the page will display in the panel to the right of the tree when the item is selected.

---

**Note:** If the name of an item appears as red italic text, it means the linked page cannot be found. Confirm that the page location can still be accessed, and that the page has not been moved, renamed or deleted.

---

To build a menu, perform the following tasks.

#### Add a Branch

1. Select the location in the tree where you would like to add a new branch.

This can be within the top level of the tree, or within an existing branch.

2. Select the **Add Branch** button on the command bar.

3. Enter a name for the branch.

**Note:** You can only add up to 10 branch levels within a menu. If you reach this limit, the **Add Branch** button will be disabled.

## Add an Item

1. Select the location in the tree where you would like to add a new item.

This can be within the top level of the tree, or within a branch.

2. Select the **Add Item** button on the command bar.

3. Enter a name for the item.

## Link to a Page

1. Select the item you would like to link to a page.

Or:

Select **Home** to link to the page that you want to display when runtime is launched.

2. Click the **Select Page...** button.

Or:

Click the **Select Page...** button in the Properties panel.

The Select a Page dialog will appear.

3. Use the drop-down menu to select a Industrial Graphics page from the active project.
4. Click **OK**.

The selected page will display to the right of the menu tree.

## Rename a Branch or Item

1. Select the branch or item you want to rename.
2. Select the **Rename** button on the command bar.

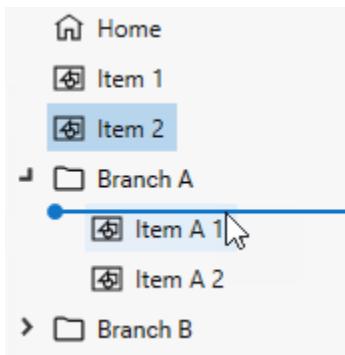

3. Enter a new name.
4. Press the **Delete** key.

### Move a Branch or Item

1. Select the branch or item you want to move to a different location in the tree.
2. Drag the branch or item to the new location.

A blue line will indicate the currently selected destination.

3. Release the mouse key.

### Delete a Branch or Item

1. Select the branch or item you want to delete.  
If you select a branch, be aware that everything within the branch will also be deleted.
2. Select the **Delete** button on the command bar.

Or:

Press the **Delete** key.

[Add an Industrial Graphics Page in Plant SCADA Studio](#)

## Pages

Graphics pages create the visual interface an operator uses to monitor and control a runtime system. They are typically designed to reflect a particular area or process within a facility.

Plant SCADA supports **Standard Pages** and **Industrial Graphics Pages**.

### Standard Pages

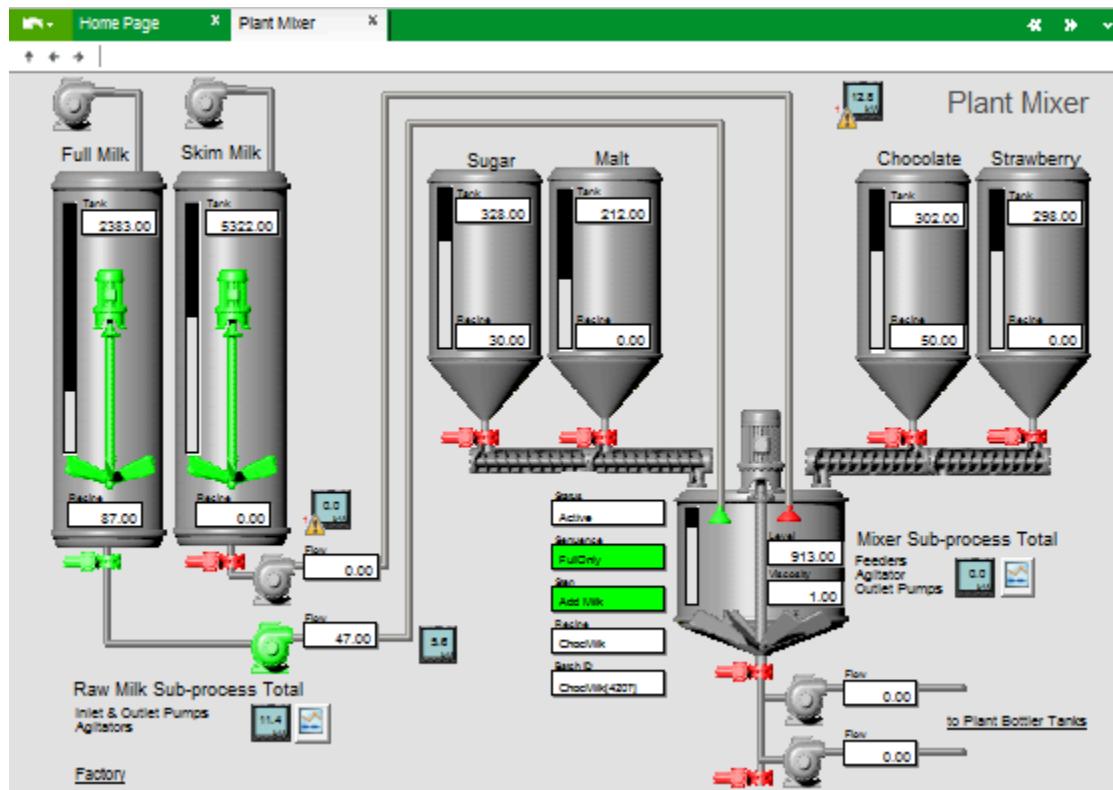

Standard pages are designed to run on Plant SCADA display clients, typically running on network computers.

To browse the standard pages associated with the active project, use the **Pages** view in the **Visualization** activity (see [Browse Pages in Plant SCADA Studio](#)). You can also use the Property Grid to view and edit some of the properties for any selected pages (see [View and Edit Page Properties in Plant SCADA Studio](#)).

## Examples

- **StruxureWare (SxW) Templates Project**

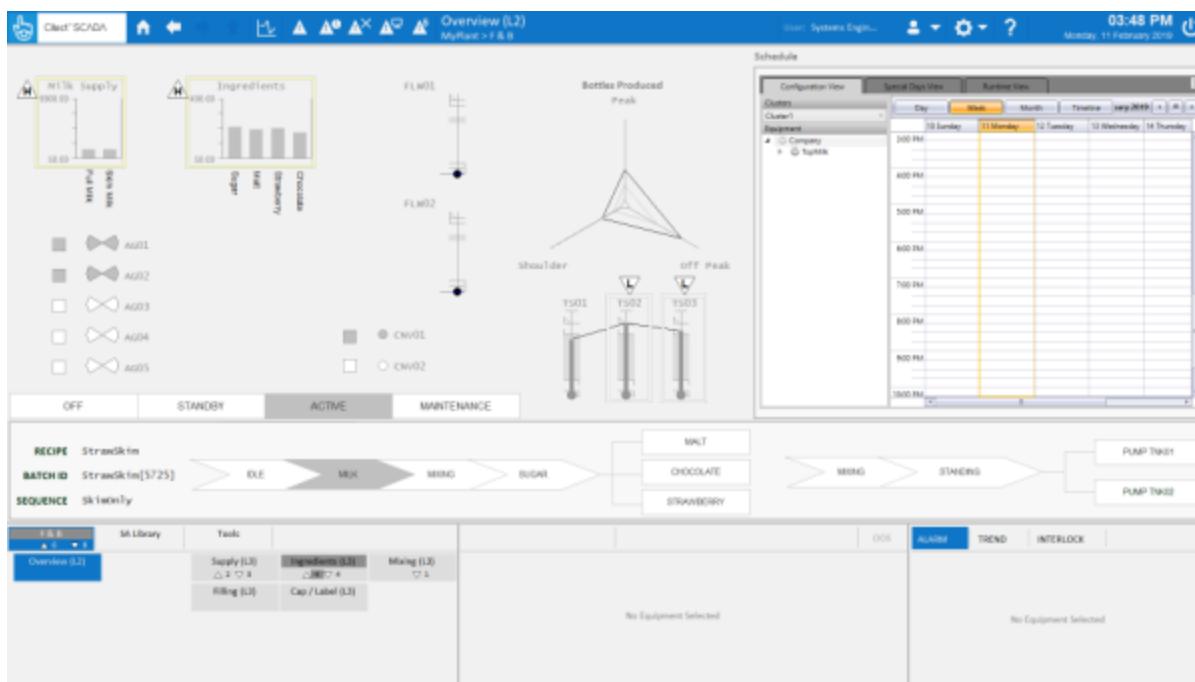

The image below shows a graphics page that represents a plant mixer based on an SxW template. This page is available to view in the Plant SCADA "Example" project.

- **Situational Awareness Starter Project**

If a project is based on the Situational Awareness Starter Project, its pages will be designed to operate within an architecture that enables the runtime environment to respond to contextual changes. A project will include master pages, and pages designed to operate within the panes of a master page (see [Key Components of a Situational Awareness Project](#)).

For example, the image below shows an overview of a production line, constructed from a set pages hosted within the panes of a master page. This page is available to view in the Plant SCADA "ExampleSA" project.

To facilitate contextual updates, pages in a Situational Awareness project may be assigned a [Content Types](#).

To configure standard graphics pages, you need to use [Graphics Builder](#). This is the tool required to create a page, and add the content that makes it reflect the area or process it will be used to monitor.

## Industrial Graphics Pages

Industrial Graphics pages are designed for delivery to web-based clients via the AVEVA Web Client. They are created and edited using AVEVA Industrial Graphics Editor.

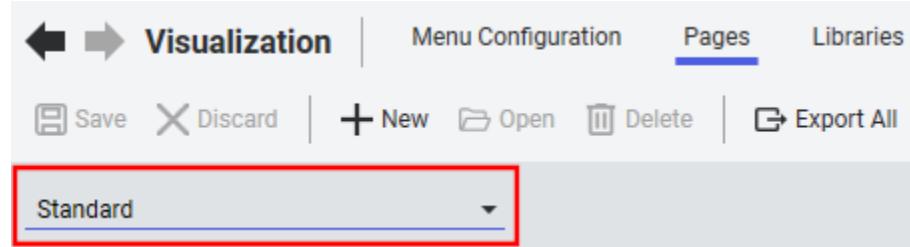

To browse the Industrial Graphics pages associated with the active project, use the **Pages** view in the **Visualization** activity (see [Browse Industrial Graphics Pages in Plant SCADA Studio](#)).

## See Also

[Menu Configuration](#)

## Browse Pages in Plant SCADA Studio

Use the **Pages** view in Plant SCADA Studio's **Visualization** activity to browse the pages associated with the active project and its included projects. To do this, select **Standard** from the drop-down menu below the command bar.

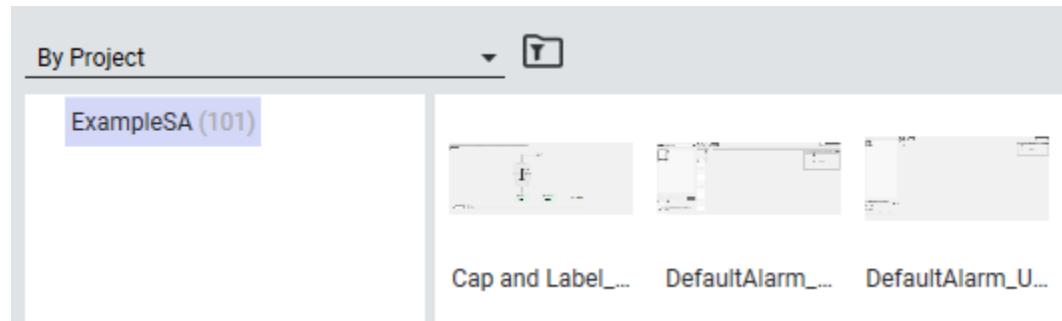

**Note:** If you want to browse Industrial Graphics pages, see [Browse Industrial Graphics Pages in Plant SCADA](#)

Studio.

You can also use the Property Grid to view and edit some of the properties for any selected pages (see [View and Edit Page Properties in Plant SCADA Studio](#)).

The tree to the left of the view shows the projects that are currently available to browse. By default, the active project is selected. When you select a project, the pages it includes are displayed in the pages list to the right.

The number to the right of a project name indicates how many pages are included in the project.

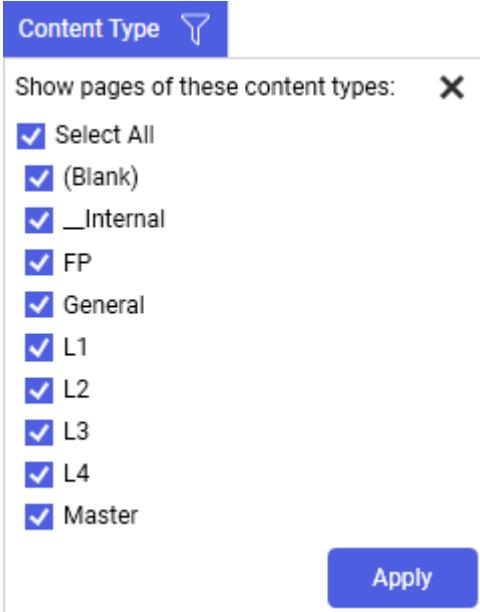

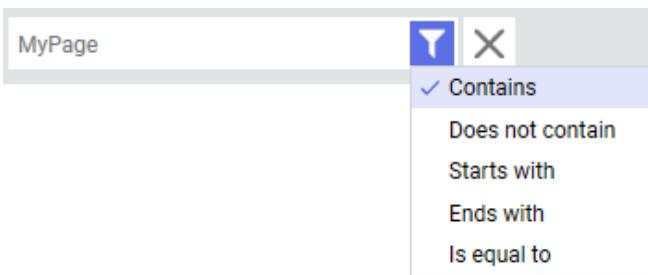

The drop-down menu above the tree allows you to select **All Items**. This option displays the pages from all the projects that are currently available to browse, and hides the project tree.

To view the pages in any included system projects, select the **Show or Hide System Projects** button.

Button	Description
	<p><b>Show or Hide System Projects</b></p> <p>When the <b>Show or Hide System Projects</b> button is selected, any system projects that are included in the active project are added to the Pages view.</p> <p>If the <b>By Project</b> option is selected for the project tree, you can individually select a system project and view a list of the pages included within it.</p> <p>If the <b>All Items</b> option is selected, the system project pages are merged into the list of pages and displayed according to the current sort order.</p>

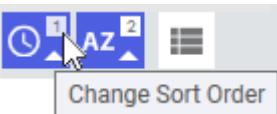

You can use the following filters to manipulate the pages list.

Tool	Description
	<p><b>Content Type Filter</b></p> <p>Allows you to filter the current list of pages by <a href="#">Content Types</a>.</p>

Tool	Description
	<p>The drop-down menu includes a list of the content types that are configured in the current project and its included projects. It also includes a "(Blank)" option for pages that do not have a content type assigned.</p>  <p>Select the content types you want to see represented in the list of pages, and click <b>APPLY</b>. At least one content type needs to be selected to apply a filter.</p> <p>Click on the <b>Select All</b> check box to select every content type.</p> <p>If every content type is currently selected, click <b>Select All</b> to clear the selections.</p>
<input type="text" value="Search items"/>	<p><b>Search Items</b></p> <p>Use the <b>Search Items</b> field to locate specific pages within the current list based on the page names.</p> <p>Click on the filter icon to the right of the field to select a comparison option.</p>  <p>To clear the current search and any active filters, click on the <b>Clear Filters</b> button (see below).</p>

Tool	Description
	<p><b>Clear Filters</b></p> <p>The <b>Clear Filters</b> button removes all the active filters that are currently applied to the list of pages.</p>
	<p><b>Display Mode</b></p> <p>The Display Mode button changes the layout of the pages list. Four options are available. The appearance of the button indicates which mode is currently selected.</p> <ul style="list-style-type: none"> <li> Small tiles (default)</li> <li> Medium tiles</li> <li> Large tiles</li> <li> Details</li> </ul> <p>The <b>Details</b> mode presents the list of pages in a tabular format with the following columns:</p> <ul style="list-style-type: none"> <li>• Name</li> <li>• Title</li> <li>• Content Type</li> <li>• Template</li> <li>• Parent Page</li> <li>• Previous Page</li> <li>• Next Page</li> <li>• Width</li> <li>• Height</li> <li>• Modified Time</li> <li>• Project</li> </ul> <p>For a description of these properties, see <a href="#">View and Edit Page Properties in Plant SCADA Studio</a>.</p>
	<p><b>Sort by Modified Time</b></p> <p>The <b>Sort by Modified Time</b> button sorts the page list according to the time each page was last modified. When this option is selected, an arrow will appear next to the clock icon to indicate if the order of the list</p>

Tool	Description
	<p>is ascending or descending.</p>  Ascending  Descending (default) <p>Clicking on the button while it is selected will toggle between these two options.</p> <p>When the <b>Sort By Modified Time</b> button is clicked, the <b>Sort By Name</b> option is turned off by default. However, you can combine the two together (see <b>Combined Sort Mode</b> below).</p>
	<p><b>Sort by Name</b></p> <p>The <b>Sort by Name</b> button sorts the page list according to page names. When this sort option is selected, an arrow will appear next to the AZ icon to indicate if the order of the list is ascending or descending</p>  Ascending (default)  Descending <p>Clicking on the button while it is selected will toggle between these two options.</p> <p>When the <b>Sort By Name</b> button is clicked, the <b>Sort By Modified Time</b> option is turned off by default. However, you can combine the two together (see <b>Combined Sort Mode</b> below).</p>
	<p><b>Combined Sort Mode</b></p> <p>You can combine the <b>Sort By Modified Time</b> and <b>Sort by Name</b> options. This sorts a list according to the primary option, then by the secondary option.</p> <p>To create a combined sort:</p> <ol style="list-style-type: none"> <li>1. Select the primary sort option, for example, <b>Sort By Modified Time</b>.  </li> <li>2. Then hold down the <b>Shift</b> key and select the <b>Sort By Name</b> button.  </li> </ol> <p>Both buttons will be highlighted to indicate that</p>

Tool	Description
	<p>they are active.</p>  <p>The numbers in the top corner of each button indicates which sort is primary (1) and which is secondary (2).</p> <p>To change the sort order, click on either number.</p>  <p>You can also change the sort direction of a particular button by clicking on it as normal.</p> <p>To remove a sort option, hold down the <b>Shift</b> key and click on the button you want to remove.</p>

If you hold the mouse over a thumbnail in the pages list or tile view, a popup will appear showing the large tile version of the thumbnail, the page name and its source project.

You can use the Pages view to perform the following tasks.

### Open pages

You can use the **Pages** view to open up to 20 selected pages in Graphics Builder. To do this:

1. Locate the page you want to open in the pages list.
2. Double-click on the page.

Or:

Select up to 20 pages, then press the Enter key.

Or:

Select up to 20 pages, then click **Open** on the Command Bar.

The selected page(s) will open for editing in Graphics Builder.

### Create a new page

You can use the **Pages** view to open a new page in Graphics Builder. To do this:

1. On the Command Bar, click **New**.

Graphics Builder will launch with **Use Template** dialog displayed.

For more information, see [Create a Graphics Page](#).

## Delete pages

You can use the **Pages** view to delete up to 500 selected pages. To do this:

1. Select the page(s) you want to delete in the pages list.
2. Press the **Delete** key.  
Or:
3. On the Command Bar, click **Delete**.

## Export data from the current view

You can export the data for the current view as a CSV file. To do this, click **Export All** on the Command Bar.

For more information, see [Export to Microsoft™ Excel](#).

## Update pages

You can use the **Pages** view to update the pages in a project. This will update all pages and library graphics in the active project and its included projects. For more information, see [Update Pages](#).

To update pages, click **Update Pages** on the Command Bar.

This option is not available if an Update Pages operation is already in progress.

## See Also

[Configure Graphics Pages](#)

## View and Edit Page Properties in Plant SCADA Studio

The **Pages** view in Plant SCADA Studio's **Visualization** activity displays the properties for selected pages in the Property Grid. See below for a description of the included properties.

You can also use the Property Grid to edit the following properties:

- Window Title
- Description
- Content Type
- Parent Page
- Previous Page

- Next Page
- Area
- Log Device.

Any other properties need to be edited directly in Graphics Builder (see [Edit the Properties for a Page](#)).

**To edit the properties for a page in Plant SCADA Studio's Property Grid:**

1. Go to the **Pages** view in the **Visualization** activity.
2. Select the required page(s). See [Browse Pages in Plant SCADA Studio](#).
3. In the Property Grid, make the required changes to the editable properties.  
If multiple pages are selected, your changes will be applied to every selected page.
4. On the Command Bar, click **Save**.

## Page Properties

### General Properties

Field	Description
<b>Name</b>	The name of the graphics page.
<b>Window Title</b>	The title that is used for the page at runtime. You can edit the title (using up to 64 characters). It can include plain text, Super Genie syntax or both (for example, "Pump ?AREA? status").
<b>Description</b>	A description of the page. You can edit the description (using up to 250 characters). The description is intended for configuration comments only. It is not used at runtime.
<b>Content Type</b>	Identifies a page as a particular type of content. For example, you can indicate if a page is a level 1 page (L1), a level 2 page (L2), or a faceplate (FP). This determines which panes will display the page at runtime when an associated piece of equipment comes in to context (see <a href="#">Content Types</a> ). Select the required content type from the drop-down menu to the right of the field. The available content types are configured in the <b>Visualization</b> activity (see <a href="#">Configure Content Types</a> ).
<b>Parent Page</b>	The name of the page that is one level up in the project's page hierarchy. See <a href="#">Page Levels</a> . You can edit the page name (using up to 64 characters). This property is optional.

Field	Description
<b>Previous Page</b>	<p>The name of the page that precedes the current page in the runtime <a href="#">Use a Browse Sequence</a>. You can edit the page name (using up to 64 characters).</p> <p>This property is optional. If not specified, the Page Previous command will be inoperative at runtime while the page is displayed.</p>
<b>Next Page</b>	<p>The name of the page that follows the current page in the runtime <a href="#">Use a Browse Sequence</a>. You can edit the page name (using up to 64 characters).</p> <p>This property is optional. If not specified, the Page Next command will be inoperative at runtime while the page is displayed.</p>
<b>Area</b>	<p>The area to which the page belongs (1–255). Only users with access to the specified area will be able to view the page. If an area is not specified, the page is accessible to every user.</p> <p>You can edit the number. If you enter an invalid value, a compile error will be generated.</p>
<b>Page Scan Time</b>	<p>Determines how often the page will be updated at runtime. It also determines the rate of execution for the <b>While Page Shown</b> command.</p> <p>If the field shows a value, it indicates the scan rate (in milliseconds).</p> <p>If the field is blank, it indicates the page will use the default scan rate as specified by the <a href="#">[Page]ScanTime</a> parameter.</p> <p><b>Note:</b> You can set the default page scan time using the <a href="#">General Options Setup</a> page of the Setup Wizard.</p>
<b>Log Device</b>	<p>Specifies the device to which messages are logged for the page's keyboard commands. You can select a device from the drop-down menu to the right of the field, or type a device name.</p> <p><b>Note:</b> You need to include the <i>MsgLog</i> field in the format of the log device for the message to be sent.</p>
<b>Inherit Cluster</b>	<p>If this field is set to "TRUE", the page will inherit cluster context from the page or Cicode task that opened the page (for example, the <a href="#">PageDisplay</a> or <a href="#">WinNewAt</a> Cicode functions).</p> <p>If this field is blank, cluster context for the page will be determined by the <b>Default Cluster</b> field (see below).</p>

Field	Description
<b>Default Cluster</b>	The default cluster context for the page. If this field is blank it indicates that <b>Inherit Cluster</b> is set to "TRUE", or no default cluster has been specified.
<b>Modified Time</b>	Indicates when the page was last modified.

**Template Properties**

Field	Description
<b>Style</b>	The style (appearance) of template that was used to create the graphics page. For a description of the available styles, see the topic <a href="#">Page Templates</a> .
<b>Resolution</b>	The default screen resolution of the template on which the page is based: <ul style="list-style-type: none"> <li>• VGA — 640 x 480 pixels (4:3)</li> <li>• SVGA — 800 x 600 pixels (4:3)</li> <li>• XGA — 1024 x 768 pixels (4:3)</li> <li>• SXGA — 1280 x 1024 pixels (5:4)</li> <li>• HD768 — 1366 x 768 pixels (16:9)</li> <li>• HD1080 — 1920 x 1080 pixels (16:9)</li> <li>• WUXGA — 1920 x 1200 pixels (16:10)</li> <li>• UHD4K — 3840 x 2160 pixels (16:9)</li> <li>• User Defined.</li> </ul>
<b>Name</b>	The name of the template on which the page is based.
<b>Title Bar</b>	If this field is selected, it indicates the page was intended to display the Windows title bar at runtime. If this is the case, the page size will allow space to accommodate the title bar.

**Appearance Properties**

Property	Description
<b>Width</b>	The width (in pixels) of the area that the operator can view at runtime.
<b>Height</b>	The height (in pixels) of the area that the operator can view at runtime.

**Event Properties**

Field	Description
<b>On Page Entry</b>	The command that is executed when the page is initializing.
<b>On Page Exit</b>	The command that is executed when the operator exits the page.
<b>While Page Shown</b>	The command that is executed continually for the entire time that the page is open.
<b>On Page Shown</b>	The command that is executed when a page is first displayed and the objects on it have been initialized.
<b>On Activate</b>	The command that is executed when the window is activated at runtime.
<b>On Deactivate</b>	The command that is executed when the window is deactivated.

For more information, see [Page Properties - Events](#).

#### Project Properties

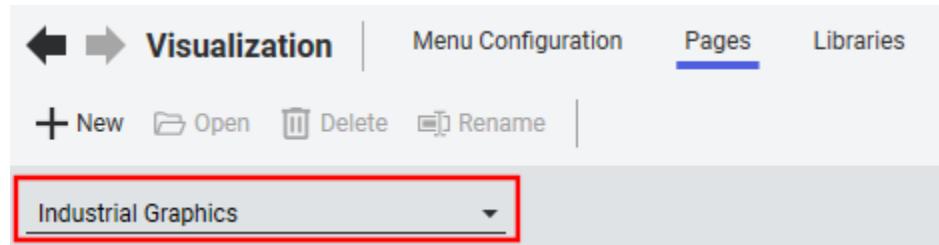

Property	Description
<b>Project</b>	The project in which the page is included.

### Browse Industrial Graphics Pages in Plant SCADA Studio

You can use the **Pages** view in Plant SCADA Studio's **Visualization** activity to browse the Industrial Graphics pages associated with the active project and its included projects. To do this, select **Industrial Graphics** from the drop-down menu below the command bar.

**Note:** If you want to browse standard Plant SCADA pages, see [Browse Pages in Plant SCADA Studio](#).

The tree to the left of the view shows the projects that are currently available to browse. By default, the active project is selected. When you select a project, the Industrial Graphics pages it includes are displayed in the pages list to the right.

The number to the right of a project name indicates how many pages are included in the project.

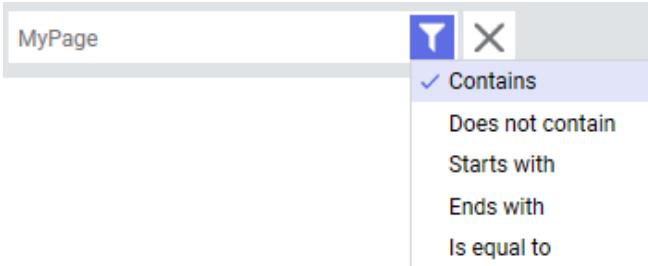

The drop-down menu above the tree allows you to select **All Items**. This option displays the pages from all the projects that are currently available to browse, and hides the project tree.

To view the pages in any included system projects, select the **Show or Hide System Projects** button.

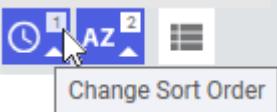

Button	Description
	<p><b>Show or Hide System Projects</b></p> <p>When the <b>Show or Hide System Projects</b> button is selected, any system projects that are included in the active project are added to the Pages view.</p> <p>If the <b>By Project</b> option is selected for the project tree, you can individually select a system project and view a list of the pages included within it.</p> <p>If the <b>All Items</b> option is selected, the Industrial Graphics pages in the system projects are merged into the list and displayed according to the current sort order.</p>

You can use the following to manipulate the pages list.

Tool	Description
<input type="text" value="Search items"/>	<p><b>Search Items</b></p> <p>Use the <b>Search Items</b> field to locate specific pages within the current list based on the page names.</p> <p>Click on the filter icon to the right of the field to select a comparison option.</p>

Tool	Description
	 <p>To clear the current search and any active filters, click on the <b>Clear Filters</b> button (see below).</p>
	<p><b>Clear Filters</b></p> <p>The <b>Clear Filters</b> button removes all the active filters that are currently applied to the list of pages.</p>
	<p><b>Display Mode</b></p> <p>The Display Mode button changes the layout of the pages list. Four options are available. The appearance of the button indicates which mode is currently selected.</p> <ul style="list-style-type: none"> <li> Small tiles (default)</li> <li> Medium tiles</li> <li> Large tiles</li> <li> Details</li> </ul> <p>The <b>Details</b> mode presents the list of pages in a tabular format.</p>
	<p><b>Sort by Modified Time</b></p> <p>The <b>Sort by Modified Time</b> button sorts the page list according to the time each page was last modified. When this option is selected, an arrow will appear next to the clock icon to indicate if the order of the list is ascending or descending.</p> <ul style="list-style-type: none"> <li> Ascending</li> <li> Descending (default)</li> </ul> <p>Clicking on the button while it is selected will toggle</p>

Tool	Description
	<p>between these two options.</p> <p>When the <b>Sort By Modified Time</b> button is clicked, the <b>Sort By Name</b> option is turned off by default. However, you can combine the two together (see <b>Combined Sort Mode</b> below).</p>
	<p><b>Sort by Name</b></p> <p>The <b>Sort by Name</b> button sorts the page list according to page names. When this sort option is selected, an arrow will appear next to the AZ icon to indicate if the order of the list is ascending or descending</p> <p> Ascending (default)</p> <p> Descending</p> <p>Clicking on the button while it is selected will toggle between these two options.</p> <p>When the <b>Sort by Name</b> button is clicked, the <b>Sort By Modified Time</b> option is turned off by default. However, you can combine the two together (see <b>Combined Sort Mode</b> below).</p>
	<p><b>Combined Sort Mode</b></p> <p>You can combine the <b>Sort By Modified Time</b> and <b>Sort by Name</b> options. This sorts a list according to the primary option, then by the secondary option.</p> <p>To create a combined sort:</p> <ol style="list-style-type: none"> <li>1. Select the primary sort option, for example, <b>Sort By Modified Time</b>. </li> <li>2. Then hold down the <b>Shift</b> key and select the <b>Sort By Name</b> button. </li> </ol> <p>Both buttons will be highlighted to indicate that they are active.</p> <p></p> <p>The numbers in the top corner of each button indicates which sort is primary (1) and which is secondary (2).</p>

Tool	Description
	<p>To change the sort order, click on either number.</p>  <p>You can also change the sort direction of a particular button by clicking on it as normal.</p> <p>To remove a sort option, hold down the <b>Shift</b> key and click on the button you want to remove.</p>

If you hold the mouse over a thumbnail in the pages list or tile view, a pop up will appear showing the large tile version of the thumbnail, the page name and its source project.

You can use the Industrial Graphics view to perform the following tasks.

### Open Industrial Graphics pages

You can select a maximum of 20 Industrial Graphics pages each time you use the open command. Each item will open in its own instance of the AVEVA Industrial Graphics Editor. To do this:

1. Locate the page you want to open in the pages list.
2. Double-click on the page.

Or:

Select up to 20 pages, then press the Enter key.

Or:

Select up to 20 pages, then click **Open** on the Command Bar.

The selected page(s) will open for editing in Industrial Graphics Editor.

### Create a new Industrial Graphics page

You can create a new page in the AVEVA Industrial Graphics Editor. To do this:

1. On the Command Bar, click **New**.

For further instructions, see [Add an Industrial Graphics Page in Plant SCADA Studio](#).

### Delete Industrial Graphics pages

You can use the **Pages** view to delete up to 500 Industrial Graphics pages. To do this:

1. Select the page(s) you want to delete in the pages list.
2. Press the **Delete** key.

Or:

On the Command Bar, click **Delete**.

The **Delete** dialog appears.

3. Click **DELETE**. If you do not want to delete the page(s), click **CANCEL**.

### Rename an Industrial Graphics page

You can use the **Pages** view to rename an Industrial Graphics page. To do this:

1. Select the page you want to rename from the pages item list.
2. On the Command Bar, click **Rename**.

The **Rename Page** dialog appears.

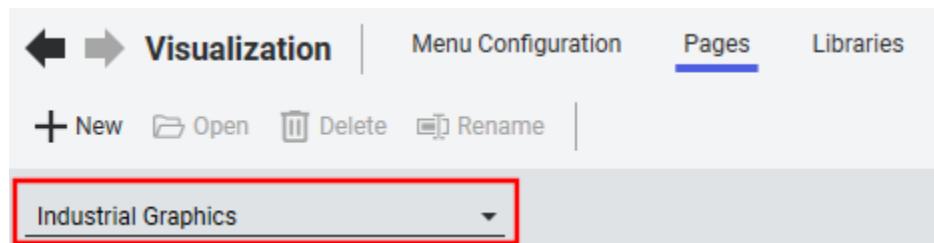

3. Use the page naming rules to update the page name (see [Add an Industrial Graphics Page in Plant SCADA Studio](#)).
4. Click **Rename**. If you do not want to rename the page, click **CANCEL**.

### Add an Industrial Graphics Page in Plant SCADA Studio

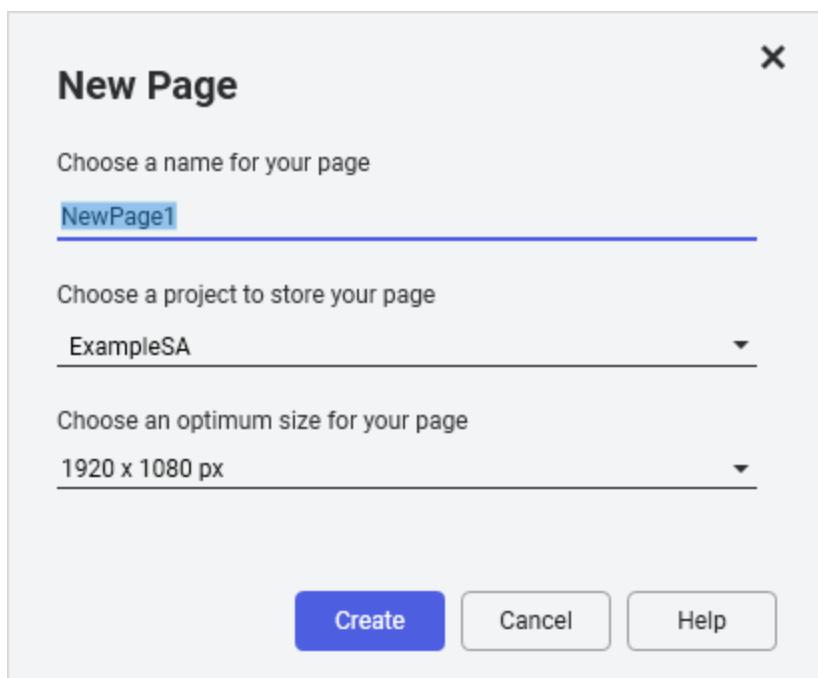

You can use the **Pages** view in Plant SCADA Studio's **Visualization** activity to add new Industrial Graphics pages to the active project.

#### To add a new Industrial Graphics page:

1. Go to the **Pages** view in the **Visualization** activity.
2. Select **Industrial Graphics** from the drop-down menu below the command bar.

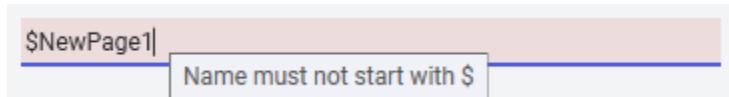

3. On the command bar, select **New**. The **New Page** dialog will appear.

4. Choose a name for the page.

The name you use needs to be unique amongst all Industrial Graphics pages and symbols in the active project and its included projects. It also needs to adhere to a set of rules (see the *Page Naming Rules* below). Based on these rules, you can only enter valid characters.

If the background of the field is highlighted, it indicates that the current name does not comply with the naming rules. Place the cursor over the field to display a tool tip with a description of the required changes.

5. Choose a project for the page from the drop-down menu. The list will include the active project, its included projects, and their respective system projects.

- The selected project from the project tree is the default selection.
- If you have not selected any project, the active project is the default selection.
- It is not recommended to select a system project, because system projects are overwritten when Plant SCADA is upgraded or reinstalled.

6. Choose an optimum size for the page from the drop-down menu, or type the width and height of the desired size in the field.

- The resolution of the selected project is used as the default selection for the page size.
- For customizing the page size, the following rules apply:
  - Min Width, Height = 0, 0
  - Max Width, Height = 7360, 4320
- The last selected / entered size will be retained as the default selection for subsequent new pages.

7. Click **CREATE**.

The page thumbnail will appear in the **Pages** view, and the page will open for editing in the Industrial Graphics Editor.

If you do not want to create the page, click **CANCEL**.

## Page Naming Rules

A page name needs to adhere to the following rules:

- Needs to be between 1 to 32 characters in length.
- Can contain any letter characters supported by Unicode.
- Can contain any decimal digit (0-9).
- Can only contain the punctuation characters # \$ and \_.
- Cannot start with a \$.
- Needs to contain at least one letter.
- Cannot be one of the following reserved words:

and	as	boolean	catch	citect
dim	discrete	do	double	each
elapsedtime	else	elseif	endif	endtry
endwhile	exit	float	for	if
in	indirect	integer	Me	message
mod	MyArea	MyContainer	MyEngine	MyHost
MyPlatform	MyViewApp	new	next	not
object	or	real	scada	shl
shr	step	string	System	then
time	to	try	while	

## See Also

[Browse Industrial Graphics Pages in Plant SCADA Studio](#)

## Libraries

You can use libraries to store items that you regularly reuse when creating graphics pages.

Plant SCADA supports two types of libraries:

- **Standard Libraries**

Standard libraries are designed to support projects that run on Plant SCADA display clients.

The items in a standard library can include:

- Symbols
- Genies
- Super Genies
- Page Templates.

The content of a library can be distributed across a project and its included projects. If you use a Starter Project to create a new project, a set of libraries are available for use in the included projects.

You can add an item to a library when it is created and saved in [Graphics Builder](#).

To browse the content of the libraries associated with the active project, use the **Libraries** view in the **Visualization** activity (see [Browse Libraries in Plant SCADA Studio](#)).

- **Industrial Graphics Libraries**

Industrial Graphics symbols are designed for delivery to web-based clients via the AVEVA Web Server. They are created and edited using AVEVA Industrial Graphics Editor.

To browse the Industrial Graphics symbols associated with the active project, use the **Libraries** view in the **Visualization** activity (see [Browse Industrial Graphics Libraries in Plant SCADA Studio](#)).

---

**Note:** When you delete an item from a library, it is only marked for deletion. To permanently delete marked items you need to "pack" your libraries. For more information, see [Pack Libraries](#).

---

## See Also

[Pages](#)

## Browse Libraries in Plant SCADA Studio

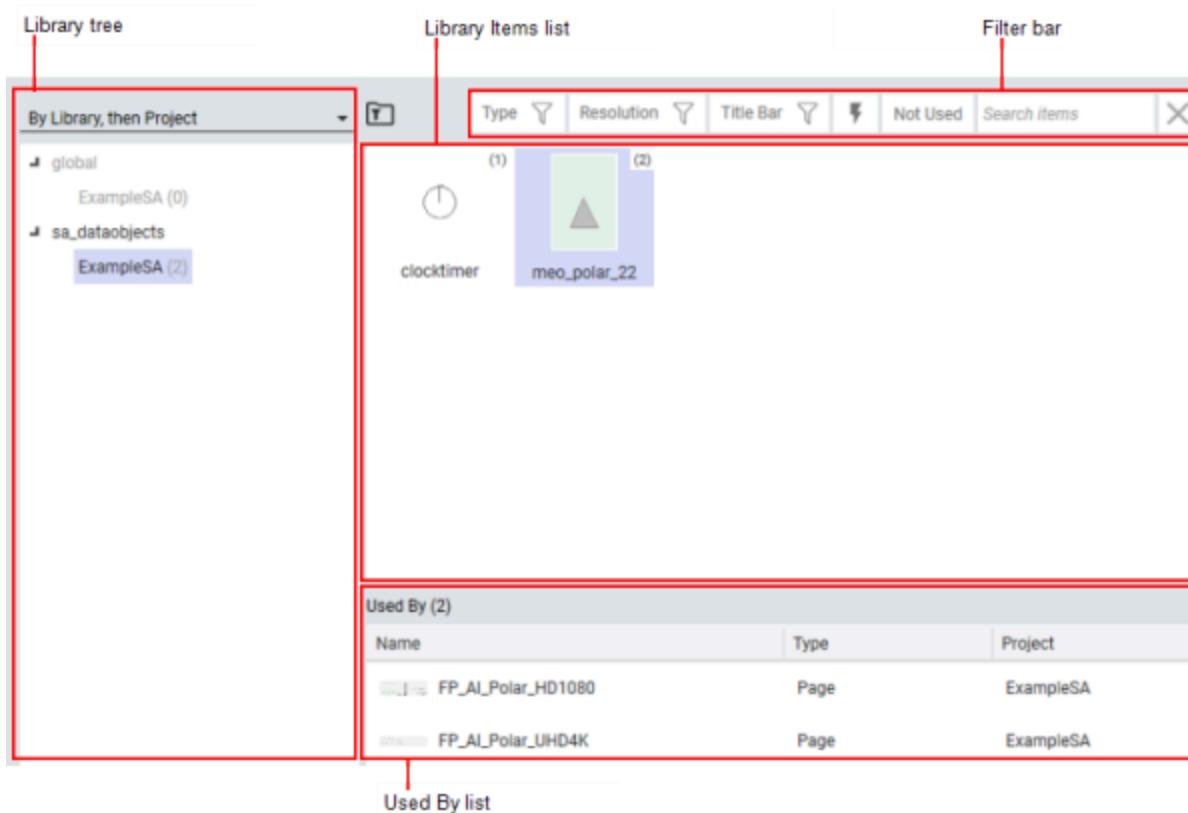

You can use the **Libraries** view in Plant SCADA Studio's **Visualization** activity to browse the content of the libraries associated with the active project and its included projects.

---

**Note:** If you want to browse Industrial Graphics libraries, see [Browse Industrial Graphics Libraries in Plant SCADA Studio](#).

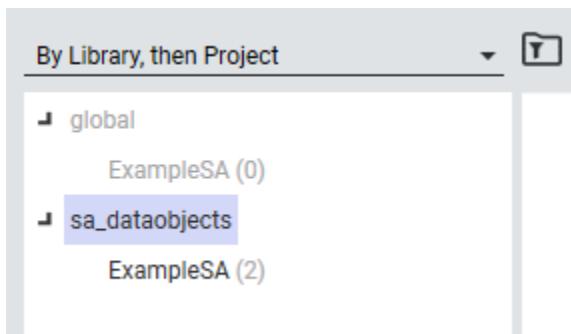

---

The Libraries view includes the following sections:

## Library Tree

The tree to the left of the view shows the projects and/or libraries that are currently available to browse.

When you select a project or library, the library items it includes are displayed in the library item list to the right. By default, the active project is selected.

The number that appears to the right of a branch indicates how many library items it includes.

By default, the tree is organized according to the setting **By Library, then Project**. The drop-down menu above the tree allows you to change this arrangement based on the following options:

- **By Library, then Project:** Libraries appear at the top level of the tree. The projects that host the library items are branched beneath. Selecting a library at the top level displays the library items from all the branched projects.
- **By Project, then Library:** Projects appear at the top level of the tree. The libraries included in each project are branched beneath. Selecting a project at the top level displays the library items from all the branched libraries.

- **By Library:** Only libraries appear in the tree. Selecting a library displays the items included in the library across all projects.
- **By Project:** Only projects appear in the tree. Selecting a project shows items from all libraries included in the project.
- **All Items:** Displays library items from all the projects that are currently available to browse. This option hides the project/library tree.

To view the libraries in any included system projects, select the **Show or Hide System Projects** button.

Button	Description
	<p><b>Show or Hide System Projects</b></p> <p>When the <b>Show or Hide System Projects</b> button is selected, any system projects that are included in the active project are added to the Libraries view.</p>  <p>If the <b>All Items</b> option is selected for the tree, the system project items are merged into the list of library items and displayed according to the current sort order.</p>

### Library Items List

This section displays the items that are included in the project or library that is currently selected in the **Library Tree**. This can include:

- Genies
- Page Templates
- Super Genies
- Symbols.

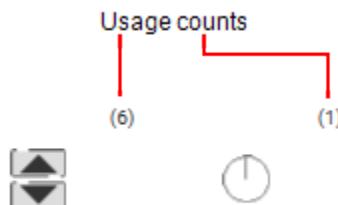

The content of the list will be dependent upon any filters that are currently applied using the Filter Bar.

The layout of the list is determined by the current selection for the **Display Mode** button (located on the Filter Bar).

Tool	Description
	<p><b>Display Mode</b></p> <p>The Display Mode button changes the layout of the item list. Four options are available. The appearance of the button indicates which mode is currently selected.</p>

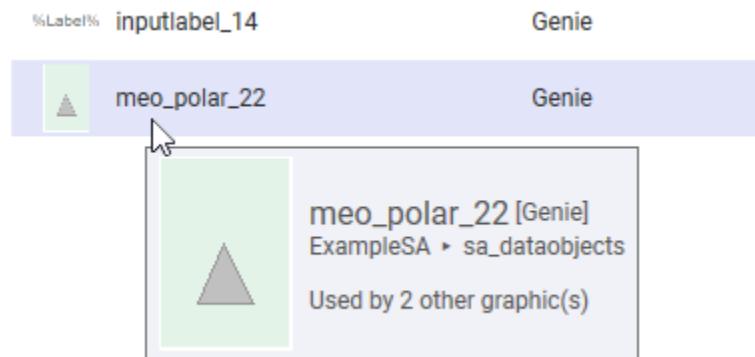

Tool	Description
	 Small tiles (default)  Medium tiles  Large tiles  Details <p>The <b>Details</b> mode present the list of library items in a tabular format with the following columns:</p> <ul style="list-style-type: none"> <li>• <b>Name</b> - Name of the library item.</li> <li>• <b>Type</b> - Genie, Super Genie, page template or symbol.</li> <li>• <b>Resolution</b> - Resolution of a page template (for example, UHD4K).</li> <li>• <b>Titlebar</b> - Indicates if a page template includes a title bar.</li> <li>• <b>Use with DspSym</b> - A check mark indicates if a Genie has DspSym enabled.</li> <li>• <b>Width</b> - Width of the item.</li> <li>• <b>Height</b> - Height of the item.</li> <li>• <b>Library</b> - Name of the library to which the item belongs.</li> <li>• <b>Modified Time</b> - The time when the last update occurred.</li> <li>• <b>Project</b> - Name of the project that hosts the item.</li> </ul>

When the library items are displayed as tiles, the number to the right of each thumbnail provides a usage count for the item. This indicates the how many pages, templates, Genies, Super Genes, or Composite Genies make use of the item.

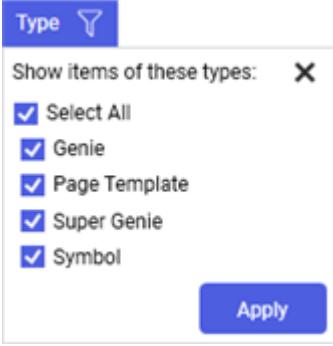

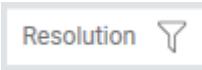

You can view details about the items a usage count represents in the **Used By** list.

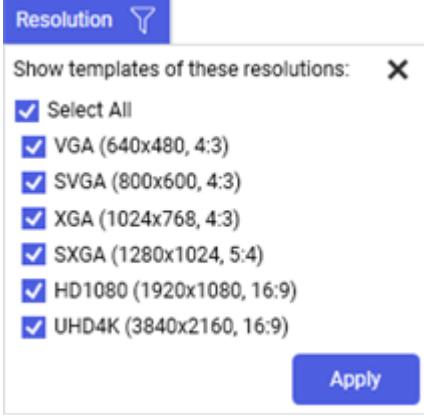

If you hold the mouse over a thumbnail in the list or tile view, a popup will appear showing the large tile version of the thumbnail, the item's name, its type, and the library and project that host it.

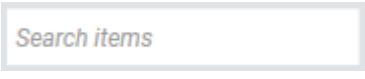

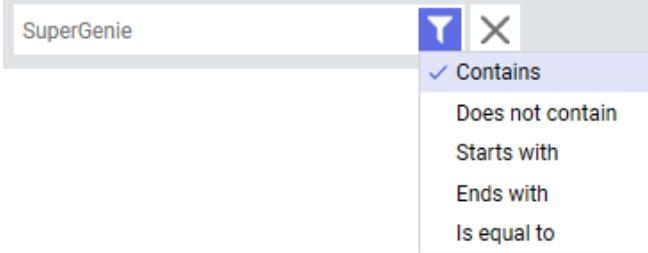

#### Filter Bar

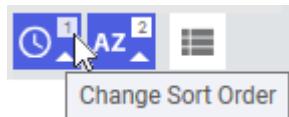

You can use the following filters to manipulate the current list of library items.

Tool	Description
	<p><b>Type Filter</b></p> <p>Allows you to filter the current list of library items according to type. The drop-down menu includes the following options:</p> <ul style="list-style-type: none"><li>• Genies</li><li>• Page Templates</li><li>• Super Genies</li><li>• Symbols.</li></ul>  <p>Show items of these types: <input type="button" value="X"/></p> <p><input checked="" type="checkbox"/> Select All <input checked="" type="checkbox"/> Genie <input checked="" type="checkbox"/> Page Template <input checked="" type="checkbox"/> Super Genie <input checked="" type="checkbox"/> Symbol</p> <p><input type="button" value="Apply"/></p> <p>Select the types you want to include in the list of library items, and click <b>APPLY</b>. At least one type needs to be selected to apply a filter. Click on the <b>Select All</b> check box to select every type. If every type is currently selected, click <b>Select All</b> to clear the selections.</p>
	<p><b>Resolution Filter</b></p> <p>Allows you to filter any page templates in the current list of library items according to resolution.</p> <p><b>Note:</b> The Resolution filter will not be available if the <b>Type</b> filter does not have <b>Page Template</b> currently selected.</p> <p>The drop-down menu includes the list of resolutions for the page templates detected in the current project and its included projects.</p>

Tool	Description
	 <p>Select the resolutions for the page templates you would like to view, and click <b>APPLY</b>. At least one resolution needs to be selected to apply a filter.</p> <p>Click on the <b>Select All</b> check box to select every resolution.</p> <p>If every resolution is currently selected, click <b>Select All</b> to clear the selections.</p>
	<p><b>Title Bar Filter</b></p> <p>Allows you to filter any page templates in the current list of library items based on whether or not they are designed to show a title bar.</p> <p><b>Note:</b> The Title Bar filter will not be available if the <b>Type</b> filter does not have <b>Page Template</b> currently selected.</p> <p>Select the type of page templates you would like to view, and click <b>APPLY</b>. At least one option needs to be selected to apply a filter.</p> <p>Click on the <b>Select All</b> check box to select all options.</p> <p>If every option is currently selected, click <b>Select All</b> to clear the selections.</p>

Tool	Description
	<p><b>DspSym Filter</b></p> <p>Allows you to filter the Genies in the current list of library items based on whether or not they are configured to work with the DspSym Cicode function (see Dynamically Instantiate a Genie at Runtime).</p> <p><b>Note:</b> The DspSym filter will not be available if the <b>Type</b> filter does not have <b>Genie</b> currently selected.</p> <p>A colored background indicates that the DspSym filter is currently selected.</p>  <p>While active, only Genies that are configured for use with DspSym are displayed in the list of library items.</p>
	<p><b>Not Used Filter</b></p> <p>Select this filter to display a list of all the items in the current project/library that have a usage count of zero. This means they are not used by any other graphic item.</p> <p>This is useful if you want to remove unused library items from your project.</p> <p><b>Note:</b> Items that have a usage count of zero may still be used indirectly through circumstances such as a menu configuration or Cicode (for example, via the DspSym function). Take care not to delete such items.</p>
	<p><b>Search Items</b></p> <p>Use the <b>Search Items</b> field to locate specific items within the current list based on the file names.</p> <p>Click on the filter icon to the right of the field to select a comparison option.</p>  <p>To clear the current search, click on the <b>Clear Filter</b> button (see below).</p>
	<p><b>Clear Filters</b></p> <p>The <b>Clear Filters</b> button removes all the active filters</p>

Tool	Description
	that are currently applied to the list of library items.
	<p><b>Sort by Modified Time</b></p> <p>The <b>Sort by Modified Time</b> button sorts the list according to the time each item was last modified. When this option is selected, an arrow will appear next to the clock icon to indicate if the order of the list is ascending or descending.</p> <p> Ascending</p> <p> Descending (default)</p> <p>Clicking on the button while it is selected will toggle between these two options.</p> <p>When the <b>Sort By Modified Time</b> button is clicked, the <b>Sort By Name</b> option is turned off by default. However, you can combine the two together (see <b>Combined Sort Mode</b> below).</p>
	<p><b>Sort by Name</b></p> <p>The <b>Sort by Name</b> button sorts the list according to item names. When this sort option is selected, an arrow will appear next to the AZ icon to indicate if the order of the list is ascending or descending.</p> <p> Ascending (default)</p> <p> Descending</p> <p>Clicking on the button while it is selected will toggle between these two options.</p> <p>When the <b>Sort By Name</b> button is clicked, the <b>Sort By Modified Time</b> option is turned off by default. However, you can combine the two together (see <b>Combined Sort Mode</b> below).</p>
	<p><b>Combined Sort Mode</b></p> <p>You can combine the <b>Sort By Modified Time</b> and <b>Sort by Name</b> options. This sorts a list according to a selected the primary option, then by the secondary option.</p> <p>To create a combined sort:</p> <ol style="list-style-type: none"> <li>1. Select the primary sort option, for example, <b>Sort By Modified Time</b>.</li> </ol>

Tool	Description
	 2. Then hold down the <b>Shift</b> key and select the <b>Sort By Name</b> button.  Both buttons will be highlighted to indicate that they are active.  The numbers in the top corner of each button indicates which sort is primary (1) and which is secondary (2). To change the sort order, click on either number.  You can also change the sort direction of a particular button by clicking on it as normal. To remove a sort option, hold down the <b>Shift</b> key and click on the button you want to remove.

### Used By List

The Used By list displays a list of items that use the item that is currently selected in the Library Items list.

Used By (2)				
Name	Type	Project	Library	Used Directly
FP_AI_Polar_HD1080	Page	ExampleSA	-	<input checked="" type="checkbox"/>
FP_AI_Polar_UHD4K	Page	ExampleSA	-	<input checked="" type="checkbox"/>

The list includes the following columns:

- **Name** — the name of the item that uses the selected library item.
- **Type** — the type of object (page, template, Genie, Super Genie or Composite Genie).
- **Project** — the project that includes the item.
- **Library** — the library that includes the item.
- **Used Directly** — indicates if the item is directly associated with the selected library item. If an item is not used directly, it means it is embedded as part of another item. For example, it may be a Genie within a Genie pasted onto a page.

You can open an item included in the Used By list by:

1. Doubling clicking within the item's row.  
Or:
2. Selecting an item and pressing the **Enter** key.

The selected item will open for editing in Graphics Builder. If the usage is a Composite Genie, the template file will open in the default XML editor.

You can use the Libraries view to perform the following tasks.

### Open the selected item(s)

You can use the **Libraries** view to open up to 20 selected items in Graphics Builder. To do this:

1. Locate an item you want to open in the items list.
2. Double-click on the item.  
Or:  
Select up to 20 items, then hit the Enter key.  
Or:  
Select up to 20 items, then click **Open** on the Command Bar.

The selected item(s) will open for editing in Graphics Builder.

### Create a new item

You can use the **Libraries** view to create a new item in Graphics Builder. To do this:

1. On the Command Bar, click **New**.

2. From the drop-down menu that appears, select the type of item you want to create. The options are:
  - Genie
  - Symbol
  - Super Genie
  - Page Template

Graphics Builder will launch with a new library item of the specified type open and ready for editing. If Page Template is selected, the Use Template dialog will display so you can choose the new template's base template.

### Delete items

You can use the **Libraries** view to delete up to 500 selected items. To do this:

1. Select the item(s) you want to delete.
2. Hit the **Delete** key.  
Or:

On the Command Bar, click **Delete**.

## Update pages

You can use the **Libraries** view to update the pages in a project. This will update all pages and library graphics in the active project and its included projects. For more information, see [Update Pages](#).

To update pages, click **Update Pages** on the Command Bar.

This option is not available if an Update Pages operation is already in progress.

## Pack Libraries

You can use the **Libraries** view to pack the libraries in a project and its included projects. This will delete all items marked for deletion from the various database files and re-index these files. For more information, see [Pack Libraries](#).

To pack libraries:

1. On the Command Bar, click **Pack Libraries**.

2. From the drop-down menu that appears, select which project(s) you want to include. The options are:
  - Active Project
  - Active Project and Included Projects

Graphics Builder will launch, and a notification will appear about the packing process.

3. Click **OK** to proceed.

This option will not be available if a packing operation is already in progress.

[Libraries](#)

## Browse Industrial Graphics Libraries in Plant SCADA Studio

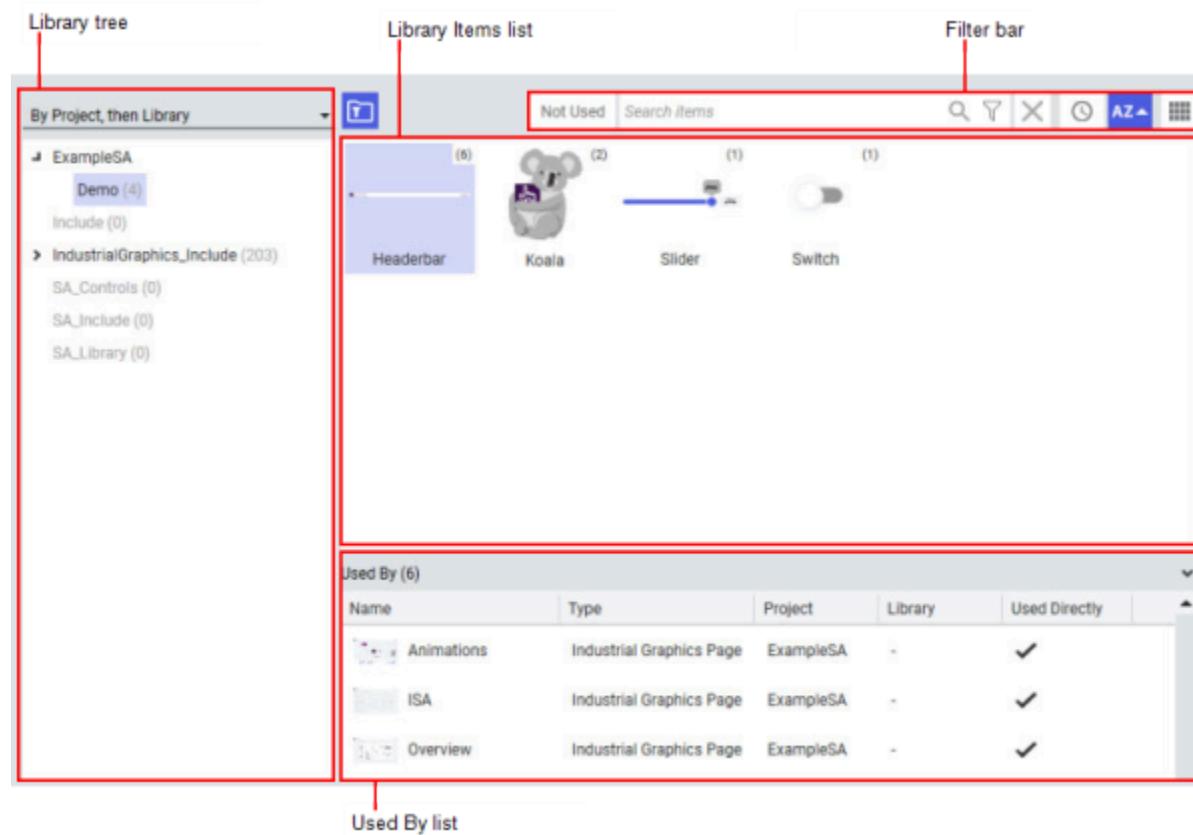

You can use the **Libraries** view in Plant SCADA Studio's **Visualization** activity to browse the Industrial Graphics symbols included in the active project and its included projects.

To do this, you need to select **Industrial Graphics** from the drop-down menu below the command bar.

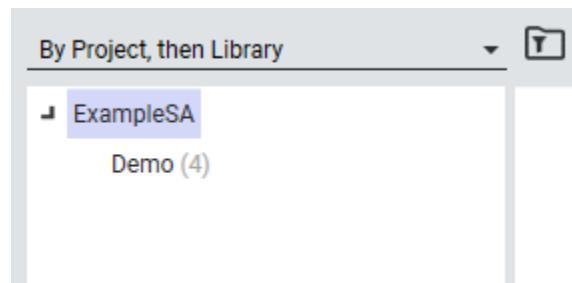

**Note:** If you want to browse standard Plant SCADA libraries, see [Browse Libraries in Plant SCADA Studio](#).

The Industrial Graphics Libraries view includes the following sections:

### Library Tree

The tree to the left of the view shows the projects and/or libraries that are currently available to browse.

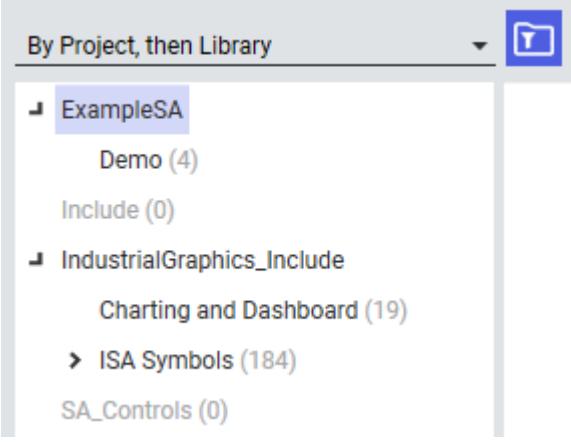

When you select a project or library, the Industrial Graphics symbols it includes are displayed in the main list. The number that appears to the right of a branch indicates how many symbols it includes.

By default, the tree is organized according to the setting **By Project, then Library**. The drop-down menu above the tree allows you to change this arrangement based on the following options:

- **By Project, then Library:** Projects appear at the top level of the tree. The libraries included in each project are branched beneath. Selecting a project at the top level displays the library items from all the branched libraries.
- **By Library:** Only libraries appear in the tree. Selecting a library displays the items included in the library across all projects.

- **By Project:** Only projects appear in the tree. Selecting a project shows items from all libraries included in the project.
- **All Items:** Displays library items from all the projects that are currently available to browse. This option hides the project/library tree.

To view the Industrial Graphics symbols in any included system projects, select the **Show or Hide System Projects** button.

Button	Description
	<p><b>Show or Hide System Projects</b></p> <p>When the <b>Show or Hide System Projects</b> button is selected, any system projects that are included in the active project are added to the tree.</p>  <p>If the <b>All Items</b> option is selected for the tree, the system project items are merged into the list of library items and displayed according to the current sort order.</p>

### Library Items List

This section displays the Industrial Graphics symbols that are included in the project or library that is currently selected in the **Library Tree**.

The content of the list will be dependent upon any filters that are currently applied using the Filter Bar.

The layout of the symbols list is determined by the current selection for the **Display Mode** button.

Button	Description
	<p><b>Display Mode</b></p> <p>The Display Mode button changes the layout of the item list. Four options are available. The appearance of the button indicates which mode is currently selected.</p> <p> Small tiles (default)</p>

Button	Description
	 Medium tiles  Large tiles  Details <p>The <b>Details</b> mode present the list of library items in a tabular format with the following columns:</p> <ul style="list-style-type: none"> <li>• <b>Name</b> - Name of the library item.</li> <li>• <b>Library</b> - Name of the library to which the item belongs.</li> <li>• <b>Project</b> - Name of the project that hosts the item.</li> </ul>

When the symbols are displayed as tiles, the number to the right of each thumbnail provides a usage count for the item. This indicates the how many pages or symbols make use of the symbol.

You can view details about the items a usage count represents in the Used By list.

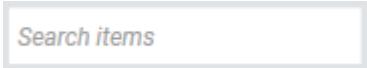

If you hold the mouse over a thumbnail in the list or tile view, a pop up will appear showing the large tile version of the thumbnail, the symbol's name, and the library and project that host it.

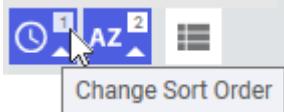

### Filter Bar

You also can use the following tools to search and sort the current list of symbols.

Tool	Description
 Not Used	<b>Not Used Filter</b> Select this filter to display a list of all the items in the current project/library that have a usage count of zero. This means they are not used by any other graphic item. This is useful if you want to remove unused library items from your project. <b>Note:</b> Symbols that have a usage count of zero may

Tool	Description
	still be used indirectly through circumstances such as a scripting.
	<p><b>Search Items</b></p> <p>Use the <b>Search Items</b> field to locate specific items within the current list based on the file names.</p> <p>Click on the filter icon to the right of the field to select a comparison option.</p>  <p>To clear the current search, click on the <b>Clear Filter</b> button (see below).</p>
	<p><b>Clear Filters</b></p> <p>The <b>Clear Filters</b> button removes any active filters that are currently applied to the list of symbols.</p>
	<p><b>Sort by Modified Time</b></p> <p>The <b>Sort by Modified Time</b> button sorts the list according to the time each item was last modified. When this option is selected, an arrow will appear next to the clock icon to indicate if the order of the list is ascending or descending.</p> <p> Ascending</p> <p> Descending (default)</p> <p>Clicking on the button while it is selected will toggle between these two options.</p> <p>When the <b>Sort By Modified Time</b> button is clicked, the <b>Sort By Name</b> option is turned off by default. However, you can combine the two together (see <b>Combined Sort Mode</b> below).</p>
	<p><b>Sort by Name</b></p> <p>The <b>Sort by Name</b> button sorts the list according to item names. When this sort option is selected, an arrow will appear next to the AZ icon to indicate if the order of the list is ascending or descending.</p>

Tool	Description
	 Ascending (default)  Descending Clicking on the button while it is selected will toggle between these two options. When the <b>Sort By Name</b> button is clicked, the <b>Sort By Modified Time</b> option is turned off by default. However, you can combine the two together (see <b>Combined Sort Mode</b> below).
 	<p><b>Combined Sort Mode</b></p> <p>You can combine the <b>Sort By Modified Time</b> and <b>Sort by Name</b> options. This sorts a list according to a selected the primary option, then by the secondary option.</p> <p>To create a combined sort:</p> <ol style="list-style-type: none"> <li>1. Select the primary sort option, for example, <b>Sort By Modified Time</b>.  </li> <li>2. Then hold down the <b>Shift</b> key and select the <b>Sort By Name</b> button.  </li> </ol> <p>Both buttons will be highlighted to indicate that they are active.</p> <p> </p> <p>The numbers in the top corner of each button indicates which sort is primary (1) and which is secondary (2).</p> <p>To change the sort order, click on either number.</p>  <p>You can also change the sort direction of a particular button by clicking on it as normal.</p> <p>To remove a sort option, hold down the <b>Shift</b> key and click on the button you want to remove.</p>

### Used By List

The Used By list displays a list of items that use the item that is currently selected in the Library Items list.

Used By (1)				
Name	Type	Project	Library	Used Directly
ISA	Industrial Graphics Page	ExampleSA	-	<input checked="" type="checkbox"/>

The list includes the following columns:

- **Name** — the name of the item that uses the selected library item.
- **Type** — the type of object.
- **Project** — the project that includes the item.
- **Library** — the library that includes the item.
- **Used Directly** — indicates if the item is directly associated with the selected library item. If an item is not used directly, it means it is embedded as part of another item. For example, it may be a symbol embedded within another symbol and pasted onto a page.

You can open an item included in the Used By list by:

1. Doubling clicking within the item's row.  
Or:
2. Selecting an item and pressing the **Enter** key.

The selected item will open for editing in AVEVA Industrial Graphics Editor.

You can use the Industrial Graphics Libraries view to perform the following tasks.

### Open the selected item(s)

You can select a maximum of 20 Industrial Graphics symbols each time you use the open command. Each item will open in its own instance of the AVEVA Industrial Graphics Editor. To do this:

1. Locate an item you want to open in the items list.
2. Double-click on the item.

Or:

Select up to 20 items, then hit the Enter key.

Or:

Select up to 20 items, then click **Open** on the Command Bar.

The selected item(s) will open for editing in the AVEVA Industrial Graphics Editor.

### Create a new Industrial Graphics symbol

You can create a new item in the AVEVA Industrial Graphics Editor. To do this:

1. On the Command Bar, click **New**.

For further instructions, see [Add an Industrial Graphics Symbol in Plant SCADA Studio](#).

### Create a new Industrial Graphics library

You can create a new library to store your Industrial Graphics symbols. To do this:

1. On the Command Bar, click **New Library**.

For further instructions, see [Add an Industrial Graphics Library in Plant SCADA Studio](#).

### Delete Industrial Graphics symbols

You can use the **Libraries** view to delete up to 500 Industrial Graphics symbols. To do this:

1. Select the symbol(s) you want to delete from the libraries item list.
2. Press the **Delete** key.

Or:

On the Command Bar, click **Delete**.

The **Delete** dialog appears.

3. Click **DELETE**. If you do not want to delete the symbol(s), click **CANCEL**.

---

**Note:** If you delete a symbol that is open in the graphics editor, it will be closed automatically and the symbol will be deleted.

---

**Note:** If you delete a symbol that is embedded in another symbol or page, a "Graphic not Available" label appears in place of the deleted symbol.

### Delete Industrial Graphics Library

You can use the **Libraries** view to delete a Industrial Graphics library. To do this:

1. Set the library tree arrangement as **By Project, then Library** to enable the **Delete Library** button.
2. Select a library you want to delete from the tree. You can select only one library at a time.
3. Press the **Delete** key.

Or:

On the Command Bar, click **Delete Library**.

The **Delete Library** dialog appears, showing the symbols available in the library, that would be deleted.

4. Click **DELETE**. If you do not want to delete the library, click **CANCEL**.

---

**Note:** If you delete a parent library, all the child libraries within the parent library will also be deleted.

## Rename an Industrial Graphics Library

You can use the **Libraries** view to rename an Industrial Graphics library. To do this:

1. Set the library tree arrangement as **By Project, then Library** to enable the **Rename Library** button.
2. Select a library you want to rename from the tree. You can select only one library at a time.
3. On the Command Bar, click **Rename Library**.

The **Rename Library** dialog appears.

4. Use the library naming rules to update the library name.
5. Click **Rename**. If you do not want to rename the library, click **CANCEL**.

## Rename Industrial Graphics Symbol

You can use the **Libraries** view to rename an Industrial Graphics symbol. To do this:

1. Select the symbol you want to rename from the libraries item list.
2. On the Command Bar, click **Rename**.

The **Rename Symbol** dialog appears.

3. Use the symbol naming rules to update the symbol name.
4. Click **Rename**. If you do not want to rename the symbol, click **CANCEL**.

## See Also

[Libraries](#)

[Add an Industrial Graphics Library in Plant SCADA Studio](#)

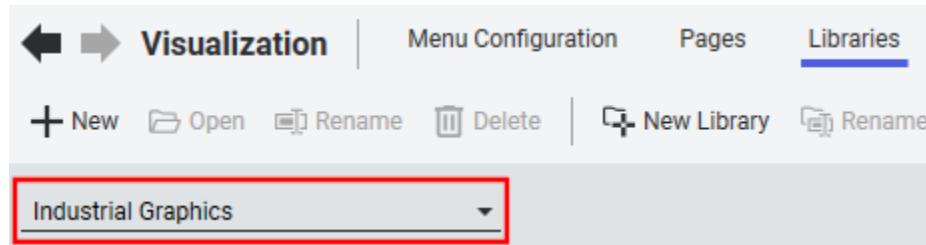

[Add an Industrial Graphics Symbol in Plant SCADA Studio](#)

## Add an Industrial Graphics Library in Plant SCADA Studio

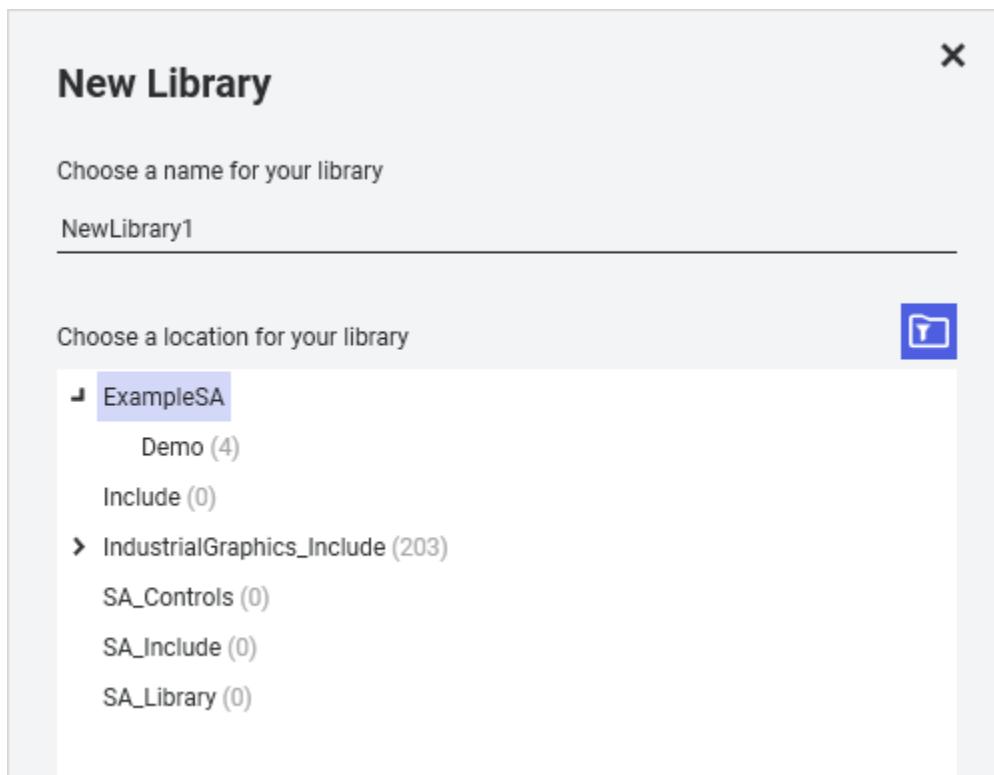

You can use the **Libraries** view in Plant SCADA Studio's **Visualization** activity to add a new Industrial Graphics library to the active project.

### To add a new Industrial Graphics library:

1. Go to the **Libraries** view in the **Visualization** activity.
2. Select **Industrial Graphics** from the drop-down menu below the command bar.

3. On the command bar, select **New Library**. The New Library dialog will appear.

**Note:** You can also launch the New Library dialog from the New Symbol dialog (see [Add an Industrial Graphics Symbol in Plant SCADA Studio](#)).

4. Choose a name for the library.

The name you use needs to be unique within the current branch of the tree. It also needs to adhere to a set of rules (see **Library Naming Rules** below). Based on these rules, you can only enter valid characters.

5. Choose a location for the library. If you select an existing library, the new library will be created as a sub-directory within it.

**Note:** You can create up to 10 library levels within the tree. If you select a location that goes beyond this limit, the Create button will be disabled.

6. Click **Create**.

The library will now appear in the tree in the **Libraries | Industrial Graphics** view.

## Library Naming Rules

A library name needs to adhere to the following rules:

- Needs to be between 1 to 64 characters in length.
- Any printable character (Alphanumeric, punctuation, space etc, but no tab, backspace, bell etc.)
- Cannot contain \$ and \.

## See Also

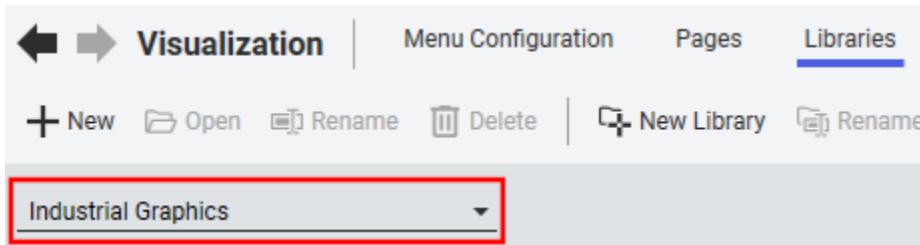

[Browse Industrial Graphics Libraries in Plant SCADA Studio](#)

## Add an Industrial Graphics Symbol in Plant SCADA Studio

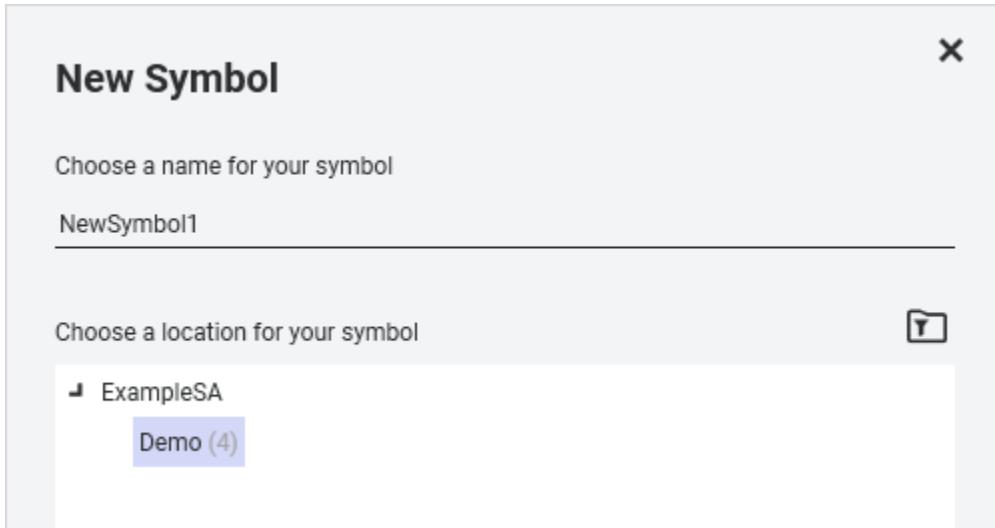

You can use the **Libraries** view in Plant SCADA Studio's **Visualization** activity to add a new Industrial Graphics symbol to the active project.

### To add a new Industrial Graphics symbol:

1. Go to the **Libraries** view in the **Visualization** activity.
2. Select **Industrial Graphics** from the drop-down menu below the command bar.

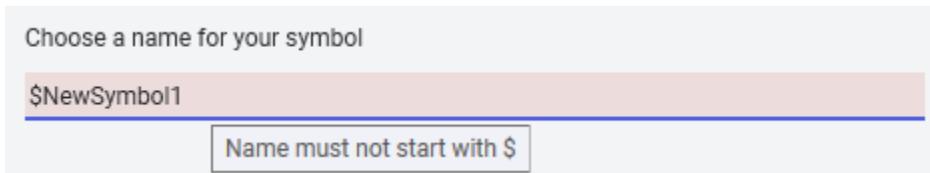

3. On the command bar, select **New**. The New Symbol dialog will appear.

4. Choose a name for the symbol.

The name you use needs to be unique within the current branch of the tree. It also needs to adhere to a set of rules (see **Symbol Naming Rules** below). Based on these rules, you can only enter valid characters.

If the background of the field is highlighted, it indicates that the current name does not comply with the naming rules. Place the cursor over the field to display a tool tip with a description of the required changes.

5. In the library tree, choose a location for the symbol.

**Note:** You cannot create a symbol in the root of a project. You need to select a library.

If required, select **New Library** (see [Add an Industrial Graphics Library in Plant SCADA Studio](#)).

6. Click **Create**.

The new symbol will appear in the tree in the specified location.

## Symbol Naming Rules

A symbol name needs to adhere to the following rules:

- Needs to be between 1 to 32 characters in length.
- Can contain any letter characters supported by Unicode.
- Can contain any decimal digit (0-9).
- Can only contain the punctuation characters # \$ and \_.
- Cannot start with a \$.
- Needs to contain at least one letter.
- Cannot be one of the following reserved words:

and	as	boolean	catch	citect
dim	discrete	do	double	each
elapsedtime	else	elseif	endif	endtry
endwhile	exit	float	for	if
in	indirect	integer	Me	message
mod	MyArea	MyContainer	MyEngine	MyHost
MyPlatform	MyViewApp	new	next	not
object	or	real	scada	shl
shr	step	string	System	then
time	to	try	while

## Embed an Industrial Graphics Symbol

You can use AVEVA™ Industrial Graphics Editor to embed an Industrial Graphics symbol on a page or within another Industrial Graphics symbol. This allows you to create re-useable graphical components that share a common source.

### To embed a Industrial Graphics symbol:

1. In the Industrial Graphics Editor, open the Industrial Graphics page or symbol that will host an embedded symbol.

2. From the **Edit** menu, select **Embed Graphic**.

Or:

Click on the Embed Graphic icon on the command toolbar.

The Embed Graphic dialog will appear.

3. In the project/library tree to the left of the dialog, select the source location for the item you would like to embed.

The drop-down menu above the tree will change its current arrangement based on the following options:

- **By Project, then Library:** Projects appear at the top level of the tree. The libraries included in each project are branched beneath. Selecting a project at the top level displays the library items from all the branched libraries.
- **By Library:** Only libraries appear in the tree. Selecting a library displays the items included in the library across all projects.
- **By Project:** Only projects appear in the tree. Selecting a project shows items from all libraries included in the project.
- **All Items:** This option hides the project/library tree and displays all symbols that are currently available to browse.

You can also display system projects in the tree by selecting the following button.

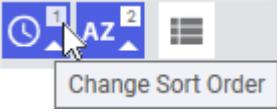

4. In the symbols list to the right of the dialog, select the item you would like to embed.

5. When you have made your selection, click on the **EMBED** button.

A cursor will appear in the Industrial Graphics Editor interface allowing you to position the embedded symbol.

The following tools may help you navigate the list of available symbols. .

Tool	Description
	<p><b>Search Items</b></p> <p>Use the <b>Search Items</b> field to locate specific items within the current list based on the file names.</p> <p>Click on the filter icon to the right of the field to select a comparison option.</p>  <p>To clear the current search, click on the <b>Clear Filter</b> button (see below).</p>
	<p><b>Clear Filters</b></p> <p>The <b>Clear Filters</b> button removes any active filters that are currently applied to the list of symbols.</p>
	<p><b>Sort by Modified Time</b></p> <p>The <b>Sort by Modified Time</b> button sorts the list according to the time each item was last modified. When this option is selected, an arrow will appear next to the clock icon to indicate if the order of the list is ascending or descending.</p> <p> Ascending</p> <p> Descending (default)</p> <p>Clicking on the button while it is selected will toggle between these two options.</p> <p>When the <b>Sort By Modified Time</b> button is clicked, the <b>Sort By Name</b> option is turned off by default. However, you can combine the two together (see <b>Combined Sort Mode</b> below).</p>
	<p><b>Sort by Name</b></p> <p>The <b>Sort by Name</b> button sorts the list according to item names. When this sort option is selected, an arrow will appear next to the AZ icon to indicate if the order of the list is ascending or descending.</p> <p> Ascending (default)</p>

Tool	Description
	 Descending Clicking on the button while it is selected will toggle between these two options. When the <b>Sort By Name</b> button is clicked, the <b>Sort By Modified Time</b> option is turned off by default. However, you can combine the two together (see <b>Combined Sort Mode</b> below).
	<b>Combined Sort Mode</b> You can combine the <b>Sort By Modified Time</b> and <b>Sort by Name</b> options. This sorts a list according to a selected the primary option, then by the secondary option. To create a combined sort: 1. Select the primary sort option, for example, <b>Sort By Modified Time</b> .  2. Then hold down the <b>Shift</b> key and select the <b>Sort By Name</b> button.  Both buttons will be highlighted to indicate that they are active.  The numbers in the top corner of each button indicates which sort is primary (1) and which is secondary (2). To change the sort order, click on either number. 
	<b>Display Mode</b> The Display Mode button changes the layout of the

Tool	Description
	<p>item list. Four options are available. The appearance of the button indicates which mode is currently selected.</p>  <ul style="list-style-type: none"><li><b>Small tiles (default)</b></li><li><b>Medium tiles</b></li><li><b>Large tiles</b></li><li><b>Details</b></li></ul> <p>The <b>Details</b> mode present the list of library items in a tabular format with the following columns:</p> <ul style="list-style-type: none"><li>• <b>Name</b> - Name of the library item.</li><li>• <b>Library</b> - Name of the library to which the item belongs.</li><li>• <b>Project</b> - Name of the project that hosts the item.</li></ul>

## Content Types

Content types allow you to identify a particular type of graphical content (such as pages or faceplates). You can use them to specify what a pane will display when a piece of equipment comes in to context. This enables the [Autofill](#) functionality in a Situational Awareness project.

For information on how to add content types to a project, see [Configure Content Types](#).

Once you have added a set of content types to a project, you can use them for the following:

- Pages — the **Content Type** property identifies a page as a particular type of page (see [Assign a Content Type to a Page](#)).
- Panes — the **ContentType** property specifies the type of content a workspace pane will display (see [Configure Panes on a Master Page](#)).

If a project was created using the Situational Awareness Starter project, the following content types will already be available via the SA\_Include project:

- L1 — Level 1 pages

- L2 — Level 2 pages
- L3 — Level 3 pages
- L4 — Level 4 pages
- FP — Faceplate pages
- General — General pages (for example, alarm or trend pages)
- \_Internal — Internal pages (any pages that are excluded by the autofill functionality and default menu).

## Configure Content Types

[Content Types](#) allow you to identify a particular type of graphical content (such as pages or faceplates). This allows you to specify what a pane will display when a piece of equipment comes into context.

### To add a content type:

1. In the **Visualization** activity, select **Content Types**.
2. Add a row to the Grid Editor.
3. Type the required information in each column, or in the fields in the Property Grid.  
For a description of the properties, see below.
4. Click **Save**.

**Note:** If your project was created using the Situational Awareness Starter project, a set of existing content types will already be available via the SA\_Include project.

## Content Types Properties

### General Properties

Property	Description
<b>Name</b>	The name of the content type. This is the name that will be used when configuring pages and panes.
<b>Comment</b>	Any useful comment, such as a description of the content type. Enter a value of 48 characters or less.

### Project Properties

Property	Description
<b>Project</b>	The project in which the report is included.

[Autofill](#)

## Keyboard Commands

Keyboard commands allow your operators to interact with the runtime system by typing instructions on the keyboard.

You can assign privileges to commands and controls, and send a message to the command log each time an operator issues a command.

You can also define a meaningful name for any key on a keyboard, providing a label that you can use to configure your keyboard commands. See [Keyboard Keys](#).

**Note:** If you want to configure commands that an operator can issue by clicking specific objects on a graphics page, see [Touch Commands](#).

### See Also

[Define System Keyboard Commands](#)

[Define Key Sequences for Commands](#)

[Keyboards](#)

## Define System Keyboard Commands

System keyboard commands specify a key sequence that an operator can enter on a keyboard to execute a particular instruction (or series of instructions).

For information on keyboard commands that only operate for a particular page or selected object, see [Keyboard Commands](#).

To add a system keyboard command:

1. In the **Visualization** activity, select **Keyboard Commands**.
2. Add a row to the Grid Editor.
3. Type the required information in each column, or in the Property Grid (see below for a description of the properties).
4. Click **Save**.

## System Keyboard Command Properties

### General Properties

Property	Description
<b>Key Sequence</b>	The key sequence for the command (32 characters).
<b>Command</b>	The commands (set of instructions) to execute when an operator enters the key sequence (253 characters).
<b>Privilege</b>	The privilege necessary by an operator to issue the command (16 characters).

Property	Description
<b>Area</b>	The area to which the command belongs (16 characters). Only operators who belong to this area will be able to issue this command. For example, if you enter Area 1 here, operators need to have access to Area 1 (plus any necessary privileges) to issue this command.
<b>Message Log</b>	<p>A text message sent to the <i>MsgLog</i> field of the log device when the selected action is performed by the operator at runtime (32 characters).</p> <p>The log device to which the message is sent is specified in the <b>Log Device</b> field below.</p> <p>The message needs to be plain text. If you want to include field data as part of a logged message, you need to insert the field name as part of the device format when you configure the device. For instance, in the <b>Format</b> field of the <b>Devices</b> form, you could enter {MsgLog,20} {FullName,15}. This would accommodate the logging of messages such as "P2 started by John Smith".</p>
<b>Log Device</b>	The device to which the <b>Message Log</b> is sent when the command is issued (16 characters).
<b>Comment</b>	Any useful comment (48 characters).

#### Project Properties

Property	Description
<b>Project</b>	The project in which the specified keyboard command is included.

[Keyboard Commands](#)

[Define Key Sequences for Commands](#)

## Define Key Sequences for Commands

To define a command, you need to specify the key sequence that the operator types to issue the command. You can specify a single key for the key sequence, for example, the function key F2:

Key Sequence	F2
--------------	----

Alternatively, you can specify several keys that needs to be typed in sequence, for example, the function key F2

followed by the Enter key:

Key Sequence	F2 Enter
--------------	----------

**Note:** If you use more than one key for the sequence, you need to separate each key with a space.

You will want to avoid the ambiguity in keyboard commands that can occur if you define separate commands that use a common key. For example, if you define a key sequence for one command as F3, and the key sequence for a second command as F3 F4, then when F3 is pressed, the first command would execute immediately; the second command could not execute. To avoid overlapping keyboard commands, add a **delimiter** to common keyboard commands, for example:

Key Sequence	F3 Enter
Command	SP1 = 50;
Key Sequence	F3 F4 Enter
Command	SP1 = 100;

These commands will not execute until the operator types the delimiter (the Enter key).

[Using a Hot Key](#)

[Using Variable Data Input](#)

[Passing Multiple Arguments](#)

[Passing Keyboard Arguments to Functions](#)

## Keyboards

You can use non-standard keyboards (as well as multiple keyboards) to control Plant SCADA. You can also define key names.

### Using non-standard keyboards

You can use many types of keyboards with your runtime system. The majority of keyboards are IBM compatible keyboards; this type of keyboard is used as a default. Some industrial keyboards may not conform with this standard; if you use a non-standard keyboard, you need to define each of the keyboards in the database.

### Using multiple keyboards

Sometimes you might need to use keyboards of different types; for example, an IBM compatible keyboard in your control room and a sealed-membrane keyboard on the plant floor. If you use more than one type of keyboard, you need to define every key for each keyboard and assign each keyboard type to the respective computer.

You need to set the keyboard type for each computer, with the [Keyboard]Type parameter.

**Note:** If you define commands that use mouse buttons, test that a double-click command cannot be mistaken for

---

a single-click command. A double-click is an extension of a single click; a single click message will be received before a double-click message.

---

## Defining key names

You can refer to a keyboard key by a meaningful name, rather than by the key itself. For example, you can refer to the F1 key as the "Help" key and the F2 key as the "Login" key. When you use the key in a command, you can use the name you have defined.

You can assign a key name to any key on the keyboard (including the alphanumeric keys A - Z, a -z, and 0 - 9). However, after a key is defined as a command key it can only be used as a command key. If you do assign a definition to an alphanumeric key (for example the character A), that key can not be used as a data key. Each time it is pressed, the definition for the key is recognized and not the keyboard character itself. Keyboard key definitions are usually only used with non-alphanumeric characters (for example the function keys).

## See Also

[Keyboard Commands](#)

[Define Key Sequences for Commands](#)

## Using a Hot Key

A command defined with a 'hot' key executes immediately the key is pressed. You can only define a single key in the key sequence, and only use a 'hot' key to define commands that act on the current keyboard buffer (for example the Backspace and Delete keys). To define a 'hot' key, prefix the key sequence with an asterisk (\*) as in the following example:

Key Sequence	*Backspace
Command	KeyBs()

At run time, this command operates in exactly the same way as the Backspace key on a standard computer keyboard. (Each time the Backspace key is pressed, the last key in the command line is removed.)

---

**Note:** You can only define a 'hot' key command as a system (global) command.

---

## See Also

[Using Variable Data Input](#)

## Using Variable Data Input

You can configure a keyboard command to accept variable data at run time. When the system is running, an operator can enter a value with the command, and the value is passed as an argument (or arguments) into the Cicode command. You can therefore define a single keyboard command that your operators use with different values. For example, you could define the following command to set the variable SP1 at run time:

Key Sequence	F3 ### Enter
Command	SP1 = Arg1;

In this example, an operator can set the variable SP1 to a new value by first pressing the F3 function key, entering the new value, and pressing the Enter key, for example:

This sets the value of SP1 to 10.

Each `#' character (in the Key Sequence) represents one keyboard character that an operator can enter in the command. In the above example, the operator can enter up to three keyboard characters when issuing the command. (The number of # characters determines the maximum number of characters that an operator can enter for the argument; if the operator enters more than three characters, an "Invalid Command" alert message displays.)

The command in the above example could be issued as follows:

or

or

When the command is issued (the operator presses the Enter key), the value is passed to the command at Arg1.

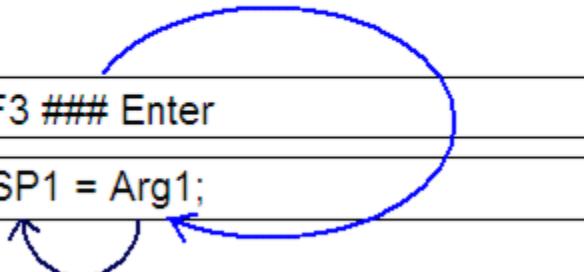

When an operator issues  
the command, the value  
is passed to Arg1 . . .

Key Sequence

F3 ### Enter

Command

SP1 = Arg1;

. . . and SP1 is set to that value.

**Note:** If an operator does not enter any data, the value of Arg1 is zero, and the variable is set to zero.

For example, the following key sequence may be used:

To avoid this, use the **ArgValue1** label, for example:

```
Command SP1 = ArgValue1;
```

The **ArgValue1** label checks for invalid input; if the input is invalid, the value of the variable is not changed and the command halts. Any instructions following an invalid ArgValue1 will not execute. You can also use the `StrToValue()` function.

## See Also

[Passing Multiple Arguments](#)

### Passing Multiple Arguments

You can pass multiple arguments into a Cicode command by separating each argument with a comma (,). Each argument is passed into the command in sequence, and is referred to in the command field as **Arg1**, **Arg2**, **Arg3**, and so on. For example:

Key Sequence	F3 ###, ### Enter
Command	SP1 = Arg1; SP2 = Arg2;

In this case, an operator can set two variables with the same command, for example:

sets the variables SP1 to 20 and SP2 to 35.

You can use up to eight arguments. However, avoid passing many arguments.

**Note:** There is no way to check if the input for each argument is valid (see example below).

## Example

An operator may not enter any data for one of the arguments. For example, the key sequence below is used.

This would mean the value of Arg2 is zero, and the second variable is set to zero. If you use multiple arguments in a command, invalid inputs might generate undesired behavior in the project or in the larger system.

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not use keystroke sequences to pass multiple arguments to Cicode commands unless possible input combinations have been tested and determined to be safe.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**See Also**

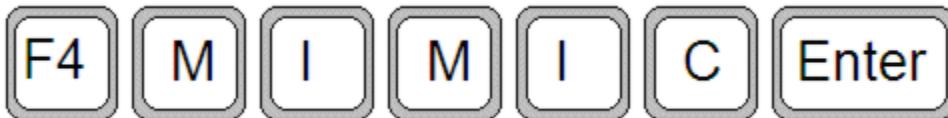

[Passing Keyboard Arguments to Functions](#)

**Passing Keyboard Arguments to Functions**

You can also pass arguments directly to functions at run time, as in the following example:

Key Sequence	F4 ##### Enter
Command	PageDisplay(Arg1);

In this example, an operator can select any graphics page (defined in the project) with a single command, for example:

This selects the "Mimic" page.

**Note:** Keyboard arguments are passed as string values. If the command (or function) requires a numeric value, Cicode converts the string to a numeric value before it is used.

If you use variable data, the operator can only enter alphanumeric characters (A - Z, a-z, and 0 - 9) for the data. Avoid using variable data input as the last item in a key sequence, as ambiguity could occur; use a delimiter.

**Reports**

You can request regular reports on the status of your plant, and reports that provide information about special conditions in your plant. Reports can be run on a request basis, at specified times, or when certain events occur (such as a change of state in a bit address). Output from a report is controlled by a device. A report can be printed when it runs or saved to disk for printing later. You can use a text editor or word processor to view, edit, or print the report, or you can display it in Plant SCADA as part of a page.

Reports can also include Cicode statements that execute when the report runs.

Reports are configured in two stages:

- Report properties
- Report format file

If report data is associated with an I/O Device that does not initialize properly at startup or goes offline while Plant SCADA is running, the associated data is not written to the report (because the values would be invalid). An error code is written instead.

## See Also

- [Run a Report](#)
- [Handling Communication Errors in Reports](#)

## Configure a Report

Before you add a report to Plant SCADA, you should configure a device for output of the report. For example, if you want to save a report to a file when it is run, set up an ASCII\_DEV device.

### To add a report:

1. In the **Visualization** activity, select **Reports**.
2. Add a row to the Grid Editor.
3. Type the required information in each column, or in the fields in the Property Grid.  
For a description of the properties, see below.
4. Click **Save**.

You will then need to edit the Report Format File (see [Format a Report](#)). Remember that Edit the report format file. Remember that for an RTF report, the report format file needs to be saved in RTF format (with an .RTF file extension).

You will also need to define your PC as a report server using the Setup Wizard (see [Reports Configuration](#)).

## Reports Properties

### General Properties

Property	Description
<b>Name</b>	The name of the report. The name can be a maximum of 79 characters. It can consist of any character other than the semi-colon (;) or single quote ('). The name needs to be unique to the cluster. <b>Note:</b> Where Cluster Name is left blank, the name needs to be unique to every defined cluster.
<b>Time</b>	The time of day to synchronize the report, in hh:mm:ss (hours:minutes:seconds). If you do not specify a time, the report is synchronized at 0:00:00 (i.e., midnight). Enter a value of 32 characters or less.

Property	Description
<b>Period</b>	<p>The period of the report, in hh:mm:ss (hours:minutes:seconds). Enter a value of 32 characters or less. Alternatively you can:</p> <ul style="list-style-type: none"> <li>• Specify a weekly period by entering the day of the week when the report is to start, for example, Monday, Tuesday, Wednesday, etc.</li> <li>• Specify a monthly period by entering the day of the month when the report is to start, for example, 1st, 2nd, 3rd, 4th, 5th, etc.</li> <li>• Specify a yearly period by entering the day and the month when the report is to start, for example, 1st January, 25th February, etc. The day and month needs to be separated by a space.</li> </ul> <p>If you do not specify a period, the report is run daily.</p>
<b>Trigger</b>	<p>Any Cicode expression (or Variable tag) to trigger the report. Enter a value of 254 characters or less. If the result of the expression (in this field) is TRUE, and the Time and <b>Period</b> fields are blank, the report is run. The report is only run when the expression becomes TRUE, and it needs to become FALSE then TRUE again before the report is re-run.</p>
<b>Report Format File</b>	<p>The name of the report format file. Enter a value of 253 characters or less. If you do not specify a file extension, it defaults to .RPT. The file name of your report format file can be up to 64 characters long, or 253 characters including the path. It can consist of any characters other than the single quote ('), and the semi-colon (;). You cannot use a Path Substitution in this field.</p> <p>If you specify a file name without a path, the file saves into the directory predefined as Run. The report is assumed (by the Plant SCADA compiler) to be ASCII unless an RTF extension is used.</p> <p><b>Note:</b> You will need to manually configure the access control list for a folder location specified in a path so that it matches the permissions that were applied to the default Run location during installation. See <a href="#">Configure Directory Security for Modified Folder Locations</a>.</p>
<b>Privilege</b>	<p>The privilege necessary by an operator to run this report if the report is a command-driven report. Enter</p>

Property	Description
	<p>a value of 16 characters or less.</p> <p>If the report is time-driven or event-driven, this property is ignored.</p> <p><b>Note:</b> If you assign an acknowledgment privilege to a report, do not assign a privilege to the command(s) that run the report. If you do assign a different privilege to the commands, an operator needs to have both privileges to run the report.</p>
<b>Area</b>	<p>The area to which this report belongs. Enter a value of 16 characters or less. Only users with access to this area (and any necessary privileges) will be able to run this report. For example, if you enter Area 1 here, operators need to have access to Area 1 (plus any necessary privileges) to run this report.</p>
<b>Output Device</b>	<p>The device where the report will be sent. Enter a value of 16 characters or less.</p> <p>For RTF reports that are to be saved as a file, select a device of type ASCII_DEV here. Due to the differing natures of their content; however, it is not recommended that the same ASCII device be used for logging both RTF and non-RTF reports.</p> <p><b>Note:</b> If two or more reports are running at the same time and are sending their output to the same printer, the output of each report can become mixed. You need to use semaphores to control the access to the printer in each report. See the <a href="#">SemOpen</a> Cicode function. If the report only contains Cicode statements (and has no output data), this property is optional.</p>
<b>Comment</b>	<p>Any useful comment. Enter a value of 48 characters or less.</p>
<b>Cluster Name</b>	<p>The name of the cluster that runs this report. If the Cluster Name is not set, then Plant SCADA considers this report to run on every defined cluster.</p>

#### Project Properties

Property	Description
<b>Project</b>	<p>The project in which the report is included.</p>

## See Also

[Format a Report](#)

[Run a Report](#)

## Format a Report

**Note:** If the report format file exists, it is loaded into the property grid for you to edit. If the file does not exist, Plant SCADA creates a new file.

### To change the report format file:

1. In the **Setup** activity, select **Reports**.
2. Select the Report you want to change from the Property Grid.
3. Edit the Report Format File field with the new format.
4. Click **Save**.

The report format file specifies how data is formatted in a report. You can use fixed text, Cicode expressions, and database variables in any report.

You use a text editor that is supported by Windows to create (and modify) the report format file. If your report format file is in RTF (Rich Text Format), use Microsoft Wordpad.

#### Including fixed text

You can include fixed text in the report, specifying the text exactly as you want it to appear (for example, Name of Report, Description, and so on).

#### Including OLE (RTF files only)

Objects can be linked to or embedded within an RTF report format file; however, such objects will not be displayed or printed from Plant SCADA.

#### Using fonts (ASCII format only)

If your format file is in ASCII format, you can use any text font supported by Windows in the report. To specify a font, use the PrintFont() function. RTF format files do not require this function, as they use the formatting features of the host word processor.

#### Including Cicode expressions and variables

You can include Cicode expressions and variables by enclosing them (and optional format specifications) in braces {} - for example:

The size of each field (number of characters) is determined by either the format specification, or by the number of characters between the braces. In the above example, the variable PV12 is formatted with four characters before the decimal point and two characters after.

You do not have to include the format, for example:

{PV12}

Here, the variable is formatted using only four characters (the number of characters between the braces).

The following rules apply when logging a report to a **database device**:

- The format (for the report field) do not specify a field size greater than the size of the relevant field specified in the device.

- No spaces are allowed between each field specification, for example:

```
{TIME(1) }{PV12:####.##}{PV12:4.2}
```

### Including blocks of Cicode

You can include a block of Cicode, using the following format:

```
{CICODE}  
Statements;  
{END}
```

The block of Cicode is delimited by the commands {CICODE} and {END}. After the {END} command, the report switches back into WYSIWYG mode. If the entire report is Cicode or the last section is Cicode, the {END} command is not necessary.

A block of Cicode does not send any output to the device unless you use either the Print() or PrintLn() functions. If you use one of these functions, the argument is printed to the device.

### Cicode variables (ASCII format only)

You can also declare variables for use within your Cicode block. This is not available in RTF or HTML format files. Declare any variables at the beginning of the file (i.e. before any report format or Cicode). Add a {CICODE} block first; for example:

```
{CICODE}  
INT nVar1;  
STRING sVar2;  
Statements;  
{END}
```

Remainder of report

### Including comments

You can include comments by using the comment character `!' enclosed in braces - for example:

```
{!This is a Comment}
```

A comment in the body of a report differs from a comment in a Cicode block: a comment in a Cicode block does not require braces.

### Including other report elements

The following table describes other elements you can include in reports.

To...	Do this...
Issue a form feed	Use a form feed specifier: {FF}
Include a plot	Use the Plot functions.
Include trend data	Use the TrnGetTable() function.
Include trend graphs	Use the TrnPlot() function.

## Report Example

The following is an example of a report format file (for a printer or ASCII file device):

```
-----  
SHIFT REPORT  
-----  
{Time(1) } {Date(2) }  
Shift Production {Shift_Prod:###.##} tons  
Total Production {Total_Prod} tons  
{! The following Cicode displays "Shift Report Complete" on the  
screen}  
{CICODE}  
Print("End of Report")  
Shift_Prod = 0; ! Reset the Shift production tonnage  
  
Prompt("Shift Report Complete");  
{END}  
{FF}
```

This report produces the following output to the device and displays "Shift Report Complete" on the graphics page.

```
-----  
SHIFT REPORT  
-----  
6:00am 12/3/92  
Shift Production 352.45 tons  
Total Production 15728 tons  
End of Report
```

## See Also

[Run a Report](#)

## Run a Report

To run a report, use one (or a combination of) the methods listed below:

### Automatically run when Plant SCADA starts up

You can run a report on startup. Plant SCADA searches for a report called "Startup" when it starts up, and if it locates this report, it is run automatically. You can change the name of the default report with the Setup Wizard.

### Automatically run at a specified time and period

The period determines when the report is run. You can specify the period in hh:mm:ss (hours:minutes:seconds), for example:

Period	Comment
1:00:00	Run the report every hour
6:00:00	Run the report every six hours
72:00:00	Run the report every three days
Monday	Run the report each Monday

Period	Comment
15th	Run the report on the 15th of each month
25th June	Run the report on the 25th of June

You can also specify the time of day to synchronize the report, for example:

Time	Comment
6:00:00	Synchronize the report at 6:00 am
12:00:00	Synchronize the report at 12:00 midday

The time synchronizes the time of day to run the report and, with the Period, determines when the report is run, for example:

Time	Period
6:00:00	1:00:00

In this example, the report is run every hour, on the hour. If you start your runtime system at 7:25am, your report is run at 8:00am, and then every hour after that.

### Automatically run when an event is triggered

You can use any Cicode expression (or variable tag) as a trigger for a report. If the result of the expression (in the **Trigger** field) becomes TRUE, and if the **Time** and **Period** fields are blank, the report is run. For example:

Time	
Period	
Trigger	RCC1_SPEED<10 AND RCC1_MC

This report is only run when the expression (Trigger) becomes TRUE, i.e., when the digital tag RCC1\_MC is ON and the analog tag RCC1\_SPEED is less than 10. The expression needs to become FALSE and then TRUE again before the report is run again.

If you use the **Time** and/or **Period** fields, the trigger is checked at the time and/or period specified, for example:

This report is run each hour, but only if the expression (Trigger) is TRUE (i.e., if the digital tag RCC1\_MC is ON and the analog tag RCC1\_SPEED is less than 10).

Time	6:00:00
Period	1:00:00
Trigger	RCC1_SPEED<10 AND RCC1_MC

This report is run each hour, but only if the expression (Trigger) is TRUE (i.e., if the digital tag RCC1\_MC is ON and the analog tag RCC1\_SPEED is less than 10).

### Run using a command

If the **Time**, **Period**, and **Trigger** fields are blank, the report can only be run by a command that calls the **Report()** Cicode function.

## See Also

[Handling Communication Errors in Reports](#)

## Handling Communication Errors in Reports

You can handle errors in communication with I/O devices (for example, an I/O device does not initialize properly at startup or goes offline while Plant SCADA is running) in two ways:

### **Write communication errors and invalid data to the report as error codes.**

If a communication error is detected (with an I/O Device) or if the data is invalid, one of the following alert messages are written to the report (instead of the value):

Error	Meaning
#ASS	The value is incorrectly associated (with a substitution string or Genie).
#COM	Communication with the I/O Device has been lost
#DIV/0	An attempt was made to divide a number by 0 (zero)
#ERR	An uncommon error has occurred. (Use the IsError function to find the occurrence.)
#MEM	Out of memory or more than 64 kb bytes of memory requested.
#PEND	Data from this device is pending an initial update to display a value.
#RANGE	The value returned is out of range
#STACK	The value has caused a stack overflow
#WAIT	Data from this scheduled device is not available as it has not reached its scheduled interval and has no cache value.

For example:

#### **Report Format:**

If the above report is run when the value of PV\_1 is out of range (for example 101.5), SP\_1 is 42.35 and OP\_1 is 60.0, the output of the report is:

#### **Report Output:**

#RANGE 42.35 60.0

When reports are written to a database device, you might sometimes want to disable the alert messages and write the values to the report (even if the values are invalid). Use the ERR\_FORMAT\_OFF command to disable

alert messages and write data as values.

For example:

**Report Format:**

```
{ERR_FORMAT_OFF}  
{PV_1} {SP_1} {OP_1}  
If the above report is run when the value of PV_1 is out of range (for example 101.5)  
, SP_1 is 42.35 and OP_1 is 60.0, the output of the report is:
```

**Report Output:**

42.35 60.0

To re-enable the alert messages, use the ERR\_FORMAT\_ON specifier.

---

**Note:** If an I/O Device goes offline and you have disabled communication errors, the value printed into the report is either 0 (zero) or the last value read from the I/O Device when the report was last run. In either case, the value is invalid.

---

## Suppress Reports

You can suppress reports that are triggered from I/O Devices if a communication error is detected by using the [Report]ComBreak parameter. For example, you might configure a report to be run every hour when a bit is on. The I/O Device associated with that bit goes offline. If the [Report]ComBreak parameter is 0, the report does not run. If the parameter is 1, and if the latest valid value that was read from that bit was 1, the report is run.

This parameter only applies to the trigger of the report, not to the data in the report.

## Security

Plant SCADA security involves three key areas:

- **Encrypted communications** - a System Management Server is used to manage certificates that allow encrypted communications between computers in a Plant SCADA system (see [Encrypted Communications](#)).
- **Security Roles** - security-related operations within Plant SCADA's engineering and runtime environments can only be performed by users assigned to a role with relevant permissions (see [Security Roles](#)).
- **Runtime System Security** - settings within a Plant SCADA project that control permissions within the runtime environment, including **Roles** and **Users** (see [Runtime System Security](#)).

## Encrypted Communications

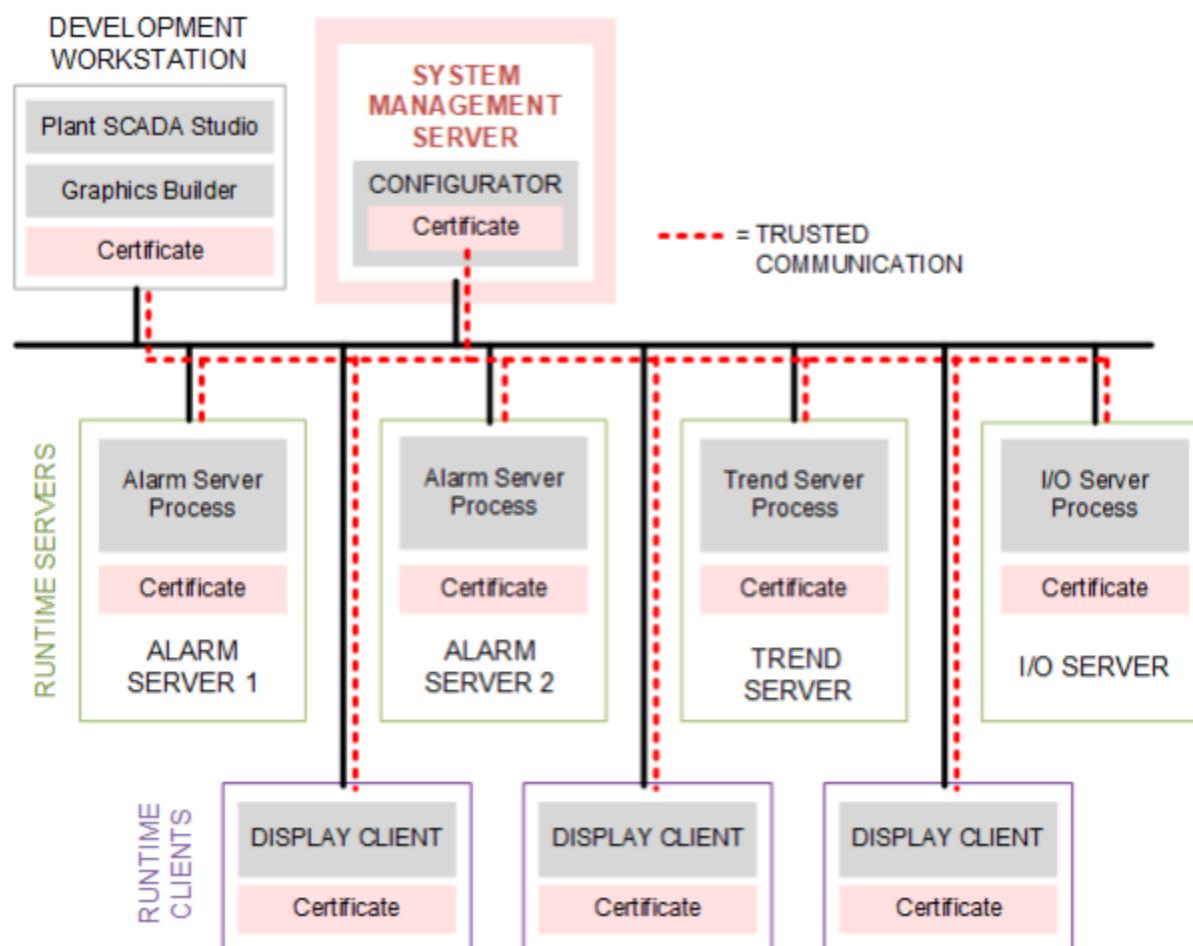

Communications between Plant SCADA processes, computers and CtAPI can be encrypted. To use encryption, a **System Management Server** is required to manage the certificates that enable trusted communications.

The components required to enable encryption are included with every installation of Plant SCADA.

Only one of the computers in a Plant SCADA system needs to be configured as the System Management Server. You use Configurator to configure the computer that will perform this role (see [Configure a System Management Server](#)).

The certificates required to establish trust can be generated automatically on the System Management Server or provided by your IT department.

Computers running AVEVA products can then use a certificate to connect to the System Management Server across an encrypted connection (see [Connect a Computer to a System Management Server](#)).

Encryption is a requirement for some Plant SCADA components, such as a Deployment Server, an Industrial Graphics Server or an OPC UA Server. To enable encryption, you need to set Runtime Manager to run as a service on any computers that host a server process. See [Enable Encryption](#).

In a typical Plant SCADA system that is also using deployment, it is recommended that the System Management Server is configured on the same computer as the Deployment Server.

---

**Note:** A System Management Server can also be installed in a large, multi-site environment running multiple AVEVA products. In such systems, the location of the System Management Server may be governed by one or more products. However, all AVEVA products should be able to connect to the System Management Server at all times so that certificates can be renewed when it is required.

## Configure a System Management Server

Plant SCADA needs post-installation configuration in order to use encrypted communications via a **System Management Server**. Encryption is a requirement for components such as a Deployment Server, an Industrial Graphics Server or an OPC UA Server.

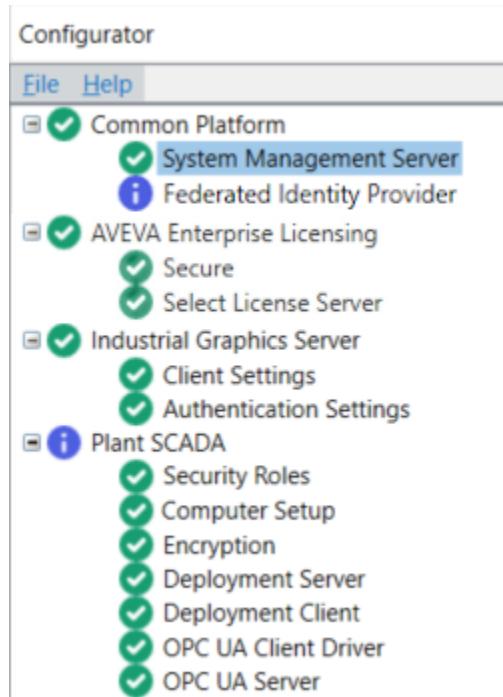

Only one of the computers in the network can be configured as a System Management Server. This is achieved using [Configurator](#).

You can then use Configurator to establish a trust relationship between one or more computers running Plant SCADA and its services. This is achieved by configuring a certificate on the System Management Server that can then be distributed to other computers to enable encrypted communications.

Certificates may be generated automatically on the System Management Server, or provided by a system administrator or IT department (see [Use Externally Provided Certificates for Encryption](#) in the Plant SCADA documentation).

### To configure the System Management Server:

1. Start the **Configurator**.
2. In the left pane, select **Common Platform | System Management Server**.

The following page is displayed:

Machines running AVEVA software must be configured to trust each other so that encrypted communications can be utilized. This is done by connecting them to a System Management Server.

- Connect to an existing System Management Server.

- This machine is the System Management Server.

There should only be one System Management Server in your topology for all AVEVA products. All other machines should be configured to connect to this System Management Server.

When configuring other machines, you should validate that the security code shown in the Configurator matches:

[Details...](#)

- No System Management Server configured. (NOT RECOMMENDED)

This option also allows you to remove any existing certificates that were managed by the System Management Server.

You can connect to an existing System Management Server or configure a new System Management Server by selecting one of the first two options, respectively. When you click Configure, a certificate and the web ports to use for communication are configured. To modify these configurations, click Advanced.

[Advanced](#)

3. Select **This machine is the System Management Server**. Review the notes on the screen before you start the configuration.

**Note:** The machine on which you want to install the System Management Server needs to be configured to have a static IP address.

4. Click **Configure**.

**Note:** If you need to change the port used by a System Management Server see the topic *Advanced Configuration for a System Management Server* in the Plant SCADA documentation.

5. On successful configuration, the message "Device configuration completed" is displayed. The security code is displayed in the **Configurator** as shown below. To view more information about the certificate, click **Details**.

#### Configuration Messages

Certificates are configured.  
Connecting to the System Management Server 'https://<IP>.com:443'.  
Registering the device.  
The device is registered.  
Device configuration completed.

If the configuration is unsuccessful, check the [Log Viewer](#).

You can access the Log Viewer by selecting **AVEVA | Operations Control Management Console** in the Windows **Start** menu.

Alternatively, view the error messages in the System Management Console.

6. Click **Close** to exit the **Configurator**.

---

**Note:** After you have configured a System Management Server, it is recommended that you either sign out or reboot the computer to ensure all settings are applied correctly.

[Connect a Computer to a System Management Server](#)

## Connect a Computer to a System Management Server

Computers running Plant SCADA need to connect to the **System Management Server** to use encrypted communication enabled by a certificate.

If you do not have a System Management Server configured, refer to the section [Configure a System Management Server](#) for instructions. AVEVA applications need to be configured to trust each other to use encrypted communications.

To connect a computer to the System Management Server, you use the System Management Server page in **Configurator**. You can launch **Configurator** at the completion of the installation procedure, or from the Windows™ Start menu.

To establish a connection, the current user on the remote computer needs to be a member of either the "aaAdministrators" or the "Administrators" group on the machine where the System Management Server is installed. This is necessary to establish a trust relationship, it is not a runtime requirement.

---

**Note:** For a Deployment Server, you need to authorize the connection to a System Management Server from Configurator's Deployment Server page. See [Configure a Deployment Server](#).

---

### To connect a computer to the System Management Server:

1. In the panel on the left side of the **Configurator** select **Common Platform**, **System Management Server**.
2. Select the option **Connect to an existing System Management Server**.
3. In the field below, select the name of the System Management Server you want to use from the drop-down list.

The Configurator uses SSDP (Simple Service Discovery Protocol) to detect a System Management Server on a remote computer. If SSDP has been blocked on your network, nothing will appear in the drop-down list.

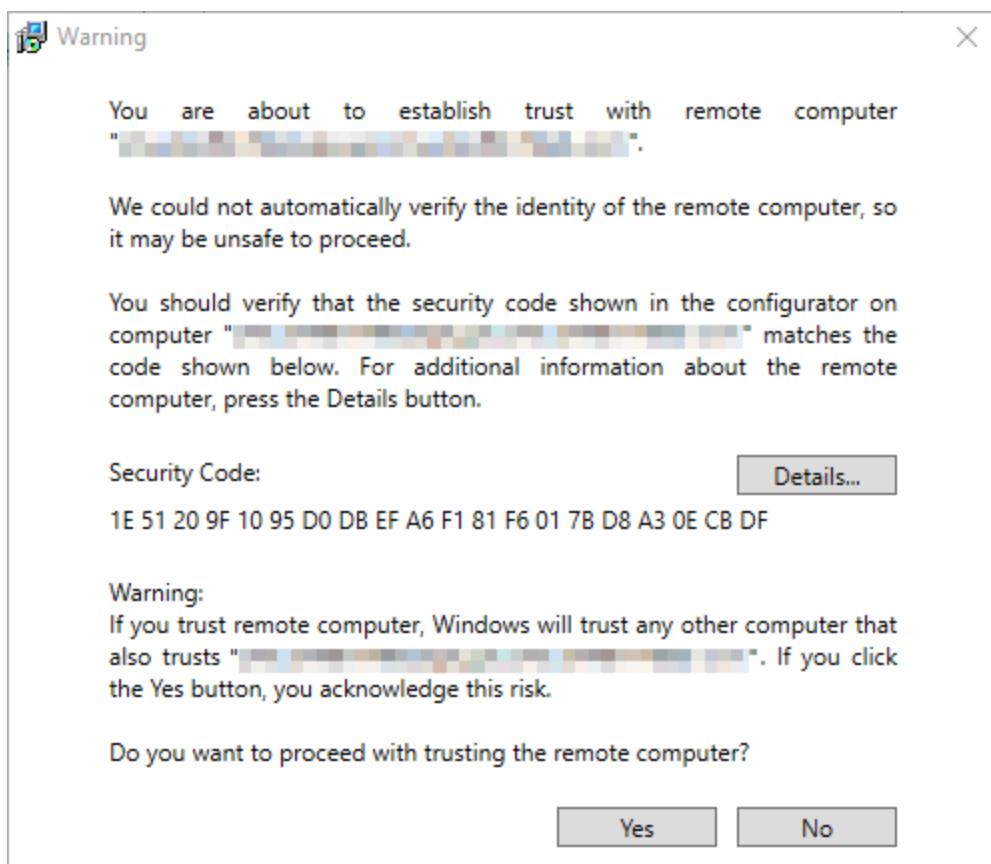

If the required computer name does not appear in the list, you can manually enter a hostname or Fully Qualified Domain Name (FQDN) for the computer on which the System Management Server is installed. Connecting via an FQDN will require a connection to a domain server.

---

**Note:** The Configurator interface refers to "redundant SSO servers". This feature is not supported by Plant SCADA, you cannot configure a computer as a redundant SSO server.

---

4. Click **Configure**. The root certificate is downloaded, and the following message is displayed.

5. Review the message carefully before you click Yes. If you select No, the configuration process will be canceled.

A dialog box may appear prompting you to log on to the System Management Server. This will occur if the current user is not a member of either the "aaAdministrators" or the "Administrators" group on the machine where the System Management Server is installed. If this happens, enter the credentials for a member of one of these groups and click OK.

The Configuration Messages area displays the steps in the configuration process and the progress.

If the configuration is unsuccessful, view details of the error messages in the System Management Console. See the topic [Troubleshooting Certificate Error Messages](#).

Alternatively, check the [Log Viewer](#).

You can access the Log Viewer by selecting **AVEVA | Operations Control Management Console** in the Windows **Start** menu.

6. Click **Close** to exit the **Configurator**.

**Note:** After you have connected a computer to a System Management Server, it is recommended that you either sign out or reboot the computer to ensure all settings are applied correctly.

Once you have connected to a System Management Server, you can modify the configuration settings by selecting **Advanced**. Refer to the topic [Advanced Configuration for a System Management Server](#) in the Plant SCADA documentation for more information.

**Note:** If you need to connect a client computer that is not on the same domain as the System Management Server (for example, it is part of a Workgroup), you need to configure the **Primary DNS Suffix** on the client to identify the domain on which the System Management Server resides. Refer to the Windows documentation for

---

instructions on how to specify a Primary DNS Suffix for a computer.

---

## Enable Encryption

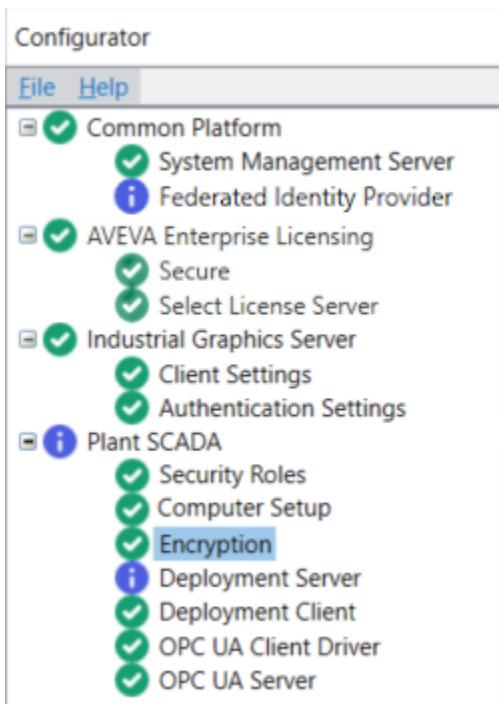

Communications between Plant SCADA processes, computers and CtAPI can be encrypted in Plant SCADA.

To use encrypted communications, you need to have a System Management Server configured. In addition, the Runtime Manager should be running as a service on any computers hosting a server process (see ).

If these prerequisites are not met, warning messages will be displayed.

### To enable encryption:

1. Launch the **Configurator** after the installation, or from the Windows™ Start menu.
2. In the left pane, select **Plant SCADA | Encryption**.

The following page is displayed.

[Help](#)

Communications between Plant SCADA processes, computers and CtAPI applications can be encrypted

Enable Encryption

Accept encrypted and non-encrypted connections (mixed mode)

*This mode is recommended only for online upgrades and/or supporting legacy CtAPI based applications*

**Encryption Prerequisites** [Refresh](#)

This computer must be registered with the System Management Server 

Runtime Manager must be configured to run as a service (not required for clients). 

3. Firstly, check that the **Encryption Prerequisites** have been met. If a red cross appears next to an item, you will need to make the required configuration changes before you can enable encryption.
  - To register the computer with the System Management Server, see [Connect a Computer to a System Management Server](#).
  - To configure Runtime Manager to run as a service, see [Configure a Runtime Computer for Encryption](#).
4. Select **Enable Encryption**.
5. If you are performing an online upgrade of Plant SCADA or running an older version of Citect SCADA, select **Accept encrypted and non-encrypted connections (mixed mode)**. Note that you can clear this option and configure your system to use encryption after the upgrade process is complete.
