The parentheses ( ) in the function name identify the statement as a function and enclose its arguments. Arguments are the values or variables that are passed into the function when it executes.

**Note:** Some functions, such as PageNext(), have no arguments. However you need to include the parentheses ( ) or Plant SCADA will not recognize that it is a function, and an error could result when the project is compiled.

## See Also

[Using Cicode Functions](#)

### Using String Arguments

Functions can require several arguments or, as in the following example, a single argument:

Command	PageDisplay("Boiler 1");
---------	--------------------------

This function displays the graphics page called "Boiler 1". Be aware that when you pass a string to a function, you need to always enclose the string in double quotes.

You can use the PageDisplay() function to display any graphics page in your system - in each case, only the argument changes. For example, the following command displays the graphics page "Boiler 2":

Command	PageDisplay("Boiler 2");
---------	--------------------------

You can use the Report() function to run a report (for example, the "Shift" report) when the command executes:

Command	Report("Shift");
---------	------------------

The following example uses the Prompt() function to display the message "Press F1 for Help" on the screen when the command executes:

Command	Prompt("Press F1 for Help");
---------	------------------------------

## See Also

[Using Cicode Functions](#)

## String Assignment

You can assign string variables in commands. For example, if BATCH\_NAME is a variable tag defined as a string data type, you can use the following command to set the tag to the value "Bread":

```
BATCH_NAME = "Bread";
```

**Note:** You need to enclose a string in double quotation marks ( " ).

## See Also

[Using Cicode Functions](#)

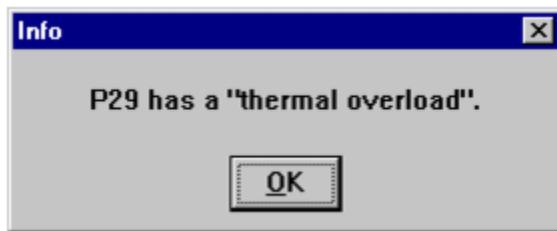

## Using the Caret Escape Sequence Character

The caret character ( ^ ) signifies a special instruction in Cicode, called an escape sequence, primarily used in the formatting of text strings. Escape sequences include formatting instructions such as new line, form feed, carriage return, backspace, horizontal and vertical tab-spaces, single and double quote characters, the caret character, and hexadecimal numbers.

Strings are commonly represented in Cicode between double quote characters ( " ) known as delimiters. If you want the string to contain a double quote character itself as part of the string, you need to precede the double quote character with the caret character ( ^" ) so that Cicode doesn't interpret the double quote in the string as the delimiter indicating the end of the string. The caret character is interpreted as a special instruction, and together with the characters immediately following it, are treated as an escape sequence instruction. See the section [Converting and Formatting Cicode Variables](#) for the list of escape sequences used in Cicode.

In the following Cicode example, both of these message functions will display the following message.

```
Message("Info", "P29 has a ^"thermal overload^".", 0);
sCurrentAlmText = "Thermal Overload";
Message("Info", "P29 has a ^""+sCurrentAlmText+"^".", 0);
```

## See Also

[Using Cicode Functions](#)

## Using Multiple Arguments

Some functions require several arguments. You need to list arguments between the parentheses, and separate each argument with a comma ( , ) as in the following example:

Command	Login("Manager", "ABC");
---------	--------------------------

The order of the arguments affects the operation of any function. The `Login()` function logs a user into your runtime system. The first argument ("Manager") indicates the name of the user, and the second argument ("ABC" ) is the user's password. If you reverse the order of the arguments, the function would attempt to login a user called "ABC" - if a user by this name does not exist, an error message displays.

## See Also

[Using Cicode Functions](#)

### Using Numeric Arguments

You can pass **numbers** (integers and floating point numbers) directly to a function, for example:

Command	AlarmAck(2, 35);
---------	------------------

## See Also

[Using Cicode Functions](#)

### Using Variable Arguments

When variables (such as real-time data) are used as arguments, the value of the variable is passed, not the variable itself. The following example uses the `DspStr()` function to display the value of a process variable at AN25:

Command	DspStr(25, "TextFont", B1_TIC_101_PV);
---------	--

In this instance, the **value** of `B1_TIC_101_PV` displays. If it is a real-time variable, the number that displays depends on its value at the time.

**Note:** If you use double quotes around variables, for example, "B1\_TIC\_101\_PV", the text string `B1_TIC_101_PV` displays, rather than the value of the variable.

## See Also

[Using Cicode Functions](#)

### Using Operator Input in Functions

You can pass operator input to functions at runtime. For example, you can define a System Keyboard Command to let the operator select a page:

Key Sequence	F10 ##### Enter
Command	PageDisplay(Arg1);

When the command executes, the page name is passed to the function as Arg1. The operator can then display any page, for example:

## See Also

[Using Cicode Functions](#)

### Returning Data from Functions

Functions return data to the calling statement (a command or expression). Some functions simply return a value that indicates whether the function was successful. For example, both the PageNext() and PageDisplay() functions return 0 (zero) if the page displays successfully, otherwise they return an error number. For a large number of simple applications, you can ignore this return value.

Some functions return data that you can use in an expression or command. For example, the Date() function returns the current date as a string. To display the current date on a graphics page, use the following expression in a text object display value property:

Numeric expression	Date();
--------------------	---------

The following example shows an entry command event for a graphics page, using a combination of two functions. The FullName() function returns the name of the user who is currently logged in to the run-time system, passing this name to the calling function, Prompt(). When the page is opened, a welcome message displays in the prompt line.

On page entry	Prompt("Hello, " + FullName())
---------------	--------------------------------

For example, if the current user is John Citizen, the message "Hello, John Citizen" displays.

### Referencing an Object Using a Name at Runtime

Use the Cicode functions [DspGetAnFromName](#), [DspGetMetadataFromName](#), [DspGetAnFromNameRelative](#) and [DspGetMetadataFromNameRelative](#) to reference objects on a page, in a genie, group and symbol.

It is important to keep the following points in mind when referencing objects:

- When referencing an object within a genie, group or symbol you need to use relative path syntax. This means you can search "up" or "down" the objects within the genie, symbol and/or group.
- The name is always relative to the object you are referencing from.
- If referencing an object within a group it will search only in the group the object belongs to.
- If referencing an object at the group level it will search for the object across the defined paths.

### Using the Syntax

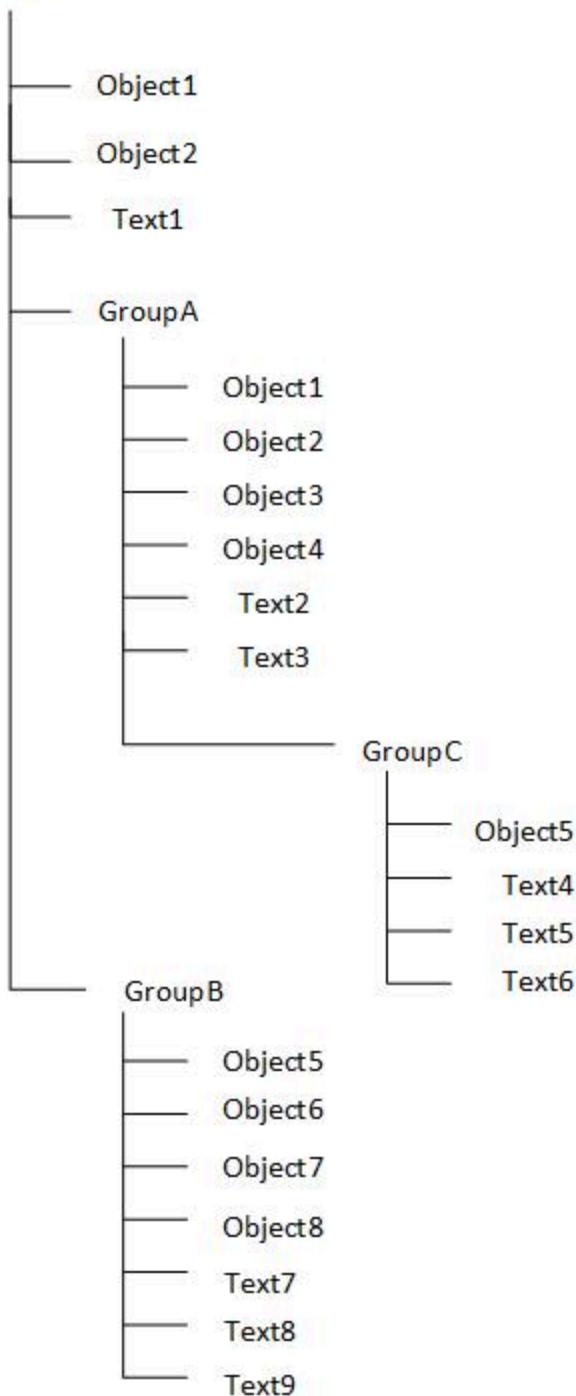

- "Name" – Used at page level. This is a fully qualified name.

- ".Name" - References itself, either in a group, genie or symbol.
- "..\Name" – References objects within a group.

## Examples

The diagram below includes objects and text on the page, and objects and text within groups A, B and C. A tree-view hierarchy has been used to illustrate how referencing can be applied.

## Page

Referenced Object	Syntax	Description
To reference "Object1" from Object2 at the root or page level	DspGetAnFromName("Object1")	Object1 is a fully qualified name. Searches at page level for this object.
To reference "Object1" from	DspGetMetadataFromName("Objec")	Object1 is a fully qualified name.

Referenced Object	Syntax	Description
Object2 at the root or page level.	t1","Pump")	Pump is the name of the metadata defined in Object1. Searches the page level for Object1 and the metadata name.
To reference "Object1" in GroupA from Object2 from the root level	DspGetAnFromName("GroupA.Object1")	"GroupA.Object2" is a fully qualified name. From the root (page) level search for Object1 within GroupA.
To reference "Object5" in GroupC from Object2 at the root level	DspGetAnFromName("GroupA.GroupC.Object5")	"GroupA.GroupC.Object5" is a fully qualified name. From the root (page)level search for Object5 within GroupC and GroupA.
To reference "Object1" in GroupA from Object4	DspGetAnFromName(".Object1")	".Object1". This means search for Object1 in the current group.
To reference "Object2" in GroupA from Object8 in Group B	DspGetAnFromName(..\..\GroupA.Object2")	"..\..\GroupA.Object2" Navigate two levels up the hierarchy, which will be root (page) level, and then search for GroupA and within Group A, Object2.
To reference "Object2" in GroupA from Text8 in Group B	DspGetAnFromNameRelative(639, "..\..\GroupA.Object2")	From AN 639 and "..\..\GroupA.Object2" navigate two levels up the hierarchy and search for Group A and within Group A, Object2. <b>Note:</b> 639 is the animation number for Text8 once pasted on the graphics page within GroupB.
To reference "Object2" in GroupA from Text8 in Group B	DspGetMetadataFromName(..\..\GroupA.Object2", "Meter")	"..\..\GroupA.Object2" Navigate two levels up the hierarchy which will be from the root (page)level, and then search for GroupA and within Group A, Object2, where the name of the metadata is "Meter".
To reference "Object1" at the root level from Object5 in GroupC	DspGetAnFromName(..\..\..\Object1")	"..\..\..\Object1" Navigate three levels up the hierarchy which will be from the root (page)level, and then search for Object1.
To reference "Object1" at the root level from Text5 in GroupC	DspGetMetadataFromNameRelative(625, "..\..\..\Object1", "Pump")	From AN 625 navigate three levels up and from the root level search for Object1 where the name of the

Referenced Object	Syntax	Description
		<p>metadata is Pump.</p> <p><b>Note:</b> 625 is the animation number for Text6 once pasted on the page within GroupC.</p>

**Note:** When referencing from an object within a group, only those objects in the group the object belongs to will be searched. For example: If you reference Object1 in Group A from Object7 in GroupB using the syntax "..\Object1", an error will be returned, as no Object1 exists in GroupB. The correct syntax to use is "..\..\GroupA.Object1".

---

## Working with Commonly Used Functions

Cicode has many functions that perform a variety of tasks. Many of these are used for building complex Plant SCADA systems. The functions you will often use are divided into six categories:

### Alarm Functions

You can use alarm functions to display alarms and their related alarm help pages, and to acknowledge, disable, and enable alarms. You can assign a privilege to each command that uses an alarm function, so that only an operator with the appropriate privilege can perform these commands. However, you should assign privileges to commands only if you have not assigned privileges to individual alarms.

- [AlarmAck](#): Acknowledges an alarm. The alarm where the cursor is positioned (when the command is executed) is acknowledged. You can also use this function to acknowledge multiple alarms.
- [AlarmComment](#): Adds a comment to the alarm summary entry at run time. The comment is added to the alarm where the cursor is positioned when the command is executed. A keyboard argument passes the comment into the function. Verify that the length of the comment does not exceed the length of the argument, or an error results.
- [AlarmDisable](#): Disables an alarm. The alarm where the cursor is positioned (when the command is executed) is disabled. You can also use this function to disable multiple alarms.
- [AlarmEnable](#): Enables an alarm. The alarm where the cursor is positioned (when the command is executed) is enabled. You can also use this function to enable multiple alarms.
- [AlarmHelp](#): Displays an alarm help page for the alarm. Each alarm in your system can have an associated help page. The help page for the alarm at the position of the cursor (when the command is executed) is displayed.

### Page Functions

With the page functions, you can display your graphics pages and the standard alarm pages.

---

**Note:** The following page functions are not supported in the server process in a multiprocessor environment. Calling page functions from the server process results in a hardware alarm being raised.

---

- [PageAlarm](#): Displays current alarms on the alarm page configured in the project.
- [PageDisabled](#): Displays disabled alarms on the alarm page configured in the project.

- **PageDisplay:** Displays a new page on the screen. The Page name or number is required as an argument. (Use the PageLast() function to go back to the last page - the page that this new page replaced).
- **PageFile:** Displays a file on the file page configured in the project.
- **PageGoto:** Displays a new page on the screen. This function is similar to the PageDisplay() function, except that if PageLast() is called, it does not return to the last page.
- **PageHardware:** Displays hardware alarms on the alarm page configured in the project.
- **PageLast:** Displays the graphics page that was displayed before the current one. You can use this function to 'step back' through the last ten pages.
- **PageNext:** Displays the next graphics page (defined in the Next Page property of the Pages form).
- **PagePrev:** Displays the previous graphics page (defined in the Prev Page property of the Pages form).
- **PageSOE:** Displays a category of sequence of events (SOE) entries on the SOE page.
- **PageSummary:** Displays summary alarm information on the alarm page configured in the project.
- **PageTrend:** Displays a standard trend page.

## Keyboard Functions

Keyboard functions control the processing of keyboard entries and the movement of the keyboard cursor on the graphics page.

- **KeyBs:** Backspaces (removes) the last key from the key command line. Use this function with a 'Hotkey' command. It is normally used to erase keyboard characters during runtime command input.
- **KeyDown:** Moves the cursor down the page to the closest animation point number (AN).
- **KeyLeft:** Moves the cursor left (across the page) to the closest animation point number (AN).
- **KeyRight:** Moves the cursor right (across the page) to the closest animation point number (AN).
- **KeyUp:** Moves the cursor up the page to the closest animation point number (AN).

## Report Functions

To run a report by operator action, use the following function:

- **Report:** Runs the report on the report server.

## Time/date Functions

The following functions return the current date and time:

- **Date:** Returns the current date as a string.
- **Time:** Returns the current time as a string.

## Miscellaneous Functions

- **Beep:** Beeps the speaker on the Plant SCADA computer.
- **FullName:** Returns the full name of the user who is currently logged in to the system.

- InfoForm: Displays the animation information form. This form displays the real-time data that is controlling the current animation.
- Login: Allows a user access to the Plant SCADA system.
- LoginForm: Displays a dialog box to allow a user to log in to the system.
- Logout: Logs the current user out of the Plant SCADA system.
- Name: Returns the user name of the user who is currently logged in to the system.
- Prompt: Displays a message on the screen. The message **String** is supplied as an argument to the function.
- Shutdown: Terminates Plant SCADA. Use this function, or the ShutdownForm() function, to shut down your system. Otherwise buffered data may be lost.
- ShutdownForm: Displays a dialog box to allow a user to shut down your Plant SCADA system.

[Cicode Function Categories](#)

[Using Cicode Functions](#)

## Writing Functions

Plant SCADA is supplied with over 600 built-in functions. One of these functions (or several functions in combination) can usually perform the required tasks in your system. However, where system functionality cannot be achieved with built-in functions, you can write your own functions.

A Cicode function is a small program: a collection of statements, variables, operators, conditional executors, and other functions.

While it is not necessary to be an experienced programmer to write simple Cicode functions, it is strongly recommended not to attempt to write large, complex functions unless you are familiar with computer programming, and have experience with Cicode. Functions are equivalent to the subroutines of BASIC and assembly language, and the subroutines and functions used in Pascal and C.

Cicode functions can have many purposes. Quite often, functions are used to store a common set of commands or statements that would otherwise require repetitious typing and messy command or expression fields.

Some functions are simple, created to avoid a long command or expression. For example, the following command increments the variable tag COUNTER:

<b>Command</b>	IF COUNTER < 100 THEN COUNTER = COUNTER + 1; ELSE COUNTER = 0; END;
----------------	--

This command would be easier to use (and re-use) if it was written as a function that can be called in the command:

<b>Command</b>	IncCounter ( );
----------------	-----------------

To be able to use the function like this, you need to write it in a Cicode file, and declare it with the FUNCTION keyword:

```
FUNCTION
IncCounter ( )
IF COUNTER < 100 THEN
COUNTER = COUNTER + 1;
```

```
ELSE
COUNTER = 0;
END
END
```

Be aware that the indented code is identical in functionality to the long command above.

By placing the command code inside a function, and using the function name in the command field as in the previous example, this function need only to be typed once. It can then be called any number of times, from anywhere in Plant SCADA that requires this functionality. Because the code exists in the one location, rather than repeated wherever needed (in potentially many places), it can be easily maintained (altered if necessary).

**Note:** This is designed specifically for editing and debugging Cicode functions.

## See Also

[Cicode Function Structure](#)

[Using Cicode Files](#)

## Cicode Function Structure

A function in Cicode can be described as a collection or list of sequential statements that Plant SCADA can perform (execute) in the logical order that they exist within the function.

A Cicode function starts with the FUNCTION statement and finishes with the END statement. Every statement that lies between the FUNCTION and END statements, will be executed by the function, when called to do so.

A typical Cicode function is structured like the following example:

```
FUNCTION
FunctionName ( )
    ! The exclamation point indicates that the rest of this line contains a comment.
    ! Further Cicode statements go here, between the function name and the END.
END
```

The line immediately following the FUNCTION statement, contains the name of the function, which is used to identify the function to Plant SCADA. This name is referred to when the function is called upon (called) to be executed (perform the statements it contains) by some other event, action, or function in Plant SCADA.

**Note:** Functions can contain statements that call other functions. These functions are then executed before returning to the rest of the statements within the calling function.

The function name has to end with parentheses ( ), which may or may not contain one or more arguments required by the function. Arguments are explained in the section titled [Function Argument Structure](#).

Every line between the function name line and the END statement line contain the statements that will be executed when the function is called in Plant SCADA. These statements are executed one at a time in logical order from top to bottom within the function. For details about function structure, see [Formatting Functions](#). For details about Cicode function syntax, see [Following Cicode Syntax](#).

For details about using comments in Cicode and in Cicode functions, see [Using Comments in Cicode](#).

## See Also

[Writing Functions](#)

## Writing Groups of Functions

To perform complex tasks you need careful design. Large, complex functions are not only more difficult to understand and debug than simple functions, but they can also hide tasks that are common to other activities.

Cicode functions allow a modular approach - complex tasks can be organized into small functions, each with a single, clear purpose. These small functions can then be called by other functions, or called directly in commands and expressions. In fact, any function can call - and be called by - any other function.

For example, you might need to write a set of functions for handling alarms. To perform any action on an alarm, you first need to know which alarm. You would identify the alarm in a separate function, and call this function from the other functions.

## See Also

[Writing Functions](#)

## Cicode Function Libraries

Cicode functions are stored within Cicode files. You can use a separate file for each stand-alone function, or group several functions together into a common file. For easy maintenance, store functions that perform related tasks in the same file - for example, store functions that act on alarm data in an **Alarms.CI** file.

---

**Note:** Every Cicode file in your project directory will be included when you compile your project.

---

## See Also

[Writing Functions](#)

## Creating a Function Outline

First, define the purpose of the function group, and create an outline of the tasks to be performed. The following example shows an outline for a group of functions that change the threshold values of analog alarms during runtime. The outline describes the workings of the function group, and is written in **pseudocode** (also called Program Design Language).

```
/*
This file contains functions to allow the operator to make runtime
changes to Analog Alarm thresholds.
This file has 4 functions. The master function calls the other
functions.
ChangeAnalogAlarmThresholds ( )
This calls in turn:
1:GetVariableTag ( )
Argument: cursor position
Displays threshold values in prompt line
Return: success or error code
*/
```

## See Also

[Writing Functions](#)

## Pseudocode

Pseudocode is a Cicode comment, enclosed between the comment markers /\* and \*/, and is ignored by the compiler. With pseudocode, you can get the logic of the function correct in a more readable structure, before you write it in Cicode syntax, leaving the pseudocode within the finished code as comments.

It is good practice to use comments as file headers at the start of each Cicode file, to describe the functions in the file - their common purpose, a broad description of how they achieve that purpose, special conditions for using them, and so on. You can also use the header to record maintenance details on the file, such as its version number and date of revision. For example:

```
/*
** FILE: Recipe Download.Ci
**
** AUTHOR: AJ Smith
**
** DATE: March 2008
**
** REVISION: 1.0 for Plant SCADA v7.1
**
** This file contains functions to allow the operator to load the
** recipe data from the SQL server to the PLC.
*/
```

Following the file header are the functions in series:

```
/*
** Main function
*/
FUNCTION
RecipeDownload ( )
! {body of function}
!
END
/*
** Function to open the SQL connection.
*/
FUNCTION
RecipeConnectSQL ( )
! {body of function}
!
END
! (and so on)
```

[Writing Functions](#)

## Considering Tag Value Quality in Cicode

When using tag values in Cicode, it is important to consider the quality of the tag and how it is determined. Just as the quality of a displayed value should be presented to a client user, the quality of a value also needs to be reflected in Cicode calculations.

For example, the type of driver used to communicate with an I/O device will greatly impact how tag value quality is determined.

- Tags from traditional drivers may be set to a bad quality when the I/O device is not contactable (or for other errors in the driver commands).
- Tags from devices using the Driver Runtime Interface (DRI) can have their quality set individually and could be set to a bad quality for reasons specific to an I/O point.

For more information on DRI-based drivers, see [Retrieving Time-stamped Data from I/O Devices](#).

Best practice is to treat quality handling like error handling, and code for scenarios where it is required.

## I/O Quality

The quality of a tag value is essentially propagated from the quality of the I/O point from which it is sourced.

- In traditional protocols, such as Modbus, quality is driven by a single error code provided in a command response or by the field device being offline. This type of protocol does not provide the ability to nominate a quality for individual I/O points. This still holds true for Modbus over TCP as well (as used by the Plant SCADA's MODNET driver).

As the response error codes are typically a result of an invalid request, these types of issues are normally addressed in commissioning and are usually not encountered during operation. However, it is still possible to lose contact with a field device at any time which will result in all tags related to that device going into bad quality.

- In more advanced protocols, such as OPC, quality is independently applied to each specific I/O point. To accommodate this, and to also cater for other advanced functionality such as unsolicited responses from the field, a newer generation of Plant SCADA drivers was developed to use the Driver Runtime Interface (DRI).

When a DRI driver is notified from the field of an update (value, quality and timestamp), this is immediately reflected in the corresponding tag. An example of a change in quality due to operational issues could be a faulty sensor. This increases the chances of a tag not being in good quality and the need for this scenario to be covered when using tag values in Cicode.

A traditional driver uses a chained sequence of request/response transactions that result in a tag update waiting on the reply back from a field device. As an I/O device is only marked online when the corresponding field device can be contacted, reverting from standby back to primary will never result in intermediate bad quality values from the switch.

However, a DRI driver uses a chained sequence of subscribe/publish transactions allowing the driver to update a tag at any time. When reverting from standby to a primary that has just returned online, it will be up to the driver to immediately provide tag updates for a new subscription without waiting to receive values from the field. If so, these values will be marked with a quality to indicate as such and will be followed by a good quality update when the field value is received.

If the driver is receiving updates from an interim gateway style device, such as an OPC Server, it will also be able

to provide similar updates.

## Implications for Cicode

Your Cicode should handle values that are not good quality in the same way it handles other error cases.

Tag extensions can be used to select the quality component of a tag (for example, TagA.Q), and this can then be checked using the [QualityGetPart](#) Cicode function.

If the quality of a tag needs to be referenced multiple times in a Cicode function, it is best practice to assign it to a variable when first required and then keep using that variable. When a tag is assigned to a Cicode variable (for example, var = TagA), that variable will also take the quality of the tag.

Further, the quality will continue to propagate through to any additional variables that are assigned an expression containing the first variable. The quality component of these variables can be extracted using the [VariableQuality](#) Cicode function, and checked using [QualityGetPart](#) as described above.

Note, however, that if a Cicode variable is assigned the value extension of a tag (for example, var = TagA.V), then the variable will always have good quality.

## Examples

### Example 1

Your Cicode needs to handle the possibility of a tag update occurring after it has determined the quality of a tag. If quality changes due to a tag update, your Cicode may proceed using an altered quality value. This can occur because of the way the Cicode execution system operates in a multi-thread environment.

This could even happen when the tag quality check and tag usage are on the same line, for example:

```
IF QualityIsGood(MyTag.Q) AND MyTag > 100 THEN
```

The easiest way to avoid this is to only use the tag when assigning to a Cicode variable, and only use the Cicode variable from then on.

In the case of the example above, a better approach would be to assign "MyTag" to a local tag at the start of the function and use this instead.

```
Int localMyTag
IF QualityIsGood(VariableQuality(localMyTag) AND localMyTag > 100 THEN
```

```
// Following example calculates flow rate based on a PLC tag 'MyDiffPress'
// and then writes value to a memory mode Disk PLC tag 'MyFlowRate'
// Returns 1 for error when BQ on the PLC tag and forces MyFlowRate to Override mode.
INT
FUNCTION
UpdateMyFlowRate()

    INT FlowFactor = 5;
    INT SpecificGravity = 1;
    //Copy the variable tag MyDiffPress to a local variable
    INT DiffPress = MyDiffPress;
    INT FlowRate = 0;
    INT Error = 0;

    IF QualityIsGood(VariableQuality(DiffPress)) THEN
        //Do this instead of using QualityIsGood(VariableQuality(MyDiffPress))
```

```
FlowRate = FlowFactor * Sqrt(DiffPress/SpecificGravity);
MyFlowRate.OverrideMode = 0;
MyFlowRate = FlowRate;
ELSE
    Error = 1;
    MyFlowRate = 0;
    MyFlowRate.OverrideMode = 4;
END
RETURN Error;
END
```

### Example 2

The following example checks the threshold of a tag value.

```
INT
FUNCTION
IsThresholdExceeded(STRING Tag1, INT Threshold)
    INT exceeded = FALSE;
    INT myVar1 = TagReadEx(MyTag1);

    IF QualityIsGood(VariableQuality(myVar1) AND myVar1 > Threshold THEN exceeded = TRUE;
    END
    RETURN exceeded;
END
```

### Example 3

The following example logs tag values to a file.

```
FUNCTION
LogMyValue(STRING MyTag)
    INT myVar1 = TagReadEx(MyTag);
    IF QualityIsGood(VariableQuality(myVar) THEN
        LogToMyFile(MyTag + " : " + IntToStr(MyTag));
    ELSE
        LogToMyFile(MyTag + " : "No Value");
    END
END
```

## Using Comments in Cicode

It is good programming practice to include comments in your Cicode files. Comments allow you to quickly understand how a function works next time you (or another designer) need to modify it.

The Cicode compiler recognizes the following single line, C style, and C++ style comments:

```
! A single line comment
WHILE DevNext ( hDev ) DO
Counter = Counter + 1 ; ! An in-line comment
END
/* A block comment is a C-style comment, and can
extend over several lines. Block comments need to
finish with a delimiter, but delimiters at the
start of each line are optional only. */
// A double-slash comment is a C++ style comment, for example:
Variable = 42; // This is a comment
```

Single line ( ! ) and C++ style ( // ) comments can have a line of their own, where they refer to the block of statements either before or after it. It is good practice to set a convention for these comments. These comments can also be on the same line as a statement, to explain that statement only. Any characters after the ! or // (until the end of the line) are ignored by the compiler.

Block (C style) comments begin with /\* and end with \*/. These C style comments need no punctuation between the delimiters.

## See Also

[Writing Functions](#)

### Using Comments for Debugging Functions

You can use comments to help with the debugging of your functions. You can use comments to temporarily have the compiler ignore blocks of statements by changing them to comments. C style and C++ style comments can be nested, for example.

```
FUNCTION
IncCounter ( )
IF COUNTER < 100 THEN
COUNTER = COUNTER + 1 ;
/* ELSE // Comment about statement
COUNTER = 0; // Another comment
*/
END
END
```

The complete ELSE condition of the IF conditional executor will be ignored (and not execute) so long as the block comment markers are used in this example.

---

**Note:** The inline ( // ) comments have no effect within the block ( /\* and \*/ ) comments (as the whole section is now one big comment), and should remain unchanged, so that when you do remove the block comments, the inline comments will become effective again.

---

### Tag Reference/TagReadEx Behavior in Cicode Expressions

The following table describes the tag reference and TagReadEx behavior in a Cicode expression if the quality of the tag is BAD:

Tag Reference / TagReadEx syntax	Error Mode/Citect.ini settings	Cicode Expression behavior
"Tag1"	ErrSet(0) [Code]HaltOnInvalidTagData = 0	Tag ref returns a BAD quality value, Cicode expression continues, Error is set.
TagReadEx("Tag1")	ErrSet(0) [Code]HaltOnError = 0	Function returns a BAD quality value, Cicode expression continues,

Tag Reference / TagReadEx syntax	Error Mode/Citect.ini settings	Cicode Expression behavior
		Error is set.
"Tag1"	ErrSet(0) [Code]HaltOnInvalidTagData = 1	Tag ref returns a BAD quality value, Cicode expression stops.
TagReadEx("Tag1")	ErrSet(0) [Code]HaltOnError = 1	Function returns a BAD quality value, Cicode expression stops.
"Tag1"	ErrSet(1)	Tag ref returns a BAD quality value, Cicode expression continues, Error is set.
TagReadEx("Tag1")	ErrSet(1)	Function returns a BAD quality value, Cicode expression continues, Error is set .
"Tag1.V"	ErrSet(0) or ErrSet(1)	Tag ref returns a GOOD quality value, Cicode expression continues, No error is set.
TagReadEx("Tag1.V")	ErrSet(0) or ErrSet(1)	Function returns a GOOD quality value, Cicode expression continues, No error is set.

[Tag Functions](#)

## Following Cicode Syntax

Some programming languages have strict rules about how the code needs to be formatted, including the indenting and positioning of the code structure. Cicode has no indenting or positioning requirements, allowing you to design your own format - provided only that you follow the correct syntax order for each statement (see [Cicode Function Syntax](#)). However, it is a good idea to be consistent with your programming structure and layout, so that it can be easily read and understood.

For details about programming standards, see the section titled [Using Cicode Programming Standards](#), which includes sections on:

- Standards for constants, variable tags, and labels
- Standards variables: declaration, scope, and naming
- Standards for functions: naming , file headers, headers
- Formatting of: declarations, statements, expressions, and functions
- Use of comments

For information on problem solving, see the sections on [Modular Programming](#), [Defensive Programming](#), [Function Error Handling](#), or [Debugging Cicode](#).

The following is an example of a simple Cicode function:

```
/*
This function is called from a keyboard command. The operator
presses the key and enters the name of the page to be displayed. If
the page cannot be displayed, an error message is displayed at the
prompt AN.
*/
INT
FUNCTION
MyPageDisplay ( STRING sPage ) ! pass in the name of the page to be displayed
! declare a local integer to hold the results of the pagedisplay function
INT Status;
! call the page Cicode pagedisplay function and store the result
Status = PageDisplay ( sPage ) ;
! determine if the page display was successful
IF Status < > 0 THEN ! error was detected
! display an error message at the prompt AN
DspError ( "Cannot Display " + sPage ) ;
END
! return the status to the caller
RETURN Status;
END
```

The rules for formatting statements in Cicode functions are simple, and help the compiler in interpreting your code.

It is good practice to use white space to make your code more readable. In the example above, the code between the FUNCTION and END statements is indented, and the statement within the IF THEN conditional executor is further indented to make the conditions and actions clear. Develop a pattern of indentation - and stick to it. Extra blank lines in the code make it easier to read (and understand).

[Writing Functions](#)

## Cicode Function Syntax

In the following function syntax example:

- Every placeholder shown inside arrow brackets ( <placeholder> ) should be replaced in any actual code with the value of the item that it describes. The arrow brackets and the word they contain should not be included in the statement, and are shown here only for your information.
- Statements shown between square brackets ( [ ] ) are optional. The square brackets should not be included in the statement, and are shown here only for your information.

Cicode functions have the following syntax:

```
[ <Scope> ]
[ <ReturnDataType> ]
FUNCTION
<FunctionName> ( <Arguments> )
```

```
<Statement> ;
<Statement> ;
<Statement> ;
RETURN <ReturnValue> ;
END
```

Where:

- <Scope> = Scope Statement: optional, PRIVATE or PUBLIC, default PUBLIC, no semicolon. See the section titled [Function Scope](#).
- <ReturnDataType> = Return Data Type Statement: optional and one of INT, REAL, STRING, OBJECT, QUALITY, or TIMESTAMP. No default, no semicolon. If no return type is declared, the function cannot return any data. See the section titled [Declaring the Return Data Type](#).
- FUNCTION = FUNCTION Statement: required, indicates the start of the function, [Restricted Cicode Keywords](#), no semicolon. See the section titled [Declaring Functions](#).
- <FunctionName> = Name statement: required, up to 32 ASCII text characters, case insensitive, no spaces, no reserved words, no default, no semicolon. See the section titled [Naming Functions](#).
- ( <Arguments> ) = Argument statement: surrounding brackets required even if no arguments used, if more than one argument - each need to be separated by a comma, can contain constants or variables of INT or REAL or STRING or QUALITY or TIMESTAMP data type, default can be defined in declaration, can be spread over several lines to aid readability, no semicolon. See the section titled .
- <Statement> = Executable Statement: required, one or more executable statements that perform some action in Plant SCADA, often used to manipulate data passed into the function as arguments, semicolon required.
- RETURN = Return Statement: optional, used to instruct Cicode to stop executing the function and return to the calling function, keyword, no semicolon. If a ReturnDataType was specified then the Return Statement should include a ReturnValue.
- <ReturnValue> = Return Value Statement; required if RETURN Statement used in function, need to be either a constant or a variable, the data type need to have been previously declared in the function Return Data Type Statement - or does not return a value, semicolon required. See the section titled [Returning Values from Functions](#).
- END = END Statement: required, indicates the end of the function, keyword, no semicolon. See the section titled [Declaring Functions](#).

## See Also

[End of Line Markers](#)

[Following Cicode Syntax](#)

[Writing Functions](#)

## End of Line Markers

Most statements within the function are separated by semicolons ( ; ) but some exceptions exist. The FUNCTION and END Statements (the start and end of the function) have no semicolons, nor does the Scope or Return Data Type Statements, nor any statement that ends with a [Restricted Cicode Keywords](#).

Where a statement is split over several lines (for example, within the IF THEN conditional executor), each line ends with a semicolon - unless it ends in a reserved word.

## See Also

[Writing Functions](#)

## Function Scope

The optional Scope Statement of a function (if used), precedes all other statements of a function declaration in Cicode, including the FUNCTION Statement.

The scope of a function can be either PRIVATE or PUBLIC, and is declared public by default. That is, if no Scope Statement is declared, the function will have public scope.

Both PRIVATE and PUBLIC are Cicode keywords and as such, are reserved.

A private scope function is only accessible (can be called) within the file in which it is declared. You call a private function using the Cicode functions [TaskNew](#), [TaskNewEx](#) and [TaskCall](#).

Public scope functions can be shared across Cicode files, and can be called from pages and Plant SCADA databases (for example, Alarm.dbf).

Because functions are public by default, to make a function public requires no specific declaration. To make a function private however, you need to prefix the FUNCTION Statement with the word **PRIVATE**.

```
PRIVATE
FUNCTION
FunctionName ( <Arguments> )
<Statement> ;
<Statement> ;
<Statement> ;
END
```

## See Also

[Writing Functions](#)

## Declaring the Return Data Type

For information about the RETURN Statement, see the section titled [Returning Values from Functions](#).

The optional Return Data Type Statement of a function (if used), follows the optional Scope Statement (if used), and precedes the FUNCTION Statement declaration in Cicode.

The return data type of a function can be only one of six possible data types: INT (32 bits), REAL (64 bits), STRING (255 bytes), OBJECT (32 bits), QUALITY or TIMESTAMP (64 bits). If no Return Data Type Statement is declared, the function will not be able to return any type of data.

INT, REAL, STRING, OBJECT, QUALITY and TIMESTAMP are Cicode keywords and as such, are reserved.

---

**Note:** In the following function syntax example, every placeholder shown inside arrow brackets (`<placeholder>`) should be replaced in the actual code with the value of the item that it describes. The arrow brackets and the word they contain should not be included in the statement, and are shown only for your information.

To declare the data type that will be returned to the calling code, prefix the FUNCTION Statement with one of the Cicode data type keywords, in the `<ReturnDataType>` placeholder in the following example.

```
<ReturnDataType>
FUNCTION
```

```
FunctionName ( <Arguments> )
<Statement> ;
<Statement> ;
<Statement> ;
END
```

The following example returns an integer of value 5:

```
INT
FUNCTION
FunctionName ( <Arguments> )
<Statement> ;
INT Status = 5;
<Statement> ;
RETURN Status;
END
```

If the RETURN Statement within the function encounters a different data type to that declared in the return data type statement, the value is converted to the declared return data type.

In the example below, the variable Status is declared as a real number within the function. However, Status is converted to an integer when it is returned to the caller, because the data type of the return was declared as an integer type in the return data type statement:

```
INT ! declare return value as integer
FUNCTION
FunctionName ( <Arguments> )
<Statement> ;
REAL Status = 5; ! declare variable as a REAL number
<Statement> ;
RETURN Status; ! returned as an integer number
END
```

If you omit the return data type, the function does not return a value.

## See Also

[Writing Functions](#)

## Declaring Functions

The required FUNCTION Statement follows the optional Scope Statement (if used) and the optional Return Data Type Statement (if used), and precedes any other statements of a function declaration in Cicode. Everything between it and the END Statement, contains the function.

Both FUNCTION and END are Cicode keywords and, as such, are reserved.

You declare the start of a function with the FUNCTION Statement, and declare the end of a function with the END Statement:

```
FUNCTION
<FunctionName> ( <Arguments> )
<Statement> ;
<Statement> ;
<Statement> ;
END
```

The FUNCTION Statement needs to be followed by the Name Statement, then the Argument Statement, before any code statements that will be processed by the function.

For information on the Name and Argument Statements, see the sections titled [Naming Arguments and Function Argument Structure](#).

The code (as represented by the <Statement> placeholders) located between the FUNCTION and END Statements, will be executed (processed by the function) when called to do so.

Functions can execute a large variety of statements, and are commonly used to process and manipulate data, including the arguments passed when the function was called, plant-floor and other Plant SCADA data, Windows data, and so on. Plant SCADA provides many built-in functions. For more information, see the section titled [Working with Commonly Used Functions](#).

## See Also

[Writing Functions](#)

### Naming Functions

The required name statement follows the FUNCTION Statement and precedes the arguments statement in a Plant SCADA function. The function name is used elsewhere in Plant SCADA to activate (call) the function to have it perform the statements it contains.

Replace the <FunctionName> placeholder in the following function example with an appropriate name for your function. See the section [Function Naming Standards](#) for details.

```
FUNCTION
<FunctionName> ( <Arguments> )
<Statement> ;
<Statement> ;
<Statement> ;
END
```

You can use up to 32 ASCII text characters to name your functions. You can use any valid name except for a [Restricted Cicode Keywords](#). The case is ignored by the Plant SCADA compiler, so you can use upper and lower case to make your names clear. For example, MixerRoomPageDisplay is easier to read than mixerroompagedisplay or MIXERROOMPAGEDISPLAY.

```
FUNCTION
MixerRoomPageDisplay ( <Arguments> )
<Statement> ;
<Statement> ;
<Statement> ;
END
```

Your functions take precedence over any other entity in Plant SCADA with the same name:

- **Variable tags.** When you call a function by the same name as a variable tag, the function has precedence. The variable tag can not be referred to because the function executes each time the name is used.
- **Built-in functions.** You can give your function the same name as any built-in Cicode function. Your function takes precedence over the built-in function - the built-in function cannot be called. Because built-in Cicode functions cannot be changed, this provides a method of 'modifying' any built-in function to suit an application. For example, you might want to display the message "Press F1 for Help" whenever you display a page. You could simply write a new function called PageDisplay(). The body of the function would be the statements that display the page and prompt message:

```
Prompt ( "Press F1 for Help" ) ;PageDisplay ( <Arguments> ) ;
```

Your function is invoked whenever you use the function name in Plant SCADA.

## See Also

[Writing Functions](#)

### Function Argument Structure

The optional Arguments Statement follows the required FUNCTION Statement and precedes the executable statements of a function in Cicode.

**Note:** The maximum number of arguments you can have in a function is 128.

When you call a function, you can pass one or more arguments to the function, enclosed within the parentheses () located after the function name statement. Replace the <Arguments> placeholder in the following function example with your Argument Statement.

```
FUNCTION
FunctionName ( <Arguments> )
<Statement> ;
<Statement> ;
<Statement> ;
END
```

For your function to perform tasks with data, it requires accessibility to the data. One way to achieve this, is to pass the data directly to the function when the function is being called. To enable this facility, Cicode utilizes arguments in its function structure. An argument in Cicode is simply a variable that exists in memory only as long as its function is processing data, so the scope of an argument is limited to be local only to the function.

Arguments cannot be arrays.

Arguments are variables that are processed within the body of the function only. You cannot use an argument outside of the function that declares it.

As arguments are variables used solely within functions, they needs to be declared just as you would otherwise declare a variable in Cicode. See the section titled [Declaring Variable Properties](#). An argument declaration requires a data type, a unique name, and may contain an initial value which also behaves as the default value for the argument.

---

**Note:**

In the following function syntax example:

- Every placeholder shown inside arrow brackets ( <placeholder> ) should be replaced in any actual code with the value of the item that it describes. The arrow brackets and the word they contain should not be included in the statement, and are shown here only for your information.
- Statements shown between square brackets ( [ ] ) are optional. The square brackets should not be included in the statement, and are shown here only for your information.

Cicode function argument statements have the following syntax:

```
<ArgumentDataType>
<ArgumentName>
[ = <InitialDefaultValue> ]
```

Where:

- <ArgumentDataType> = Argument Data Type Statement: required, INT, REAL, STRING, OBJECT, QUALITY, or TIMESTAMP. See the section titled [Declaring Argument Data Type](#).

- <ArgumentName> = Argument Name Statement: required, up to 32 ASCII text characters, case insensitive, no spaces, no reserved words. See the section titled [Naming Arguments](#).
- <InitialDefaultValue> = Argument Initialization Statement: optional, preceded by equals (=) assignment operator, a value to assign to the argument variable when first initialized, needs to be the same data type as that declared in the argument <ArgumentDataType> parameter, defaults to this value if no value passed in for this argument when the function was called.

See the section titled [Setting Default Values for Arguments](#).

The Argument Statement in a Cicode function can have only one set of surrounding parentheses ( ), even if no arguments are declared in the function.

If more than one argument is used in the function, each needs to also be separated by a comma.

Argument Statements can be separated over several lines to aid in their readability.

When you call a function, the arguments you pass to it are used within the function to produce a resultant action or return a value. For information on passing data to functions, see the section titled [Passing Data to Functions \(Arguments\)](#). For information on returning results from functions, see the section titled [Returning Data from Functions](#).

Arguments are used in the function and referred to by their names. For instance, if we name a function AddTwoIntegers, and declare two integers as arguments naming them FirstInteger and SecondInteger respectively, we would end up with a sample function that looks like the following:

```
INT
FUNCTION
AddTwoIntegers ( INT FirstInteger, INT SecondInteger )
INT Solution ;
Solution = FirstInteger + SecondInteger ;
RETURN Solution ;
END
```

In this example, the function would accept any two integer values as its arguments, add them together, and return them to the caller as one integer value equal to the summed total of the arguments values passed into the function.

This functionality of passing values into a function as arguments, manipulating the values in some way, then being able to return the resultant value, is what makes functions potentially very powerful and time saving. The code only needs to be written once in the function, and can be utilized any number of times from any number of locations in Plant SCADA.

## See Also

[Writing Functions](#)

## Declaring Argument Data Type

If an argument is listed in a Cicode function declaration, the Argument Data Type Statement is required, and is listed first before the required Argument Name Statement and the optional Argument Initialisation Statement.

The argument data type of a function can be only one of six possible data types:INT (32 bits), REAL (64 bits), STRING (255 bytes), OBJECT (32 bits), QUALITY (64 bits) or TIMESTAMP (64 bits).

INT, REAL, STRING, OBJECT, QUALITY and TIMESTAMP are Cicode keywords and as such, are reserved.

---

**Note:** In the following function syntax example:

- 
- Every placeholder shown inside arrow brackets (**<placeholder>**) should be replaced in any actual code with the value of the item that it describes. The arrow brackets and the word they contain should not be included in the statement, and are shown here only for your information.
  - Statements shown between square brackets ([ ]) are optional. The square brackets should not be included in the statement, and are shown here only for your information.
- 

To declare the argument data type that will be used in the function, you need to prefix the Argument Name Statement with one of the Cicode data type keywords, in the **<ArgumentDataType>** placeholder in the following example.

```
FUNCTION
FunctionName ( <ArgumentDataType> <ArgumentName> [ =
<InitialDefaultValue> ] )
<Statement> ;
<Statement> ;
<Statement> ;
END
```

The Argument Statement in a Cicode function needs to have only one set of surrounding parentheses () brackets, even if no arguments are declared in the function.

If more than one argument is used in the function, each needs to also be separated by a comma.

Argument Statements can be separated over several lines to aid in their readability.

## See Also

[Writing Functions](#)

## Naming Arguments

If an argument is listed in a Cicode function declaration, the Argument Name Statement is required, and is listed second, after the required Argument Data Type Statement, and before the optional Argument Initialization Statement.

The argument name is used only within the function to refer to the argument value that was passed into the function when the function was called. The name of the argument variable should be used in the executable statements of the function in every place where you want the argument variable to be used by the statement.

---

**Note:** In the following function syntax example:

- Every placeholder shown inside arrow brackets (**<placeholder>**) should be replaced in any actual code with the value of the item that it describes. The arrow brackets and the word they contain should not be included in the statement, and are shown here only for your information.
  - Statements shown between square brackets ([ ]) are optional. The square brackets should not be included in the statement, and are shown here only for your information.
- 

Replace the **<ArgumentName>** placeholder in the following function example with an appropriate name for your Argument variable. See the section titled [Function Argument Structure](#) for details.

```
FUNCTION
FunctionName ( <ArgumentDataType> <ArgumentName> [ = <InitialDefaultValue> ] )
<Statement> ;
<Statement> ;
<Statement> ;
END
```

You can use up to 32 ASCII text characters to name your arguments. You can use any valid name except for a

**Restricted Cicode Keywords.** The case is ignored by the Plant SCADA compiler, so you can use upper and lower case to make your names clear. For example, iPacketQty is easier to read than ipacketqty or IPACKETQNTY.

```
FUNCTION
FunctionName ( INT iPacketQty )
<Statement> ;
<Statement> ;
<Statement> ;
END
```

To refer to the argument (in the body of your function) you use the name of the argument in an executable statement:

```
INT
FUNCTION
AddTwoIntegers ( INT FirstInteger, INT SecondInteger )
INT Solution ;
Solution = FirstInteger + SecondInteger ;
RETURN Solution ;
END
```

## See Also

[Writing Functions](#)

## Setting Default Values for Arguments

If an argument is listed in a Cicode function declaration, the Argument Initialisation Statement is optional, and if used, is listed last in the Argument Statement after the required Argument Data Type and the Argument Name Statements. The Argument Initialization Statement needs to be preceded by an equals ( = ) assignment operator.

**Note:** In the following function syntax example:

- Every placeholder shown inside arrow brackets ( <placeholder> ) should be replaced in any actual code with the value of the item that it describes. The arrow brackets and the word they contain should not be included in the statement, and are shown here only for your information.
- Statements shown between square brackets ( [ ] ) are optional. The square brackets should not be included in the statement, and are shown here only for your information.

Replace the <InitialDefaultValue> placeholder in the following function example with an appropriate value for your Argument variable.

```
FUNCTION
FunctionName (<ArgumentDataType> <ArgumentName> [ =
<InitialDefaultValue> ])
<Statement> ;
<Statement> ;
<Statement> ;
END
```

The default value for an argument needs to be of the same data type as declared for the argument in the Argument Data Type Statement.

You assign a default argument variable value in the same manner that you assign a Cicode variable value, by using the equals ( = ) assignment operator. For example:

```
FUNCTION
PlotProduct ( INT iPackets = 200 , STRING sName = "Packets" )
<Statement> ;
```

```
<Statement> ;
<Statement> ;
END
```

If you assign a default value for an argument, you may omit a value for that argument when you call the function, because the function will use the default value from the declaration. To pass an empty argument to a function, omit any value for the argument in the call. For example, to call the PlotProduct function declared in the previous example, and accept the default string value of "Packets", a Cicode function call would look like:

```
PlotProduct(500)
```

Be aware that the second argument for the function was omitted from the calling code. In this instance, the default value for the second argument ( "Packets" ) would remain unchanged, and so would be used as the second argument value in this particular function call.

If you do call that function and pass in a value for that argument in the call, the default value is replaced by the argument value being passed in. However, the arguments are reinitialized every time the function is called, so each subsequent call to the function will restore the default values originally declared in the function.

If the function has more than one argument and none of them are explicitly declared in the function declaration, the default values for the undeclared arguments will be used.

For more information on function calls, callers, and calling, see the section titled [Calling Functions from Commands and Expressions](#).

Argument Statements can be separated over several lines to aid in their readability.

## See Also

[Writing Functions](#)

## Returning Values from Functions

Many of the built-in Cicode functions supplied with Plant SCADA return a data value to their calling statement. Mathematical functions return a calculated value. The Date() and Time() functions return the current date and time. Other functions, like PageDisplay(), perform an action, and return a value indicating either the success of the action or the type of error that occurred.

You can also use return values in your own functions, to return data to the calling statement. The return value is assigned in the RETURN Statement:

The optional RETURN Statement of a function (if used), needs to be placed in the executable Statements section of a Cicode function between the FUNCTION and END Statements. Because the RETURN Statement is used to return data values that have usually been manipulated by the function, they are usually placed last just before the END Statement.

```
<ReturnDataType>
FUNCTION
FunctionName ( <Arguments> )
<Statement> ;
<Statement> ;
<Statement> ;
RETURN <ReturnValue> ;
END
```

The RETURN Statement consists of the RETURN keyword, optionally followed by a value to be returned, and finished with the semicolon (;) [End of Line Markers](#).

The RETURN value needs to be of the same data type as was declared in the Return Data Type Statement at the start of the function declaration. The return data type of a function can be only one of six possible data types: INT (32 bits), REAL (64 bits), STRING (255 bytes), OBJECT (32 bits), QUALITY or TIMESTAMP (64 bits). If no Return Data Type Statement is declared, the function will not be able to return any type of data.

If the RETURN Statement within the function encounters a different data type to that declared in the Return Data Type Statement, the value is converted to the declared return data type. For information about the Return Data Type Statement, see the section titled [Declaring the Return Data Type](#).

FUNCTION, INT, REAL, STRING, OBJECT, QUALITY, and TIMESTAMP are Cicode keywords and as such, are reserved.

**Note:** In the following function syntax example every placeholder shown inside arrow brackets (*<placeholder>*) should be replaced in any actual code with the value of the item that it describes. The arrow brackets and the word they contain should not be included in the statement, and are shown here only for your information.

To declare the value that will be returned to the calling code, you need to replace the *<ReturnValue>* placeholder in the following example with an appropriate data value to match the Return Data Type as declared in the function.

```
<ReturnDataType>
FUNCTION
FunctionName ( <Arguments> )
<Statement> ;
<Statement> ;
RETURN <ReturnValue> ;
END
```

The following example returns an integer of value 5:

```
INT
FUNCTION
FunctionName ( <Arguments> )
<Statement> ;
INT Status = 5; <Statement> ;
RETURN Status;END
```

The RETURN statement passes a value back to the calling procedure (either another function, command or expression). Outside of the function, the return value can be read by the calling statement. For example, it can be used by the caller as a variable (in a command), or animated (in an expression).

## See Also

[Writing Functions](#)

## Using Variables

A variable is a named location in the computer's memory where data can be stored. Cicode variables can store the basic data types (such as strings, integers, and real numbers) and each variable is specific for its particular data type. For example, if you set up a Cicode variable to store an integer value, you cannot use it for real numbers or strings.

**Note:** Each data type uses a fixed amount of memory: integers use 4 bytes of memory, real numbers use 8 bytes, and strings use 1 byte per character. PLC INT types use only 2 bytes.

The computer allocates memory to variables according to the data type and the length of time you need the variable to be stored.

Real-time variables (such as PLC variables) are already permanently stored in database files on your hard disk. Any variable you use in a database field command or expression needs to be defined as a variable tag, or the compiler will report an error when the system is compiled.

Working with variables involves the following:

- Declaring Variable Properties
- Declaring the Variable Data Type
- Naming variables
- Setting Default Variable Values
- Using Variable Scope
- Using Database Variables.

---

**Note:** Cicode variables can handle a wide range of Plant SCADA variable tag data types. For example, a Cicode variable of INT data type can be used to store I/O device data types: BCD, BYTE, DIGITAL, INT, LONG, LONGBCD, and UINT.

---

## See Also

- [Variable Declaration Standards](#)  
[Variable Naming Standards](#)  
[Variable Scope Standards](#)  
[Using Arrays](#)

## Declaring Variable Properties

You need to declare each variable used in your functions (except for variables that are configured as variable tags). In the declaration statement, you specify the name and data type of the variable. You can also set a default value for the variable.

## See Also

- [Using Variables](#)

## Declaring the Variable Data Type

You can use variables of the following data types:

INT	Integer (32 bits)	-2,147,483,648 to 2,147,483,647
REAL	Floating point (64 bits)	-1.7E308 to 1.7E+308 with 15 digits of precision
STRING	Text string (255 bytes maximum, including null termination character)	ASCII (null terminated)

OBJECT	ActiveX control object reference (32 bits)	
QUALITY	Represents the Plant SCADA quality (64 bits)	QUAL_GOOD, QUAL_BAD, QUAL_UNCR
TIMESTAMP	Represents the number of 100-nanosecond intervals since January 1, 1601 (64 bits)	

If you want to specify a digital data type, use the integer type. Digital types can either be TRUE(1) or FALSE(0), as can integer types.

**Note:**

- Cicode may internally store floating point values as 64 bit to minimize rounding errors during floating point calculations.
- When comparing REAL values in Cicode it is recommended you use the Round() function before doing the comparison.

## QUALITY Data Type

The QUALITY data type is a new data type in Cicode which incorporates the Plant SCADA quality. The QUALITY data type and the Cicode quality labels can be used in Cicode expressions.

The operators allowed for the QUALITY data type are:

- Assignment operator: =.
- Relational operators: =, <>.

The assignment operation also allows for the QUALITY data type.

**Example:**

```
QUALITY q1;
QUALITY q2;

q1 = q2;
q1 = Tag1.Field.Q;

//the following expression will generate a compiler error as a tag //element can be
modified only as a whole
Tag1.Field.Q = q1;
```

A set of Cicode functions are provided which allow quality fields to be initialized, a specific quality field to be extracted, and other operations on the QUALITY data type. Conversion between the QUALITY data type and other Cicode data types is not allowed. Direct conversion from Quality to string will return an empty string.

**Example:**

```
//this will generate a compiler error
INT n = Tag1.Q;
```

## TIMESTAMP Data Type

The TIMESTAMP data type represents the date and time as a 64-bit value by specifying the number of 100-nanosecond intervals since January 1, 1601. This data type is always in Coordinated Universal Time (UTC).

The operators allowed for the TIMESTAMP data type are:

- Assignment operator: =.
- Relational operators: =, <>, <, >, <=, >=.

### Example:

```
TIMESTAMP t1;
TIMESTAMP t2;
t1 = Tag1.T;
t1 = t2;
IF t1 < Tag2.T THEN
// insert code here
END
STRING sStr;
REAL Result;
INT x, y;
OBJECT hObject;
```

The first 32 characters of a variable name needs to be unique.

### [Using Variables](#)

## Naming Variables

Throughout the body of the function, the variable is referred to by its name. You can name a variable any valid name except for a reserved word, for example:

```
STRING sStr;
REAL Result;
INT x, y;
OBJECT hObject;
```

The first 32 characters of a variable name needs to be unique.

[Variable Naming Standards](#)

## Setting Default Variable Values

When you declare variables, you can set them to an initial (startup) value; for example:

```
STRING Str = "Test";
REAL Result = ;
INT x = 20, y = 50;
```

## See Also

[Using Variables](#)

### Using Variable Scope

Scope refers to the accessibility of a function and its values. A Cicode variable can be defined as any one of three types of scope - global, module, and local. By default, Cicode variables are module scope, unless they are declared within a function.

Variables have the following format:

```
DataType Name [=Value];
```

### Global Variables

A global Cicode variable can be shared across all Cicode files in the system (as well as across include projects). They cannot be accessed on pages or databases (for example, Alarm.dbf).

Global Cicode variables are prefixed with the keyword **GLOBAL**, and needs to be declared at the start of the Cicode file. For example:

```
GLOBAL STRING sDefaultPage = "Mimic";
INT
FUNCTION
MyPageDisplay(STRING sPage)
INT iStatus;
iStatus = PageDisplay(sPage);
IF iStatus <> 0 THEN
PageDisplay(sDefaultPage);
END
RETURN iStatus;
END
```

The variable **sDefaultPage** could then be used in any function of any Cicode file in the system.

---

**Note:** Use global variables sparingly if at all. If you have many such variables being used by many functions, finding bugs in your program can become time consuming. Use local variables wherever possible. Global Cicode STRING types are 256 bytes.

---

### Module Variables

A module Cicode variable is specific to the file in which it is declared. This means that it can be used by any function in that file, but not by functions in other files.

By default, Cicode variables are defined as module, therefore prefixing is not required (though a prefix of **MODULE** could be added if desired). Module variables should be declared at the start of the file. For example:

```
STRING sDefaultPage = "Mimic";
INT
FUNCTION
MyPageDisplay(STRING sPage)
INT Status;
Status = PageDisplay(sPage);
IF Status <> 0 THEN
PageDisplay(sDefaultPage);
```

```
END
RETURN Status;
END
INT
FUNCTION
DefaultPageDisplay()
PageDisplay(sDefaultPage);
END
```

**Note:** Use module variables sparingly if at all. If you have many such variables being used by many functions, finding bugs in your program can become time-consuming. Use local variables wherever possible.

## Local Variables

A local Cicode variable is only recognized by the function within which it is declared, and can only be used by that function. You need to declare local variables before you can use them.

Any variable defined within a function (that is, after the function name) is a local variable, therefore no prefix is needed. Local variables are destroyed when the function exits.

Local variables take precedence over global and module variables. If you define a local variable in a function with the same name as a global or module variable, the local variable is used; the global/module variable is unaffected by the function. This situation should be avoided, however, as it is likely to cause confusion.

### Local Variables and Variable Tags

Local variables have limited functionality compared with variable tags. Limitations are:

- Qualities of Override, OverrideMode, ControlMode and Status elements are showing Bad with extended substatus QUAL\_EXT\_INVALID\_ARGUMENT. Writing to the elements returns error Invalid argument passed (274).
- Values of Override, OverrideMode, ControlMode and Status elements are showing 0.
- Respective timestamps and quality of Field, Valid and default elements are the same.
- Field, Valid and default elements can be read.
- Field and default elements can be written.

## See Also

[Using Variables](#)

[Variable Scope Standards](#)

## Using Database Variables

You can use any variable that you have defined in the database (with the Variable Tags form) in your functions. To use a database variable, specify the tag name:

<Tag>

Where *Tag* is the name of the database variable.

For example, to change the value of the database variable "LT131" at run time, you would use the following statement in your function:

LT131=1200; !Changes the value of LT131 to 1200

## See Also

[Using Variables](#)

## Using Arrays

A Cicode variable array is a collection of Cicode variables of the same data type, in the form of a list or table. You name and declare an array of variables in the same way as any other Cicode variable. You can then refer to each element in the array by the same variable name, with a number (index) to indicate its position in the array. Working with arrays involves the following:

### Declaring Array Properties

Arrays have several properties that you need to declare to the compiler along with the array name: data type, size and dimension. You can also set default values for individual elements of the array. An array declaration has the following syntax:

```
DataType Name[Dim1Size,{Dim2Size},{Dim3Size}]{=Values};
```

### Declaring the Array Data Type

As with any other Cicode variable, arrays can have four Data Types:

INT	Integer (32 bits)
REAL	Floating point (64 bits)
STRING	Text string (255 bytes)
OBJECT	ActiveX object (32 bits)
QUALITY	Plant SCADA Quality (64 bits)
TIMESTAMP	Date and Time (64 bits)

### Naming Arrays

Throughout the body of a Cicode function, a Cicode variable array is referred to by its name, and individual elements of an array are referred to by their index. The index of the first element of an array is 0 (that is a four element array has the indices 0,1,2, and 3). You can name a variable any valid name except for a [Restricted Cicode Keywords](#); for example:

```
STRING StrArray[5]; ! list
REAL Result[5][2]; ! 2-D table
INT IntArray[4][3][2]; ! 3-D table
```

### Declaring the Variable Array Size

You need to declare the size of the array (the number of elements the array contains, from 1 to 32,767), for

example:

```
STRING StrArray[5];
```

This single dimension array contains 5 elements. The compiler multiplies the number of elements in the array by the size of each element (dependent upon the Data Type), and allocates storage for the array in consecutive memory locations.

You cannot declare arrays local to a function. However, they can be declared as Module (that is at the beginning of the Cicode file), or Global. When referring to the array within your function, take care to remain within the size you set when you declared the array. The example below would cause an error:

```
STRING StrArray[5];
...
StrArray[10] = 100;
...
```

The compiler allows storage for 5 strings. By assigning a value to a 10<sup>th</sup> element, you cause a value to be stored outside the limits of the array, and you could overwrite another value stored in memory.

## Setting Default (Initial) Array Values

When you declare an array, you can (optionally) set the individual elements to an initial (or start-up) value within the original declaration statement. For instance, naming a string array "ArrayA", sizing it to hold 5 elements, and initializing the array with string values, would look like the following example:

```
STRING ArrayA[5] = "This", "is", "a", "String", "Array";
```

This array structure would contain the following values:

```
ArrayA[0] = "This"
ArrayA[1] = "is"
ArrayA[2] = "a"
ArrayA[3] = "String"
ArrayA[4] = "Array"
```

## Passing Array Elements as Function Arguments

To pass a Cicode variable array element to a Cicode function, you need to provide the element's address; for example:

```
/* Pass the first element of ArrayA. */
MyFunction (ArrayA[0])
/* Pass the second element of ArrayA. */
MyFunction (ArrayA[1])
/* Pass the fifth element of ArrayA. */
MyFunction (ArrayA[4])
```

## Using One-dimensional Arrays

To use a one-dimensional array:

```
STRING ArrayA[5] = "This", "is", "a", "String", "Array";
This array sets the following values:
ArrayA[0] = "This"
ArrayA[1] = "is"
ArrayA[2] = "a"
ArrayA[3] = "String"
```

```
ArrayA[4] = "Array"
```

## Using Two-dimensional Arrays

To use a two-dimensional array:

```
REAL ArrayA[5][2]=1,2,3,4,5,6,7,8.3,9.04,10.178;
```

This array sets the following values:

ArrayA[0][0]=1	ArrayA[0][1]=2
ArrayA[1][0]=3	ArrayA[1][1]=4
ArrayA[2][0]=5	ArrayA[2][1]=6
ArrayA[3][0]=7	ArrayA[3][1]=8.3
ArrayA[4][0]=9.04	ArrayA[4][1]=10.178

## Using Three-dimensional Arrays

To use a three-dimensional array:

```
INT ArrayA[4][3][2]=1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,  
16,17,18,19,20,21,22,23,24;
```

This array sets the following values:

ArrayA[0][0][0]=1	ArrayA[0][0][1]=2	ArrayA[0][1][0]=3
ArrayA[0][1][1]=4	ArrayA[0][2][0]=5	ArrayA[0][2][1]=6
ArrayA[1][0][0]=7	ArrayA[1][0][1]=8	ArrayA[1][1][0]=9
ArrayA[1][1][1]=10	ArrayA[1][2][0]=11	ArrayA[1][2][1]=12
ArrayA[2][0][0]=13	ArrayA[2][0][1]=14	ArrayA[2][1][0]=15
ArrayA[2][1][1]=16	ArrayA[2][2][0]=17	ArrayA[2][2][1]=18
ArrayA[3][0][0]=19	ArrayA[3][0][1]=20	ArrayA[3][1][0]=21
ArrayA[3][1][1]=22	ArrayA[3][2][0]=23	ArrayA[3][2][1]=24

You use arrays in your functions in the same way as other variables, but arrays have special properties that, in many situations, reduce the amount of code you need to write.

## Using Array Elements in Loops

You can set up loops that deal efficiently with arrays by incrementing the index number. The following example shows a method of initializing an array:

```
REAL Array[10]
```

```
:  
FOR Counter = 0 TO 9 DO  
Array[Counter] = 0  
END  
RETURN Total  
:
```

## Using the Table (Array) Functions

Cicode has built-in functions for processing Cicode variable arrays:

- To perform calculations (max, min, total, etc.) on array elements.
- To look up the index number of an array element.
- To shift the elements of an array left or right.

---

**Note:** Plant SCADA also provides a set of array functions that support associations with animation objects. See [Array Functions](#).

---

## Using Cicode Macros

Cicode has the following macros:

- **IFDEF:** Determines one of two possible outcomes based on the existence of a specified non-alarm tag at compile time. Use one of the macros below for alarm tags.
- **IFDEFAdvAlm:** Determines one of two possible outcomes based on the existence of a specified advanced alarm tag at compile time.
- **IFDEFAnaAlm:** Determines one of two possible outcomes based on the existence of a specified analog alarm tag at compile time.
- **IFDEFDigAlm:** Determines one of two possible outcomes based on the existence of a specified digital alarm tag at compile time.
- **IFDEFHresAlm :** Determines one of two possible outcomes based on the existence of a specified time stamped alarm tag at compile time.

## See Also

[Macro Arguments](#)

### IFDEF

The IFDEF macro allows you to define two possible outcomes based on whether or not a specified tag exists within a project at the time of compiling. The macro can be implemented anywhere a simple expression is used,

including fields within relevant Plant SCADA dialogs.

The macro was primarily created to avoid the "Tag not found" compile error being generated whenever a genie was missing an associated tag. By allowing a "0" or "1" to be generated within the **Hidden When** field of a Genie's properties, elements could simply be hidden if a required tag was missing, allowing the genie to still be pasted onto a graphics page.

The macro accepts three arguments: the first specifies the tag that requires confirmation, the second defines the outcome if the tag exists, the third defines the outcome if it does not exist. In the case of a genie being pasted on a graphics page, the IFDEF function would be configured as follows in the **Hidden When** field of the object properties dialog:

```
IFDEF("Bit_1",0,1)
```

If the tag "Bit\_1" is defined in the tag database, the value in the **Hidden When** field will be 0. If Bit\_1 is undefined, the value will be 1. Since the object is hidden when the value is TRUE (1), the object will be hidden when Bit\_1 is undefined. See Hiding Graphics Objects for details.

Beyond this purpose, the IFDEF macro can be broadly used as a conditional variable. The [*<value if defined>*] and [*<value if not defined>*] arguments can support any variable, expression, or constant. The [*<value if defined>*] argument is optional; if you leave it blank it will generate the current variable. You can also use nested IFDEF macros.

---

**Note:** As different types of alarms can share the same name, you have to use a variation of IFDEF to check for the existence of alarm tags. See IFDEFAnaAlm for analog alarms, IFDEFDigAlm for digital alarms, or IFDEFAdvAlm for advanced alarms.

---

## Syntax

```
IFDEF(TagName, [<value if defined>], <value if not defined>)
```

## Return Value

If the tag specified in the first argument exists, the value defined by the second argument is returned. This could be a variable, expression, or constant, or the current tag value if the argument has been left blank. If the specified tag does not exist, the variable, expression, or constant defined by the third argument is returned.

## Example

```
! Generate the tag value if tag "Bit_1" is defined
! Generate an empty string if "Bit_1" is not defined
IFDEF("Bit_1","","")
! Generate a zero value (0) if tag "Bit_1" is defined
! Generate a true value (1) if "Bit_1" is not defined
IFDEF("Bit_1",0,1)
```

For more examples of how to implement the IFDEF macro, see Tech Note TN5672 via the AVEVA Knowledge and Support Center.

## IFDEFAdvAlm

Based on the IFDEF macro, IFDEFAdvAlm allows you to define two possible outcomes based on whether or not a specified advanced alarm tag exists within a project at the time of compiling. The macro can be implemented anywhere a simple expression is used, including fields within relevant Plant SCADA dialogs.

The macro accepts three arguments: the first specifies the advanced alarm tag that requires confirmation, the second defines the outcome if the alarm exists, the third defines the outcome if it does not exist.

**Note:** As different types of alarms can share the same name, you have to use a variation of IFDEF to check for the existence of alarm tags. See [IFDEFAnaAlm](#) for analog alarms, or [IFDEFDigAlm](#) for digital alarms.

## Syntax

**IFDEFAdvAlm**(TagName, [<value if defined>], <value if not defined>)

## Return Value

If the advanced alarm tag specified in the first argument exists, the value defined by the second argument is returned. This could be a variable, expression, or constant, or the current tag value if the argument has been left blank. If the specified alarm does not exist, the variable, expression, or constant defined by the third argument is returned.

## Example

```
! Generate tag value if advanced alarm "AdvAlarm_1" is defined
! Generate an empty string if "AdvAlarm_1" is not defined
IFDEFAdvAlm("AdvAlarm_1","","")
! Generate a zero value (0) in Hidden When field if advanced alarm
"AdvAlarm_1" is defined
! Generate a true value (1) in Hidden When field if "AdvAlarm_1"
is not defined
IFDEFAdvAlm("AdvAlarm_1",0,1)
```

For more examples of how to implement the IFDEF macro, see Tech Note TN5672 via the AVEVA Knowledge and Support Center.

## Using Cicode Macros

### IFDEFAnaAlm

Based on the IFDEF macro, IFDEFAnaAlm allows you to define two possible outcomes based on whether or not a specified analog alarm tag exists within a project at the time of compiling. The macro can be implemented anywhere a simple expression is used, including fields within relevant Plant SCADA dialogs.

The macro accepts three arguments: the first specifies the analog alarm tag that requires confirmation, the second defines the outcome if the alarm exists, the third defines the outcome if it does not exist.

**Note:** As different types of alarms can share the same name, you have to use a variation of IFDEF to check for the existence of alarm tags. See [IFDEFDigAlm](#) for digital alarms, or [IFDEFAdvAlm](#) for advanced alarms.

### Syntax

**IFDEFAnaAlm**(TagName, [<value if defined>], <value if not defined>)

### Return Value

If the analog alarm tag specified in the first argument exists, the value defined by the second argument is returned. This could be a variable, expression, or constant, or the current tag value if the argument has been left blank. If the specified alarm does not exist, the variable, expression, or constant defined by the third argument is returned.

### Example

```
! Generate tag value if analog alarm "AnaAlarm_1" is defined
! Generate an empty string if "AnaAlarm_1" is not defined
IFDEFAnaAlm("AnaAlarm_1","", "")
! Generate a zero value (0) in Hidden When field if analog alarm
"AnaAlarm_1" is defined
! Generate a true value (1) in Hidden When field if "AnaAlarm_1"
is not defined
IFDEFAnaAlm("AnaAlarm_1",0,1)
```

For further examples of how to implement the IFDEF macro, see Tech Note TN5672 via the AVEVA Knowledge and Support Center.

[Using Cicode Macros](#)

## IFDEFDigAlm

Based on the IFDEF macro, IFDEFDigAlm allows you to define two possible outcomes based on whether or not a specified digital alarm tag exists within a project at the time of compiling. The macro can be implemented anywhere a simple expression is used, including fields within relevant Plant SCADA dialogs.

The macro accepts three arguments: the first specifies the digital alarm tag that requires confirmation, the second defines the outcome if the alarm exists, the third defines the outcome if it does not exist.

**Note:** As different types of alarms can share the same name, you have to use a variation of IFDEF to check for the existence of alarm tags. See [IFDEFAnaAlm](#) for analog alarms or [IFDEFAdvAlm](#) for advanced alarms.

## Syntax

```
IFDEFDigAlm(TagName, [<value if defined>], <value if not defined>)
```

## Return Value

If the digital alarm tag specified in the first argument exists, the value defined by the second argument is returned. This could be a variable, expression, or constant, or the current tag value if the argument has been left blank. If the specified alarm does not exist, the variable, expression, or constant defined by the third argument is returned.

Example

```
! Generate tag value if digital alarm "DigAlarm_1" is defined
! Generate an empty string if "DigAlarm_1" is not defined
IFDEFDigAlm("DigAlarm_1","", "")
! Generate a zero value (0) in Hidden When field if digital alarm
"DigAlarm_1" is defined
! Generate a true value (1) in Hidden When field if "DigAlarm_1"
is not defined
IFDEFDigAlm("DigAlarm_1",0,1)
```

For more examples of how to implement the IFDEF macro, see Tech Note TN5672 via the AVEVA Knowledge and Support Center.

## IFDEFHresAlm

Based on the IFDEF macro, IFDEFHresAlm allows you to define two possible outcomes based on whether or not a specified time stamped alarm tag exists within a project at the time of compiling. The macro can be implemented anywhere a simple expression is used, including fields within relevant Plant SCADA dialogs.

The macro accepts three arguments: the first specifies the digital alarm tag that requires confirmation, the second defines the outcome if the alarm exists, the third defines the outcome if it does not exist.

**Note:** As different types of alarms can share the same name, you have to use a variation of IFDEF to check for the existence of alarm tags. See [IFDEFAnaAlm](#) for analog alarms or [IFDEFAdvAlm](#) for advanced alarms.

## Syntax

```
IFDEFHresAlm(TagName, [<value if defined>], <value if not defined>)
```

## Return Value

If the time stamped alarm tag specified in the first argument exists, the value defined by the second argument is returned. This could be a variable, expression, or constant, or the current tag value if the argument has been left blank. If the specified alarm does not exist, the variable, expression, or constant defined by the third argument is returned.

## Example

```
! Generate tag value if time stamped alarm "TimestampedAlarm_1" is defined
! Generate an empty string if "TimestampedAlarm_1" is not defined
IFDEFHresAlm("TimestampedAlarm_1",,, "")
! Generate a zero value (0) in Hidden When field if digital alarm "TimestampedAlarm_1" is
defined
! Generate a true value (1) in Hidden When field if "TimestampedAlarm_1"
is not defined
IFDEFHresAlm("TimestampedAlarm_1",0,1)
```

For more examples of how to implement the IFDEF macro, see Tech Note TN5672 via the AVEVA Knowledge and Support Center.

[IFDEF](#), [IFDEFAnaAlm](#), [IFDEFDigAlm](#), [IFDEFAdvAlm](#)

## See Also

[Macro Arguments](#)  
[Using Cicode Macros](#)

## Macro Arguments

The Cicode macros use the following arguments.

## TagName

The name of the tag you would like the IFDEF macro to confirm the existence of. The Plant SCADA compiler will check the current project database for a tag matching this name.

## [<value if defined>]

Defines the outcome of the macro if the specified tag exists in the current project. This argument is optional, which means you can:

- Generate any variable, constant, or expression.
- Generate the current value for the specified tag by leaving the argument blank.

## <value if not defined>

Defines the outcome of the macro if the specified tag does not exist in the current project. This will generate any variable, constant, or expression, including a blank string (" ") if you want nothing to be presented.

## See Also

[Using Cicode Macros](#)

## Converting and Formatting Cicode Variables

Plant SCADA provides the following functions for converting variables.

- IntToStr: converts an integer variable into a string
- IntToReal: converts an integer into a floating-point variable
- RealToStr: converts a floating-point variable into a string
- StrToInt: converts a string into an integer variable
- StrToReal: converts a string into a floating-point variable

You can convert data types without using these Cicode functions, but the result of the format conversion might not be what you expect. If you want more control over the conversion process, use the appropriate Cicode functions.

---

**Note:** Variables of type *object* cannot be converted to any other type.

---

When variables are automatically converted, or when the return value from a function call is converted, specific rules apply.

## Converting Variable Integers to Strings

To convert an integer variable to a string:

```
IntVar=5;  
StringVar=IntVar;
```

The value of StringVar is set to "5".

The format of the string is specified when the variable is defined in the database. However you can override this default format with the string format (:) operator, and use the # format specifier to set a new format. For example:

```
IntVar=5;
```

```
StringVar=IntVar:####
```

The value of StringVar = " 5 ". (The '#' formatting characters determine the size and number of decimal places contained in the string, that is a length of 4 with no decimal places.)

## Converting Variable Integers to Real Numbers

When calling statements such as comparison or arithmetic operations that involve a mixture of variables of REAL and INT data types, there is no need to explicitly convert the variable of INT data type to REAL data type using the IntToReal function. Plant SCADA will automatically convert variables of INT data type to REAL data type before the operation is carried out.

However, if the expression only consists of variables of INT data type, the result of the expression will remain as INT data type and be subjected to its limitations such as integer overflow and wraparound. This does not change even if the expression is to be assigned to a variable of REAL data type.

If you want to increase the range of the expression, you will need to convert at least one of its operands to REAL data type using the IntToReal function.

### Example

```
INT nVar1 = 1000000001;
INT nVar2 = 2000000002;
REAL rVar1 = 1.000001;
REAL rVar2 = 0.0;

// rVar2 = 1000000002.000001, IntToReal is not needed when operands are mixture of INT and
REAL data types
rVar2 = nVar1 + rVar1;

// rVar2 = -1294967293.0, result is wrapped around due to range overflow of integer data
type
rVar2 = nVar1 + nVar2;

// rVar2 = 3000000003.0, result is prompted to REAL data type when one of the INT operands
is converted
rVar2 = nVar1 + IntToReal(nVar2);
```

## Converting Real Numbers to Strings

To convert a real number variable to a string:

```
RealVar=5.2;
StringVar=RealVar;
```

The value of StringVar is set to "5.2".

---

**Note:** Unpredictable results may occur if you use large numbers with a large number of decimal places.

The format of the string is specified when the variable is defined in the database. However you can override this default format with the string format (:) operator, and use the # format specifier to set a new format. For example:

```
StrTag1=RealTag1:#####.###
```

The value of StringVar = " 5.200 ". (The '#' formatting characters determine the size and number of decimal places contained in the string, that is a length of 10 including a decimal point and three decimal places.)

## Converting Strings to Integers

To convert a string variable to an integer:

```
StringVar="50.25";
IntVar=StringVar;
```

The value of IntVar is set to 50. If StringVar contains any characters other than numeric characters, IntVar is set to 0.

## Converting Strings to Real Numbers

To convert a string variable to a real number:

```
StringVar="50.25";
RealVar=StringVar;
```

The value of RealVar is set to 50.25. If StringVar contains any characters other than numeric characters, RealVar is set to 0.

## Formatting Text Strings

A string in Cicode is represented as text positioned between double quote ( " ) delimiters. For example:

```
"This is my text string."
```

A string value can be assigned to a string variable. For example:

```
STRING sMyStringVariable;
sMyStringVariable = "This is my text string.;"
```

More than one string can be joined together (concatenated) using the Cicode 'plus' mathematical operator ( + ). For example:

```
STRING sMyStringVariable;
sMyStringVariable = "This is my text string." + "This is my second
text string.;"
```

The two strings would be joined together and assigned to the string variable sMyStringVariable. However, if subsequently displayed somehow, like in the following MESSAGE example, the concatenated string would look wrong because there is no space character positioned between the string sentences.

```
STRING sMyStringVariable;
sMyStringVariable = "This is my text string." + "This is my second
text string.;"
```

```
MESSAGE("String Concatenation Example",sMyStringVariable,32);
```

To overcome this potential formatting problem, you could include an extra space as the last character in the strings, or include the space as a third string in the concatenation. For example:

```
sMyStringVariable = "This is my text string. " + "This is my
second text string. ";
```

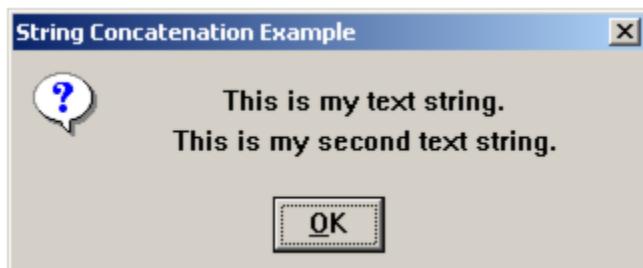

or

```
sMyStringVariable = "This is my text string." + " " + "This is my  
second text string. ";
```

However, these are considered poor programming practices and not recommended. Instead, you can use special string formatting commands known as *escape sequences*.

If the two strings (as used in the previous example), were formatted using appropriate escape sequences positioned within the strings, and subsequently displayed somehow, like in the following MESSAGE example, the concatenated string would look different, For example:

```
STRING sMyStringVariable;  
STRING s.NewLine = "^n";  
sMyStringVariable = "This is my text string." + s.NewLine + "This  
is my second text string. " ;  
MESSAGE("String Concatenation Example",sMyStringVariable,32);
```

Strings and string variables can also be concatenated as in the previous example. Be aware of how the newline escape sequence ( ^n ) was assigned to the string variable s.NewLine, and how this value was concatenated between the other strings and assigned to the string variable sMyStringVariable for display in the MESSAGE function.

## Escape Sequences (String Formatting Commands)

Cicode supports several escape sequences that you can use in text strings for custom formatting of the string. By using the appropriate Cicode escape sequences listed below you can format the string display to do such things as divide onto separate lines at specific positions, insert tab spaces, insert quotes, or to display Hexadecimal numbers.

Cicode escape sequences are preceded by a caret ( ^ ) character. The caret character is interpreted as a special instruction, and together with the characters immediately following it, are treated as an Cicode escape sequence formatting command. The escape sequences used in Cicode are:

^b	backspace
^f	form feed
^n	new line
^t	horizontal tab
^v	vertical tab
^'	single quote
^"	double quote

<code>^^</code>	caret
<code>^r</code>	carriage return
<code>^0xhh</code>	where <i>hh</i> is a hexadecimal number (for example, <code>^0x1A</code> )

## Working with Operators

With Cicode, you can use the data operators that are standard in a large number of programming languages: mathematical, bit, relational, and logical operators.

### See Also

[Using Mathematical Operators](#)

[Using Bit Operators](#)

[Using Relational Operators](#)

[Using Logical Operators](#)

[Order of Precedence of Operators](#)

### Using Mathematical Operators

Standard mathematical operators allow you to perform arithmetic calculations on numeric variables - integers and floating point numbers.

Operator	Description
<code>+</code>	Addition
<code>-</code>	Subtraction
<code>*</code>	Multiplication
<code>/</code>	Division
<code>MOD</code>	Modulus (Remainder)

### Example

The following are examples of mathematical operators

Command	<code>PV12 = PV10 + PV11;</code>
Comment	PV12 is the sum of PV10 and PV11
Command	<code>Counter = Counter - 1;</code>

Comment	The value of Counter is decreased by 1
Command	PV12 = Speed * Counter;
Comment	PV12 is the product of Speed and Counter
Command	Average = Total / ShiftHrs;
Comment	Average is Total divided by ShiftHrs
Command	Hold = PV12 MOD PV13;
Comment	If PV12 = 10 and PV13 = 8, Hold equals 2 (the <b>remainder</b> when PV12 is divided by PV13)

**Note:** Cicode uses the standard order of precedence, that is multiplication and division are calculated before addition and subtraction. In the statement  $A=1+4/2$ , 4 is divided by 2 before it is added to 1, and the result is 3. In the statement  $A=(1+4)/2$ , 1 is first added to 4 before the division, and the result is 2.5.

You can also use the addition operator (+) to concatenate (join) two strings.

Operator	Description
+	Concatenate

## Example

Command	Message = "For info see " + "Supervisor";
Comment	Message now equals "For info see Supervisor"

## See Also

[Working with Operators](#)

## Using Bit Operators

With a bit operator, you can compare the corresponding bits in two numeric expressions. (A bit is the smallest unit of data a computer can store.)

Operator	Description
BITAND	AND
BITOR	OR
BITXOR	Exclusive OR

For example:

Command	Tag3 = Tag1 BITAND Tag2;
Command	Tag3 = Tag1 BITAND 0xFF;
Command	Tag3 = Tag1 BITOR Tag2;
Command	Tag3 = Tag1 BITXOR Tag2;

## See Also

[Working with Operators](#)

## Using Relational Operators

Relational operators describe the relationship between two values. The relationship is expressed as one value being larger than, the same as, or smaller than another. You can use relational operators for both numeric and string variables, however you can only test variables of the same type. A numeric variable cannot be compared with a string variable.

Operator	Description
=	Is equal to
<>	Is not equal to
<	Is less than
>	Is greater than
<=	Is less than or equal to
>=	Is greater than or equal to

For example:

Command	IF Message = "Alarm Active" THEN ...
Expression	PV12 <> PV10;
Command	IF (Total + Count) / Avg < 10 THEN ...
Expression	Counter > 1;
Command	IF PV12 <= PV10 THEN ...
Expression	Total >= Shift * Hours;

## See Also

[Working with Operators](#)

## Using Logical Operators

With logical operators, you can test several conditions as either TRUE or FALSE.

Operator	Description
AND	Logical AND
OR	Logical OR
NOT	Logical NOT

Examples:

Command	Result = (PV12 = 10 AND PV13 = 2);
Comment	If PV12 equals 10 and PV13 equals 2 then Result is TRUE(1)
Expression	Motor_1 AND Motor_2;
Comment	If both Motor_1 and Motor_2 are TRUE, that is Digital bits are 1 or ON, then the expression is TRUE
Expression	PV12 = 1 OR PV13 > 2 OR Counter <> 0;
Comment	If either PV12 equals 1 or PV13 is greater than 2 or Counter is not equal to 0, then the expression is TRUE
Command	Result = (Motor1_Ol OR Motor2_Ol);
Comment	If either Motor1_Ol or Motor2_Ol is TRUE, that is Digital bit is 1 or ON, then Result is TRUE (1)
Command	IF NOT PV12 = 10 THEN ...
Comment	If PV12 does not equal 10 then the result is TRUE. This is functionally identical to IF PV12 <> 10 THEN ...
Expression	NOT Tag_1;
Comment	This expression is TRUE if Tag_1 = 0. This is commonly used for testing digital variables

## See Also

[Working with Operators](#)

## Order of Precedence of Operators

Operators have a set of rules that govern the order in which operations are performed. These rules are called the

order of precedence. The precedence of Cicode operators from highest to lowest is:

1.	()
2.	NOT
3.	*, /, MOD
4.	:
5.	+, -
6.	>, <, <=, >=
7.	=, <>
8.	AND
9.	OR
10.	BITAND, BITOR, BITXOR

## See Also

[Working with Operators](#)

## Working with Conditional Executors

The statements that control decisions and loops in your functions are called conditional executors. Cicode uses four conditional executors:

- If
- For
- While
- Select case.

## See Also

[Formatting Executable Statements](#)

[Setting IF ... THEN Conditions](#)

[Using FOR ... DO Loops](#)

[Using WHILE ... DO Conditional Loops](#)

[Using the SELECT CASE statement](#)

## Setting IF ... THEN Conditions

The IF statement executes one or more statements based on the result of an expression. You can use If in one of

two formats: If Then and If Then Else.

```
If Expression Then
Statement(s);
END
-OR-
If Expression Then
Statement(s);
Else
Statement(s);
END
```

When you use the **If Then** format, the statement(s) following are executed only if the expression is TRUE, for example:

```
INT Counter;
IF PV12 = 10 THEN
Counter = Counter + 1;
END
```

In this example, the Counter increments only if the tag PV12 is equal to 10, otherwise the value of Counter remains unchanged. You can include several statements (including other IF statements), within an IF statement, for example:

```
INT Counter;
IF PV12 = 10 THEN
Counter = Counter + 1;
IF Counter > 100 THEN
Report("Shift");
END
END
```

In this example, the report runs when the Counter increments, that is when PV12 = 10, and the value of the counter exceeds 100.

You can use the **If Then Else** format for branching. Depending on the outcome of the expression, one of two actions are performed, for example:

```
INT Counter;
IF PV12 = 10 THEN
Report("Shift");
ELSE
Counter = Counter + 1;
END
```

In this example, the report runs if PV12 is equal to 10 (TRUE), or the counter increments if PV12 is anything but 10 (FALSE).

## See Also

[Working with Conditional Executors](#)

## Using FOR ... DO Loops

A For loop executes a statement or statements a specified number of times.

```
FOR Variable=Expression To Expression DO
Statement(s);
END
```

The following function uses a For loop:

```
STRING ArrayA[5] = "This", "is", "a", "String", "Array";
INT
FUNCTION
DisplayArray()
INT Counter;
FOR Counter = 0 TO 4 DO
Prompt(ArrayA[Counter]);
Sleep(15);
END
END
```

This function displays the single message "This is a String Array" on the screen one word at a time pausing for 15 seconds between each word.

## See Also

[Working with Conditional Executors](#)

## Using WHILE ... DO Conditional Loops

A While loop executes a statement or statements in a loop as long as a given condition is true.

```
WHILE Expression DO
Statement(s);
END
```

The following code fragment uses a WHILE loop:

```
INT Counter;
WHILE DevNext(hDev) DO
Counter = Counter + 1;
END
/* Count the number of records in the device (hDev) */
```

Be careful when using WHILE loops in your Cicode functions: WHILE loops can cause excessive loading of the CPU and therefore reduce system performance. If you use a WHILE loop to loop forever, you should call the Cicode function `Sleep()` so that Plant SCADA can schedule other tasks. The `Sleep()` function increases the performance of your Plant SCADA system if you use many WHILE loops.

## See Also

[Working with Conditional Executors](#)

## Nested Loops

You can "nest" one loop inside the other. That is, a conditional statement can be placed completely within (nested inside) a condition of another statement.

## See Also

[Working with Conditional Executors](#)

## Using the SELECT CASE statement

The select case statement executes on several groups of statements, depending on the result of an expression. SELECT CASE statements are a more efficient way of writing code that would otherwise have to be done with nested IF THEN statements.

```
SELECT CASE Expression
CASE CaseExpression1,CaseExpression2
Statement(s);
CASE CaseExpression3 TO CaseExpression4
Statement(s);
CASE IS >CaseExpression5,IS<CaseExpression6
Statement(s);
CASE ELSE
Statement(s);
END SELECT
```

Where **CaseExpressionn** is any one of the following forms:

- expression
- expression TO expression

Where the TO keyword specifies an inclusive range of values. The smaller value needs to be placed before TO.

- IS <relop> expression.

Use the IS keyword with relational operators (**<relop>**). Relational operators that may be used are <, <=, =, <>, >, >= .

If the Expression matches any CaseExpression, the statements following that CASE clause are executed up to the next CASE clause, or (for the last clause) up to the END SELECT. If the Expression matches a CaseExpression in more than one CASE clause, only the statements following the first match are executed.

The CASE ELSE clause is used to indicate the statements to be executed if no match is found between the Expression and any of the CaseExpressions. When there is no CASE ELSE statement and no CaseExpressions match the Expression, execution continues at the next Cicode statement following END SELECT.

You can use multiple expressions or ranges in each CASE clause. For example, the following line is valid:

```
CASE 1 To 4, 7 To 9, 11, 13, Is > MaxNumber
```

You can also specify ranges and multiple expressions. In the following example, CASE matches strings that are exactly equal to "everything", strings that fall between "nuts" and "soup" in alphabetical order, and the current value of "TestItem":

```
CASE "everything","nuts" To "soup",TestItem
```

SELECT CASE statements can be nested. Each SELECT CASE statement needs to have a matching END SELECT statement.

For example, if the four possible states of a ship are Waiting, Berthed, Loading, and Loaded, the Select Case statement could be run from a button to display a prompt detailing the ship's current state.

```
select case iStatus
CASE 1
Prompt("Waiting");
CASE 2
Prompt("Berthed");
CASE 3
Prompt("Loading");
CASE 4
Prompt("Loaded");
CASE Else
```

```
Prompt("No Status");
END SELECT
```

## See Also

[Working with Conditional Executors](#)

## Performing Advanced Tasks

This section introduces and explains event handling, Plant SCADA tasks, Plant SCADA threads, how Plant SCADA executes, and multitasking - including foreground and background tasks, controlling tasks, and pre-emptive multitasking.

### Handling Events

Cicode supports event handling. You can define a function that is called only when a particular event occurs. Event handling reduces the overhead that is required when event trapping is executed by using a loop. The following example illustrates the use of the OnEvent() function:

```
INT
FUNCTION MouseCallback()
INT x, y;
DspGetMouse(x,y);
Prompt("Mouse at "+x:"#####", "+y:#####");
RETURN 0;
END
OnEvent(0,MouseCallback);
```

The function MouseCallBack is called when the mouse is moved - there is no need to poll the mouse to check if it has moved. Plant SCADA watches for an event with the OnEvent() function.

Because these functions are called each time the event occurs, you should avoid complex or time consuming statements within the function. If the function is executing when another call is made, the function can be blocked, and some valuable information may be lost. If you do wish to write complex event handling functions, you should use the queue handling functions provided with Cicode.

### How Plant SCADA Executes

Your multi-tasking operating system gives Plant SCADA access to the CPU through threads. However, this access time is not continuous, as Plant SCADA needs to share the CPU with other applications and services.

---

**Note:** Be careful when running other applications at the same time as Plant SCADA. Some applications place high demands on the CPU and reduce the execution speed of Plant SCADA.

---

The Plant SCADA process has many operations to perform, including I/O processing, alarm processing, display management, and Cicode execution - operations that are performed continuously. And, because Plant SCADA is a real-time system, it needs to perform the necessary tasks within a minimum time - at the expense of others. For this reason, Plant SCADA is designed to be multitasking, so it can efficiently manage its own tasks.

Plant SCADA performs its tasks in a specific order in a continuous loop (cycle). Plant SCADA's internal tasks are scheduled at a higher priority than that of Cicode and have access to the CPU before the Cicode. For example, the Alarms, Trends, and I/O Server tasks all get the CPU before any of your Cicode tasks. The reports are scheduled at the same priority as your Cicode. Plant SCADA background spoolers and other idle tasks are lower

priority than your Cicode.

For Cicode, which consists of many tasks, Plant SCADA uses round-robin single priority scheduling. With this type of scheduling each task has the same priority. When two or more Cicode tasks exist, they each get a CPU turn in sequence. This is a simple method of CPU scheduling.

**Note:** If a Cicode task takes longer than its designated CPU time to execute, it is preempted until the next cycle - continuing from where it left off.

---

## Multitasking

Multitasking is when you can run more than one task at the same time. Windows supports this feature at the application level. For example you can run MS-Word and MS-Excel at the same time.

Plant SCADA also supports multitasking internally; that is you can tell Plant SCADA to do something, and before Plant SCADA has completed that task you can tell Plant SCADA to start some other task. Plant SCADA will perform both tasks at the same time. Plant SCADA automatically creates the tasks, leaving you to call the functions.

Multitasking is a feature of Plant SCADA not the operating system. Many applications cannot do this, for example if you start a macro in Excel, while that macro is running you cannot do any other operation in Excel until that macro completes.

A multitasking environment is useful when designing your Cicode. It allows you to be flexible, allowing the operator to perform one action, while another is already taking place. For example, you can use Cicode to display two different input forms at the same time, while allowing the operator to continue using the screen in the background.

## Foreground and Background Tasks

Cicode tasks (or threads) can be executing in either foreground or background mode. A foreground task is one that displays and controls animations on your graphics pages. Any expression (not a command) entered in a property field (that is Text, Rectangle, Button, etc.) is executed as a foreground task. Any other commands and expressions are executed in background mode.

The difference between a background and foreground task is that a background task can be pre-empted. That is, if system resources are limited, the task (for example, the printing of a report) can pause to allow a higher priority task to be executed. When the task is completed (or when system resources become available) the original task resumes. Foreground tasks are the highest priority and can not be pre-empted.

## Controlling Tasks

You can use the Task functions to control the execution of Cicode tasks, and use the Plant SCADA Kernel at runtime to monitor the tasks that are executing. Since Plant SCADA automatically creates new tasks (whenever you call a keyboard command, etc.), schedules them, and destroys them when they are finished, users rarely need to consider these activities in detail.

Sometimes it is desirable to manually 'spawn' a new task. For example, suppose your Cicode is polling an I/O Device (an operation which needs to be continuous), but a situation arises that requires operator input. To display a form would temporarily halt the polling. Instead you can spawn a new task to get the operator input, while the original task continues polling the device.

**Note:** The TaskNew Cicode function is used to spawn new tasks.

---

## Pre-emptive Multitasking

Cicode supports pre-empted multitasking. If a Cicode task is running, and a higher priority task is scheduled, Plant SCADA will suspend the original task, complete the higher priority task and return to the original task.

Preemption is supported between Cicode threads and other internal processes performed by Plant SCADA. You can, therefore, write Cicode that runs forever (for example, a continuous while loop) without halting other Cicode threads or Plant SCADA itself. For example:

```
INT FUNCTION MyLoopFunction()
WHILE TRUE DO
// Whatever is required in the continuous loop
Sleep(1); // Optional
END
END
```

In the above example, the function `Sleep()` is used to force preemption. The `Sleep()` function is optional, however it will reduce the load on the CPU, because the loop is suspended each second (it will not repeat at a high rate).

## Cicode Editor

You use the Cicode Editor to write, edit, and debug your Cicode code. The Cicode Editor behaves similarly to other code editing tools like Microsoft Dev Studio, and contains many advanced editing features such as:

- Dockable windows and toolbars.
- Syntax highlighting - color highlighting of syntax functions.
- IntelliSense AutoPrompt - function definition tooltips.
- IntelliSense AutoComplete - automatic inline prompting and completion of functions with their parameters.
- AutoCaseCorrect - automatic case correction of function keywords.
- AutoIndent - automatic indent alignment of code.
- AutoScroll - automatic mouse middle button support.
- Drag and Drop - copy or move of selected text.
- Bookmark and Breakpoint indicator bar - single click set and reset of bookmarks and breakpoints.
- Keyboard Shortcuts support.

Click the "Launch Cicode Editor" button in Activity Bar of the Plant SCADA Studio to start the Cicode Editor.

Cicode files are stored as text files. For more information see [Using Cicode Files](#).

**Note:** Be careful not to confuse a Cicode file (\*.ci) with an Include file (\*.cii).

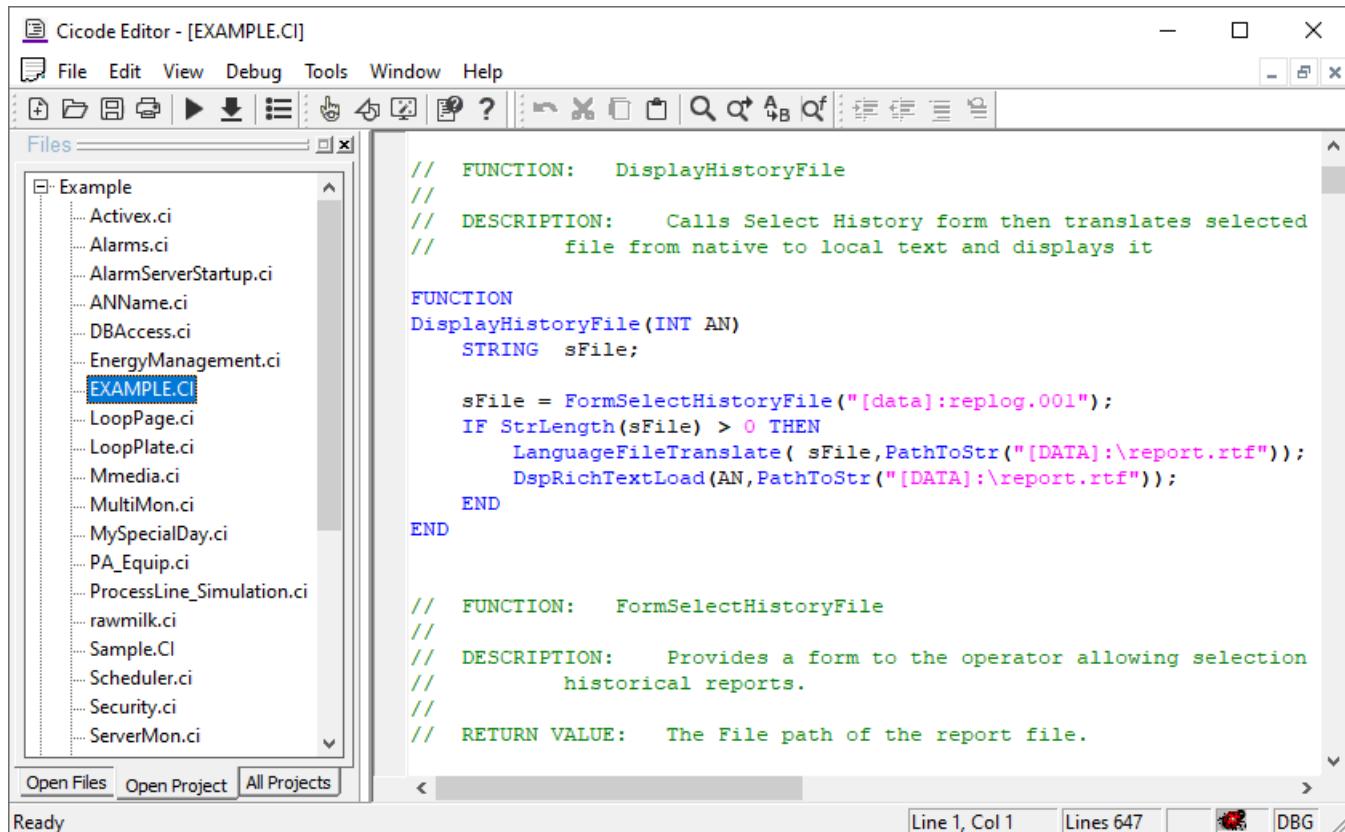

You could use any text editor to view or edit the Cicode files, however, the Cicode Editor provides integrated views specific to Cicode. As well as the features listed above, it includes:

- Breakpoint window
- Output window
- Global Variable Window
- Stack window
- Thread window

- Compile Errors window
- VBA Watch window
- Files window

To minimize potential future problems with maintaining your Cicode files, you should adopt a programming standard as early as possible, as discussed in the section [Using Cicode Programming Standards](#). Maintain structured Cicode files, by logically grouping your Cicode functions within the files, and by choosing helpful descriptive names.

Modular programming methods are discussed in the section [Modular Programming](#). Cicode functions are introduced in the section titled [Using Cicode Functions](#). Suggestions for debugging your Cicode is included in the section titled [Debugging Cicode](#).

```
// FUNCTION:    DisplayHistoryFile
//
// DESCRIPTION:   Calls Select History form then translates selected
//                 file from native to local text and displays it

FUNCTION
DisplayHistoryFile(INT AN)
    STRING sFile;

    sFile = FormSelectHistoryFile("[data]:replug.001");
    IF StrLength(sFile) > 0 THEN
        LanguageFileTranslate( sFile, PathToStr("[DATA]:\report.rtf"));
        DspRichTextLoad(AN,PathToStr("[DATA]:\report.rtf"));
    END
END

// FUNCTION:    FormSelectHistoryFile
//
// DESCRIPTION:   Provides a form to the operator allowing selection
//                 historical reports.
//
// RETURN VALUE:  The File path of the report file.
```

## Creating Cicode Files

### To create a new Cicode file:

1. Start the Cicode Editor.
2. Choose **File | New**, or click **New**.

Save the Cicode file after creating it. The file is only stored on disk after you save it.

## See Also

[Cicode Editor](#)

### Creating Functions

#### To create a new Cicode function:

1. Start the Cicode Editor.
2. Choose **File | New**, or click **New**.
3. Type in your new Cicode function in the blank space, or at the end of the file. Format the Cicode function correctly, following the documented syntax.
4. Save the Cicode file.

## See Also

[Cicode Editor](#)

### Saving Files

#### To save a Cicode file:

1. Choose **File | Save**, or click **Save**.
2. If the file is new, you will be prompted by the Save as dialog. Plant SCADA automatically suggests a name.
3. Type in a new name in the **File name** field.
4. Click **Save** to save the file, or **Cancel** to abort the save.

To save your Cicode file under a new name, choose **Save as** instead of **Save**. The original file will remain in your project under the original filename, until you delete it. All source files in your project directory will be included when you compile your project.

## See Also

[Cicode Editor](#)

[Creating Cicode Files](#)

[Opening Cicode Files](#)

### Opening Cicode Files

#### To open a Cicode file:

1. Start the Cicode Editor.
2. Choose **File | Open**, or click **Open**.
3. Select a file from the list. You can use the dialog controls to open other projects and directories.

4. Click the **Open** button to open the file, or **Cancel** to abort.

---

**Note:** Double clicking on any Cicode file (\*.ci) in the explorer will launch the Cicode Editor and open the Cicode file. However, be careful not to confuse a Cicode file with an Include file (\*.cii).

---

[Creating Cicode Files](#)

## Deleting Cicode Files

### To delete a Cicode file:

1. Run the Cicode Editor.
2. **Choose File | Open**, or click the **Open** button.
3. Select the target file from the list. You can use the dialog controls to open other projects and directories.
4. Press the **Delete** key.
5. Click the **Yes** button to confirm delete, or **No** to abort.
6. Click the **Cancel** button to close the Open form.

## See Also

[Cicode Editor](#)  
[Creating Cicode Files](#)

## Finding Text in Cicode Files

### To find text in a Cicode file:

1. Choose **Edit | Find**, or click the **Find** button.
  2. Complete the Find dialog, filling in the **Find what** field.
  3. Click the **Find Next** button to begin searching, or **Cancel** to abort.
- The search is performed down the file from the cursor. Hits are highlighted.

## See Also

[Cicode Editor](#)

## Compiling Cicode Files

### To compile Cicode:

1. Run the Cicode Editor.
2. Choose **File | Compile**, or click the Compile button.

---

**Note:** You cannot compile Cicode functions individually. When you compile Plant SCADA, it automatically compiles the entire contents of the project.

---

## Viewing Errors Detected by the Cicode Compiler

### To view errors detected by the Cicode compiler:

Do either of the following:

- From the **Compile Errors** in the **File** menu of the Project Editor, click **Goto**. This launches the Cicode Editor and opens the appropriate file at the correct line.
- Choose **View | Compile Errors**, then double-click the compile error you want to view.

## See Also

### Find User Function

If you need to locate a Cicode function in your Cicode source files, you can use the **Find User Function** option.

### To locate a function within a Cicode source file:

1. Open the Cicode file you would like to search.
2. From the **Edit** menu, select **Find User Function**.
3. The Find User Function dialog box will open.
4. In the **Find** field, enter a function name (or part of a function name). If required, select the **Find Exact Match** check box.
5. Click **OK**.

A list of functions that match your search criteria will be displayed.

---

**Note:** If you leave the **Find** field empty and click **OK**, a full list of functions appears in the list.

---

### To edit the Cicode file that contains a function:

- Within the search results, select a function and click **Edit**.

Or:

- Within the search results, double-click on a function.

The file containing the selected function will open in the Cicode Editor.

## See Also

[Cicode Editor](#)

### Cicode Editor Windows

The [Cicode Editor](#) has several editing and debug windows that you can use to display information about running Cicode and VBA.

The available Cicode Editor windows are:

- [Breakpoint Window](#)
- [Output Window](#)
- [Global Variable Window](#)
- [Stack Window](#)
- [Thread Window](#)
- [Compile Errors Window](#)
- [Citect VBA Watch window](#)
- [Files window.](#)

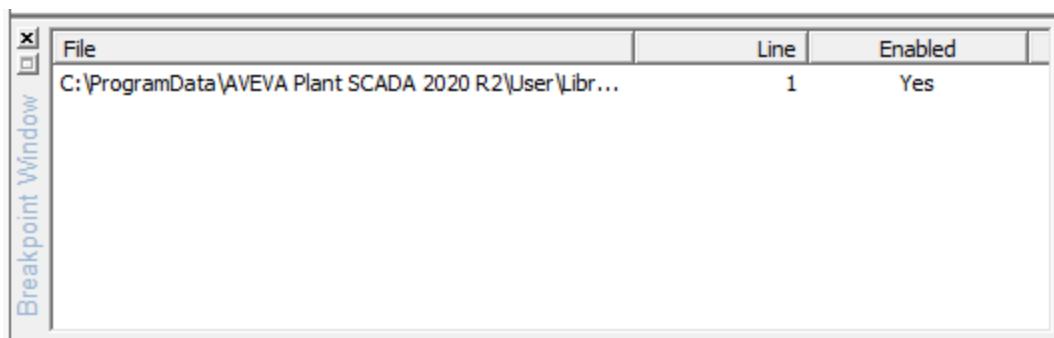

You can display a particular window by selecting it from the **View** menu, or you can use the buttons on the View toolbar.

## See Also

[Docking Windows and Toolbars](#)

### Breakpoint Window

The Breakpoint Window is used to list all breakpoints that are currently set within the project. Double clicking an item in the list loads the file into the editor and jumps to the breakpoint position. Right-clicking an item allows the enable/disable/removal of the list item.

The Breakpoint Window has the following fields:

- **File:** the full name and location of the code file in which the breakpoint exists.
- **Line:** the line number (in the code file) where the breakpoint is located.
- **Enabled:** indicates if the breakpoint is enabled or not. **Yes** indicates it is active, **No** indicates it is not.

## See Also

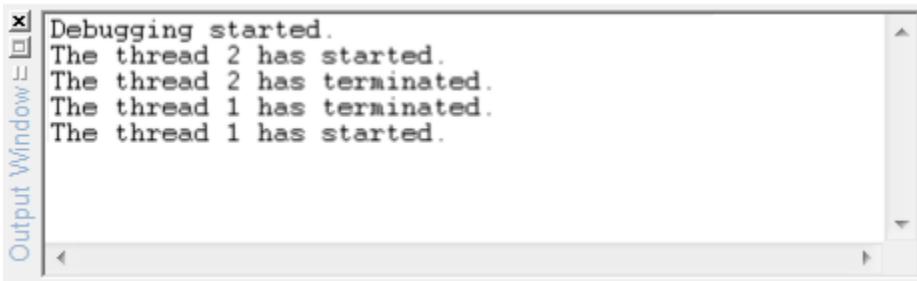

[Docking Windows and Toolbars](#)

[Cicode Editor Windows](#)

## Output Window

The Output Window lists the output messages sent by Plant SCADA during debugging. It states when threads start and terminate, and if a break occurs. This window will show messages sent by the TraceMsg() function.

The Output window shows entries in the order that they occur:

**Note:** you need to be in debug mode to view the messages.

## See Also

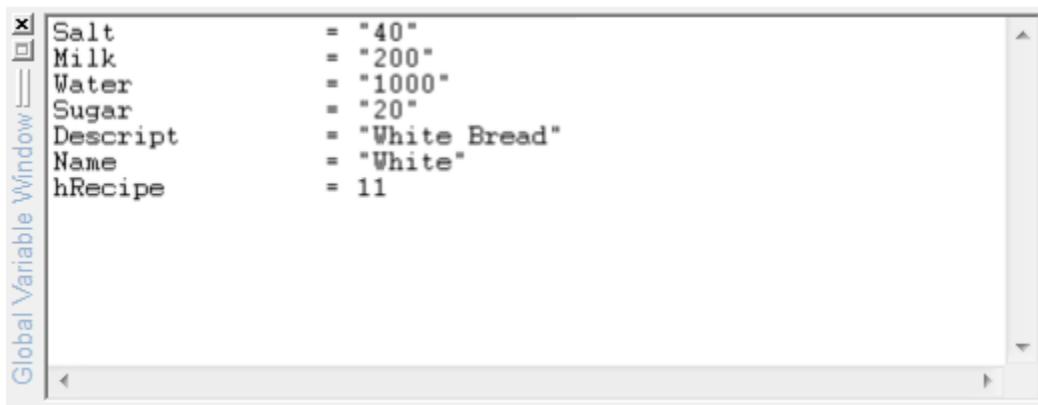

[Docking Windows and Toolbars](#)

[Cicode Editor Windows](#)

## Global Variable Window

The Global Variables Window lists the names and values of all global variables processed to date in the running project during debugging. A global variable is added to the list when it is first assigned a value. Each time the

Global variable is processed, its value will be updated in the Global Variable Window.

**Note:** you need to be in debug mode to view global variable values in this window.

## See Also

[Docking Windows and Toolbars](#)

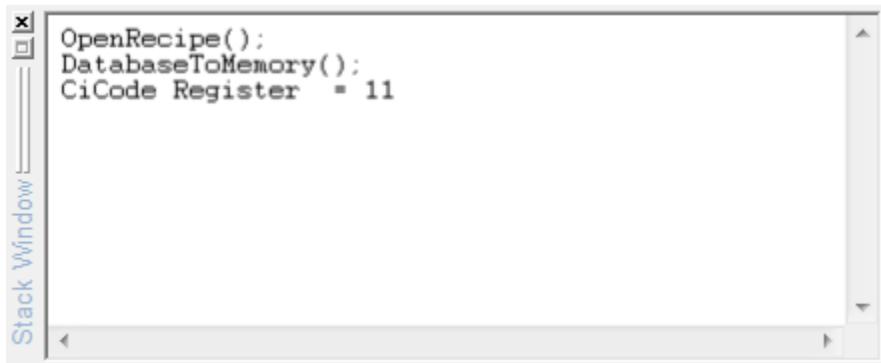

[Cicode Editor Windows](#)

## Stack Window

The Call Stack window lists the stack values of the current thread. The stack consists of the functions called (including the arguments), any variables used in the functions, and return values. This is especially useful during debugging to trace the origin of the calling procedures.

A stack is a section of memory that is used to store temporary information. For example, when you call a Cicode function, the variables used inside the function exist only as long as the function runs.

To view the values of arguments and variables in a procedure, place a breakpoint within the procedure under watch. When that breakpoint is reached, the Stack Window will display the current call stack of the procedure containing the breakpoint. The values of the stack are updated as the values change.

**Note:** you need to be in debug mode to view this window.

## See Also

[Docking Windows and Toolbars](#)

## Cicode Editor Windows

### Thread Window

The Threads History window displays the history for Cicode threads.

Name	HND	User	CPU	State	CPU_Time	Poll...	Slice	Use %
_TagSimulateTask	1	(null)	00	Sleep	00:00:00.127	250	559	0.0
_TagSimulateTask	2	(null)	00	Sleep	00:00:00.100	250	546	0.0
_LibControl_Process	3	(null)	02	Sleep	00:00:10.553	250	14...	4.6
_LibControl_Process	5	(null)	01	Sleep	00:00:07.387	250	24...	6.0
_DspLogo_Process	6	(null)	00	Wait	00:00:00.017	250	11	0.2
_TagSimulateTask	8	(null)	00	Sleep	00:00:00.126	250	542	0.1
_TagSimulateTask	10	(null)	00	Sleep	00:00:00.114	250	545	0.0

The Thread Window has the following fields:

- **Name:** The name of the Cicode thread. This is the name of the function called to start the thread (from the TaskNew() function for example).

If you click on the Name of the Cicode thread, you will make the selected thread the current focus of the Debugger. The Debugger will change the display to show the source of the new thread.

**Note:** If the thread was not started from TaskNew(), the Name shown will be **Command**.

- **Hnd:** The Cicode thread handle.
- **CPU:** The amount of CPU the Cicode thread is currently using, as a percentage of the total CPU usage. Cicode is efficient and this value should be quite small (0-25%). If this value is large it can indicate a problem with the **Note:** you need to be in debug mode to view this window.
- **State:** The state of the Cicode thread. The states are defined as follows:
  - **Ready:** The Cicode is ready to be run.
  - **Sleep:** Suspended using the Sleep() function.
  - **Run:** The thread is running.
- **CPU\_Time:** The total amount of CPU time that the Cicode thread has consumed. This tracks how much CPU time the thread has used over its lifetime.

**Note:** You need to be in debug mode to view this window.

### See Also

[Docking Windows and Toolbars](#)

[Cicode Editor Windows](#)

### Compile Errors Window

The Compile Errors window lists any code errors that have occurred during compile. You can double-click on the file name in the list, to open that code file in the Cicode Editor, and jump to the line of code that caused the compile error.

## See Also

[Docking Windows and Toolbars](#)

[Cicode Editor Windows](#)

## Citect VBA Watch Window

When in debugging mode, you can use the VBA Watch window to watch the value of any VBA variables in the current scope. Click in the **Variable** column and type in the name of the variable under watch. As it comes into scope, its value is updated and appears in the **Value** column.

**Note:** You need to be in debug mode to view this window.

## See Also

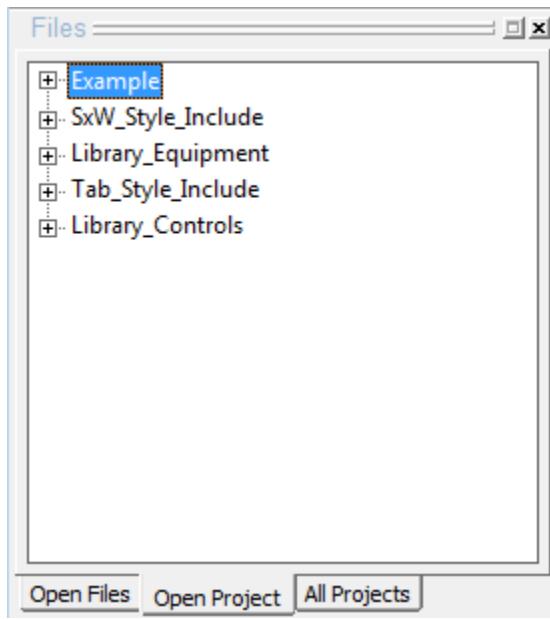

[Docking Windows and Toolbars](#)

[Cicode Editor Windows](#)

## Files Window

The Files window contains three tabs.

- The **All Projects** tab displays a tree hierarchy view of all projects and their Cicode and VBA files available within Plant SCADA project.
- The **Open Project** tab displays a tree hierarchy view of the currently selected project, and all included projects. The currently selected project will be the top entry.
- The **Open Files** tab lists the names of all files currently open for editing in the Cicode Editor.

**Note:** Clicking any of the file names displayed in the tree will open that file in the editor and give it the focus.

## See Also

[Docking Windows and Toolbars](#)

[Cicode Editor Windows](#)

## Cicode Editor Options

The [Cicode Editor](#)'s error handling behavior is controlled through the Cicode Editor Options dialog. This dialog can be used to specify:

- How errors are handled in running Cicode
- The circumstances that will start the debugger
- How the debugger behaves when in debug mode.

There are two tabs on the dialog:

- [Windows and Bars Tab](#)
- [Options Tab](#)

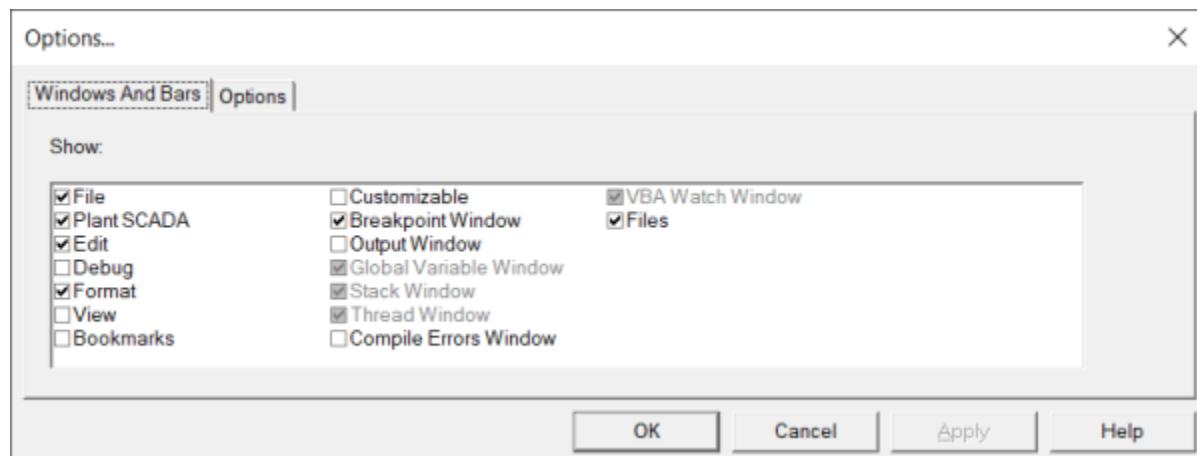

### To view/hide the Cicode Editor Options dialog:

1. Run the Cicode Editor.
2. On the **Debug** menu, select **Options**.  
Or:  
Press Ctrl + T.

## See Also

[Debugging Cicode](#)

## Windows and Bars Tab

The Windows and Bars tab displays the current display state of the listed Toolbars and Debug Windows within

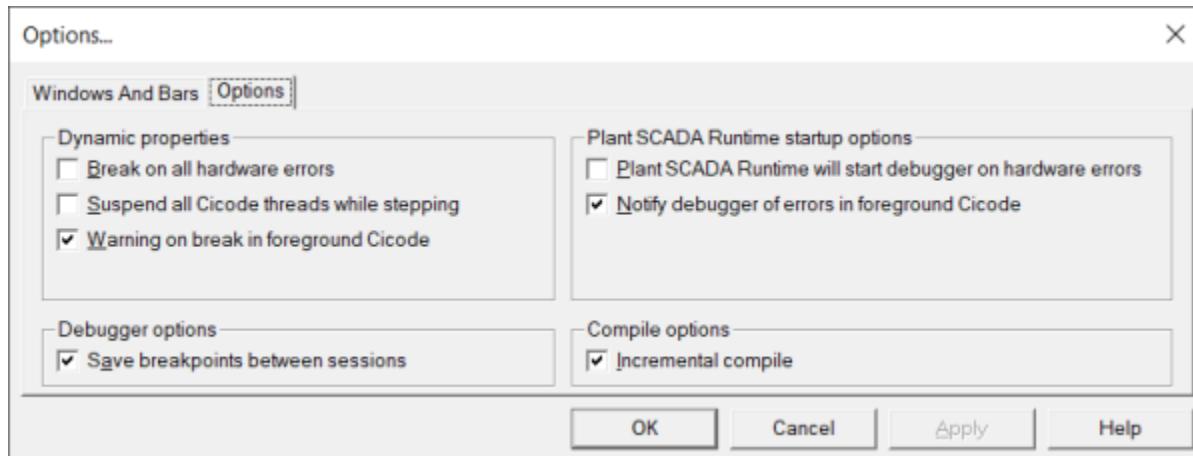

the Cicode Editor. A check mark in the checkbox next to the Window or Toolbar name enables the display of that Window or Toolbar in the Cicode Editor. A grayed-out checkbox indicates that the window is disabled (presently unable to be displayed). For example: Many of the debug windows which display the active state of project Cicode variables are disabled when a Cicode project is not running, and therefore the Cicode Editor cannot be in debug mode).

**Note:** Right-click in the toolbar area to view a menu of available toolbars and debug windows. For a description the buttons, see [Cicode Editor](#).

## See Also

[Cicode Editor Options](#)

### Options Tab

The Options properties tab has the following features:

### Dynamic Properties

- **Break on all hardware errors**

Stops a Cicode thread if a hardware error is detected. A Cicode error will be generated and the thread will terminate (without executing the rest of the function).

- **Suspend all Cicode threads while stepping**

All Cicode threads will be suspended while the debugger is stepping (or when the debugger reaches a breakpoint, or the user performs a manual break). If you try to run any Cicode thread at such a time (by pressing a button at runtime, and so on), the **Command paused while in debug mode** message will display in the runtime prompt line.

This option allows better isolation of any software errors that are detected, especially those that occur when your Cicode thread interacts with other threads. Foreground Cicode cannot be suspended and will continue running when this option is set.

**Note:** This option will help prevent all new Cicode threads from running (including keyboard and touch commands), and should not be used on a running plant.

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not use the following option during normal plant or process operations:

- Suspend all Cicode threads while stepping.

This option is only for use during system testing and commissioning.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

- **Warning on break in foreground Cicode**

If a break point is 'hit' in a foreground Cicode task, the **Foreground Cicode cannot break (343)** error message is generated, and will be displayed on the Hardware Alarm page. Disable this option to stop the alarm message from displaying.

## Plant SCADA Runtime Startup Options

- **Plant SCADA Runtime will start debugger on hardware error**

Plant SCADA will automatically start the debugger when a Cicode generated hardware error is detected. The debugger will display the Cicode source file, and mark the location of the error.

**Note:** This option will interrupt normal runtime operation, and should only be used during testing and commissioning of systems.

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not use the following option during normal plant or process operations:

- Plant SCADA will start debugger on hardware errors.

This option is only for use during system testing and commissioning.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

- **Notify debugger of errors in foreground Cicode**

Plant SCADA will automatically start the debugger if an error is detected in a foreground task. The debugger will display the Cicode source file, and mark the location of the error.

This option is overridden by the **Plant SCADA Runtime will start debugger on hardware errors** option. That is, if the above option is disabled, then this option is disabled also.

**Note:** Foreground Cicode cannot be suspended. The break point will be marked, but you will not be able to step through the function.

## Debugger Options

- **Save breakpoints between sessions**

Save the location and states of breakpoints between running sessions of the Cicode Editor and Debugger. This means breakpoints inserted using the Cicode Editor can later be recalled when an error is detected - even though the file (and application) has been closed.

## Compile Options

- **Incremental compile**

Enables the incremental compilation of the project.

## See Also

[Cicode Editor Options](#)

## Docking Windows and Toolbars

The windows and toolbars of the [Cicode Editor](#) can be docked or free floating within the editing and debugging environment.

## Toolbars

Toolbars are docked by default within the toolbar area at the top of the Cicode Editor.

To show/hide a toolbar, right-click within the toolbar area and make a selection from the menu that appears.

## Windows

Windows are docked by default in the document display area of the Cicode Editor (beneath the toolbar).

- **Docked windows** are those that fit within the Cicode Editor display area by docking (attaching) themselves to an internal edge of the display area. Docked windows cannot be resized manually, and will share the display space with the Editor toolbars and other docked windows.
- **Floating windows** are those that are not docked to the editor, nor are necessarily constrained by the editor boundaries. Floating windows can be resized manually, and are subject to layering (Z-order), in which they can be partly or wholly obscured by another window.

Windows and toolbars can be moved about in the Cicode Editor environment by clicking and dragging the titlebar of a window. Docking behaviour is by default, and can be overridden by holding down the CTRL key during the drag-and-drop to force the window or bar to be free floating.

The position of the mouse during the drop action determines which side the window or toolbar docks to. Docking outlines of the window or toolbar are displayed with gray lines during the drag action to indicate the potential docked position.

[Cicode Editor Windows](#)

## Debugging Cicode

To help you locate Cicode errors, you can switch the Cicode Editor to debug mode to analyze running Cicode. You can toggle debugging on and off as required, but Plant SCADA needs to be running for the debugger to work.

---

**Note:** The Cicode Editor cannot debug foreground Cicode. A break in a foreground Cicode will result in the **Foreground Cicode cannot break** message.

---

### To switch to debug mode:

1. Run the Cicode Editor.
2. From the **Debug** menu, select **Start Debugging**.

Or:

Click the **Toggle Debug** button on the toolbar.

Or:

To start a debugging session without the project being recompiled, select **Start Debugging Without Compile** from the **Debug** menu. You can only use this option if you have already compiled the project at least once.

### WARNING

#### UNINTENDED EQUIPMENT OPERATION

Do not use the following command to start Plant SCADA if you have uncompiled project changes that are necessary for the safe operation of your plant and process.

- Start Debugging Without Compile

This option is only intended to assist debugging an already compiled project.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

---

If the current project is not running, Plant SCADA will automatically launch it. The bug icon in the bottom right-hand corner is green when debugging.

---

**Note:** You can use the parameter [\[Debug\]CodeDebug](#) to enable Cicode debugging for a specific server process. You cannot debug a process that is running as a Windows™ service.

---

## Debugging a Function

### To debug a function:

1. Run the Cicode Editor.
2. Open the file containing the function you wish to debug.
3. Switch to debug mode (see above).

If the current project is not running, Plant SCADA will automatically launch it. The bug icon in the bottom right-hand corner is green when debugging.

4. Insert a breakpoint where you want to start debugging.
  5. From the **View** menu, select any debug windows you want to use. If you are unsure, you can use them all.
  6. Initiate the thread by calling the function. You can do this directly from the Cicode window in the Kernel, or by using a function, etc.
- The function will break at the specified breakpoint. You can then use the step tools to step through and trace your function.
7. Click the Toggle Debug button to stop debugging, or choose **Debug | Stop Debugging**.

## Using Breakpoints

To debug a function, you need to first be able to stop it at a particular point in the code. You can place a breakpoint on any line in the source code functions. Breakpoints may be inserted or removed while editing or debugging without the need for them to be saved with the file.

### To insert/remove a breakpoint:

1. Open the Cicode Editing window.
2. Position the cursor on the line where you want the breakpoint to be placed or removed.
3. Click the Debug indicator bar. Alternatively, you can press **F9** or choose **Debug | Insert/Remove Breakpoint**.

The breakpoint appears as a large red dot at the beginning of the line.

You can also enable or disable breakpoints you have inserted into your Cicode.

### To enable/disable a breakpoint:

1. Open the Cicode Editing Window.
2. Position the cursor on the line where the breakpoint is located.
3. Press **Ctrl + F9**, or choose **Debug | Enable/Disable Breakpoint**.

A disabled breakpoint appears as a large dark gray (disabled) dot at the beginning of the line.

---

**Note:** You can also use the **DebugBreak** Cicode function to halt a process thread.

---

## Start Debugging on Hardware Error

For a detected hardware error to halt a function, you need to have the following options enabled:

1. **Break on all hardware errors.**  
Or:  
2. **Break on hardware errors in active thread.**

These are available on the **Options** tab of the Cicode Editor Options dialog (**Debug | Options**).

When the break occurs, the default Cicode Editor will be launched (if it is not open already), with the correct code file, function, and break point line displayed. To launch the debugger in this case, you also need to have the **Plant SCADA will start debugger on hardware errors** option set.

## Function Error Handling

Once you have halted a thread, the debugger marks the position in the code with an arrow. Now you can step through the function, line by line, and watch what happens in the debug window (see below). The following tools are provided in the Cicode Editor, to control stepping through functions.

Step Into	Advances the current Cicode thread by one statement. If the statement is a user defined function, the debugger steps into it (the pointer jumps to the first line of the source code).
Step Over	Advances the current Cicode thread by one statement. If the statement is a user defined function, the debugger steps over it (the function is not expanded).
Step Out	Advances to the end of the current function and return. If there is no calling function, the thread terminates.
Continue	Re-starts normal execution of the current Cicode thread. If there are no more breaks, the thread terminates normally.

## Cicode Errors

This section describes the error codes used by Plant SCADA in the following situations:

- [Hardware/Cicode Errors](#)
- [Cicode and General Errors](#)
- [MAPI Errors](#)

### Hardware/Cicode Errors

Plant SCADA 'traps' system errors automatically. When Plant SCADA detects a system error, it generates a hardware alarm, and the corresponding error message is placed in the alarm description. Each error has an associated (unique) error number.

You can use the IsError() function to get the number of the last error. Alternatively, you can trap and process errors within your user functions. Use the ErrSet() function to enable or disable error trapping. Plant SCADA 'traps' system errors automatically. When a system error occurs, Plant SCADA generates a hardware alarm, and the corresponding error message is placed in the alarm description. Each error has an associated (unique) error number. Number 0 means no error, errors start from 1.

Range	Source	Cause
1 - 31	PLC or I/O Device Generic errors	The I/O device is reporting an error, or Plant SCADA is experiencing the reported error trying communicate

Range	Source	Cause
		with an I/O device. Often caused by incorrect configuration or poor cabling. For a detailed list of these errors, see the <i>Error Messages</i> topic in the <b>Topology   I/O Devices   Troubleshooting Device Communications</b> section of the Plant SCADA help.
256 -511	General	<p>General errors are wide ranging, from animation to server problems. However, there are two main causes of general errors:</p> <ol style="list-style-type: none"> <li>1. Device External devices such as printers, databases, and files can cause many different hardware errors since they are beyond the control of Plant SCADA. Often the device itself is improperly configured or non-existent.</li> <li>2. Cicode Cicode errors are generated when your project configuration calls a Cicode function in an invalid way, or when a Cicode function returns an error or does illegal operations. For a detailed list of these errors see <a href="#">Cicode and General Errors</a>.</li> </ol>
382 - 383	Invalid tag data	This will indicate that the tag data validation process has identified a discrepancy with the tag index values. For more information, see the topic <i>Validating Distributed Project Data for Tag-based Drivers</i> in the <b>Topology   I/O Devices</b> section of the Plant SCADA help.

You can use the `IsError()` function to get the number of the last error. Alternatively, you can trap and process errors within your user functions. Use the `ErrSet()` function to enable or disable error trapping.

## Cicode and General Errors

The table below describes the general errors in Cicode.

Error No.	Error title	Description
<b>0</b>	No Error	No error
<b>32</b>	The unit the tag is on has not been connected to yet	When the error for a tag has specific values the tag test can show "#WAIT" for this error. This occurs for scheduled or Dial-up devices.
<b>53</b>	The tag is not known by the server being talked to at this time	The reason for a tag being unknown by the I/O or alarm system may not be that it does not exist, just that the server it is on is yet to come up and tell us about it. However, more often than not, it is because it does not exist.
<b>55</b>	Tag value is limited	Tag value is limited to be within range.
<b>256</b>	General software error	An internal Plant SCADA software error is detected. Contact Technical Support for this product and provide details on what causes the error.
<b>257</b>	Value is out of range	A numeric value is out of range. An out-of-range value has been passed to a function, or an array index is off the end of an array, or a value that is outside of the specified engineering scale has been assigned to a I/O Device variable. You can disable range checking on PLC variables with the CodeSetMode() function.
<b>258</b>	Buffer has been overrun	A buffer has been overrun. More data has been passed to a function than it can write to its temporary buffers. Try again by calling the function twice, with half the data in each call.
<b>259</b>	Array has been overrun	An array passed to a function is too small for the data requested. Define a larger array or reduce the maximum data size requested.

Error No.	Error title	Description
<b>260</b>	Path does not exist	The specified path to a device or file does not exist. During a function call (that tried to open a file), a non-existent path was specified. Call the function again with the correct path.
<b>261</b>	File does not exist	The specified file or device does not exist. During a function call (that tried to open a file), the file could not be found. Call the function again with the correct file name. This error will also be detected if you try to call TrnDelHistory() on a file that has not been added using TrnAddHistory().
<b>262</b>	Cannot open file	The specified file cannot be opened. During a function call (that tried to open a file), the file could not be opened. There may be a mode error (for example, from trying to open a read-only file in write mode), or the file may be open by others, or the operating system resources may be too low to open the file.  Check that the file does exist (use File Manager), and that you have the correct rights to open it. (Check with your network supervisor that you have correct rights to open the file).
<b>263</b>	Cannot read file	The specified file cannot be read. Either an error has been detected during a read operation, or the end of file was unexpectedly found, or a disconnection from the file server occurred, or the operating system is out of resources.
<b>264</b>	Cannot write to file	The specified file cannot be written to. During a function call (that tried to write to a file), a write error has been detected. There could be a

Error No.	Error title	Description
		disk full error, or a disconnection from of the file server may have occurred, or the operating system is out of resources.
<b>265</b>	Invalid file type	An attempt was made to open a file of the wrong type, for example, you tried to open an ASCII file as a dBASE file.
<b>266</b>	Field not found in file	The specified field does not exist in the device or database. A function that is trying to access an individual field in a database cannot find that field. Check that you have specified the correct field name and database name.
<b>267</b>	File mode is invalid	An operation has been attempted on a file or device that is of the wrong mode, for example, you tried to perform a seek on a printer device.
<b>268</b>	Key not found in file	The requested key was not found when a key search was performed on a database device, that is the record specified on an indexed search cannot be found. Either the record does not exist or you have specified the wrong key.
<b>269</b>	Bad handle specified	A bad handle has been passed to a function. You have called a function that requires a device handle, font handle, window handle, etc., but you passed a number that does not associate with a read device, font, or window (for example, you called WinGoto(100) when no window with the handle "100" exists). Check where the handle or number was retrieved from, and verify that it is the same handle. This error may also be detected if you have closed or destroyed the resource and you then try to access it.

Error No.	Error title	Description
<b>271</b>	No more free handles left	All the available file handles have been used, that is too many files or databases are open at the same time. Open fewer files at one time or increase the number of file handles in the [CtEdit]DBFiles parameter.
<b>272</b>	Out of memory	Plant SCADA is out of memory. Increase the amount of memory in the computer or use smaller databases.
<b>273</b>	Divide by zero	An attempt has been made to divide a number by zero.
<b>274</b>	Invalid argument passed	An invalid argument has been passed to a Cicode function. This is a general error message and is generated when arguments passed to a function are out of range or are invalid. Check the value of arguments being passed to the function. If arguments are input directly from the operator, you should check that the correct arguments are being passed to the function.
<b>275</b>	Overflow	A calculation has resulted in a numeric value overflow. Check for operations that will generate large numbers.
<b>276</b>	No privilege for operation	A user has requested an operation for which he or she has no privilege.
<b>277</b>	Not in correct area	A user has requested data that does not belong to the current user area.
<b>278</b>	Report already busy	A request has been made to run a report that is already running. You can get the current state of a report with the RepGetControl() function. You can ignore this error message (because the report is already

Error No.	Error title	Description
		running).
<b>279</b>	Report is late for execution	The report cannot run at the rate requested in the configuration. An attempt could have been made to run a report too frequently, and the required data cannot be read from the I/O Device(s) in time for the next report.
<b>280</b>	Invalid report ID specified	The specified report name does not exist, or the user has no privilege to run the report, or the report is not in the current user area. Check the name of the report and the current user's privilege and areas.
<b>281</b>	No server could be found	The specified Plant SCADA server cannot be found. Either the server is not running or there is some disturbance in the network. Check that the network is set up correctly, and you are using the same Server Name on both the client and server.
<b>282</b>	Foreground Cicode cannot block	You cannot block the foreground Plant SCADA task. You may have called a blocking function from one of the Page animation databases.
<b>283</b>	Trend has missed samples	The trend cannot run at the rate requested in the configuration. An attempt could have been made to trend the data too frequently, and the required data cannot be read from the I/O Device(s) in time for the next trend. Either increase the performance of the communication link to the PLCs or slow the rate of trend data acquisition.
<b>284</b>	Device is disabled	An attempt was made to access a device that is disabled. You can disable any devices (printers and other logging devices) with the DevDisable() function. When Plant SCADA (or your Cicode function)

Error No.	Error title	Description
		tries to access a disabled device, this message returns and all output is lost.
<b>285</b>	Foreground Cicode run is too long	The foreground Cicode task is taking too long to animate the display page. The Cicode is too complex and is taking too long to execute. Simplify the Cicode that is animating the page, or increase the [Code] TimeSlice parameter. If you cannot simplify the Cicode, you can create a separate task using TaskNew() to calculate your complex operation, and then use the Display functions to display the results. Cicode running from a TaskNew() call is in background mode and can run as long as required.
<b>286</b>	Out of Cicode threads	Plant SCADA has run out of Cicode tasks. Run fewer tasks (for example, reports, key commands, and Cicode tasks) in parallel, or increase the number of tasks with the [Code]Threads parameter. This error can be caused by a configuration error if you keep creating tasks that do not finish.
<b>287</b>	Floating point exception trap	An invalid floating-point number has been found. Check the floating-point data from the I/O Device.
<b>288</b>	Out of buffers	Plant SCADA is out of dynamic buffers. You have called a function that requests buffer space but no buffers are available. Check which function is causing the error and increase the associated buffers, or slow the rate of transfer to that function. If the error occurs on a server or LAN device, increase the number of buffers with the [Lan]ReadPool parameter.  This error can also be detected if

Error No.	Error title	Description
		<p>something is stopping the release of the buffers, for example, if network communication has stopped or a PLC has just come off-line. The error 'Out of buffers' can also be generated in the following ways:</p> <p>Calling QueWrite() when the queue functions have run out of buffers. You can increase the number of queue buffers with the [Code] Queue parameter.</p> <p>Calling WinFree() to free the last Cicode window. If WinFree() did free the last window, Plant SCADA would have no windows left.</p> <p>To verify which function is causing the hardware error, display the {ERRPAGE} and {ERRDESC} fields on the hardware alarm.</p>
<b>289</b>	Name does not exist	The specified name does not exist in this context. You are probably using the wrong name.
<b>290</b>	Not finished	A request has been made for trend data that has not yet finished trending.
<b>291</b>	File not Plant SCADA format	The specified file is not in Plant SCADA format. The file (trend, graphic, or any other file) is in an invalid format. Check that the name of the file is valid or that the file has not become corrupted.
<b>292</b>	Invalid function	The specified function name does not exist. You have tried to create a task, or called a remote procedure, or set an event function that does not exist.
<b>293</b>	File error	A general file error has been detected. Either a general hardware error has occurred, or the operating system is out of resources, or the file server is

Error No.	Error title	Description
		down.
<b>294</b>	File EOF	The end of the file was found. An attempt was made to read data off the end of a file or database.
<b>295</b>	Cicode stack overflow	<p>A Cicode evaluation stack overflow has occurred. There are too many local function variables or nested function calls. Reduce the number of local variables or increase the [Code] Stack parameter.</p> <p>The Cicode stack is used to store local function variables and function calls. If you have many nested functions and a large number of local function variables, the Cicode stack may overflow. When the Cicode stack overflows, the Cicode that caused the overflow is halted.</p> <p>You can estimate the size of the stack by counting the maximum number of local function variables in the deepest function calls. For example, if function A has 10 variables and calls function B with 30 variables, which calls function C with 40 variables, the stack needs to be <math>10 + 30 + 40 = 80</math> deep.</p>
<b>296</b>	Queue empty	An attempt has been made to read an element from an empty queue.
<b>297</b>	Semaphore owner died	The owner of a Cicode semaphore was halted, killed, or returned without releasing the semaphore. Reset the shared resource back to a known state (because the task that died may have left it in a mess), and then continue. For example, if you are sharing a printer, do a form feed.
<b>298</b>	Semaphore timeout	The requested semaphore was still in use after the specified timeout. Either try to get the semaphore

Error No.	Error title	Description
		again or abort the operation and tell the operator of the detected error.
<b>299</b>	Cancelled	The specified form or command was cancelled. This error is returned when a user presses the <b>Cancel</b> button on a form. The normal procedure is to abort the operation.
<b>300</b>	Trend not found	The trend does not exist at the specified AN and page. A trend function may have been called when the trend is not defined for that AN.
<b>301</b>	Trend pen not found	The required trend pen name does not exist in the Trends database or is not in the current user area. Check that the pen name exists and check the current user's privilege and area.
<b>302</b>	Trend data not valid	The requested trend data is not valid. Either the I/O Device data was bad, or the Plant SCADA trend server was shut down, or the trend data was disabled.
<b>303</b>	Invalid animation number	The AN specified in the function is not defined. You called one of the DspXXX animation functions, but you specified an animation number that was out of range or that had been deleted.
<b>304</b>	File server inoperative, stand-by active	Plant SCADA has detected that a file server has become inoperative, and will switch to the standby file server. The file server's inoperative condition is due to errors of the network or of the file server computer. This error is displayed only if you have enabled redundant file servers. If a redundant file server is not enabled, Plant SCADA and Windows become inoperative

Error No.	Error title	Description
		when the file server becomes inoperative. You should report this error to the operators to fix the file server.
<b>305</b>	Conflicting types of animation	The same AN is being used for two different types of animation. This error is detected if you try to display two (or more) incompatible types of animation on the same AN (for example, you try to display a symbol at a AN where a bar graph is already displayed). Check the configuration. If you need to display a new animation, you need to first delete the old animation with the DspDel() function.
<b>306</b>	SQL field value truncated	A maximum of 1000bytes (1Kb) can be returned from a single field call. If the field data is larger than this limit, it is truncated. You have tried to access a database where one of the fields is greater than 1000 bytes in size. Change the database field size to less than 1000 bytes so it can be accessed. In fact, you should change the field size to less than 256 bytes, the maximum allowable length of a Cicode string.
<b>307</b>	SQL database error	A general SQL error. Call the SQLErrMsg() function for details of the detected error.
<b>308</b>	SQL null field data returned	Data has been requested from a field that contained no data, or the SQL server does not support this type of field data. Plant SCADA will return an empty string. Call the SQLFieldInfo() function to list the fields in the database.
<b>309</b>	Trend data is gated	You have requested trend data that was gated (set to logging disabled) by the trigger expression (that is when it was acquired). The data is

Error No.	Error title	Description
		returned with the gated values set to 0.
<b>310</b>	Incompatible server version	Two servers are running incompatible versions of the Plant SCADA software. Install the latest version on each server. Contact Technical Support to arrange for an upgrade.
<b>311</b>	Alarm tag synchronize error	When the Alarm server shuts down it writes an alarm save file. If the alarm server is in tag mode (rather than record mode) this message will display. You can set the mode with the [Alarm]SaveStyle parameter. You can ignore this message as it is an alert only.
<b>312</b>	MAPI generic error	A generic MAPI error has been detected. Call the MailError() function to retrieve the MAPI error.
<b>313</b>	No MAPI	The MAPI mail system is not installed, or incorrectly installed on the computer.
<b>314</b>	MAPI offline	The computer is not logged on to the MAPI mail system. Call the MailLogon() function to log on to the MAPI mail system.
<b>315</b>	MAPI no mail	No mail was available. This message is returned from the MailRead() function if no mail is available.
<b>316</b>	dBASE record locked by another	The dBASE file is being accessed by another user. Check if the dBASE file has been opened in exclusive mode by the other user. This error can also be detected if another user is updating the dBASE file, and will usually occur if it is an indexed database, and the file is on a slow file server. You can adjust dBASE access with the [General]LockRetry and [General]LockDelay

Error No.	Error title	Description
		parameters.
<b>317</b>	Not in this version	The operation is not supported in this version of Plant SCADA or view-only client. You need to upgrade to a higher version of Plant SCADA or install a control client.
<b>318</b>	Invalid page function	You have called the PageGoto(), PageNext(), PagePrev(), PageDisplay(), or PageLast() as an exit command in the Pages database.
<b>319</b>	Low physical memory	Plant SCADA is low on physical memory. Increase available physical memory (not virtual memory). Reduce the size of SMARTDRV cache, close any other windows programs that are running, or add more RAM to your computer. You can set the minimum size of memory required by Plant SCADA with the [Memory]MinPhyK parameter. This parameter sets a value for the minimum physical memory before Plant SCADA will generate this error message.  This error may also be detected if your swap file is large (that is greater than 20 Mb). Reduce the size of your swap file. The swap file is configured with the Windows Control Panel (386 Enhanced icon).
<b>320</b>	Cannot free window	The WinFree() function has been called but Plant SCADA has no windows left. (Be aware that the last window and any child windows owned by the last window cannot be removed.)
<b>321</b>	Font cannot be found	The specified font cannot be found. Check the font name.
<b>322</b>	Cannot connect to LAN	Plant SCADA has detected an error on the network.

Error No.	Error title	Description
<b>323</b>	Super Genie not Associated	A Super Genie variable has not been associated correctly. This error can be detected if a variable passed to the Super Genie is the wrong data type or the variable does not exist. The error will also be detected if the Ass() function has not been called for the variable.
<b>325</b>	Project is not compiled	Changes have been made to the project while the system was running. Either restart the system or shutdown and re-compile.
<b>326</b>	Could not run the Plant SCADA compiler	The Plant SCADA compiler could not be found. Either the computer has run out of memory, or the compiler has been removed from its directory.
<b>327</b>	User type not found	An attempt was made to create a user of a type that has not been defined in the users database.
<b>328</b>	User already exists	An attempt was made to create a new user with the same name as an existing user.
<b>329</b>	Cannot have mixed trends	An attempt was made to display both a periodic trend and an event trend in the same trend window. Check the project configuration (Trend Tags and Page Trends databases) for mixed trends displayed in a trend window.
<b>336</b>	Event type trend is expected	One of the arguments passed to this trend function is only valid for event type trends.
<b>337</b>	Trend in file does not exist	The trend name inside the trend file does not exist in the trend database. It is likely that the trend file belongs to a trend which is deleted from the system configuration.

Error No.	Error title	Description
<b>338</b>	Plot Functions Sequence Mismatch	Plot functions are to be written in sequence since they depend on the data set up by other plot functions. Please refer to the description section for each Plot Function for the order of plot functions.
<b>339</b>	Plot Marker is not Defined	An undefined plot marker symbol has been used. Use the PlotSetMarker function <b>before</b> the PlotLine, PlotXYLine or PlotMarker functions.
<b>340</b>	Invalid subgroup size	The subgroup size specified for this SPC trend is not valid.
<b>341</b>	Trend Cursor Disabled	The trend cursor is currently disabled.
<b>342</b>	Debug break	The DebugBreak() Cicode function has been called. This indicates an invalid condition detected in user written Cicode. Enable the Cicode debugger to find the cause of the problem.
<b>343</b>	Foreground Cicode cannot break	A breakpoint has been hit in foreground Cicode. Foreground Cicode cannot be blocked. You can disable this error message in Debug Options, accessed through the Debug menu in the Cicode Editor.
<b>344</b>	Format overflow	This error occurs when the string being used to return an error message is not long enough for the information to go into it.
<b>345</b>	Data not ready	This error is returned when the requested data is not ready to be returned. Try again later.
<b>346</b>	Dynamic Out of licence points	The dynamic point count has exceeded the point limit. See Plant SCADA Licence Point Count.
<b>347</b>	Assertion did not succeed in user Cicode	An assertion in your Cicode has been proven FALSE, and the task

Error No.	Error title	Description
		terminated. Assertions are made using the Assert() function. If you set the [Code]DebugMessage parameter to 1, the assertion is logged and the operator prompted.
<b>348</b>	Property does not exist	The tag property does not exist.
<b>350</b>	RDB file not found	A RDB file is not found. Try a full compile and re-start.
<b>353</b>	Cannot connect to FTP	Problems connecting to the FTP server for file copy. Check that the service is running correctly by using a 3rd party tool outside Plant SCADA.
<b>354</b>	Unrecognized object class	The automation object to be used is not known or registered.
<b>355</b>	Object has no interface	The automation objects interface no longer exists. This is either a logic or code error.
<b>356</b>	Object automation exception	Generic automation exception code for logging issues.
<b>357</b>	Too many arguments	Formatting issues likely due to too many arguments (automation)
<b>358</b>	Too few arguments	Less arguments available than expected (automation)
<b>359</b>	Named object already exists	An object tried to be created when it was already existed and it was not expected to exist. Check your Cicode (automation)
<b>360</b>	Unrecognized named object	The name of an object did not match the internal records. Check your Cicode (automation).
<b>361</b>	Page CTG/RDB record mismatch	An animation object id was not found in the records. Try a full compile and re-start.
<b>362</b>	Object event queue flooded	Plant SCADA has run out of Cicode tasks while processing ActiveX events. Create fewer concurrent

Error No.	Error title	Description
		ActiveX events, or increase the number of tasks with the [Code]Threads parameter.
<b>363</b>	Incorrect number of arguments	Internal error in Cicode handling of objects. Try a full recompile and restart.
<b>364</b>	No 'this' argument	Internal error in Cicode handling of objects. Try a full recompile and restart.
<b>367</b>	File cannot be printed	Unable to print the specified file on the specified port.
<b>368</b>	Animation number invalid	Unable to display the animation at the given AN.
<b>369</b>	Wrong type for text display	Unable to display the given animation as text.
<b>370</b>	No FileFind instances to close	There are no FileFind instances to close.
<b>371</b>	No dialback response returned	The retry count for the dialback response has been exceeded.
<b>372</b>	Unrecognised ActiveX object	The ActiveX graphics data was unable to be loaded as it is an unrecognised object.
<b>374</b>	Date Time Conflict	A Date and/or time conflict has been detected. If you are attempting a TrnAddHistory(), verify that the file you are adding does not have a conflicting time or date with existing trend files.
<b>375</b>	Password Expired	The password has expired. Change password or adjust the [General]PasswordExpiry settings.
<b>376</b>	Error Writing to Files of Trend	An error has occurred while attempting to write to a trend file.
<b>377</b>	Error Reading Files of Trend	An error has occurred while attempting to read from a trend file.

Error No.	Error title	Description
<b>379</b>	Cannot modify field	The Users.DBF cannot be modified by direct user manipulation.
<b>380</b>	Name Exists	The user name specified already exists in the Users.DBF.
<b>381</b>	File Format Error	The file is not in the desired format. It may be corrupted.
<b>382</b>	Page data / variable tag data mismatch	Page data / variable tag data mismatch with tag-based driver.
<b>384</b>	The code this queue/semaphore was waiting for exited due to an error	Cicode task has been flagged as locked or inactive. This will not apply if a Cicode task was killed deliberately by the Cicode logic.
<b>385</b>	Cannot download websignature.xml	Unable to download the webclient signature file.
<b>388</b>	OID check disabled	Attempting to open a DBF file without checking to see if it has changed.
<b>391</b>	Unsupported Cicode function in Web Client	A number of Cicode functions can only be run in a non Web context. This error is flagging that such a function was tried from a Web client.
<b>392</b>	Timeout from Rnd Alarm Server	The timeout for receiving alarm data from the redundant alarm server has been exceeded.
<b>393</b>	RDB and associated page mismatch	The RDB page version does not match the one expected after compilation.
<b>394</b>	Remote license lost	The remote licence can not be found.
<b>400</b>	Project or file is Read-Only	The operation could not be completed because the project or file is read only.
<b>401</b>	Redundant server not found	The redundant server is current not available or was not found.
<b>402</b>	Cluster not specified	Cicode call is ambiguous because

Error No.	Error title	Description
		no cluster was specified.
<b>403</b>	Cluster not found	The provided cluster name was not seen as a valid cluster name.
<b>404</b>	Cluster name and tag mismatch	A cluster name and a tag with a cluster name prefix were both passed, but they do not match each other.
<b>405</b>	Cluster not connected	The operation cannot continue as the cluster is not connected.
<b>406</b>	Cluster already connected	The operation cannot continue as the cluster is already connected.
<b>407</b>	Databrowse pending	Databrowse session currently being connected and is not yet available for further commands.
<b>408</b>	Databrowse not supported	This normally means that data has been requested from the wrong client / server type, that is a client request on a server or vice versa.
<b>409</b>	Databrowse type not found	Browse type unknown. Check that the versions of citect32 are the same.
<b>410</b>	Databrowse session not found	iSession handle is invalid.
<b>411</b>	Databrowse session exists	Cannot open a session as it already exists.
<b>412</b>	Databrowse session EOF	Cannot browse beyond end of file. No more records left in the browse.
<b>413</b>	Databrowse field not found	The specified field is not present in the file.
<b>414</b>	Databrowse invalid field	The specified field is not valid for this browse function.
<b>415</b>	Databrowse no command	Browse command unknown. Check that the versions of citect32 are the same.
<b>416</b>	Databrowse no next cluster	Internal flag that all clusters have been processed. Users use this in

Error No.	Error title	Description
		Cicode to determine that there are no more clusters.
<b>417</b>	Cluster required for operation	The operation cannot continue as the cluster is required for operation of a server.
<b>418</b>	No server of type on cluster	There is no server of the required type configured on the server.
<b>419</b>	Client / Server ID mismatch	An ID given to a Cicode function is not of the correct type.
<b>420</b>	Not available outside process	This functionality is not available outside a process boundary for example, AlarmFirstCatRec is only able to be called from inside the Alarm Server process.
<b>421</b>	Invalid tran handle detected	Plant SCADA's internal communications subsystem detected an error while trying to send a message.
<b>422</b>	Dial call did not succeed	An attempt to make a call to a remote I/O device did not succeed. You can find more information on the cause of this problem (if it is reproducible) by setting [Dial]Debug=1 and [Dial]DebugLevel=3 and looking in the syslog.dat.
<b>423</b>	Waiting for initial data	Occurs when attempted to read the value before the initial value has been retrieved from the device.
<b>424</b>	Tag not found	Occurs when attempt to read or subscribe to a tag that does not exist.
<b>425</b>	No connector	Not used.
<b>426</b>	Write to named pipe did not succeed	An attempt to send a message via a name pipe has did not succeed.
<b>427</b>	Redirect from non-Cicode task	A function cannot be redirected to another component as a proxy RPC unless it is in the context of a

Error No.	Error title	Description
		Cicode call.
<b>428</b>	Data browse record is invalid	The specified record is not valid for this browse function.
<b>429</b>	Can't plot symbol to printer	The Cicode PlotMarker() function can only plot a symbol to the display. This error occurs when the PlotMarker() Cicode function is used with a user-defined marker and a printer was specified as the output when PlotOpen() was called.
<b>430</b>	Alarm sort parameters mismatch	The [Alarm]SortMode parameter value on client is different as compared to the value on the alarm server. This value should be same in order to display alarms in correct order on the client.
<b>431</b>	Summary sort parameters mismatch	Values for [Alarm]SummarySort and [Alarm]SummarySortMode parameters on client are different as compared to the values on the alarm server. These values should be same in order to display alarm summary in correct order on the client.
<b>432</b>	Property not ready	A specific tag property has been read in synchronous mode, before the value has been retrieved from the server. (similar to subscription value is pending)
<b>433</b>	Cicode type mismatch	Some server side changes are now allowed for Cicode, without restarting the client. This means that now it is possible to change a tag type to one that now cannot be converted as it was before. Eg val = TagA - TagB, If TagA has been converted from Integer to String, then the Cicode will raise a Cicode type mismatch as the '-' operation is not supported for strings

Error No.	Error title	Description
<b>434</b>	Invalid data conversion	Attempt to convert a value to a type that cannot store the value for example, ULong to Long, and the value is greater than the Long type can handle.
<b>436</b>	User password invalid	The password is incorrect. Check that the user name and password are typed in correctly.
<b>437</b>	Unable to load security provider	Cannot load or initialize the Windows security provider. This indicates that the installation of operating system may be corrupted or the Windows security provider was not included.
<b>439</b>	Authentication did not succeed	Cannot authenticate the given Windows user name and password. Check that the user name and password are typed in correctly
<b>440</b>	Authentication session does not exist	Cannot find the authentication session during the authentication process for the Windows user. This indicates that there was miscommunications in between client and server.
<b>441</b>	Role checking did not succeed	Cannot perform the role-check process for the Windows user. Check that the roles database in the project is not corrupted.
<b>442</b>	No linked role	The given Windows user is not linked to any role defined in the project.
<b>443</b>	Acquire user credentials did not succeed	Cannot obtain the user credential handle from Windows.
<b>444</b>	Acquire user access token did not succeed	Cannot obtain the user access token. This indicates that the security context of the Windows user was invalid.
<b>445</b>	Encrypt data did not succeed	Cannot encrypt the user information during the Windows

Error No.	Error title	Description
		user authentication process. This indicates that the security context of the Windows user was invalid.
<b>446</b>	Decrypt data did not succeed	Cannot decrypt the user information during the Windows user authentication process. This indicates that the security context of the Windows user was invalid.
<b>447</b>	The name of the table can not be found in the kernel.	Cicode UsrKernelTableInfo() has asked for a table that does not exist.
<b>449</b>	Invalid logout	The logout was called when there is no one logged in or the logged on user is system default user.
<b>450</b>	Invalid tag data	Invalid tag data has been detected.
<b>453</b>	Subscription value is pending	Occurs when a tag has been subscribed to, and attempted to read the value before the initial value has been retrieved from the server.
<b>457</b>	Old and new SQL functions mixed	An attempt has been made to terminate a SQL session by calling SQLDisconnect when it was opened by SQLCreate and SQLOpen, or by calling SQLClose and SQLDispose when it was opened by SQLConnect.
<b>512</b>	Time out error	Did not execute requested action on time.
<b>513</b>	Access denied error	Access denied to perform requested action.
<b>514</b>	Write unsuccessful	Can not write to view-only client. User needs to login with valid user credentials to get write access and to control alarms.
<b>517</b>	Can't swap pages from foreground	Cannot swap the page on foreground Cicode.
<b>518</b>	Too Many arguments for function	Too many arguments have been

Error No.	Error title	Description
		passed to a Cicode function. Check the number of arguments being passed to the function. If arguments are input directly from the operator, you should check that the correct number of arguments are being passed to the function.
<b>519</b>	Remote Cicode call Interrupted	Cicode call that triggers an RPC remote call is interrupted before the expected result is returned.
<b>520</b>	Alarm category out of range	A category number is out of its valid range (from 0 to 16375 inclusively).
<b>521</b>	Data browse record is deleted	A record is deleted during reload of ART server.
<b>522</b>	Trend archive property mismatch	A trend records archive properties are changed during start-up or reload.
<b>523</b>	Alarm priority out of range	A priority is out of its valid range on alarm category or alarm priority configuration. Its valid range is 0 – 255 (inclusively) on category configuration and 1 – 255 (inclusively) on priority configuration.
<b>524</b>	ComBreak is obsolete parameter	[Page]ComBreak and [Page]ComBreakText are obsolete parameters.
<b>525</b>	Tag in Last Usable Value	Tag quality is uncertain and its value is the last usable value.
<b>526</b>	Tran authentication unsuccessful	Login did not authenticate correctly.
<b>527</b>	High watermark reached on Tran	High watermark is reached on transaction, network is overloaded.
<b>528</b>	Reduced size of resized page	The specified resized page has been reduced in size to fit the constraints of the maximum height and width of 4096.

Error No.	Error title	Description
<b>529</b>	Too few arguments	Too few arguments have been passed to a Cicode function. Check the number of arguments being passed to the function. If arguments are input directly from the operator, you should check that the correct number of arguments are being passed to the function.
<b>530</b>	Null pointer as an argument	A string with invalid pointer has been passed to SCADA execution system.
<b>532</b>	Tag resolve timeout	Server responses to tag exists requests have timed out.
<b>533</b>	Server reload before initialize	The attempt to initiate a server side online change did not succeed because the server has not been fully initialized.
<b>534</b>	Server reload not prepared	The attempt to reload the main alarm server when the non-main alarm server is not reloaded first.
<b>535</b>	Alarm command partial success	An alarm command has succeeded on at least one cluster but has been unsuccessful on at least one other cluster in a multi cluster environment.
<b>536</b>	No record found for the operation	Indicates that for the given scope there is no record found for the requested operation.
<b>537</b>	Operation unsuccessful	Indicates that the requested operation was unsuccessful.
<b>540</b>	Database not connected	The connection to database, such as the alarm runtime database has not been established. This could be the hosting server such as the alarm server is not available, or the logon to the database was unsuccessful.
<b>541</b>	Data browse timeout	The data browse session timed out while opening the session.

Error No.	Error title	Description
<b>542</b>	Language changed remotely	The language for alarm display has changed remotely.
<b>543</b>	XML exception	Load or parse error in the XML.
<b>544</b>	Invalid Xpath expression	Invalid Xpath expression.
<b>545</b>	Invalid XML operation	Invalid operation on an XML document.
<b>546</b>	Exceeded XML Boundary	Exceeded the boundary, unable to add more to XmlDocument or XmlNode.
<b>547</b>	Exceeded Boundary	Cannot create a new connection or transaction, boundary exceeded.
<b>548</b>	Invalid Proxy dll	Specified dll is not a valid proxy dll.
<b>549</b>	Missing Proxy Method	Specified method cannot be found in proxy dll.
<b>550</b>	Invalid Proxy Method	Specified method cannot be invoked from proxy dll.
<b>551</b>	Ambiguous Proxy Method	More than one method in proxy dll matches the binding criteria.
<b>552</b>	Invalid OP Proxy Method	The method in proxy dll has one or more unspecified parameters.
<b>553</b>	Proxy Load Error	Cannot load proxy dll. For example, proxy dll may have a dependency that cannot be found.
<b>554</b>	Transaction Process Error	Other errors occurred when processing a transaction. The transaction cannot be processed.
<b>555</b>	Invalid URL	Web service address provided is not valid/well formed URL.
<b>556</b>	Transaction not ready	Not all parameters are loaded before processing the transaction.
<b>557</b>	Tag Name Exceed Length	Tag name exceeds the 254 character length limit.
<b>559</b>	CiVBA is not supported when an	A call to CiVBA code is not

Error No.	Error title	Description
	alarm server is in Ext Mem mode	supported when an alarm server is operating in Extended Memory mode.
<b>560</b>	ActiveX is not supported for x64 when an alarm server is in Ext Mem mode	A call to an ActiveX function is not supported when an alarm server is operating in Extended Memory mode.
<b>561</b>	AlarmSum index not current	The index passed to AlarmSum* functions must be current. I.E. either: - the index returned by most recent call to AlarmSumFirst/Last/Find/Next/Prev, OR - the index returned by the most recent call to AlarmSumAppend/Split.
<b>562</b>	AlarmSum not initialized	The alarm sum session needs to be initialized, by calling AlarmSumFirst/Last/Find, before AlarmSumNext/Prev is able to be called.
<b>563</b>	AlarmSum busy	AlarmSum* functions should not be called from multiple concurrent Cicode tasks. If busy this error will occur.
<b>564</b>	AlarmSum record deleted	The alarm summary record represented by the index is deleted.
<b>565</b>	AlarmSum invalid field name	The alarm summary Cicode function does not accept the specified field name.
<b>566</b>	Attempt to call x86 dll in x64 process	A 32 bit application has been called in a 64 bit process.
<b>567</b>	Attempt to call x64 dll in x86 process	A 64 bit application has been called in a 32 bit process.
<b>568</b>	Too many alarm record filters	The number of alarm record filters applied to a query needs to be less than 1000.

Error No.	Error title	Description
<b>569</b>	Attempted to index to an alarm that is currently out of range	The value specified for an alarm list offset needs to be within the range of alarm entries currently stored in the client cache.
<b>577</b>	View only client: Read Only	A View Only client cannot update tag values. To update tags via that machine, it needs to be reconfigured as a full remote client.
<b>578</b>	Cannot read the private key of a certificate when doing TLS exchange	The encrypted connection between a server and another computer is not working. This can occur if Runtime Manager is not running as a service. Check the settings described in Enable Encryption.
<b>579</b>	The TLS exchange to secure the connection failed	The encrypted connection between a server and another computer is not working. Check your <b>DNS Name</b> settings (see Add a Computer), and review the settings described in Enable Encryption.
<b>580</b>	Cannot find a certificate for the given thumbprint	The encrypted connection between a server and another computer is not working. Check the settings described in Enable Encryption.
<b>581</b>	A server has been configured to preference an IP address type that does not exist, or is not enabled, on this computer	Check the server's IP address configuration.
<b>582</b>	No action is required as alarm is already in the intended state	This error indicates that a redundant pair of alarm servers are temporarily out of synchronization. This means the standby alarm server has not yet carried out a property update that occurred on the main alarm server. You can limit the occurrence of this error with the parameter [Alarm]StandbyCommandDelay.
<b>583</b>	URL too long	The current URL for a Web Content control is longer than 255 characters. See

Error No.	Error title	Description
		DspWebContentGetURL.
<b>584</b>	Role passed to UserCreate() function is not defined	A role specified for a user via the UserCreate function has not been defined in Plant SCADA Studio's <b>Security</b> activity.

## Windows Socket Error Codes

The following Plant SCADA error codes are mapped to standard Windows socket errors. Generally these errors are beyond Plant SCADA's control, that is, there is an external reason why Plant SCADA cannot use the TCP/IP connection (assuming there are no Plant SCADA configuration issues).

Error No.	Error title	Description
<b>1330</b>	WSAENETDOWN	(10050) Network is down.
<b>1331</b>	Socket unreachable	(10051) Network is unreachable.
<b>1332</b>	Network reset	(10052) Network dropped connection on reset.
<b>1333</b>	Connection aborted	(10053) Software caused connection abort.
<b>1334</b>	Connection reset	(10054) Connection reset by peer.
<b>1335</b>	No buffers available	(10055) No buffer space available.
<b>1340</b>	Socket timeout	(10060) Connection timed out.
<b>1341</b>	Connection refused	(10061) Connection refused.
<b>1343</b>	Name too long	(10063) Item Name too long.
<b>1344</b>	Host down	(10064) Host is down.
<b>1345</b>	Host unreachable	(10065) No route to host.

## MAPI Errors

The table below describes the MAPI errors in Cicode.

Error number	Error Title	Description
0	SUCCESS_SUCCESS	The command completed successfully.
1	MAPI_USER_ABORT	The command was aborted by the user.
2	MAPI_E_FAILURE	General MAPI error.
3	MAPI_E_LOGIN_FAILURE	The login did not succeed, either the login user is unknown, misspelt, or the password is incorrect.
4	MAPI_E_DISK_FULL	The disk is full. The mail system will copy files into the temporary directory when mail is read. This can fill up the local hard disk.
5	MAPI_E_INSUFFICIENT_MEMORY	Insufficient memory to complete the command.
6	MAPI_E_ACCESS_DENIED	More privilege is required to complete the requested command.
8	MAPI_E_TOO_MANY_SESSIONS	You have tried to open too many sessions to the mail system.
9	MAPI_E_TOO_MANY_FILES	Too many attached files in a message.
10	MAPI_E_TOO_MANY_RECIPIENTS	Too many recipients for a mail message.
11	MAPI_E_ATTACHMENT_NOT_FOUND	Cannot find the attached file.
12	MAPI_E_ATTACHMENT_OPEN_FAILURE	Cannot open the specified attached file. Often because the file does not exist.
13	MAPI_E_ATTACHMENT_WRITE_FAILURE	Cannot write the attached file.
14	MAPI_E_UNKNOWN_RECIPIENT	Recipient of the mail message is unknown. Check if the user is configured in the mail system or check the spelling of the user's name.

Error number	Error Title	Description
15	MAPI_E_BAD_RECIPTYPE	Unknown recipient type.
16	MAPI_E_NO_MESSAGES	No new messages to read.
17	MAPI_E_INVALID_MESSAGE	The mail message is invalid.
18	MAPI_E_TEXT_TOO_LARGE	Text message is too large to be sent. If you want to send large text messages, write the text to a file and attach the file to the mail message.
19	MAPI_E_INVALID_SESSION	Mail session is invalid. You should not get this error message; contact Technical Support for this product.
20	MAPI_E_TYPE_NOT_SUPPORTED	You should not get this error message; contact Technical Support for this product.
21	MAPI_E_AMBIGUOUS_RECIPIENT	The recipient of the mail message is ambiguous. Specify the exact user name to which the mail is to be sent.
22	MAPI_E_MESSAGE_IN_USE	Mail message is in use. You should not get this error message: contact Technical Support for this product.
23	MAPI_E_NETWORK_FAILURE	Mail cannot be sent or received as the network has experienced an error.
24	MAPI_E_INVALID_EDITFIELDS	You should not get this error message; contact Technical Support for this product.
25	MAPI_E_INVALID_RECIPS	You should not get this error message; contact Technical Support for this product.
26	MAPI_E_NOT_SUPPORTED	Command is not supported by this implementation of MAPI.

## Using Cicode Programming Standards

Implementing programming practices results in Cicode that is more robust, manageable, and predictable in execution, regardless of the author. Using programming standards entails:

- Adopting modular programming techniques.
- Helping to ensure that programs are adequately described by suitable module headers.
- Formatting code to improve readability.

The following topics are presented as a suggested means of achieving good programming standards:

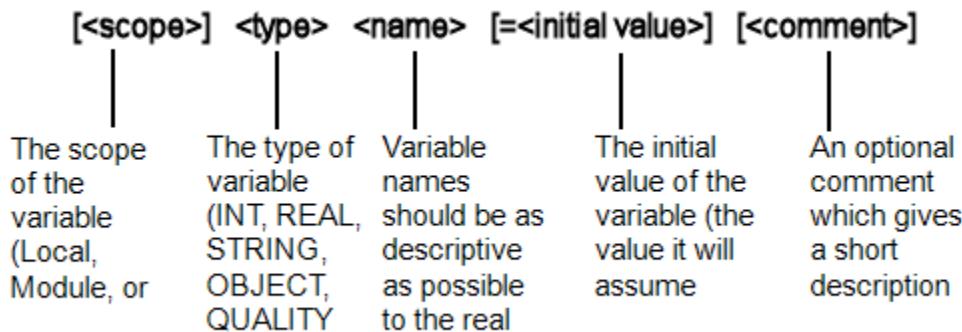

- Variable Declaration Standards
- Variable Scope Standards
- Variable Naming Standards
- Standards for Constants, Variable Tags, and Labels
- Formatting Simple Declarations
- Formatting Executable Statements
- Formatting Expressions
- Cicode Comments
- Formatting Functions
- Modular Programming
- Defensive Programming
- Function Error Handling
- Debug Error Trapping

## See Also

[Using Cicode Functions](#)

### Variable Declaration Standards

When declaring variables you should use consistent formatting. A variable declaration has up to five parts. Each part is separated by at least one tab stop:

**Note:** Parts contained within square brackets are optional. For example, you may omit the variable scope (it defaults to local). Parts contained within greater than (<) and less than (>) signs should be replaced with the relevant text/value. For example, you would replace <initial value> with an actual value. (You would not bracket your value with greater than and less than signs.)

When declaring your variables, the parts of each should align vertically (the scope part of each should be vertically aligned, the type part of each should be aligned, etc.). Each part of the declaration is allotted a set amount of space. If one part is missing, its space should be left blank. The missing part should not affect the positioning of the next part:

```
Module int miRecipeMax=100;  
int iRecipeMax;  
string sRecipeDefault ="Tasty";
```

## See Also

[Declaring the Variable Data Type](#)  
[Using Cicode Programming Standards](#)

## Variable Scope Standards

### Local variable standards

Local Variables should be initialized, for example:

```
INT iFile = 0;  
STRING sName = "";  
INT bSuccess = FALSE;
```

### Module variable standards

Module Variables should be initialized, for example:

```
MODULE INT mhForm = -1;  
MODULE STRING msPageName = "Loop";
```

### Global variable standards

Global variables should be initialized, for example:

```
GLOBAL INT ghTask = -1;  
GLOBAL STRING gsLastPage = "Menu";
```

## Variable Naming Standards

The following naming conventions should be applied to variables:

- Variable names should have a small case letter prefix as follows:

Type	Prefix	Used for
INT (32 bits)	i	index, loop counter
INT (32 bits) and OBJECT (32 bits)	h	handle
INT (32 bits)	b	boolean (TRUE/FALSE)
REAL (64 bits)	r	real type variables
STRING (255 bytes)	s	string type variables

- Variable names typically consist of up to three words. Each word in a variable name should start with a capital letter, for example:  
`iTrendType, rPeriod, sFileName`
- Module variable names should be prefixed with an "m", for example:  
`miTrendType, mrPeriod, msFileName`
- Global variable names should be prefixed with a "g", for example:  
`giTrendType, grPeriod, gsFileName`
- Local variable names should not be prefixed (when you declare a variable without specifying the scope, it is considered a Local variable by default):  
`iTrendType, rPeriod, sFileName`

## See Also

## Standards for Constants, Variable Tags, and Labels

When coding constants, variable tags and labels in Cicode you should try to use the following standards:

- [Constants](#)
- [Variable Tags](#)
- [Labels.](#)

## See Also

[Using Cicode Programming Standards](#)

## Constants

In Cicode there is no equivalent of #defines of C language, or a type that will force variables to be constants (read-only variables). However, the variable naming convention makes constants easily identifiable so developers will treat those variables as read-only variables.

- Constants are recommended to have the prefix 'c'.
- Constants need to be declared and initialized at the beginning of the Cicode file and under no circumstances assigned a value again.

For example:

```
INT ciTrendTypePeriodic = 1;  
INT ciTrendTypeEvent = 2;  
STRING csPageName = "Mimic";
```

## See Also

[Using Cicode Programming Standards](#)

## Variable Tags

Variable tags that have been defined in the database (with the Variable Tags form) can be used in all functions in the Cicode files. Variable tags are identifiable because they will not have a prefix (also, they are generally in uppercase letters).

## See Also

[Using Cicode Programming Standards](#)

## Labels

Labels, like variable tags, can be used in all functions in the Cicode files. They can be either all upper case letters or mixed case. In order to differentiate them from the variable tags and other Cicode variables they should have an `\_` (underscore) in front of them. For example:

\_BILLING\_EVENT, \_UNIT\_OFFLINE, \_AfterHoursEvent

---

**Note:** There are a few labels without an underscore defined in the Labels form in the INCLUDE project. Although they do not follow the guidelines set in this document their wide usage makes changing those labels impractical. These labels are: TRUE, FALSE, BAD\_HANDLE, XFreak, XOutsideCL, XAboveUCL, XBelowLCL, XOutsideWL, XUpTrend, XDownTrend, XGradualUp, XGradualDown, XErratic, XStratification, XMixture, ROutsideCL, RAboveUCL, RBelowLCL

---

## See Also

[Using Cicode Programming Standards](#)

## Formatting Simple Declarations

The following conventions should be observed when formatting simple Cicode declarations:

- Only one item should be declared per declaration; there should be no comma separated list of variables.
- Tab stops should be used for declarations and indentation.

For example:

```
INT hFile,hForm; // WRONG
INT hFile; // RIGHT
INT hForm; // RIGHT
```

The reasons for this are:

- Only the first identifier in the WRONG case is obvious and the others are often missed in a quick glance;.
- It is harder to add a comment or initialization to an item in the WRONG case.
- Types, items, and initialization within a group of declarations should be vertically aligned.

For example:

```
STRING sFileName = "temp.dat"; // WRONG
INT iOffset = -1; // WRONG
```

```
INT iState = 3; // WRONG
STRING sFileName = "temp.dat"; // RIGHT
INT iOffset = -1; // RIGHT
INT iState = 3; // RIGHT
```

## See Also

[Using Cicode Programming Standards](#)

## Formatting Executable Statements

The following conventions should be observed when formatting executable statements:

- Statements are placed on new lines, indented one tab stop from the level of their surrounding block.

**Note:** Do not place more than one statement on a single line. While this practice is permitted in other programming languages, in Cicode the subsequent statements will not be interpreted and will effectively be lost, potentially affecting your program's runtime behavior.

### UNINTENDED EQUIPMENT OPERATION

Do not place more than one statement per line.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

Although it may be argued that some statements are logically related, this is not sufficient justification. If they are logically related, place the statements on consecutive lines and separate the statements by a blank line before and after. For example:

```
hFile = -1; hForm = -1; // WRONG
hFile = -1; // RIGHT
hForm = -1; // RIGHT
```

**IF statements** can be used in one of the formats below. When indenting the IF statements, a tab stop should be used. For example:

- **Simple IF block**

```
IF <expression> THEN
...
END
```

- **IF-THEN-ELSE block**

```
IF <expression> THEN
...
ELSE
...
END
```

- To simulate **ELSEIF blocks**, use nested statements. For example:

```
IF <expression> THEN
...
```

```
ELSE
IF <expression> THEN
...
ELSE
IF <expression> THEN
...
ELSE
...
END
END
END
```

- For **WHILE** and **FOR** statements see [Working with Conditional Executors](#).

## See Also

[Working with Conditional Executors](#)

[Using Cicode Programming Standards](#)

## Formatting Expressions

The following conventions should be observed when formatting Cicode functions:

- When an expression forms a complete statement, it should, like any other statement, occupy one or more lines of its own and be indented to the current level. Operators should be surrounded by spaces. For example:

```
i= i*10+c-'0'; // WRONG
i = i * 10 + c - '0'; // RIGHT
```

- When a sub-expression is enclosed in brackets, the first symbol of the sub-expression should be placed hard against the opening bracket. The closing bracket should be placed immediately after the last character for the sub-expression. For example:

```
a = b * ( c - d ); // WRONG
a = b * (c - d); // RIGHT
```

- The round brackets which surround the arguments of a function attract no spaces, for example:

```
DisplayText( "hello" ); // WRONG
DisplayText("hello"); // RIGHT
```

- Commas, whether used as operators or separators, would be placed hard against the previous symbol and followed by a space. For example:

```
DevSeek(hDev ,0ffset); // WRONG
DevSeek(hDev, Offset); // RIGHT
```

## Cicode Comments

Comments are designed to aid understanding and maintenance of code. You should place comments in the notes of the function header so as not to clutter up the code. Small one-line comments are acceptable to explain some small part of the code which may be hard to understand in the normal header comment.

## See Also

[Using Cicode Programming Standards](#)

## Formatting Functions

Cicode functions have up to seven parts: Scope, Type, Keyword, Name, Argument(s), Statement(s), Keyword.

- **[Scope]**

The scope of the function. If the scope is omitted, the function will be Public by default. That is, it will be available to all Cicode files, pages, and Plant SCADA databases (for example, Alarm.dbf). To make a function Private (that is only available within the file in which it is declared), you need to prefix it with the word PRIVATE.

- **[Type]**

The return type of the function. This should be on a separate line.

- **Keyword**

The keyword FUNCTION. This should be on a separate line.

- **Name**

The function name. Function names should follow the Function Naming Standards. This should be on a separate line.

- **Argument(s)**

The argument list. The arguments are separated by commas and they can have default values. The argument list is normally on the same line as the function name but multiple line argument list is also acceptable if it improves readability.

- **Statement(s)**

The statements. Each statement should be on a separate line.

- **Keyword**

The keyword END which marks the end of the function. This should be on a separate line.

---

**Note:** Parts contained within square brackets - [ ] - are optional. For example, the scope may be omitted and if so, it will default to Public. Parts contained within greater than & less than signs - < > - should be replaced with the relevant text/value. For example, you would replace <initial value> with an actual value. You would not bracket your value with greater than & less than signs.

---

## Example:

```
FUNCTION  
PlotInit()
```

```
<statements>
END
INT
FUNCTION
PlotOpen(STRING sName, INT nMode)
INT hPlot = _BAD_HANDLE;
...
hPlot = ....;
...
RETURN hPlot;
END
PRIVATE
STRING
FUNCTION
WasteInfoName(INT nType, INT nMode)
STRING sName = "Sydney";
...
sName = ....;
...
RETURN sName;
END
```

## See Also

[Writing Functions](#)

[Using Cicode Functions](#)

[Using Cicode Programming Standards](#)

## Format Templates

The format of a format template string is:

[text]{<name>[,width[,justification]]}[text]...

Rules for valid format template display

1. If the "width" value is not present then the width is set to the length of the number of characters inclusive between '{' and '}'. This means that the field value may be truncated or padded depending on the name value length.
2. If the "width" value is specified then that is the length of the field. This means that the name value length may be truncated or padded.
3. The justification is made up of a single character with the following behaviours as specified:
  - 'R' or 'r' will align the field on the right hand side. If the width is longer than the name value length then the left hand side of the name value is padded with spaces.
  - 'L' or 'l' will align the field on the left hand side. If the width is longer than the name value length then the right hand side of the name value is padded with spaces.
  - 'Z' or 'z' will align the field on the right hand side. If the width is longer than the name value length then the left hand side of the value is padded with zeros.
  - 'N' or 'n' will remove any extra padding that is used. Essentially any padding of the name value is trimmed.

4. If a justification is not specified then the name value is assumed to be left justified.
5. Any spaces appearing after the first comma onwards in the format template will be stripped out at no penalty to the user.

## Malformed format template display

There are two types of malformed templates and below are examples of each and the resulting output.

- **Internal malformation**

This is when there is a correct open and close brace '{' and '}' but inside the format template there is a malformation. For example there may be a space not a comma separating the name and the width. In this case the whole field is ignored which means nothing between and including '{' and '}' is displayed.

For example, take the following string:

```
< { LocalTimeDate , 20 , R } > TagLabel < { Tag , 20 L } > DescriptionLabel < {  
Desc , 20 , L } >
```

The output would as follows:

```
< 2009-07-17 11:13:17 > TagLabel < > DescriptionLabel < ValidAlarm1Desc >
```

---

**Note:** The "Tag" name value is not outputted as the field has no ',' between the width and justification.

- **Brace malformation**

This is when there is an open brace '{' but no closing brace '}'. In this case the malformation is printed as a string literal.

For example, take the following string:

```
< { LocalTimeDate , 20 , R } > TagLabel < { Tag , 20 , L > DescriptionLabel < {  
Desc , 20 , L } >
```

The output would be as follows:

```
< 2009-07-17 11:31:44 > TagLabel < { Tag , 20 , L > DescriptionLabel <  
ValidAlarm1Desc >
```

---

**Note:** The "Tag" name value is outputted as a literal as no closing brace '}' is detected.

## See Also

[Writing Functions](#)

[Using Cicode Functions](#)

[Using Cicode Programming Standards](#)

## Function Naming Standards

Function names should contain at least the following information:

- A three-to-five letter description of the function type (Trend, Plot, Win).
- A one or two word description of the data to be operated on (Info, ClientInfo, Mode).
- A one word action to be taken (Get, Set, Init, Read).

For example:

```
PlotInit();TrendClientOpen();TrendClientInfoRead();
```

## See Also

[Naming Functions](#)

## Source File Headers

Source files (the files that contain your Cicode) should have a header to provide a basic overview of the file. This header should be formatted as follows:

```
/** FILE: <name of file.CI>
/**
***** MODULE CONSTANTS*****
<module constants> //<comments (optional)>
***** MODULE VARIABLES *****
<module variables> //<comments (optional)>
*****
```

**Note:** Declare all module variables at the MODULE VARIABLES section at the beginning of the file and initialize the module variables.

For example:

```
/** FILE: Recipe.CI
/**
/** DESCRIPTION: Contains all functions for gathering recipe data.
/**
/** FUNCTIONS: PUBLIC
/** OpenRecipeDatabase
/** CloseRecipeDatabase
/** ReadRecipeData
/** WriteRecipeData
/** GatherRecipeData
/** RecipeForm
/** OpenRecipeDatabase
/**
/** PRIVATE
/** ButtonCallback
/**
***** MODULE CONSTANTS*****
module int cmiRecipeMax =100; //Maximum number of recipes
***** MODULE VARIABLES *****
module int miRecipeNumber =0; //Minimum number of recipes
*****
```

## Function Headers

Functions should have a descriptive header, formatted as follows:

```
/** FUNCTION : <name of function>
/**
/** DESCRIPTION : <suggests the operation, application source and
/** multi-tasking issues>
/** REVISION DATE BY COMMENTS
/** <revision number> <date> <author> <comments about the change>
```

```
/***
/** ARGUMENTS: <argument description>
/**
/** RETURNED VALUE: < description of possible return values>
/**
/** NOTES:
```

The order of functions in a file is important for efficient operation.

Initialization and shutdown functions should be placed at the top of the file. Command functions should be next. Local utility functions should be at the bottom of the file.

For example:

```
/** FUNCTION : OpenRecipeDatabase
/**
/** DESCRIPTION : Opens the specified database.
/**
/** REVISION DATE BY COMMENTS
/** 1 28/09/97 BS Original
/** 2 05/10/97 SFA AddedINI checking
/**
/** ARGUMENTS:
/**
/** STRING sName Name of the recipe database.
/**
/** INT dwMode Mode to open the recipe database.
/** 0 for read only, 1 for read/write.
/**
/** RETURNED VALUE: Handle if successful, otherwise -1.
/**
/** NOTES:
INT
FUNCTION
OpenRecipeDatabase(STRING sName, INT dwMode)
...
END
```

## Modular Programming

One of the more effective programming practices involves partitioning large, complex programming challenges into smaller and more manageable sub-tasks and reusable functions. A similar approach should be taken when using a programming language like Cicode to complete a task. Reducing the task to smaller tasks (or functions) has the following advantages:

- **Reduced Complexity** - Once the function is created and tested, the detailed operation about how it works need not be revisited. Users need only focus on the results produced by the function.
- **Avoids Duplicate Code** - Creating a generic function instead of copying similar code reduces the total amount of code in the system. It also means the function can be reused by separate code areas. This makes the code more maintainable because it is smaller in size, and only one instance needs to be modified.
- **Hides Information** - Information can be in the form of operations, data, or resources. Access to information can be controlled when functions are written that provide a limited set of actions to be performed on the information. For example, if a user wishes to log a message to a database, he or she should only send the message to a function, say `LogDBaseMessage("hello world")`, and the function should control the database resource. The function then becomes the single interface to the database resource. Resources that have

multiple interfaces to them are harder to control. This is because in a multitasking environment, the user cannot control or even know in advance the order of code execution, and hence a resource may be modified at the same time by different tasks. Information hiding can also smooth out any wrinkles in standard functions, minimizing possible misuse of resources such as semaphores, queues, devices, and files. Functions that do this are often called 'wrapper' functions as they add a protective shell to existing functions.

- **Improves Performance** - Optimizing code that resides in one place immediately increases the performance of code that calls this function. Scattered code will require multiple areas to be modified should any optimization be necessary.
- **Isolates Complex Code** - Code that requires complex operations such communications protocols, complex algorithms, boolean logic, or complex data manipulation is susceptible to errors. Placing this code in a separate function reduces the possibility of this code corrupting or halting other code.
- **Improves Readability** - A small function with meaningful parameter names assists readability as it is a step towards self-documenting code and reduces the need to scan multiple pages of code to establish what the operation is meant to achieve.

Modular programming has a few rules that define how functions should be structured - Cohesion - and how they are related to other functions - Coupling.

## See Also

[Defensive Programming](#)

[Using Cicode Programming Standards](#)

## Cohesion

A goal of modular programming is to create simple functions that perform a single task, but perform that task well. This can be described as how 'cohesive' a function is.

Two factors that affect the level of cohesion are:

- Number of tasks the function performs.
- Similarity of the tasks.

The following table illustrates the different levels of cohesion:

Number of tasks	Similarity	Cohesion level	Example
1	Not applicable	High	<code>Sin(x)</code>
More than 1	Similar	Moderate	<code>SinAndTan(x)</code>
More than 1	Dissimilar	Low	<code>SinAndLength(x)</code>
Many	Radically different	None	<code>SinAndDateAndTimeAndSQLNext(x)</code>

For example, the function `Sin(x)` will perform one task - return the trigonometric Sine value of `x`. This is an example of a highly cohesive function. The function `SinAndTan(x)` performs two tasks - calculate the trigonometric Sine and Tan of the value `X`. This function has lower cohesion than `Sin(x)` because it performs two

tasks.

Highly cohesive functions are more dependable, easier to modify, and easier to debug than functions that have lower levels of cohesion and are hence acceptable and encouraged.

Low cohesion functions are typically complex, prone to errors, and are more costly to fix. Low cohesion functions are regarded as poor programming practice and discouraged.

## Coupling

Another rule of modular programming is to reduce the number of relationships between functions. This is referred to as function coupling. Functions that have few, or no, relationships between them are loosely coupled. Loosely coupled functions provide simple, visible interfaces to the function. This makes the functions easier to use and modify. For example, the Cicode function **TimeCurrent()** is a loosely coupled function. To use this function, a user need only call its name, and the function will return with the desired result. The user does not need to be aware of any relationships because there are no parameters passed to the function, and it does not read from, or write to, any global data. There is very little likelihood of error with this function; it only returns a time/date variable and does not support error codes. In the unlikely event that the function did not return the time/date variable, it would be through no error of the calling function because it has no relationship to it.

Functions that have many relationships between them are tightly coupled. For example, a user written function like **AddCustomerRecord(hDatabase, sFirstName, sSurname, sAddress, sAge, sPhone)** has a higher level of coupling than the function **TimeCurrent()**. Tightly coupled functions are inflexible in their use, less robust, and harder to maintain. The **AddCustomerRecord()** function is less robust because it could experience an error of its own accord, or if the function calling it passes bad data to it. Tightly coupled functions are harder to maintain because modifying a function with many relationships in it may result in modifications to other functions to accept the data.

The different types of function relationships are listed below:

- **Passed parameters.** A simple, visible form of loose coupling that is encouraged. Once the number of parameters passed to a function exceeds seven, you should consider partitioning the function into two smaller functions. These types of relationships are acceptable.
- **Control information.** Control information causes the called function to behave in a different way. For example, the function **ChangeData(iMode)**, behaves differently depending on the value of the variable **iMode** that is passed into it. It may be responsible for deleting, inserting, or updating data. In addition to being a tightly coupled function, it has low cohesion because it performs multiple tasks. This function could be divided into three separate functions to perform the separate tasks. These types of relationships are moderately acceptable.
- **Shared common data.** This is often referred to as global variable data. This is an invisible form of tight coupling that, particularly in pre-emptive, multi-tasking environments, can result in an unpredictable, hard-to-maintain program. When functions write to the global variable data there is no monitoring of or restriction on who is writing to the variable. Hence the value can be indeterminate. Global variables are acceptable when they are used for read-only purposes, otherwise their use is discouraged. Similarly, module variable data in Plant SCADA should be treated the same way. The use of local function variables is encouraged to decrease function coupling.

## Defensive Programming

Defensive programming is an approach to improve software and source code. It aims to improve general quality by reducing the number of software bugs. It promotes making the source code readable and understandable. It

aims to make your code behave in a predictable manner despite unexpected input or user actions.

You should try to:

- Verify that your code does not produce unexplained hardware alarms.
- Check that denominators in division are not zero.
- Check that array indexes cannot go out of range.
- Check that arguments from external sources are valid.
- Check that loop terminations are obvious and achievable.
- Only write code once. If you find that two sections of code look identical or almost identical it is worth spending the time to re-write or re-design it. This will generally reduce the size of the code in question by a third or more, which reduces complexity and therefore maintenance and debugging time. An effective method to achieve this is to convert the identical code to a new function.
- Do not access the module data in any function other than the member functions.
- Write the member functions whenever an array is defined. Do not try to pass arrays between functions, make the arrays the centre piece of the object.
- Cicode is a multitasking language. Several tasks (commands, expressions and tasks created by TaskNew function) can be executed concurrently. This powerful feature of Cicode should be used with care as some of the functions may be modifying module data. It is essential that the number of tasks running at any point in time be minimized. This may require the use of semaphores to help protect the module data from interference and corruption. (For the use of semaphores, refer to SemOpen, SemClose, SemSignal and SemWait functions in on-line help or the Cicode Reference manual).

## **WARNING**

### **UNINTENDED EQUIPMENT OPERATION**

- Write your Cicode programs with the minimum number of concurrent instructions suitable to your application.
- Use semaphores or some related means to coordinate program flow if your program will execute a high number of concurrent instructions.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

## **See Also**

[Using Cicode Programming Standards](#)

[Modular Programming](#)

[Function Error Handling](#)

## **Function Error Handling**

Errors are handled by examining the return values of the functions. The Cicode functions can be classified as regards their return value as follows:

Functions returning	Calling functions should check for
Error code only	0 no error (success) > 0 error code
Handles	-1 bad handle ≥ 0 valid handle
Random values	The return of IsError()

The following Cicode functions can halt the current task:

DevOpen, DevHistory, DevNext, DevPrev, DevSeek, DevFind, DevFlush, DevRecNo, DevRead, DevReadLn, DevAppend, DevDelete, DevZap, DevControl, DevPrint, DevModify, ErrTrap; FileOpen, FileClose, FileReadBlock, FileWriteBlock, FileSeek, FileDelete, FileRename, FileSize, FileReadLn, FileCopy; FormNew; SQLConnect, SQLTraceOn, SQLTraceOff, SQLErrMsg.

If an error is detected in one of these functions, your Cicode task will generate a hardware error and be halted. You may stop your Cicode task from being halted by using the [ErrSet](#) function and checking for errors using [IsError](#).

The parameter [\[Code\]HaltOnError](#) allows you to stop any errors detected in these functions from halting your Cicode. If you set the following:

```
[code]
HaltOnError=0
```

then your Cicode will continue to run after a hardware error is detected in these functions.

**For example:**

- **Example of error code only**

```
INT
FUNCTION
ExampleInit()
INT nError = 0;
nError = ExampleOpen("MyForm");
IF nError = 0 THEN
...
END
END
INT
FUNCTION
ExampleOpen(STRING sName)
INT nError = 0;
...
IF <an error has been detected> THEN
nError = 299;
END
RETURN nError;
END
```

- **Example of handles**

```
INT
FUNCTION
ExampleInit()
INT hFile = BAD_HANDLE;
```

```
...
hFile = ExampleFileOpen("MyFile.txt");
IF hFile <> BAD_HANDLE THEN
...
END
END
FUNCTION
ExampleFileOpen(STRING sName)
INT hFile = BAD_HANDLE;
hFile = FileOpen(sName, "r+");
IF hFile = BAD_HANDLE THEN
hFile = FileOpen(sName, "r");
END
RETURN hFile;
END
```

- **Example of random values**

```
INT
FUNCTION
ExampleInit()
INT nSamples = 0;
...
ErrSet(1);
nSamples = ExampleSamples();
IF IsError() = 0 THEN
...
END
ErrSet(0);
END
INT
FUNCTION
ExampleSamples()
INT nSamples = 0;
INT nError = 0;
...
ErrTrap(nError);
RETURN nSamples;
END
```

## See Also

[Debugging Cicode](#)

## Debug Error Trapping

The functions listed below can also be used during normal project execution to trap run-time problems:

- [DebugMsg Function](#)
- [Assert Function](#)

## See Also

[Debugging Cicode](#)

## DebugMsg Function

DebugMsg internally calls the TraceMsg function if the debug switch is on. The implementation of this function can be found in DEBUG.CI in the INCLUDE project. You can turn the debug switch on or off by doing any of the following:

- Calling DebugMsgSet(INT bDebugMsg) on the Kernel Cicode window. (Or, this function can be called from a keyboard command or something similar.)
- Changing the [\[Code\]DebugMessage](#) parameter in the INI file.

For example:

```
INT
FUNCTION
FilePrint(STRING sDeviceName, STRING sFileName)

INT hFile;
INT hDev;
STRING Str1;

hDev = DevOpen(sDeviceName, 0);
IF (hDev = -1) THEN
DebugMsg("Invalid arg to FilePrint - 'DeviceName'");
RETURN 261; /* File does not exist */
END
hFile = FileOpen(sFileName, "r");
IF (hFile = -1) THEN
DebugMsg("Invalid arg to FilePrint - 'FileName'");
DevClose(hDev);
RETURN 261; /* File does not exist */
END
WHILE NOT FileEof(hFile) DO
Str1 = FileReadLn(hFile);
DevWriteLn(hDev, Str1);
END
FileClose(hFile);
DevClose(hDev);
RETURN 0;
END
```

## Assert Function

Assert reports an error if the test passed by the argument does not return the expected value. The implementation of this function can be found in DEBUG.CI in the INCLUDE project.

For example:

```
INT
FUNCTION
FileDisplayEx(STRING sFileName)

INT hFile;

hFile = FileOpen(sFileName, "r");
ASSERT(hFile <> -1);
```

```
...
FileClose(hFile);
RETURN 0;
END
```

[Using Cicode Functions](#)

### AccControl

Controls accumulators, for example, motor run hours. You can reset the values of Run Time, Totalizer Inc, and No. of Starts (defined in the accumulator database), re-read these values from the I/O device, or flush pending writes of these values to the I/O device.

### Syntax

LONG **AccControl**(*sName*, *nMode* [, *sClusterName*] )

*sName*:

The name of the accumulator or a mask for the names of accumulators. You can use the following wildcards:

- \* matches all following characters, for example, "Motor\*" matches all accumulators starting with the word "Motor"

- ? matches any single character, for example, "Motor?10" matches "MotorA10" and "MotorB10"

This argument can be prefixed by the name of the cluster for example ClusterName.AccumulatorName.

*nMode:*

The mode of the control:

- 1 - Reset Run Time and Totalizer value
- 2 - Reset No. of Starts
- 3 - Reset Run Time, Totalizer value, and No. of Starts
- 4 - Flush pending writes to the I/O device
- 5 - Re-read Run Time, Totalizer value, and No. of Starts from the I/O device

*sClusterName:*

Name of the cluster in which the accumulator resides. This is optional if you have one cluster or are resolving the reports server via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Example

```
! Reset all accumulator variables for accumulator "MCC123".  
AccControl("MCC123", 3, "ClusterXYZ");
```

## See Also

[Accumulator Functions](#)

## AccumBrowseClose

The AccumBrowseClose function terminates an active data browse session and cleans up all resources associated with the session.

This function is a non-blocking function. It does not block the calling Cicode task.

## Syntax

INT **AccumBrowseClose**(*iSession*)

*iSession*

The handle to a browse session previously returned by an [AccumBrowseOpen](#) call.

## Return Value

0 (zero) if the accumulator browse session exists, otherwise an error code is returned.

## Related Functions

[AccumBrowseFirst](#), [AccumBrowseGetField](#), [AccumBrowseNext](#), [AccumBrowseNumRecords](#), [AccumBrowseOpen](#), [AccumBrowsePrev](#)

## See Also

[Accumulator Functions](#)

### AccumBrowseFirst

The AccumBrowseFirst function places the data browse cursor at the first record.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

INT **AccumBrowseFirst**(*iSession*)

*iSession*

The handle to a browse session previously returned by a [AccumBrowseOpen](#) call.

## Return Value

0 (zero) if the accumulator browse session exists, otherwise an error code is returned.

## Related Functions

[AccumBrowseClose](#), [AccumBrowseGetField](#), [AccumBrowseNext](#), [AccumBrowseNumRecords](#), [AccumBrowseOpen](#), [AccumBrowsePrev](#)

## See Also

[Accumulator Functions](#)

### AccumBrowseGetField

The AccumBrowseGetField function retrieves the value of the specified field from the record the data browse cursor is currently referencing.

This function is a non-blocking function. It does not block the calling Cicode task.

## Syntax

STRING **AccumBrowseGetField**(LONG *Session*, STRING *FieldName*)

*Session*:

The handle to a browse session previously returned by a [AccumBrowseOpen](#) call.

**FieldName:**

The name of the field that references the value to be returned. Supported fields are:

AREA, CLUSTER, EQUIPMENT, NAME, PRIV, RUNNING, STARTS, TOTALISER, TRIGGER, VALUE

See [Browse Function Field Reference](#) for information about fields.

## Return Value

The value of the specified field as a string. An empty string may or may not be an indication that an error has been detected. The last error should be checked in this instance to determine if an error has actually occurred.

## Related Functions

[AccumBrowseClose](#), [AccumBrowseFirst](#), [AccumBrowseNext](#), [AccumBrowseNumRecords](#), [AccumBrowseOpen](#), [AccumBrowsePrev](#)

## Example

```
STRING fieldValue = "";
STRING fieldName = "TYPE";
INT errorCode = 0;
...
fieldValue = AccumBrowseGetField(iSession, sFieldName);
IF fieldValue <> "" THEN
    // Successful case
ELSE
    // Function returned an error
END
...
```

## See Also

[Accumulator Functions](#)

## AccumBrowseNext

The AccumBrowseNext function moves the data browse cursor forward one record. If you call this function after you have reached the end of the records, error 412 is returned (Databrowse session EOF).

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**INT AccumBrowseNext(*iSession*)**

*iSession*

The handle to a browse session previously returned by a [AccumBrowseOpen](#) call.

## Return Value

0 (zero) if the accumulator browse session exists, otherwise an error code is returned.

## Related Functions

[AccumBrowseClose](#), [AccumBrowseFirst](#), [AccumBrowseGetField](#), [AccumBrowseNumRecords](#), [AccumBrowseOpen](#), [AccumBrowsePrev](#)

## See Also

[Accumulator Functions](#)

## AccumBrowseNumRecords

The AccumBrowseNumRecords function returns the number of records that match the filter criteria.

This function is a non-blocking function. It does not block the calling Cicode task.

## Syntax

LONG **AccumBrowseNumRecords**(*iSession*)

*iSession*

The handle to a browse session previously returned by a [AccumBrowseOpen](#) call.

## Return Value

The number of records that have matched the filter criteria. A value of 0 denotes that no records have matched. A value of -1 denotes that the browse session is unable to provide a fixed number. This may be the case if the data being browsed changed during the browse session.

## Related Functions

[AccumBrowseClose](#), [AccumBrowseFirst](#), [AccumBrowseGetField](#), [AccumBrowseNext](#), [AccumBrowseOpen](#), [AccumBrowsePrev](#)

## Example

```
INT numRecords = 0;  
...  
numRecords = AccumBrowseNumRecords(iSession);  
IF numRecords <> 0 THEN  
    // Have records  
ELSE  
    // No records  
END  
...
```

## See Also

[Accumulator Functions](#)

### AccumBrowseOpen

The AccumBrowseOpen function initiates a new browse session and returns a handle to the new session that can be used in subsequent data browse function calls.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**INT AccumBrowseOpen( STRING *Filter*, STRING *Fields* [, STRING *Clusters*] )**

### *Filter:*

A filter expression specifying the records to return during the browse. An empty string indicates that all records will be returned. Where a fieldname is not specified in the filter, it is assumed to be tagname. For example, the filter "AAA" is equivalent to "name=AAA".

The following regular expressions are supported: \*expr, expr\*, and \*expr\*. To specify an exclusion filtering condition, use the NOT keyword after the = operator.

---

**Note:** Use the following fields with care in filters since they return the actual value of the variable tag which they refer to.

RUNNING, STARTS, TOTALISER, TRIGGER, VALUE.

---

### *Fields:*

Specifies via a comma delimited string the columns to be returned during the browse. An empty string indicates that the server will return all available columns. Supported fields are:

AREA, CLUSTER, EQUIPMENT, ITEM, NAME, PRIV, RUNNING, STARTS, TOTALISER, TRIGGER, VALUE.

See [Browse Function Field Reference](#) for information about fields.

### *Clusters:*

An optional parameter that specifies via a comma delimited string the subset of the clusters to browse. An empty string indicates that the connected clusters will be browsed.

## Return Value

Returns an integer handle to the browse session. Returns -1 when an error is detected.

The returned entries will be ordered alphabetically by name. After a reload of the Report Server, any new records may be added at the end.

## Related Functions

[AccumBrowseClose](#), [AccumBrowseFirst](#), [AccumBrowseGetField](#), [AccumBrowseNext](#), [AccumBrowseNumRecords](#),  
[AccumBrowsePrev](#)

## Example

```
INT iSession;
...
iSession = AccumBrowseOpen("NAME=ABC*", "NAME,AREA",
"ClusterA,ClusterB");
IF iSession <> -1 THEN
    // Successful case
ELSE
    // Function returned an error
END
...
```

## See Also

[Accumulator Functions](#)

## AccumBrowsePrev

The AccumBrowsePrev function moves the data browse cursor back one record. If you call this function after you have reached the beginning of the records, error 412 is returned (Databrowse session EOF).

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

INT **AccumBrowsePrev**(*iSession*)

*iSession*

The handle to a browse session previously returned by a [AccumBrowseOpen](#) call.

## Return Value

0 (zero) if the accumulator browse session exists, otherwise an error code is returned.

## Related Functions

[AccumBrowseClose](#), [AccumBrowseFirst](#), [AccumBrowseGetField](#), [AccumBrowseNext](#), [AccumBrowseNumRecords](#), [AccumBrowseOpen](#)

## ActiveX Functions

Following are functions relating to ActiveX objects:

---

**Note:** ActiveX objects are not supported on a 64-bit process, such as an alarm server operating in Extended Memory mode. If a call to an ActiveX function occurs from a 64-bit process, an error code will be returned, a hardware alarm will be raised and the Cicode thread will stop.

---

For information regarding methods you can use to extend Plant SCADA that do not require ActiveX, see the topic [Extensibility](#) in the Plant SCADA documentation.

<a href="#">_ObjectCallMethod</a>	Calls a specific method for an ActiveX object.
<a href="#">_ObjectGetProperty</a>	Retrieves a specific property of an ActiveX object.
<a href="#">_ObjectSetProperty</a>	Sets a specific property of an ActiveX object.
<a href="#">AnByName</a>	Retrieves the animation point number of an ActiveX object.
<a href="#">CreateControlObject</a>	Creates a new instance of an ActiveX object.
<a href="#">CreateObject</a>	Creates the automation component of an ActiveX object.
<a href="#">ObjectAssociateEvents</a>	Allows you to change the ActiveX object's event class.
<a href="#">ObjectAssociatePropertyWithTag</a>	Establishes an association between a variable tag and an ActiveX object property.
<a href="#">ObjectByName</a>	Retrieves an ActiveX object.
<a href="#">ObjectHasInterface</a>	Queries the ActiveX component to determine if its specific interface is supported.
<a href="#">ObjectIsValid</a>	Determines if the given handle for an object is valid.
<a href="#">ObjectToStr</a>	Converts an object handle to a string.

## See Also

[Cicode Function Categories](#)

[Using Cicode Functions](#)

### [\\_ObjectCallMethod](#)

Calls a specific method for an ActiveX object. (See the documentation for your ActiveX object for details on methods and properties.)

**Note:** The parameter list passed to the control can only have Cicode variables or variable tags; it cannot use values returned directly from a function because an ActiveX control may modify parameters passed to it.

For example:

```
//Calculate a value and pass to ActiveX control
_ObjectCallMethod(hControl, "DoSomething", CalcValue());
```

This is not allowed because the return value of a function cannot be modified. The following should be used instead:

```
INT nMyValue;
//Calculate Value
```

```
nMyValue = CalcValue();
//Pass Value to ActiveX control
_ObjectCallMethod(hControl, "DoSomething", nMyValue);
```

## Syntax

VARIANT **\_ObjectCallMethod**(*hObject*, *sMethod*, *vParameters*)

*hObject*:

The handle for the object (as returned by the [ObjectByName](#) function).

*sMethod*:

The name of the method.

*vParameters*:

A variable length parameter list of method arguments. The variables will be passed however you enter them, and will then be coerced into appropriate automation types. Likewise, any values modified by the automation call will be written back - with appropriate coercion - into the passed Cicode variable.

## Return Value

The return value from the method - if successful, otherwise an error code is returned.

## Related Functions

[ObjectByName](#), [DspAnCreateControlObject](#), [CreateObject](#), [CreateControlObject](#)

## Example

See [CreateControlObject](#).

## See Also

[ActiveX Functions](#)

## **\_ObjectGetProperty**

Gets a specific property of an ActiveX object.

## Syntax

VARIANT **\_ObjectGetProperty**(*hObject*, *sProperty*)

*hObject*:

The handle for the object (as returned by the [ObjectByName](#) function).

*sProperty*:

The name of the property you want to get.

## Return Value

The value of the property - if successful, otherwise an error code is returned.

## Related Functions

[ObjectName](#), [DspAnCreateControlObject](#), [CreateObject](#), [CreateControlObject](#)

## Example

See [CreateControlObject](#)

## See Also

[ActiveX Functions](#)

## \_ObjectSetProperty

Sets a specific property of an ActiveX object.

## Syntax

**INT \_ObjectSetProperty(*hObject*, *sProperty*, *vValue*)**

*hObject*:

The handle for the object (as returned by the [ObjectName](#) function).

*sProperty*:

The name of the property you want to set.

*vValue*:

The value to which the property will be set. This value can be of any data type. Appropriate coercion will take place when creating the equivalent automation parameter.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[ObjectName](#), [DspAnCreateControlObject](#), [CreateObject](#), [CreateControlObject](#)

## Example

See [CreateControlObject](#)

## See Also

[ActiveX Functions](#)

### AnByName

Retrieves the animation point number of an ActiveX object.

## Syntax

LONG **AnByName**(*sName*)

*sName*:

The name given to the ActiveX object. This name is visible in the "Identification" tab of the ActiveX control in the Graphics Builder and is used to access the object.

If the animation number for an object is 35 and you renamed the object to "Fred", use AnByName("Fred"); which will return 35.

If you left the name of the object as the default use AnByName("AN35"); which will return 35.

## Return Value

The animation point number of the object - if successful, otherwise an error code is returned.

## Related Functions

[CreateControlObject](#)

## See Also

[ActiveX Functions](#)

### CreateControlObject

Creates a new instance of an ActiveX object.

An object created using this function remains in existence until the page is closed or the associated Cicode Object is deleted. This function does not require an existing animation point. When the object is created, an animation point is created internally. This animation point is freed when the object is destroyed.

**Note:** ActiveX objects are not supported on a 64-bit process, such as an alarm server operating in Extended Memory mode. If a call to this function occurs from a 64-bit process, an error code will be returned, a hardware alarm will be raised and the Cicode thread will stop.

For information regarding methods you can use to extend Plant SCADA that do not require ActiveX, see the topic [Extensibility](#) in the Plant SCADA documentation

## Syntax

OBJECT **CreateControlObject**(*sClass*, *sName*, *x1*, *x2*, *y1*, *y2*, *sEventClass*)

*sClass*:

The class of the object. You can use the object's human readable name, its program ID, or its GUID. If the class does not exist, the function will return an error message.

For example:

- "Calendar Control 8.0" - human readable name
- "MSCAL.Calendar.7" - Program ID
- "{8E27C92B-1264-101C-8A2F-040224009C02}" - GUID

*sName*:

The name for the object in the form of "AN" followed by its AN number, for example, "AN35". This name is used to access the object.

*x1*:

The x coordinate of the object's top left hand corner as it will appear in your Plant SCADA window.

*y1*:

The y coordinate of the object's top left hand corner as it will appear in your Plant SCADA window.

*x2*:

The x coordinate of the object's bottom right hand corner as it will appear in your Plant SCADA window.

*y2*:

The y coordinate of the object's bottom right hand corner as it will appear in your Plant SCADA window.

*sEventClass*:

The string you would like to use as the event class for the object.

## Return Value

The newly created object, if successful, otherwise an error is generated.

## Related Functions

[DspAnCreateControlObject](#), [CreateObject](#), [AnByName](#)

## Example

```
// This function creates a single instance of the calendar control
at the designated location with an object name of "CalendarEvent"
and an event class of "CalendarEvent"//
FUNCTION
CreateCalendar()
    OBJECT Calendar;
    STRING sCalendarClass;
    STRING sEventClass;
    STRING sObjectName;
    sCalendarClass = "MSCal.Calendar.7";
```

```
sEventClass = "CalendarEvent";
sObjectName = "MyCalendar";
Calendar = CreateControlObject(sCalendarClass, sObjectName, 16,
100, 300, 340, sEventClass);
END
// This function shows how to change the title font of the
calendar//
FUNCTION
CalendarSetFont(STRING sFont)
    OBJECT Font;
    OBJECT Calendar;
    Calendar = ObjectByName("MyCalendar");
    Font = _ObjectGetProperty(Calendar, "TitleFont");
    _ObjectSetProperty(Font, "Name", sFont);
END
// This function shows how to change the background color of the
calendar//
FUNCTION
CalendarSetColor(INT nRed, INT nGreen, INT nBlue)
    OBJECT Calendar;
    Calendar = ObjectByName("MyCalendar");
    _ObjectSetProperty(Calendar, "BackColor",
PackedRGB(nRed,nGreen,nBlue));
END
// This function shows how to call the NextDay method of the
calendar//
FUNCTION
CalendarNextDay()
    OBJECT Calendar;
    Calendar = ObjectByName("MyCalendar");
    _ObjectCallMethod(Calendar, "NextDay");
END
// This function shows you how to write a mouse click event
handler for the calendar//
FUNCTION
CalendarEvent_Click(OBJECT This)
    INT nDay;
    INT nMonth;
    INT nYear;
    nDay = _ObjectGetProperty(This, "Day");
    nMonth = _ObjectGetProperty(This, "Month");
    nYear = _ObjectGetProperty(This, "Year");
    ...
    Your code goes here...
    ...
END
```

## See Also

[ActiveX Functions](#)

### CreateObject

Creates a new instance of an ActiveX object. If you use this function to create an ActiveX object, it will have no

visual component (only the automation component will be created).

If you assign an object created with the CreateObject function to a local variable, that object will remain in existence until the variable it is assigned to goes out of scope. This means that such an object will only be released when the Cicode function that created it ends.

If you assign an object created with the CreateObject function to a module or global scope variable, then that object will remain in existence until the variable either has another object assigned or is set to NullObject, *provided the CreateObject call is not made within a loop*.

Objects created by calls to CreateObject within WHILE or FOR loops are only released on termination of the Cicode function in which they are created, regardless of the scope of the variable to which the object is assigned. The use of CreateObject within a loop may therefore result in the exhaustion of system resources, and is not generally recommended unless performed as shown in the examples below.

**Note:** ActiveX objects are not supported on a 64-bit process, such as an alarm server operating in Extended Memory mode. If a call to this function occurs from a 64-bit process, an error code will be returned, a hardware alarm will be raised and the Cicode thread will stop.

For information regarding methods you can use to extend Plant SCADA that do not require ActiveX, see the topic [Extensibility](#) in the Plant SCADA documentation.

## **WARNING**

### **UNINTENDED EQUIPMENT OPERATION**

Do not use the CreateObject() function within a loop except in strict accordance with the following instructions.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

## **Syntax**

OBJECT **CreateObject(sClass)**

*sClass:*

The class of the object. You can use the object's human readable name, its program ID, or its GUID. If the class does not exist, the function will return an error.

For example:

- "Calendar Control 8.0" - human readable name
- "MSCAL.Calendar.7" - Program ID
- "{8E27C92B-1264-101C-8A2F-040224009C02}" - GUID

## **Return Value**

The newly created object, if successful, otherwise an error is generated.

## **Related Functions**

[DspAnCreateControlObject](#), [CreateControlObject](#)

## Example

The following examples show correct techniques for calling CreateObject() within a loop.

```
/* In the example below, the variable objTest is local. Resources
associated with calls to ProcessObject() will be released each
time that function ends. */
FUNCTION Forever()
    WHILE 1 DO
        ProcessObject();
        Sleep(1);
    END
END
FUNCTION ProcessObject()
    .OBJECT objTest;
    objTest=CreateObject("MyObject");
    - do something
END
/* In the example below, the variable objTest is global. Resources
associated with calls to ProcessObject() will be released when
objTest is set to NullObject. */
FUNCTION Forever()
    WHILE 1 DO
        ProcessObject();
        Sleep(1);
    END
END
FUNCTION ProcessObject()
    objTest=CreateObject("MyObject");
    - do something
    objTest=NullObject;
END
```

## See Also

[ActiveX Functions](#)

### ObjectAssociateEvents

Allows you to change the ActiveX object's event class. If you have inserted an object on a graphics page using Graphics Builder, it allows you to change the event class to something other than the default of "PageName\_ObjectName".

## Syntax

**INT ObjectAssociateEvents(*sEventClass*, *hSource*)**

*sClass*:

The class of the object. You can use the object's human readable name, its program ID, or its GUID. If the class does not exist, the function will report an error.

*hSource*:

The source object firing the events which are to be handled by the event handler.

For example:

- "Calendar Control 8.0" - human readable name
- "MSCAL.Calendar.7" - Program ID
- "{8E27C92B-1264-101C-8A2F-040224009C02}" - GUID

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DspAnCreateControlObject](#), [CreateControlObject](#)

## Example

### Inserting ActiveX objects using Cicode

If you have created an ActiveX object using Cicode (for example, by calling the function [CreateControlObject](#)), the parameter 'sEventClass' would have required you to define an event class for the object to enable event handling. If you want to change the class you used, you can call **ObjectAssociateEvents**.

### Inserting ActiveX objects via Graphics Builder

If you have inserted an ActiveX object in Graphics Builder, runtime will automatically create an event class for the object in the form **PageName\_ObjectName**. If this is the case, you may want to change the object's event class.

Using the example of an ActiveX sludge tank controller, the default event class for the object could be "PageName\_AN35". This means any events handlers for the object would take the form "PageName\_AN35\_Click" (presuming this example relates to a click event). You may want to define this more clearly, in which case you can call the following:

```
// This function redefines the event class for the ActiveX sludge
tank controller at AN35 to "SludgeTank". //
ObjectAssociateEvents ("SludgeTank", ObjectByName("AN35"));
..
```

With the event class for the object now defined as "SludgeTank", the event handlers can take the form "SludgeTank\_Click".

This would be useful if you define event handlers in relation to an object that will eventually be copied to other graphics pages, as it will reduce the need to redefine the event handlers to identify the default event class associated with each new placement of the object.

## See Also

[ActiveX Functions](#)

### ObjectAssociatePropertyWithTag

Establishes an association between an ActiveX property and a variable tag. This means that any changes made to an ActiveX object property will be mirrored in the variable tag.

Generally, ActiveX objects issue "property change notifications" to Plant SCADA whenever a change occurs to a specific property value. This notification tells Plant SCADA when to read the property value.

**Note:** An association will not succeed if property change notifications are not supported and the *OnChangeEvent* argument is left blank. Verify that the scaling and units of the associated tag are compatible with the ActiveX property values. However, some property changes do not trigger property change notifications. If this is the case, you need to choose an appropriate "on change" event instead - an event fired by the ActiveX object in response to a change. An "appropriate" event is one that happens to be fired whenever the property value changes. For example, the MS Calendar Control fires an AfterUpdate event whenever a day button is pressed.

## Syntax

**INT ObjectAssociatePropertyWithTag(*sObject*, *sPropertyName*, *sTagName* [, *sOnChangeEvent*] )**

*sObject*:

The object instance that associates a property with a tag.

*sPropertyName*:

The name of the ActiveX property to associate with the tag.

*sTagName*:

The name of the Plant SCADA variable tag to associate with the property.

*sOnChangeEvent*:

The name of the "on change" event that informs Plant SCADA of a change to the ActiveX object. This is required where the ActiveX object does not automatically generate a property change notification. Choose an event that happens to be fired whenever the ActiveX object property changes, for example, the MS Calendar Control fires an AfterUpdate event whenever a day button is pressed.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DspAnCreateControlObject](#), [CreateObject](#), [CreateControlObject](#)

## See Also

[ActiveX Functions](#)

## ObjectName

Retrieves an ActiveX object. This is useful when you know the object by name only (this will often be the case for objects created during configuration, rather than those created at runtime using a Cicode function).

## Syntax

**OBJECT ObjectByName(STRING *Name*)**

**Name:**

The name used to access the object, as specified when creating it in Cicode. For objects created in the Graphics Builder, the object name is set in the Access (Identification) tab, and defaults to "AN" followed by its AN number, for example, "AN35". The *Name* argument should be enclosed in quotes:

"<Name>".

**Return Value**

The requested object, if successful, otherwise an error is generated.

**Related Functions**

[DspAnCreateControlObject](#), [CreateObject](#), [CreateControlObject](#)

**Example**

See [CreateControlObject](#).

**See Also**

[ActiveX Functions](#)

**ObjectHasInterface**

Queries the ActiveX component to determine if its specific interface is supported. (Refer to the ActiveX object's documentation for details of its interfaces.)

**Syntax**

OBJECT **ObjectHasInterface**(*hObject*, *sInterface*)

***hObject*:**

The handle for the object (as returned by the [ObjectByName](#) function).

***sInterface*:**

The name of the interface (case sensitive).

**Return Value**

0 if the interface is not supported, otherwise 1.

**Related Functions**

[ObjectByName](#), [CreateObject](#), [CreateControlObject](#)

**Example**

```
hPen = _ObjectGetProperty(hControl, "Pen");
IF ObjectHasInterface(hPen, "IDigitalPen") THEN
    //Fill is only supported on digital pen
    _ObjectSetProperty(hPen, "Fill", 0)
END
```

## See Also

[ActiveX Functions](#)

### ObjectIsValid

Determines if the given handle for an object is a valid handle. This function is useful for programmatically checking that an object was returned for a call.

## Syntax

```
INT ObjectIsValid(hObject)
```

*hObject*:

The handle for the object (as returned by the [ObjectByName](#) function).

## Return Value

0 if the handle is not valid, otherwise 1.

## Related Functions

[ObjectByName](#), [CreateObject](#), [CreateControlObject](#)

## Example

```
hFont = _ObjectGetProperty(hControl, "Font");
IF ObjectIsValid(hFont) THEN
    _ObjectSetProperty(hFont, "Size", 22)
END
```

## See Also

[ActiveX Functions](#)

### ObjectToStr

Converts an object handle to a string. This means you can print the object handle in a trace message, which allows you confirm if the handle is valid.

## Syntax

STRING **ObjectToStr(hObject)**

*hObject*:

The handle for the object (as returned by the [ObjectName](#) function).

## Return Value

A string containing the converted object handle

## Related Functions

[ObjectName](#), [CreateObject](#), [CreateControlObject](#)

## Alarm Functions

Alarm functions display alarms and their related alarm help pages, and acknowledge, disable, and enable alarms. They provide information about alarms and allow your operators to add comments to alarm records. You can also access alarms at the record level (on the alarms server) for more complex operations.

See also [Alarm Filter Functions](#).

<a href="#">AlarmAck</a>	Acknowledges alarms.
<a href="#">AlarmAckRec</a>	Acknowledges alarms by record number.
<a href="#">AlarmAckTag</a>	Acknowledges a specified alarm
<a href="#">AlarmActive</a>	Determines if any alarms are active in the user's area.
<a href="#">AlarmCatGetFormat</a>	Returns the display format string of the specified alarm category.
<a href="#">AlarmClear</a>	Clears acknowledged, inactive alarms from the active alarm list.
<a href="#">AlarmClearRec</a>	Clear an alarm by its record number.
<a href="#">AlarmClearTag</a>	Clear an alarm by its tag name.
<a href="#">AlarmComment</a>	Allows users to add comments to alarm summary entries during runtime.
<a href="#">AlarmCommentRecID</a>	Allows an operator to add a comment to a selected

	alarm summary or SOE entry during runtime.
AlarmCount	Counts the available alarms for the selected filter criteria.
AlarmCountEquipment	Counts the available alarms for specified equipment in conjunction with the selected filter criteria.
AlarmCountList	Counts the available alarms for the selected alarm list.
AlarmDelete	Deletes alarm summary entries that are currently displayed.
AlarmDisable	Disables alarms.
AlarmDisableRec	Disables alarms by record number.
AlarmDisableTag	Disables alarms by tag name.
AlarmDsp	Displays alarms.
AlarmDspClusterAdd	Adds a cluster to a client's alarm list.
AlarmDspClusterInUse	Determines if a cluster is included in a client's alarm list.
AlarmDspClusterRemove	Removes a cluster from a client's alarm list.
AlarmDspLast	Displays the latest, unacknowledged alarms.
AlarmDspNext	Displays the next page of alarms.
AlarmDspPrev	Displays the previous page of alarms.
AlarmEnable	Enables alarms.
AlarmEnableRec	Enables alarms by record number.
AlarmEnableTag	Enables alarms by tag name.
AlarmEventQue	Opens the alarm event queue.
AlarmFirstCatRec	Searches for the first occurrence of an alarm category and type.
AlarmFirstPriRec	Searches for the first occurrence of an alarm priority and type.
AlarmFirstTagRec	Searches for the first occurrence of an alarm tag, name, and description.
AlarmGetDelay	Gets the delay setting for an alarm.

<a href="#">AlarmGetDelayRec</a>	Gets the delay setting for an alarm via the alarm record number.
<a href="#">AlarmGetDsp</a>	Gets field data from the alarm record that is displayed at the specified AN.
<a href="#">AlarmGetFieldRec</a>	Gets alarm field data from the alarm record number.
<a href="#">AlarmGetInfo</a>	Gets information about an alarm list displayed at an AN.
<a href="#">AlarmGetOrderbyKey</a>	Retrieves the list of key(s) used to determine the order of the alarm list.
<a href="#">AlarmGetThreshold</a>	Gets the thresholds of analog alarms.
<a href="#">AlarmGetThresholdRec</a>	Gets the thresholds of analog alarms by the alarm record number.
<a href="#">AlarmHelp</a>	Displays the help page for the alarm where the cursor is positioned.
<a href="#">AlarmHighestPriority</a>	Returns the priority and alarm state of the current highest priority alarm for the given equipment.
<a href="#">AlarmListCreate</a>	Creates an alarms list at a specified AN.
<a href="#">AlarmListDestroy</a>	Destroys an alarms list at a specified AN.
<a href="#">AlarmListDisplay</a>	Displays an alarms list at a specified AN.
<a href="#">AlarmListFill</a>	Fills an alarm list at a specified AN to be used by another routine.
<a href="#">AlarmNextCatRec</a>	Searches for the next occurrence of an alarm category and type.
<a href="#">AlarmNextPriRec</a>	Searches for the next occurrence of an alarm priority and type.
<a href="#">AlarmNextTagRec</a>	Searches for the next occurrence of an alarm tag, name, and description.
<a href="#">AlarmNotifyVarChange</a>	Activates a time-stamped digital or time-stamped analog alarm
<a href="#">AlarmQueryFirstRec</a>	Searches for the first occurrence of an alarm category (or priority) and type.
<a href="#">AlarmQueryNextRec</a>	Searches for the next occurrence of an alarm category (or priority) and type.

<a href="#">AlarmSetDelay</a>	Changes the delay setting for an alarm.
<a href="#">AlarmSetDelayRec</a>	Changes the delay set for an alarm via the alarm record number.
<a href="#">AlarmSetInfo</a>	Changes the display parameters for the alarm list displayed at an AN.
<a href="#">AlarmSetQuery</a>	This function is now obsolete. Use the Alarm Filter Functions.
<a href="#">AlarmSetThreshold</a>	Changes the thresholds of analog alarms.
<a href="#">AlarmSetThresholdRec</a>	Changes the thresholds of analog alarms by the alarm record number.
<a href="#">AlarmSplit</a>	Splits an alarm summary entry which has no Off time.
<a href="#">AlarmSumAppend</a>	Appends a new blank record to the alarm summary.
<a href="#">AlarmSumCommit</a>	Commits the alarm summary record to the alarm summary device.
<a href="#">AlarmSumDelete</a>	Deletes alarm summary entries.
<a href="#">AlarmSumFind</a>	Finds an alarm summary index for an alarm record and alarm on time.
<a href="#">AlarmSumFirst</a>	Gets the oldest alarm summary entry.
<a href="#">AlarmSumGet</a>	Gets field information from an alarm summary entry.
<a href="#">AlarmSumLast</a>	Gets the latest alarm summary entry.
<a href="#">AlarmSumNext</a>	Gets the next alarm summary entry.
<a href="#">AlarmSumPrev</a>	Gets the previous alarm summary entry.
<a href="#">AlarmSumSet</a>	Sets field information in an alarm summary entry.
<a href="#">AlarmSumSplit</a>	Duplicates an alarm summary entry.
<a href="#">AlarmSumType</a>	Retrieves a value that indicates a specified alarm's type.
<a href="#">AlarmTagFromEquipment</a>	Returns the first tag associated with a piece of equipment.
<a href="#">AlmBrowseAck</a>	Acknowledges the alarm tag at the current cursor position in an active data browse session.
<a href="#">AlmBrowseClose</a>	This function is now obsolete.

AlmBrowseClose	Closes an alarm tag's browse session.
AlmBrowseDisable	Disables the alarm tag at the current cursor position in an active data browse session.
AlmBrowseEnable	Enables the alarm tag at the current cursor position in an active data browse session.
AlmBrowseFirst	Gets the oldest alarm tags entry.
AlmBrowseGetField	Gets the field indicated by the cursor position in the browse session.
AlmBrowseNext	Gets the next alarm tags entry in the browse session.
AlmBrowseNumRecords	Returns the number of records in the current browse session.
AlmBrowseOpen	Opens an alarm tags browse session.
AlmBrowsePrev	Gets the previous alarm tags entry in the browse session.
AlmSummaryAck	Acknowledges the alarm at the current cursor position in an active data browse session.
AlmSummaryClear	Clears the alarm at the current cursor position in an active data browse session.
AlmSummaryClose	Closes an alarm summary browse session.
AlmSummaryCommit	Commits the value changes made by AlmSummarySetFieldValue().
AlmSummaryDelete	Deletes alarm summary entries from the browse session.
AlmSummaryDeleteAll	Deletes all alarm summary entries from the browse session.
AlmSummaryDisable	Disables the alarm at the current cursor position in an active data browse session.
AlmSummaryEnable	Enables the alarm at the current cursor position in an active data browse session.
AlmSummaryFirst	Gets the oldest alarm summary entry.
AlmSummaryGetField	Gets the field indicated by the cursor position in the browse session.
AlmSummaryLast	Places the data browse cursor at the latest summary

	record from the last cluster of the available browsing cluster list.
AlmSummaryNext	Gets the next alarm summary entry in the browse session.
AlmSummaryNumRecords	Retrieves the number of records in an alarm summary browse session.
AlmSummaryOpen	Opens an alarm summary browse session.
AlmSummaryPrev	Gets the previous alarm summary entry in the browse session.
AlmSummarySetFieldValue	Sets the value of the field indicated by the cursor position in the browse session. AlmSummaryCommit() is required to commit the value changes. The value changes are discarded if the cursor moves away.
AlmTagsAck	This command is now deprecated. Use the AlmBrowseAck function instead.
AlmTagsClear	This command is now deprecated.
AlmTagsClose	This command is now deprecated. Use the AlmBrowseClose function instead.
AlmTagsDisable	This command is now deprecated. Use the AlmBrowseDisable function instead.
AlmTagsEnable	This command is now deprecated. Use the AlmBrowseEnable function instead.
AlmTagsFirst	This command is now deprecated. Use the AlmBrowseFirst function instead.
AlmTagsGetField	This command is now deprecated. Use the AlmBrowseGetField function instead.
AlmTagsNext	This command is now deprecated. Use the AlmBrowseNext function instead.
AlmTagsNumRecords	This command is now deprecated. Use the AlmBrowseNumRecords function instead.
AlmTagsOpen	This command is now deprecated. Use the AlmBrowseOpen function instead.
AlmTagsPrev	This command is now deprecated. Use the AlmBrowsePrev function instead.

HwAlarmQue	Returns the handle of the hardware alarm queue.
------------	---

[Cicode Function Categories](#)

[Using Cicode Functions](#)

## AlarmAck

Acknowledges alarms. You can acknowledge the alarm where the cursor is positioned, one or more alarm lists on the active page, a whole category of alarms, or alarms of a particular priority.

---

**Note:** This function cannot be used with StruxureWare templates.

This command takes the currently logged in user into account. In other words, only the alarms that the user can see are acknowledged.

---

**Note:** This function will only work while the record is writable which is controlled by the ArchiveAfter parameter. Refer to the topic [Configure the Archiving Parameters](#) for more information.

You would normally call this function from a keyboard command. No action is taken if the specified alarms have already been acknowledged.

---

**Note:** Alarm commands on single clusters will return either 0 if successful or an error code if unsuccessful. Alarm commands across multiple clusters may also return a partial success result, whereby a command has been successful on 'at least' one cluster but unsuccessful on another cluster.

If this function is not called from a foreground task, it becomes a blocking function.

## Syntax

**INT AlarmAck(INT Mode, INT Value [, STRING ClusterName])**

*Mode:*

The type of acknowledgment:

0 - Acknowledge a single alarm.

- Set *Value* to the AN where the alarm is displayed.
- If *Value* is set to 0, the current cursor position will be used.

1 - Acknowledge a page of alarms. An alarm page can contain more than one alarm list:

- Set *Value* to the AN where the alarm list is displayed.
- Set *Value* to 0 to acknowledge the (displayed) alarm list (on the active page) where the cursor is positioned.
- Set *Value* to -1 to acknowledge all (displayed) alarm lists on the active page. This only applies to alarm lists created using AlarmDsp (and not those created using AlarmDspLast).

2 - Acknowledge a category of alarms:

- Set *Value* to the alarm category (0 to 16375) of the alarms to be acknowledged. Please be aware that Alarm category 0 indicates all categories; alarm category 255 indicates hardware alarms.
- Set *Value* to the group number to acknowledge a group of categories.

3 - Acknowledge alarms of a specific priority.

Set *Value* to the alarm priority (0-255) of the alarms to be acknowledged. Alarm priority 0 indicates all priorities. Hardware alarms are not affected by priority.

Set *Value* to the group handle to acknowledge a group of alarms of different priorities.

---

**Note:** Alarm Summary page no longer supports Modes 1, 2, and 3.

*Value*:

Used with Mode 1 and 2 to specify which alarms to acknowledge.

*sClusterName*:

Used with Mode 2 or 3 to specify the name of the cluster in which the alarms being acknowledged reside. This argument is optional if the client is connected to only one cluster containing an alarm server or are resolving the alarm server via the current cluster context.

This argument is not required where the *mode* is 2 and the value is 255 (hardware alarm category).

This argument is enclosed in quotation marks "".

## Return Value

0 (zero) if successful, otherwise an error code will return

---

**Note:** In some cases this function is non-blocking. Under these circumstances, any error that is detected when the alarm server processes the command will not be returned.

AckGrp(STRING CategoryGroup)
    INT hGrp;
    hGrp=GrpOpen("CatGroup",1);
    StrToGrp(hGrp,CategoryGroup);
    AlarmAck(2,hGrp, "clusterXYZ");
    GrpClose(hGrp);
END
```

## See Also

[Alarm Functions](#)

### AlarmAckRec

Acknowledges alarms by record number on both the primary and standby alarm servers. This function can be called from alarm server or client and should not be used with a MsgRPC() call to the alarm server.

This is a blocking function. If the function is called from a foreground task that is unable to block, an error will be returned.

## Syntax

INT **AlarmAckRec**(LONG *Record* [, STRING *ClusterName*] )

*Record*:

The alarm record number, returned from any of the following alarm functions:

- AlarmFirstCatRec or AlarmNextCatRec: used to search for a record by alarm category, area, and type (acknowledged, disabled, etc.).
- AlarmFirstPriRec or AlarmNextPriRec: used to search for a record by alarm priority, area, and type (acknowledged, disabled, etc.).

- **AlarmFirstTagRec** or **AlarmNextTagRec**: used to search for a record by alarm tag, name, and description.
- **AlarmGetDsp**: used to find the record that is displayed at a specified AN, for either an alarm list or alarm summary entry. Set the sField argument in **AlarmGetDsp** to "RecNo".

To store this value, use data type Int in Cicode or Long for variable tags (Long needs 4 bytes).

#### *ClusterName:*

Specifies the name of the cluster in which the Alarm Server resides. This is optional if you have one cluster or are resolving the alarm server via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

0 (zero) if successful, otherwise an error code is returned.

        AlarmAckRec(Current);
        Current=Next;
    END
END
```

## See Also

[Alarm Functions](#)

## AlarmAckTag

Acknowledge a specified alarm.

If this function is not called from a foreground task, it becomes a blocking function.

## Syntax

INT **AlarmAckTag**(STRING *Tag*, [, STRING *ClusterName*])

*Tag*:

A string that identifies the alarm to acknowledge. It can be one of the following:

- An alarm tag — for example, "Fire1"
- An alarm equipment item — for example, "Motor1.AlarmFire"

If you enter an empty string (" "), the function will return an error code at runtime.

*ClusterName*:

The cluster where the tag resides

## Return Value

0 (zero) if successful, otherwise an error code will return.

## See Also

[Alarm Functions](#)

## AlarmActive

Determines if any alarms are active in the user's area. Call this function from the Page Strings database, to display an alarm message at a specified AN on a graphics page. You can specify the type of alarms, for example, active hardware alarms or disabled non-hardware alarms.

## Syntax

INT **AlarmActive**(*nType* [, *sClusterName*])

*nType*:

The type of alarms to check:

Non-hardware alarms

0 - Active alarms

1 - Unacknowledged alarms, ON and OFF

2 - Highest priority unacknowledged alarm

3 - Disabled alarms

Hardware alarms

5 - Active alarms

6 - Unacknowledged alarms, ON and OFF

*sClusterName*:

The name of the cluster to check for active alarms. If this argument is blank or empty, the function will check the connected clusters.

## Return Value

- 1 or 0 for Non-hardware alarms (modes 0, 1, and 3).
- The priority of the highest priority unacknowledged alarm (mode 2).
- The number of active alarms for Hardware alarms (modes 5 and 6).

## Example

Strings	
AN	9
Expression	AlarmActive(5)
True Text	"Hardware Alarms Active"
False Text	"No Active Hardware Alarms"
Comment	Display the alarm status at AN 9

## See Also

[Alarm Functions](#)

### AlarmCatGetFormat

Returns the display format string of the specified alarm category.

## Syntax

STRING **AlarmCatGetFormat(INT Category [, INT Type] )**

*Category:*

The alarm category.

*Type:*

The type of display format string:

0 - Alarm format. Default value.

1 - Summary format.

2 - SOE format

## Return Value

The display format string of the specified category. If the alarm category is not specifically defined or it has no format string specified in your project, the format string of category 0 will be returned.

## Example

```
sFormat = AlarmCatGetFormat(0, 0);
! sFormat is assigned to the format string as defined in the Alarm Format field of the
Alarm Categories form for category 0 in your project.
```

## See Also

[Alarm Functions](#)

### AlarmClear

Clears an acknowledged (and off) alarm from the active alarm list. You can clear the alarm where the cursor is positioned, one or more alarm lists on the active page, a whole category of alarms, or alarms of a particular priority.

If you set the [\[Alarm\]AckHold](#) parameter to 1, alarms that go off and have been acknowledged are not removed from the active list until this function is called.

## Syntax

`INT AlarmClear(Mode, Value [, ClusterName] )`

*Mode*:

The type of clear:

0 - Clear a single alarm where the cursor is positioned:

- Set *Value* to 0 (zero) - it is not used.

1 - Clear a page of alarms. An alarm page can contain more than one alarm list:

- Set *Value* to the AN where the alarm list is displayed.
- Set *Value* to 0 to clear the (displayed) alarm list (on the active page) where the cursor is positioned.
- Set *Value* to -1 to clear every (displayed) alarm list on the active page.

2 - Clear a category of alarms:

- Set *Value* to the alarm category (0 to 16375) of the alarms to clear. Please be aware that alarm category 0 indicates all categories; alarm category 255 indicates hardware alarms.
- Set *Value* to the group number to clear a group of categories.

3 - Clear alarms of a specific priority.

- Set *Value* to the alarm priority (0-255) of the alarms to be cleared.

Alarm priority 0 indicates all priorities. Hardware alarms are not affected by priority. Set *Value* to the group handle to clear a group of alarms of different priorities.

*Value*:

Used with Mode 1 or 2 to specify which alarms to clear.

*ClusterName*:

Used with Mode 2 or 3 to specify the name of the cluster in which the alarms being cleared reside. This argument is optional if the client is connected to only one cluster containing an Alarm Server or you are resolving the alarm server via the current cluster context.

This argument is not required where the *mode* is 2 and the value is 255 (hardware alarm category).

This argument is enclosed in quotation marks "".

## Return Value

0 (zero) if successful, otherwise an error is returned.

[Alarm Functions](#)

## AlarmClearRec

Clears an alarm by its record number on both the Primary and Standby Alarms Servers. This function can be called from Alarm Server or Client.

This function should not be used with a MsgRPC() call to the Alarm Server.

## Syntax

INT **AlarmClearRec**(*Record* [, *ClusterName*] )

*Record*:

The alarm record number, returned from any of the following alarm functions:

- **AlarmFirstCatRec** or **AlarmNextCatRec** - used to search for a record by alarm category, area, and type (acknowledged, disabled, etc.).
- **AlarmFirstPriRec** or **AlarmNextPriRec** - used to search for a record by alarm priority, area, and type (acknowledged, disabled, etc.).
- **AlarmFirstTagRec** or **AlarmNextTagRec** - used to search for a record by alarm tag, name, and description.
- **AlarmGetDsp** - used to find the record that is displayed at a specified AN, for either an alarm list or alarm summary entry. Set the *sField* argument in **AlarmGetDsp** to "RecNo".

To store this value, use data type Int in Cicode or Long for variable tags (Long needs 4 bytes).

*ClusterName*:

Specifies the name of the cluster in which the Alarm Server resides. This is optional if you have one cluster or are resolving the alarm server via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

0 (zero) if successful, otherwise an error is returned.

[Alarm Functions](#)

## AlarmClearTag

Clears alarms by Tag on both the Primary and Standby Alarms Servers.

If this function is not called from a foreground task, it becomes a blocking function.

## Syntax

INT **AlarmClearTag**(*STRING Tag*, [, *STRING ClusterName*])

**Tag:**

A string that identifies the alarm to acknowledge. It can be one of the following:

- An alarm tag — for example, "Fire1"
- An alarm equipment item — for example, "Motor1.AlarmFire"

Specify an empty string (" ") to match all alarm tags.

**ClusterName:**

The cluster where the tag resides.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[AlarmAckTag](#), [AlarmEnableTag](#), [AlarmDisableTag](#)

## See Also

[Alarm Functions](#)

## AlarmComment

Allows an operator to add a comment to a selected alarm summary or SOE entry during runtime. You would normally call this function from a keyboard command.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**INT AlarmComment(STRING Comment[,INT AN])**

**Comment:**

The comment to add to the alarm summary entry or SOE entry. Currently for the Alarm summary page the maximum length of a comment is 128 characters. The maximum length for a comment on the SOE page is 244 characters. If you exceed the maximum length it will be truncated and an ellipsis appended.

**AN:**

An animation identifier. Enter the value of the AN where the alarm is displayed. If AN is not specified, the default value will be 0, which means the current cursor position will be used.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[AlarmDsp](#)

## Example

System keyboard	
Key Sequence	Com ##### Enter
Command	AlarmComment(Arg1)
Comment	Add an alarm comment to the alarm where the cursor is positioned

**Note:** If you have installed Plant SCADA on an English operating system and want to add comments at runtime using a Unicode language (such as Korean, Russian or Chinese), you will need to change the Windows™ **Region** setting for the runtime computer. To do this, go to **Control Panel** and open the **Region** dialog box. On the **Administrative** tab, use the **Change system locale** button to select the required system locale. Be aware that you will have to restart your computer. When you launch runtime, select the matching **Language** on the login form. Your runtime comments will be recorded using the specified language characters.

### AlarmCommentRecID

Allows an operator to add a comment to a selected alarm summary or SOE entry during runtime. You would normally call this function from a keyboard command.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**INT AlarmCommentRecID(*sComment*, *sRecID*, *nListType*, *sCluster*)**

*Comment:*

The comment to add to the alarm summary entry or SOE entry. Currently for the Alarm summary page the maximum length of a comment is 128 characters. The maximum length for a comment on the SOE page is 244 characters. If you exceed the maximum length it will be truncated and an ellipsis appended.

*RecID:*

Can be the value:

- from the SOE record's "RECORDID" field. OR
- from the Summary record's "SUMMARYID" field.

**Note:** The Summary Alarm List is not provided in the Situational Awareness Starter Project.

*nListType:*

Following are the nListType values for SOE or Alarm Summary lists.

10 - All summary alarms

15 - Sequence of events with configuration events filtered out

16 - Sequence of events with configuration events

*sCluster:*

Specifies the cluster context for the alarms displayed in the list.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

## Example

System keyboard	
Key Sequence	Com ##### Enter
Command	AlarmCommentReID(Arg1)
Comment	Add an alarm comment to the alarm where the cursor is positioned

## See Also

[Alarm Functions](#)

## AlarmCount

Counts the available alarms for the selected filter criteria.

Alarm counts will display and update at different rates depending on how extensively they are used in your system. Consider the number of counts being used on pages, combined with the number of clients using those pages at any one time. The number of configured alarms will also contribute to the alarm count update rate. For example on a system with 50,000 configured alarms and 10 clients displaying a page with 100 alarm counts, the alarm count update rate will be degraded.

This function is a blocking function if *CachedMode* is set to zero (0).

## Syntax

LONG **AlarmCount**(INT *Type* [, STRING *FilterCriteria* [, LONG *KeepAliveSeconds* [, INT *CachedMode*]])

*nType:*

The type of alarms to display:

#### **Non-hardware alarms**

- 0 - All active alarms, that is Types 1 and 2
- 1 - All unacknowledged alarms, ON and OFF
- 2 - All acknowledged ON alarms
- 3 - All disabled alarms
- 4 - All configured (non-hardware) alarms, that is Types 0 to 3, plus acknowledged OFF alarms.

#### **Hardware alarms**

- 5 - All active alarms, that is Types 6 and 7
- 6 - All unacknowledged alarms, ON and OFF
- 7 - All acknowledged ON alarms
- 8 - All disabled alarms
- 9 - All configured alarms, that is Types 5 to 8

#### **Alarm General**

- 11 - All ON alarms
- 12 - All OFF alarms
- 13 - All ON hardware alarms
- 14 - All OFF hardware alarms
- 17 - All unacknowledged ON alarms
- 18 - All unacknowledged OFF alarms

If you omit the *Type*, the default is 1.

#### *FilterCriteria:*

A filter name OR filter text.

See the topic [Implementing Alarm Filters Using Cicode](#) for more information about filter syntax.

#### *KeepAliveSeconds:*

Optional length of time (in seconds) that the count will remain in memory. Default is 30 seconds.

#### *CachedMode:*

Optional flag that causes the current cached value to be supplied even when the value is being refreshed. This makes the function non-blocking. If the property has not yet been cached, an error is set.

0 - Do not force cached read. Cicode is blocking

1 - Force cached read. Cicode is non-blocking

Default value is 1 (true).

A count in memory will be accessed when its filter criteria matches a subsequent filter criteria and the count's *KeepAliveSeconds* period will be extended.

A count will stay in the cache for 'at least' the duration specified by *KeepAliveSeconds*, and may stay in the cache for an unspecified period of time before being discarded.

The period set for an existing count will be overridden in the event a longer duration is set using *KeepAliveSeconds*.

A count that is added to the cache is not immediately available for reading, so a foreground call to `AlarmCount` that causes a new count to be added will return a value of -1 and an error of 345 (Data not ready).

## Return Value

Returns counted alarms for the selected filter criteria. Returns -1 when an error is detected.

## Example

```
INT iRet, iErr; // return values
INT iCountWhile=0; // loop counter

// counts all unacknowledged alarms, ON and OFF, default non-blocking cicode
iRet = AlarmCount(1);
iErr = IsError(); //check error code

// repeat the above non-blocking function
INT iCountWhile=0; // loop counter
WHILE (iRet = 0) AND (iErr = 0) AND (iCountWhile < 10) DO
    SleepMS(100);
    iRet = AlarmCount(1);
    iErr = IsError();
    iCountWhile = iCountWhile + 1;
END

// counts all disabled alarms, default non-blocking cicode
iRet = AlarmCount(3);
iErr = IsError();

// repeat this non-blocking function as shown above (see while loop)
// counts all unacknowledged alarms with category 10 - non-blocking cicode
iRet = AlarmCount(1,"Category=10",1,1);
iErr = IsError();

// repeat this non-blocking function as shown above (see while loop)
// counts all unacknowledged alarms with category 10 - blocking cicode
iRet = AlarmCount(1,"Category=10",1,0);
IF iRet = -1 THEN
    iErr = IsError(); // get error code)
END

// counts all unacknowledged tag alarms of equipA without it's children equipment
// and keeps the count in memory for 3 seconds - blocking cicode
// (where is equipment structure is equipA.equipB.equipC.equipD)
iRet = AlarmCount(1,"Equipment=equipA",3,0);
IF iRet = -1 THEN
    iErr = IsError(); // get error code)
END

// counts all acknowledged ClusterA tag ON alarms of equipA and it's children equipment
// and keeps the count in memory for 3 seconds - blocking cicode
// (where is equipment structure is equipA.equipB.equipC.equipD)
iRet = AlarmCount(2,"Equipment=equipA*;cluster=ClusterA",3,0);
IF iRet = -1 THEN
    iErr = IsError(); // get error code)
END
```

```
// counts all active tag alarms of equipB and it's children equipment
// and keeps the count in memory for 3 seconds - non-blocking cicode
// (where is equipment structure is equipA.equipB.equipC.equipD)

[Alarm Functions](#)

## AlarmCountEquipment

Counts the available alarms for specified equipment and referenced equipment in conjunction with the selected filter criteria.

## Syntax

**LONG AlarmCountEquipment(INT Type [,STRING EquipmentFilter, [STRING FilterCriteria [, LONG KeepAliveSeconds [, INT CachedMode, [INT IncludingReference]]]]])**

*nType:*

The type of alarms to display:

**Non-hardware alarms**

0 - All active alarms, that is Types 1 and 2

1 - All unacknowledged alarms, ON and OFF

2 - All acknowledged ON alarms

3 - All disabled alarms

4 - All configured (non-hardware) alarms, that is Types 0 to 3, plus acknowledged OFF alarms.

#### Hardware alarms

5 - All active alarms, that is Types 6 and 7

6 - All unacknowledged alarms, ON and OFF

7 - All acknowledged ON alarms

8 - All disabled alarms

9 - All configured alarms, that is Types 5 to 8

#### Alarm General

11 - All ON alarms

12 - All OFF alarms

13 - All ON hardware alarms

14 - All OFF hardware alarms

17 - All unacknowledged ON alarms

18 - All unacknowledged OFF alarms

If you omit the Type, the default is 1.

#### *EquipmentFilter:*

A comma-separated list of equipment names or categories (RefCat) to filter alarms prior to applying the other filter specified on the FilterCriteria argument. This field has been extended to support wildcards, and hence accept partial filter strings.

Filtering using an equipment name or category (RefCat):

Expression has been extended to allow:

- "EQUIPMENT=XYZ" (this may have an asterisk as the last character, which is interpreted as a wildcard). This restricts the result to only equipment that match this filter. Multiple "EQUIPMENT=" elements are treated as having an "OR" condition. This filter is evaluated on the client.
- "REFCAT=XYZ" (this may have an asterisk as the first and/or last character, these are interpreted as wildcards). This restricts the result to only equipment that match this filter, however, this filter is applied after any equipment filters and reference expansions have taken place. Multiple "REFCAT=" elements are treated as having an "OR" condition, and these in turn are treated as having an "AND" condition with the "EQUIPMENT=" elements. This filter is evaluated on the client.
- "PAGE=XYZ" (this is an exact literal match only). This restricts the result to only those equipment that match this filter. This filter cannot be combined with other equipment filter elements. This filter is evaluated on the server.

What this means is:

- "XYZ" is equivalent to "EQUIPMENT=XYZ\*"
- "PAGE=PageXYZ" includes all the equipment that have "PageXYZ" in the PAGE field in the Equipment table.

---

**Note:** Filters that take the form "XYZ" should no longer be used. It is recommended you use the "EQUIPMENT=XYZ" form, further "XYZ" can now be expressed as "EQUIPMENT=XYZ,EQUIPMENT=XYZ.\*" as this will include all items on the "XYZ" equipment and all items on sub-equipment of the "XYZ" equipment.

---

#### *FilterCriteria:*

A filter name OR filter text.

See the topic [Implementing Alarm Filters Using Cicode](#) for more information about filter syntax.

*KeepAliveSeconds:*

Optional length of time (in seconds) that the count will remain in memory. Default is 30 seconds.

*CachedMode:*

Optional flag that causes the current cached value to be supplied even when the value is being refreshed. This makes the function non-blocking. If the property has not yet been cached, an error is set.

0 - Do not force cached read. Cicode is blocking

1 - Force cached read. Cicode is non-blocking

Default value is 1 (true).

A count in memory will be accessed when its filter criteria matches a subsequent filter criteria and the count's *KeepAliveSeconds* period will be extended.

A count will stay in the cache for 'at least' the duration specified by *KeepAliveSeconds* and may stay in the cache for an unspecified period of time before being discarded.

The period set for an existing count will be overridden in the event a longer duration is set using *KeepAliveSeconds*.

A count that is added to the cache is not immediately available for reading, so a foreground call to *AlarmCount* that causes a new count to be added will return a value of -1 and an error of 345 (Data not ready).

*IncludingReference:*

0 - Do not include alarms belonging to referenced equipment in Alarm Count for current equipment

1 - Include alarms belonging to referenced equipment in Alarm Count for current equipment. This is set by default.

## Return Value

Returns counted alarms for the selected filter criteria. Returns -1 when an error is detected.

## Example

```
// counts all unacknowledged alarms, ON and OFF (default non-blocking Cicode) in
Plant.Area.Room* equipment and any lower-level equipment.
iRet = AlarmCountEquipment(1, "Plant.Area.Room");

// counts all disabled alarms (default non-blocking Cicode) in any lower-level equipment
from Plant.Area.
iRet = AlarmCountEquipment(3, "Plant.Area.");

// counts all unacknowledged alarms in Plant.Area.Room*, Plant.Area.Flat* equipment and any
lower-level equipment with category 10 (non-blocking Cicode)
iRet = AlarmCountEquipment(1, "Plant.Area.Room, Plant.Area.Flat", "Category=10", 1, 1);

// counts all unacknowledged alarms in Plant.Area.Room.* , Plant.Area.Flat.* equipment and
any lower-level equipment with category 10 (non-blocking Cicode).
// Note that Plant.Area.Room and Plat.Area.Flat equipment themselves do not count as a
period is given at the end of each expression.
iRet = AlarmCountEquipment(1, "Plant.Area.Room., Plant.Area.Flat.", "Category=10", 1, 1);
```

## Related Functions

[AlarmCount](#), [AlarmCountList](#)

## See Also

[Alarm Functions](#)

### AlarmCountList

Counts the available alarms for the selected filter criteria.

## Syntax

LONG **AlarmCountList**(INT *AN*)

*AN*:

An animation identifier of an alarm list.

## Return Value

Returns counted alarms for the selected filter criteria. Returns -1 when an error is detected.

## Example

```
// counts all listed alarms on the selected alarm page
INT iRet, iErr; // return values
iRet = AlarmCountList(21);
IF iRet = -1 THEN
    iErr = IsError(); // get error code)
END
```

## Related Functions

### AlarmDelete

Deletes alarm summary entries that are currently displayed. You can delete the alarm where the cursor is positioned, one or more alarm lists on the active page, a whole category of alarms, or alarms of a particular priority.

You would normally call this function from a keyboard command.

If this function is not called from a foreground task, it becomes a blocking function.

**Note:** This function will only work while the record is writable which is controlled by the ArchiveAfter Parameter. Refer to the topic *Configure the Archiving Parameters* in the main help for more information.

## Syntax

```
INT AlarmDelete(Mode, Value [, ClusterName] )
```

*Mode*:

The type of deletion:

0 - Delete a single alarm.

- Set *Value* to the AN where the alarm is displayed.
- If *Value* is set to 0, the current cursor position will be used.

1 - Delete a page of alarms. AN alarm page can contain more than one alarm list:

- Set *Value* to the AN where the alarm list is displayed.
- Set *Value* to 0 to delete the (displayed) alarm list (on the active page) where the cursor is positioned.
- Set *Value* to -1 to delete every (displayed) alarm list on the active page.

2 - Delete a category of alarms.

- Set *Value* to the alarm category (0-16375) of the alarms to delete. Please be aware that alarm category 0 indicates all categories; alarm category 255 indicates hardware alarms.

- Set *Value* to the group number to delete a group of categories.

3 - Delete alarms of a specific priority.

- Set *Value* to the alarm priority (0-255) of the alarms to be deleted.

Alarm priority 0 indicates all priorities. Hardware alarms are not affected by priority. Set *Value* to the group handle to delete a group of alarms of different priorities.

*Value*:

Used with Mode 1 or 2 to specify which alarms to delete.

*ClusterName*:

Used with Mode 2 or 3 to specify the name of the cluster in which the alarms being deleted reside. This argument is optional if the client is connected to only one cluster containing an Alarm Server or you are resolving the alarm server via the current cluster context. This argument is enclosed in quotation marks "".

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[GrpOpen](#), [AlarmSumDelete](#), [AlmSummaryDelete](#)

## Example

System keyboard	
Key Sequence	DelSum
Command	AlarmDelete(0, 0)
Comment	Delete the alarm summary entry where the cursor is positioned

Key Sequence	ShiftDelSum
Command	AlarmDelete(1, -1)
Comment	Delete a page of alarm summary entries
System keyboard	
Key Sequence	SumDelete ### Enter
Command	AlarmDelete(2, Arg1, "clusterXYZ")
Comment	Delete alarm summary entries of a specified category in cluster XYZ
System keyboard	
Key Sequence	DelSum ##### Enter
Command	AlarmDelete(3,Arg1, "clusterXYZ")
Comment	Delete alarm summary entries of a specified priority in cluster XYZ

## See Also

[Alarm Functions](#)

### AlarmDisable

Disables alarms. You can disable the alarm where the cursor is positioned, one or more alarm lists on the active page, a whole category of alarms, or alarms of a particular priority.

You would normally call this function from a keyboard command. No action is taken if the alarms are already disabled. Use the [AlarmEnable](#) function to re-enable an alarm.

After you disable an alarm, the behavior is determined by the [\[Alarm\]DisplayDisable](#) parameter for your system to choose between taking the alarm off scan or suppressing it from the active alarm display.

If this function is not called from a foreground task, it becomes a blocking function.

## Syntax

**INT AlarmDisable(INT Mode, INT Value [, STRING ClusterName [, INT EndTime [, STRING Comment]]])**

*Mode:*

The type of disable:

0 - Disable a single alarm.

- Set *Value* to the AN where the alarm is displayed.

- If *Value* is set to 0, the current cursor position will be used.

1 - Disable a page of alarms. An alarm page can contain more than one alarm list:

- Set *Value* to the AN where the alarm list is displayed.

- Set *Value* to 0 to disable the (displayed) alarm list (on the active page) where the cursor is positioned.

- Set *Value* to -1 to disable all (displayed) alarm lists on the active page. This only applies to alarm lists created using [AlarmDsp](#) (and not those created using [AlarmDspLast](#)).

2 - Disable a category of alarms.

- Set *Value* to the alarm category (0-16375) of the alarms to be disabled. Please be aware that alarm category 0 indicates all categories; alarm category 255 indicates hardware alarms.

- Set *Value* to the group number to disable a group of categories.

3 - Disable alarms of a specific priority.

- Set *Value* to the alarm priority (0-255) of the alarms to be disabled.

Alarm priority 0 indicates all priorities. Hardware alarms are not affected by priority. Set *Value* to the group handle to disable a group of alarms of different priorities.

*Value:*

Used with Mode 1 and 2 to specify which alarms to disable.

*ClusterName:*

Used with Mode 2 or 3 to specify the name of the cluster where the alarms being disabled reside in. This argument is optional if the client is connected to only one cluster containing an alarm server, or if the alarm server is resolved via the current cluster context.

This argument is not required where the *mode* is 2 and the value is 255 (hardware alarm category).

This argument is enclosed in quotation marks "".

*EndTime:*

A date/time variable that indicates when the alarm will no longer be disabled. If this parameter is omitted or set to 0, the alarm will be disabled indefinitely.

*Comment:*

An optional comment limited to 200 characters explaining why the alarm is disabled. If the comment exceeds 200 characters, hardware error 274 ("Invalid argument passed") will be displayed.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[GrpOpen](#), [AlarmEnable](#), [AlarmDisableRec](#)

## Examples

```
// Disable the alarm where the cursor is positioned
AlarmDisable(0, 0);
// Disable a page of alarms
AlarmDisable(1, -1);
// Disable category 3 alarms in cluster XYZ
AlarmDisable(2, 3, "XYZ");
// Disable the alarm where the cursor is positioned for the next 60 minutes
nEndTime = DateAdd(TimeCurrent(), 3600);
AlarmDisable(0, 0, "Cluster1", nEndTime, "Shelve alarm for 60 minutes.");
// Disable a page of alarms until 20 Dec 2016 6:30am local time
nEndTime = DateAdd(StrToDate("20/12/2016"), StrToTime("6:30"));
AlarmDisable(1, -1, "Cluster1", nEndTime, "Shelve alarms until 20 Dec 2016 6:30am");
```

## See Also

[Alarm Functions](#)

### AlarmDisableRec

Disables alarms by record number on both the Primary and Standby Alarms Servers. This function can be called from alarm server or client and should not be used with a MsgRPC call to the alarm server.

This is a blocking function. If the function is called from a foreground task that is unable to block, an error will be returned.

## Syntax

INT **AlarmDisableRec**(LONG *Record* [, STRING *ClusterName* [, INT *EndTime* [, STRING *Comment*]]) )

*Record*:

The alarm record number, returned from any of the following alarm functions:

- *AlarmFirstCatRec()* or *AlarmNextCatRec()* - used to search for a record by alarm category, area, and type (acknowledged, disabled, etc.).
- *AlarmFirstPriRec()* or *AlarmNextPriRec()* - used to search for a record by alarm priority, area, and type (acknowledged, disabled, etc.).
- *AlarmFirstTagRec()* or *AlarmNextTagRec()* - used to search for a record by alarm tag, name, and description.
- *AlarmGetDsp()* - used to find the record that is displayed at a specified AN, for either an alarm list or alarm summary entry. Set the *sField* argument in *AlarmGetDsp()* to "RecNo".

To store this value, use data type Int in Cicode or Long for variable tags (Long needs 4 bytes).

*ClusterName*:

Specifies the name of the cluster in which the Alarm Server resides. This is optional if you have one cluster or are resolving the alarm server via the current cluster context. The argument is enclosed in quotation marks "".

**EndTime:**

A date/time variable that indicates when the alarm will no longer be disabled. If this parameter is omitted or set to 0, the alarm will be disabled indefinitely.

**Comment:**

An optional comment limited to 200 characters explaining why the alarm is disabled. If the comment exceeds 200 characters, hardware error 274 ("Invalid argument passed") will be displayed.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[AlarmFirstTagRec](#), [AlarmNextTagRec](#), [AlarmDisable](#)

## Examples

```
/* Disable/enable the specified "Pump" alarm. Flag determines
whether the alarm is disabled (Flag=0) or enabled (Flag=1). */
FUNCTION
DisablePumps(STRING sTag, INT Flag)
    INT Current;
    INT Next;
    Current=AlarmFirstTagRec(sTag, "Pump", "");
    WHILE Current<>-1 DO
        Next=AlarmNextTagRec(Current,sTag, "Pump", "");
        IF Flag=0 THEN
            AlarmDisableRec(Current);
        ELSE
            AlarmEnableRec(Current);
        END
        Current=Next;
    END
END

// Disable alarm for the next 60 minutes
Current=AlarmFirstTagRec(sTag, "Pump", "");
nEndTime = DateAdd(TimeCurrent(), 3600);
AlarmDisableRec(Current, "Cluster1", nEndTime, "Shelve alarm for 60 minutes.");

// Disable alarm until 20 Dec 2016 6:30am local time
Current=AlarmFirstTagRec(sTag, "Pump", "");
nEndTime = DateAdd(StrToDate("20/12/2016"), StrToTime("6:30"));
AlarmDisableRec(Current, "Cluster1", nEndTime, "Shelve alarms until 20 Dec 2016 6:30am");
```

## See Also

[Alarm Functions](#)

## AlarmDisableTag

Disables alarms by Tag on both the Primary and Standby Alarms Servers.

If this function is not called from a foreground task, it becomes a blocking function.

## Syntax

```
INT AlarmDisableTag(STRING Tag, [, STRING ClusterName] [, INT EndTime [, STRING Comment]] )
```

*Tag*:

A string that identifies the alarm to acknowledge. It can be one of the following:

- An alarm tag — for example, "Fire1"
- An alarm equipment item — for example, "Motor1.AlarmFire"

Specify an empty string (" ") to match all alarm tags.

*ClusterName*:

The cluster where the tag resides.

*EndTime*:

A date/time variable that indicates when the alarm will no longer be disabled. If this parameter is omitted or set to 0, the alarm will be disabled indefinitely.

*Comment*:

An optional comment limited to 200 characters explaining why the alarm is disabled. If the comment exceeds 200 characters, hardware error 274 ("Invalid argument passed") will be displayed.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

// Disable alarm until 20 Dec 2016 6:30am local time
nEndTime = DateAdd(StrToDate("20/12/2016"), StrToTime("6:30"));
AlarmDisableTag("ALARM_1", "Cluster1", nEndTime, "Shelve alarms until 20 Dec 2016 6:30am");
```

## See Also

[Alarm Functions](#)

## AlarmDsp

Displays an alarm list, starting at a specified AN and then on subsequent ANs. You specify the number of alarms to display, the type of alarms and the name of the cluster the alarms belong to, for example, active hardware alarms or disabled non-hardware alarms in cluster XYZ. Before you call this function, you need to first add animation points to the graphics page for each alarm to be displayed.

If you only need to display the standard alarm page, use the PageAlarm function - it uses this AlarmDsp() function to display alarms. If you need more control over the display of alarms you can use this function, but only to display alarms on the alarm page. Use the AlarmDspLast function to display alarms on another graphics page (it uses less memory).

## Syntax

**INT AlarmDsp(INT AN, INT Count [, INT Type] [, STRING ClusterName] [, INT NoDraw] [, STRING CallbackFunc] )**

**AN:**

The AN where the first alarm is to display.

---

**Note:** The [\[Animator\]MaxAn](#) parameter sets the maximum AN which AlarmDsp will work with.

---

**Count:**

The number of alarms to display.

**nType:**

The type of alarms to display:

### Non-hardware alarms

0 - All active alarms, that is Types 1 and 2

1 - All unacknowledged alarms, ON and OFF

2 - All acknowledged ON alarms

3 - All disabled alarms

4 - All configured (non-hardware) alarms, that is Types 0 to 3, plus acknowledged OFF alarms.

### Hardware alarms

5 - All active alarms, that is Types 6 and 7

6 - All unacknowledged alarms, ON and OFF

7 - All acknowledged ON alarms

8 - All disabled alarms

9 - All configured alarms, that is Types 5 to 8

### Alarm Summary

10 - All summary alarms

15 – Sequence of events with configuration events filtered out

16 - Sequence of events

### Alarm General

11 - All ON alarms

12 - All OFF alarms

13 - All ON hardware alarms

14 - All OFF hardware alarms

17 - All unacknowledged ON alarms

18 - All unacknowledged OFF alarms

If you omit the Type, the default is 1.

*ClusterName:*

The cluster name to which the alarms belong. This is optional if you have one cluster or are resolving the alarm server via the current cluster context. The argument is enclosed in quotation marks "".

If the client is connected to only one cluster containing an alarm server then this argument is optional, the list returned will be limited to alarms within this cluster.

If the client is connected to clusters containing more than one alarm server then the Cluster Name needs to be specified. If a cluster name is not specified, alarms are returned for all clusters.

*NoDraw:*

Makes call to alarm server to update the ALMCB but does not automatically perform the animation of the data when the result is returned.

*CallbackFunc:*

Callback function to associate with the return of the ALMCB data from the Alarm Server.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[AlarmDspNext](#), [AlarmDspPrev](#), [AlarmDspLast](#), [AlarmGetInfo](#), [AlarmDspClusterAdd](#), [AlarmDspClusterRemove](#), [AlarmDspClusterInUse](#)

## Example

Advanced Animation	
Command	AlarmDsp(20,15,3)
Comment	Display 15 disabled alarms at AN 20

## See Also

[Alarm Functions](#)

## AlarmDspClusterAdd

Adds a cluster to a client's alarm list. Alarms in the specified cluster (that correspond to the mode set in [AlarmDsp](#)) will be added to the alarm list at the AN number.

## Syntax

**INT AlarmDspClusterAdd(*nAN*, *sClusterName*)**

*nAN*:

The AN used in the original AlarmDsp call.

*sClusterName*:

The name of the cluster to be used for this alarm list. The argument is enclosed in quotation marks ("").

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[AlarmDspClusterRemove](#), [AlarmDspClusterInUse](#)

## See Also

[Alarm Functions](#)

## AlarmDspClusterInUse

Determines if a cluster is included in a client's alarm list.

## Syntax

**INT AlarmDspClusterInUse(*nAN*, *sClusterName*)**

*nAN*:

The AN used in the original [AlarmDsp](#) call.

*sClusterName*:

The name of the cluster to query an alarm list for to determine if it's included. The argument is enclosed in quotation marks ("").

## Return Value

Returns a Boolean value: True (1) if successful, otherwise False (0) is returned.

## Related Functions

[AlarmDspClusterAdd](#) [AlarmDspClusterRemove](#) [AlarmDsp](#)

## See Also

[Alarm Functions](#)

### AlarmDspClusterRemove

Removes a cluster from a client's alarms list. Alarms for the specified cluster will be removed from the alarms list at the AN number.

If the cluster to be removed is the last cluster, the call will be unsuccessful.

## Syntax

**INT AlarmDspClusterRemove(*nAN*, *sClusterName*)**

*nAN*:

The AN used in the original [AlarmDsp](#) call.

*sClusterName*:

The name of the cluster to remove from this alarm list. The argument is enclosed in quotation marks ("").

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[AlarmDspClusterAdd](#), [AlarmDspClusterInUse](#), [AlarmDsp](#)

## See Also

[Alarm Functions](#)

### AlarmDspLast

Displays the latest alarms, at a specified AN with the cluster name. Use this function to display the last alarms. You can specify the number of alarms to display of a specified type, for example, active hardware alarms or disabled non-hardware alarms.

## Syntax

**INT AlarmDspLast(*nAN* [, *nCount*] [, *nType*] [, *sClusterName*] [, *iNoDraw*] [, *sCallbackFunc*] )**

*nAN*:

The AN where the last alarms are to be displayed.

---

**Note:** The [\[Animator\]MaxAn](#) parameter sets the maximum AN which **AlarmDspLast** will work with.

---

*Count*:

The number of alarms to display. If you omit the Count, the default is 1.

*nType:*

The type of alarms to display:

#### **Non-hardware alarms**

0 - All active alarms, that is Types 1 and 2

1 - All unacknowledged alarms, ON and OFF

2 - All acknowledged ON alarms

3 - All disabled alarms

4 - All configured (non-hardware) alarms, that is Types 0 to 3, plus acknowledged OFF alarms.

#### **Hardware alarms**

5 - All active alarms, that is Types 6 and 7

6 - All unacknowledged alarms, ON and OFF

7 - All acknowledged ON alarms

8 - All disabled alarms

9 - All configured alarms, that is Types 5 to 8

#### **Alarm Summary**

10 - All summary alarms

15 – Sequence of events with configuration events filtered out

16 - Sequence of events

#### **Alarm General**

11 - All ON alarms

12 - All OFF alarms

13 - All ON hardware alarms

14 - All OFF hardware alarms

17 - All unacknowledged ON alarms

18 - All unacknowledged OFF alarms

If you omit the Type, the default is 1.

*sClusterName:*

The cluster name to which the alarms belong. This is optional if you have one cluster or are resolving the alarm server via the current cluster context. The argument is enclosed in quotation marks " ".

If a cluster name is not specified, alarms are returned for all clusters.

*iNoDraw:*

Makes call to alarm server to update the ALMCB but does not automatically perform the animation of the data when the result is returned.

*sCallbackFunc:*

Callback function to associate with the return of the ALMCB data from the Alarm Server.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[AlarmDsp](#)

## Example

Advanced Animation	
Command	AlarmDspLast(11, 'ClusterXYZ')
Comment	Display the last alarm at AN 11
Advanced Animation	
Command	AlarmDspLast(21,3, 'ClusterXYZ')
Comment	Display the last 3 alarms at AN 21

## See Also

[Alarm Functions](#)

## AlarmDspNext

Displays the next page of alarms. This function pages down (scrolls) the alarms displayed by the [AlarmDsp](#) function. You would normally call this function from a keyboard command.

## Syntax

**INT AlarmDspNext(INT AN)**

**AN:**

The AN where the alarm list is displayed, or:

-1 - Scroll every alarm list displayed on the page.

0 - Scroll the alarm list where the cursor is positioned.

---

**Note:** An alarm page can contain more than one alarm list.

---

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[AlarmDsp](#), [AlarmDspPrev](#)

## Example

System keyboard	
Key Sequence	NextAlarm
Command	AlarmDspNext(20)
Comment	Display the next page of alarms (from the alarm list) at AN20

## See Also

[Alarm Functions](#)

## AlarmDspPrev

Displays the previous page of alarms. This function pages up (scrolls) the alarms displayed by the [AlarmDsp](#) function. You would normally call this function from a keyboard command.

## Syntax

**INT AlarmDspPrev(INT AN)**

**AN:**

The AN where the alarm list is displayed, or:

-1 - Scroll every alarm list displayed on the page.

0 - Scroll the alarm list where the cursor is positioned.

---

**Note:** An alarm page can contain more than one alarm list.

---

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[AlarmDsp](#), [AlarmDspNext](#)

## Example

System keyboard	
Key Sequence	PrevAlarm
Command	AlarmDspPrev(20)
Comment	Display the previous page of alarms (from the alarm list) at AN20

## See Also

[Alarm Functions](#)

### AlarmEnable

Enables an alarm on the active alarm list. You can enable the alarm where the cursor is positioned, one or more alarm lists on the active page, a whole category of alarms, or alarms of a particular priority.

No action is taken if the alarms are already enabled. You would normally call this function from a keyboard command.

If this function is not called from a foreground task, it becomes a blocking function.

## Syntax

**INT AlarmEnable(INT Mode, INT Value [, STRING ClusterName [, INT bAcknowledge]] )**

*Mode:*

The type of enable:

0 - Enable a single alarm where the cursor is positioned.

- Set *Value* to the AN where the alarm list is displayed.

• If *Value* is set to 0, the current cursor position will be used.

1 - Enable a page of alarms. An alarm page can contain more than one alarm list:

- Set *Value* to the AN where the alarm list is displayed.

• Set *Value* to 0 to enable the (displayed) alarm list (on the active page) where the cursor is positioned.

• Set *Value* to -1 to enable all (displayed) alarm lists on the active page. This only applies to alarm lists created using AlarmDsp (and not those created using AlarmDspLast).

2 - Enable a category of alarms.

• Set *Value* to the alarm category (0-16375) of the alarms to be enabled. Please be aware that alarm category 0 indicates all categories; alarm category 255 indicates hardware alarms.

- Set *Value* to the group number to enable a group of categories.

3 - Enable alarms of a specific priority.

- Set *Value* to the alarm priority (0-255) of the alarms to be enabled.

Alarm priority 0 indicates all priorities. Hardware alarms are not affected by priority. 3) Set *Value* to the group handle to enable a group of alarms of different priorities.

**Value:**

Used with Mode 0, 1 and 2 to specify which alarms to enable.

**ClusterName:**

Used with Mode 2 or 3 to specify the name of the cluster where the alarms being enabled reside in. This argument is optional if the client is connected to only one cluster containing an Alarm Server or are resolving the alarm server via the current cluster context.

This argument is not required where the *mode* is 2 and the value is 255 (hardware alarm category).

This argument is enclosed in quotation marks "".

**bAcknowledge:**

Forces acknowledgment of an alarm after it is enabled. The accepted values are:

0 — (default) enforced acknowledgment will not be applied.

1 — alarm will be acknowledged when enabled.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[GrpOpen](#), [AlarmDisable](#), [AlarmEnableRec](#)

## Examples

```
// Enable the alarm where the cursor is positioned
AlarmEnable(0, 0);

// Enable a page of alarms
AlarmEnable(1, -1);

// Enable category 3 alarms in cluster XYZ
AlarmEnable(2, 3, "XYZ");

// Enable the alarm where the cursor is positioned and enforce acknowledgment
AlarmEnable(0, 0, "Cluster1", 1);
```

## See Also

[Alarm Functions](#)

### AlarmEnableRec

Enables alarms by record number on both the primary and standby alarms servers. This function can be called from an alarm server or client and should not be used with a MsgRPC call to the alarm server.

This is a blocking function. If the function is called from a foreground task that is unable to block, an error will be returned.

## Syntax

```
INT AlarmEnableRec(INT Record [, STRING ClusterName [, INT bAcknowledge]])
```

### Record:

The alarm record number, returned from any of the following alarm functions:

- `AlarmFirstCatRec()` or `AlarmNextCatRec()` — used to search for a record by alarm category, area, and type (acknowledged, disabled, etc.).
- `AlarmFirstPriRec()` or `AlarmNextPriRec()` — used to search for a record by alarm priority, area, and type (acknowledged, disabled, etc.).
- `AlarmFirstTagRec()` or `AlarmNextTagRec()` — used to search for a record by alarm tag, name, and description.
- `AlarmGetDsp()` — used to find the record that is displayed at a specified AN, for either an alarm list or alarm summary entry. Set the `sField` argument in `AlarmGetDsp()` to "RecNo".

To store this value, use data type Int in Cicode or Long for variable tags (Long needs 4 bytes).

### ClusterName:

Specifies the name of the cluster in which the Alarm Server resides. This is optional if you have one cluster or are resolving the alarm server via the current cluster context. The argument is enclosed in quotation marks " ".

### bAcknowledge:

Forces acknowledgment of an alarm after it is enabled. The accepted values are:

- 0 — (default) enforced acknowledgment will not be applied.  
1 — alarm will be acknowledged when enabled.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[AlarmFirstTagRec](#), [AlarmNextTagRec](#), [AlarmEnable](#), [AlarmDisableRec](#), [AlarmGetDsp](#)

## Examples

```
/* Disable/enable the specified "Pump" alarm. Flag determines
whether the alarm is disabled (Flag=0) or enabled and acknowledged (Flag=1). */
FUNCTION
DisablePumps(STRING sTag, INT Flag)
    INT Current;
    INT Next;
    Current=AlarmFirstTagRec(sTag,"Pump","");
    WHILE Current<>-1 DO
        Next=AlarmNextTagRec(Current,sTag,"Pump","");
        IF Flag=0 THEN
            AlarmDisableRec(Current);
        ELSE
            AlarmEnableRec(Current,"",1);
        END
    
```

```
    Current=Next;  
    END  
END
```

## See Also

[Alarm Functions](#)

### AlarmEnableTag

Enables alarms by Tag on both the Primary and Standby Alarms Servers.

If this function is not called from a foreground task, it becomes a blocking function.

## Syntax

```
INT AlarmEnableTag(STRING Tag [, STRING ClusterName [, INT bAcknowledge]])
```

*Tag*:

A string that identifies the alarm to acknowledge. It can be one of the following:

- An alarm tag — for example, "Fire1"
- An alarm equipment item — for example, "Motor1.AlarmFire"

Specify an empty string (" ") to match all alarm tags.

*ClusterName*:

The cluster where the tag resides.

*bAcknowledge*:

Forces acknowledgment of an alarm after it is enabled. The accepted values are:

0 — (default) enforced acknowledgment will not be applied.

1 — alarm will be acknowledged when enabled.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[AlarmAckTag](#), [AlarmDisableTag](#), [AlarmClearTag](#)

## Example

```
// Enable alarm and enforce acknowledgment  
AlarmEnableTag("ALARM_1", "Cluster1", 1);
```

## See Also

[Alarm Functions](#)

### AlarmEventQue

Opens the alarm event queue. The alarms server writes events into this queue as they are processed. These events include activated, reset, acknowledged, enabled and disabled alarms.

**Note:** This function can only be called on the alarm server.

To read events from this queue, use the [QueRead\(\)](#) or [QuePeek\(\)](#) functions. The data put into the queue is the alarm record identifier (into the **Type** field) and the alarm event format (into the **Str** field). The function puts every state change into the queue and Plant SCADA does not use this queue for anything.

To use this function, you need to enable the alarm event queue with the [\[Alarm\]EventQue](#) parameter. This parameter will tell the Alarms Server to start placing events into the queue. The [\[Alarm\]EventFmt](#) parameter defines the format of the data placed into the string field. You can enable the EventQue parameter without setting the event format so that the Alarms Server does not place a formatted string into the queue.

Enabling this formatting feature can increase CPU loading and reduce performance of the Alarms Server as every alarm is formatted and placed in the queue. You should reconsider using this feature if a decrease in performance is noticeable.

The maximum length of each queue is controlled by the [\[Code\]Queue](#) parameter. You may need to adjust this parameter so as not to miss alarm events. When the queue is full, the alarms server will discard events.

#### **WARNING**

##### **UNINTENDED EQUIPMENT OPERATION**

You may need to adjust the [\[Code\]Queue](#) parameter so as not to miss alarm events. When the queue is full, the Alarms Server will discard events.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

## Syntax

`AlarmEventQue()`

## Return Value

The handle of the alarm event queue, or -1 if the queue cannot be opened.

## Related Functions

[QueRead](#), [QuePeek](#), [TagWriteEventQue](#)

## Example

```
hQue = AlarmEventQue()
WHILE TRUE DO
    QueRead(hQue, nRecord, sAlarmFmt, 1);
    /* do whatever with the alarm event */
    ...
    Sleep(0);
END
```

### AlarmFirstCatRec

Searches for the first occurrence of an alarm category and type. You can search all areas, the current area only, or specify an area to limit the search.

This function returns an alarm record identifier that you can use in other alarm functions, for example, to acknowledge, disable, or enable the alarm, or to get field data on that alarm.

---

**Note:** Record numbers obtained from [AlarmGetDsp](#) are not valid for this function.

This is a blocking function. If the function is called from a foreground task that is unable to block, the return value will be -1 and a hardware alarm set. Use [IsError\(\)](#) to retrieve the error code.

## Syntax

LONG **AlarmFirstCatRec**(INT *Category*, INT *Type* [, INT *Area*] [, STRING *ClusterName*] )

### *Category*:

The alarm category or group number to match. Set Category to 0 (zero) to match all alarm categories.

### *nType*:

The type of alarms to display:

#### **Non-hardware alarms**

0 - All active alarms, that is Types 1 and 2

1 - All unacknowledged alarms, ON and OFF

2 - All acknowledged ON alarms

3 - All disabled alarms

4 - All configured (non-hardware) alarms, that is Types 0 to 3, plus acknowledged OFF alarms.

#### **Alarm General**

11 - All ON alarms

12 - All OFF alarms

17 - All unacknowledged ON alarms

18 - All unacknowledged OFF alarms

If you omit the Type, the default is 1.

---

**Note:** If you call this function with the *Type* argument set to an unsupported value, it may return unexpected results.

**Area:**

The area in which to search for alarms. If you do not specify an area, or if you set Area to -1, only the current area will be searched.

**ClusterName:**

Specifies the name of the cluster in which the Alarm Server resides. This is optional if you have one cluster or are resolving the alarm server via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

The alarm record identifier or -1 if no match is found.

## Related Functions

[AlarmDisableRec](#), [AlarmEnableRec](#), [AlarmGetThresholdRec](#), [AlarmSetThresholdRec](#)

## Example

See [AlarmAckRec](#)

## See Also

[Alarm Functions](#)

### AlarmFirstPriRec

Searches for the first occurrence of an alarm priority and type. You can search all areas, the current area only, or specify an area to limit the search.

This function returns an alarm record identifier that you can use in other alarm functions, for example, to acknowledge, disable, or enable the alarm, or to get field data on that alarm.

---

**Note:** Record numbers obtained from [AlarmGetDsp](#) are not valid for this function.

---

This is a blocking function. If the function is called from a foreground task that is unable to block, the return value will be -1 and a hardware alarm set. Use [IsError\(\)](#) to retrieve the error code.

---

**Note:** This function will return a match for an Acknowledge Off alarm with [\[Alarm\]AckHold=1](#) even after it has been cleared using [AlarmClear](#) or [AlarmClearRec](#).

## Syntax

LONG **AlarmFirstPriRec**(INT *Priority*, INT *Type* [, INT *Area*] [, STRING *ClusterName*] )

***Priority:***

The alarm Priority or group handle of a group of alarm priorities. Set Priority to 0 (zero) to match all alarm priorities.

***nType:***

The type of alarms to display:

#### Non-hardware alarms

- 0 - All active alarms, that is Types 1 and 2
- 1 - All unacknowledged alarms, ON and OFF
- 2 - All acknowledged ON alarms
- 3 - All disabled alarms
- 4 - All configured (non-hardware) alarms, that is Types 0 to 3, plus acknowledged OFF alarms.

#### Alarm General

- 11 - All ON alarms
- 12 - All OFF alarms
- 17 - All unacknowledged ON alarms
- 18 - All unacknowledged OFF alarms

If you omit the Type, the default is 1.

---

**Note:** If you call this function with the *Type* argument set to an unsupported value, it may return unexpected results.

---

#### Area:

The area in which to search for alarms. If you do not specify an area, or if you set Area to -1, only the current area will be searched.

#### ClusterName:

Specifies the name of the cluster in which the Alarm Server resides. This is optional if you have one cluster or are resolving the alarm server via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

The alarm record identifier or -1 if no match is found. If you do not specify an area, only alarms in the current area on the alarms server are searched.

## Related Functions

[GrpOpen](#), [AlarmNextCatRec](#), [AlarmNextPriRec](#), [AlarmGetFieldRec](#), [AlarmAckRec](#), [AlarmDisableRec](#),  
[AlarmEnableRec](#), [AlarmGetThresholdRec](#), [AlarmSetThresholdRec](#)

## Example

```
/* Acknowledge all unacknowledged (Type 1) alarms of the specified
alarm priority. */
FUNCTION
AutoAccept(INT iPriority)
    INT iCurrent;
    INT iNext;
    iCurrent=AlarmFirstPriRec(iPriority,1,-1);
    WHILE iCurrent <>-1 DO
        iNext=AlarmNextPriRec(iCurrent,iPriority,1,-1);
```

```
    AlarmAckRec(iCurrent);
    iCurrent=iNext;
END
END
```

## See Also

[Alarm Functions](#)

### AlarmFirstTagRec

Searches for the first occurrence of an alarm tag, name, and description.

This is a blocking function. If the function is called from a foreground task that is unable to block, the return value will be -1 and a hardware alarm set. Use IsError() to retrieve the error code.

---

**Note:** Record numbers obtained from [AlarmGetDsp](#) are not valid for this function.

This function returns an alarm record identifier that you can use in other alarm functions, for example, to acknowledge, disable, or enable the alarm, or to get field data on that alarm.

---

**Note:** This function will return a match for an Acknowledge Off alarm with [Alarm]AckHold=1 even after it has been cleared using [AlarmClear](#) or [AlarmClearRec](#).

For complex filtering operations it is more efficient to use the alarm tag browse functions [AlmBrowseOpen](#) and [AlmBrowseNext](#)

## Syntax

LONG **AlarmFirstTagRec**(STRING Tag, STRING Name, STRING Description [, STRING ClusterName] )

*Tag:*

A string that identifies the tag to be matched. It can be one of the following:

- An alarm tag — for example, "Fire1"
- An alarm equipment item — for example, "Motor1.AlarmFire"

Specify an empty string (" ") to match all alarm tags.

*Name:*

The alarm name to be matched. Specify an empty string (" ") to match all alarm names.

*Description:*

The alarm description to be matched. Specify an empty string (" ") to match all alarm descriptions.

*ClusterName:*

Specifies the name of the cluster in which the Alarm Server resides. This is optional if you have one cluster or are resolving the alarm server via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

The alarm record identifier or -1 if no match is found.

---

**Note:** The order in which alarms are returned has changed from version 7.20. In later versions, unacknowledged alarms are no longer returned first.

## Related Functions

[Alarm Functions](#)

## AlarmGetDelay

Gets the delay setting for the alarm the cursor is currently positioned over.

## Syntax

LONG **AlarmGetDelay**(*nType*)

*nType*:

The type of delay:

- 0 - Delay (digital alarm/advanced alarm)
- 1 - High high delay (analog alarm)
- 2 - High delay (analog alarm)
- 3 - Low delay (analog alarm)
- 4 - Low low delay (analog alarm)
- 5 - Deviation delay (analog alarm)

## Return Value

The alarm delay if successful, otherwise -1 is returned. Use [IsError\(\)](#) to retrieve extended error information.

## Related Functions

## See Also

[Alarm Functions](#)

## AlarmGetDelayRec

Gets the delay setting for an alarm via the alarm record number.

This is a blocking function. If the function is called from a foreground task that is unable to block, the return value will be -1 and a hardware alarm set.

## Syntax

```
LONG AlarmGetDelayRec(LONG Record, INT Type [, STRING ClusterName] )
```

### Record:

The alarm record number, returned from any of the following alarm functions:

- AlarmFirstCatRec() or AlarmNextCatRec() - used to search for a record by alarm category, area, and type (acknowledged, disabled, etc.).
- AlarmFirstPriRec() or AlarmNextPriRec() - used to search for a record by alarm priority, area, and type (acknowledged, disabled, etc.).
- AlarmFirstTagRec() or AlarmNextTagRec() - used to search for a record by alarm tag, name, and description.
- AlarmGetDsp() - used to find the record that is displayed at a specified AN, for either an alarm list or alarm summary entry. Set the *sField* argument in AlarmGetDsp() to "RecNo".

### Type:

The type of delay:

- 0 - Delay (digital alarm/advanced alarm)
- 1 - High high delay (analog alarm)
- 2 - High delay (analog alarm)
- 3 - Low delay (analog alarm)
- 4 - Low low delay (analog alarm)
- 5 - Deviation delay (analog alarm)

### ClusterName:

Specifies the name of the cluster in which the Alarm Server resides. This is optional if you have one cluster or are resolving the alarm server via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

The alarm delay if successful, otherwise -1 is returned. Use IsError() to retrieve extended error information.

## Related Functions

[AlarmSetDelayRec](#), [AlarmGetDelay](#), [AlarmGetDsp](#)

## See Also

[Alarm Functions](#)

## AlarmGetDsp

Gets field data from the alarm record that is displayed at the specified AN. You can use this function for Alarm Pages, Sequence of Events pages, and Alarm Summary pages (an Alarm Page, SOE Page, and Alarm Summary needs to be displayed before this function can be used).

You can call this function on an Alarms Server or a client to get the contents of any field in the alarm record at that AN.

You can return the record number of the alarm record for use in other alarm functions, for example, to acknowledge, disable, or enable an alarm (on an Alarms Server).

The `AlarmGetDsp()` function does not support hardware alarms.

If this function is not called from a foreground task, it becomes a blocking function.

## Syntax

STRING `AlarmGetDsp(INT AN, STRING Field)`

*AN*:

AN number of an ALMCB Alarm record. Equal to AN where actual ALMCF resides + Offset into the list of ALMCF records.

*Field*:

The name of the field from which the data is retrieved.

The contents of the following fields can be retrieved when the alarm page is displayed.

ALMCOMMENT, AREA, CATEGORY, CAUSE1..8, CLUSTER, COMMENT, CONSEQUENCE1..8, CUSTOM1..8, DATE, DATEEXT, DEADBAND, DELAY, DEVDELAY, DEVIATION, DESC, DISABLECOMMENT, DISABLEENDDATE, DISABLEENDDATEEXT, DISABLEENDTIME, EQUIPMENT, FONT, FORMAT, HDELAY, HELP, HHDELAY, HIGH, HIGHHIGH, LDELAY, LLDELAY, LOGSTATE, LOW, LOWLOW, NAME, PAGING, PAGINGGROUP, PRIORITY, RATE, RECN0, RESPONSE1..8, RESPONSEN0, STATE, STATE\_DESC, TAG, TIME, TYPE, USERLOCATION, VALUE.

The contents of any of the above fields (except for State) and the following fields can be retrieved when the Alarm Summary is displayed:

ACKDATE, ACKDATEEXT, ACKTIME, DELTATIME, FULLNAME, NATIVE\_SUMDESC, NATIVE\_COMMENT, OFFDATE, OFFDATEEXT, OFFMILLI, OFFTIME, ONDATE, ONDATEEXT, ONMILLI, ONTIME, SUMSTATE, SUMDESC, USERNAME.

The following fields can be retrieved when the Alarm SOE is displayed:

ALMCOMMENT, AREA, CATEGORY, CLUSTER, COMMENT, CUSTOM1..8, DATE, DATEEXT, DEADBAND, DEVIATION, EQUIPMENT, FULLNAME, HIGH, HIGHHIGH, LOGSTATE, LOW, LOWLOW, MESSAGE, NAME, NATIVE\_COMMENT, NATIVE\_SUMDESC, PAGING, PAGINGGROUP, PRIORITY, RATE, RECORDID, STATE, STATE\_DESC, SUMDESC, SUMSTATE, TAG, TIME, TYPE, USERLOCATION, USERNAME.

See [Browse Function Field Reference](#) for more information about these fields.

## Return Value

The alarm field data (as a string) or empty string "".

## Related Functions

[AlarmDsp](#)

## Example

```
! Display the tag and category for the alarm at the specified AN.
FUNCTION
AlarmData(INT AN)
    STRING Category;
    STRING Tag;
    Category=AlarmGetDsp(AN,"Category");
    Tag=AlarmGetDsp(AN,"Tag");
    Prompt("Alarm "+Tag+" is Category "+Category);
END
```

## See Also

[Alarm Functions](#)

### AlarmGetInfo

Gets data on the alarm list displayed at a specified AN. Use this function to display the current alarm list information on an alarm page. If only one alarm list has been configured on an alarm page, modes 2 and 3 of this function return the current alarm page information.

---

**Note:** You cannot retrieve the order by key setting for an alarm list using this function, as it can only returns numeric values. To retrieve this information, use the function [AlarmGetOrderbyKey](#).

---

If this function is not called from a foreground task, it becomes a blocking function.

## Syntax

LONG **AlarmGetInfo**(INT *AN*, INT *Type* [, STRING *ClusterName*])

*AN*:

The AN where the alarm list (with the required information) is displayed. Set the AN to 0 (zero) to get information on the alarm list where the cursor is positioned.

*Type*:

The type of data:

0 - Alarm page number. The vertical offset (in pages) from the AN where the alarm list commenced. The alarm list need to have scrolled off the first page for this type to return a non-zero value.

1 - Alarm list offset. The vertical offset (in lines) from the AN where the alarm list commenced. You need to have scrolled off the first page of alarms for this type to return a non zero value.

2 - Category of alarms displayed on the alarm list. You can use a group number to display a group of categories.

3 - Type of alarms displayed on the alarm list. See [AlarmDsp\(\)](#) for a list of these types.

7 - Priority of alarms displayed on the alarm list. The return value may be a group number if the alarm list

contains alarms of more than one priority.

8 - Display mode of the alarm list.

9 - Sorting mode of the alarm list.

10 – Reading this field is invalid, use the function [AlarmGetOrderbyKey](#).

11 – Retrieves the error code for the last alarm summary request that was not able to be processed due to a buffer overflow. The last request error value will be reset on the next successful response from the servers.

12 – Returns values as follows:

- 0 = no named filter, and no custom filter.
- 1 = named filter set, no custom filter (this means that the content of the named filter is empty).
- 2 = no named filter, but there is custom filtering applied (this is possible if the filter is edited via the AN using `AlarmFilterEdit` functions or some other method).
- 3 = named filter set, custom filtering is applied (it is possible that this is due to the named filter being edited or any other method through the AN).

13 – Returns values as follows;

- 0 = data from none of the clusters is ready
- 1 = only data from some clusters is ready
- 2 = data from all clusters is ready

14 - Identifies if the data is available for a particular cluster. Returns 1 if data is ready, or 0.

15 – Auto-refresh mode, where mode is:

- -1 = always auto refresh
- 0 = auto refresh disabled
- 1 = auto refresh page 1, disable on all other pages.

**Note:** Type 15 is only in use if displaying the alarm summary (AlarmDsp Type 10).

16 – Timeout occurred. This value is set to 0 when a data fetch is initiated for the supplied alarm list (indicated by AN). This value is set to 1 if a timeout occurs within the fetch. The timeout period is specified by the INI parameter [Alarm]AlarmListRequestTimeout.

- 0 = no timeout occurred
- 1 = timeout occurred.

17 – Alarm page number for specified AN is displayed. When the alarm list is scrolled by vertical offset (in lines), the list may span across two pages of alarms. Calling this function returns the page number of the alarm list that the specified AN is displaying. This differs to Type 0 which returns the page number based on the first line of the alarm display.

*ClusterName:*

Specifies the name of the cluster in which the Alarm Server resides. This is only required for type 14. The argument is enclosed in quotation marks " ".

## Return Value

Alarm list data as a numeric value.

## Related Functions

[AlarmDsp](#), [AlarmSetInfo](#), [AlarmGetOrderbyKey](#).

## Example

```
/* In the following examples, data is returned on the alarm
list where the cursor is positioned. */
page = AlarmGetInfo(0,0);
! returns the alarm page number.
offset = AlarmGetInfo(0,1);
! returns the alarm list offset.
cat = AlarmGetInfo(0,2);
! returns the alarm category displayed.
type = AlarmGetInfo(0,3);
! returns the type of alarms displayed.
```

## See Also

[Alarm Functions](#)

## AlarmGetFieldRec

Gets the contents of the specified field in the specified alarm record.

This is a blocking function. If the function is called from a foreground task that is unable to block, the return value will be -1 and a hardware alarm set. Use IsError() to retrieve the error code.

## Syntax

STRING **AlarmGetFieldRec**(LONG *Record*, STRING *Field* [, INT *Ver* [, STRING *ClusterName*]])

### *Record:*

The alarm record number, returned from any of the following alarm functions:

- `AlarmFirstCatRec()` or `AlarmNextCatRec()` - used to search for a record by alarm category, area, and type (acknowledged, disabled, etc.).
- `AlarmFirstPriRec()` or `AlarmNextPriRec()` - used to search for a record by alarm priority, area, and type (acknowledged, disabled, etc.).
- `AlarmFirstTagRec()` or `AlarmNextTagRec()` - used to search for a record by alarm tag, name, and description.

To store this value, use data type Int in Cicode or Long for variable tags (Long needs 4 bytes).

### *Field:*

The name of the field from which the data is retrieved.

ACKDATE, ACKDATEEXT, ACKMILLI, ACKTIME, ACKUTC, ACQDESC, ACQERROR, ALARMTYPE, ALMCOMMENT, AREA, ARR\_SIZE, CATEGORY, CAUSE1...8, CLASSIFICATION, CLUSTER, COMMENT, CONSEQUENCE1...8, CUSTOM1...8, DATE, DATEEXT, DEADBAND, DELAY, DELTAMILLI, DELTATIME, DESC, DEVDELAY, DEVIATION, DISABLECOMMENT, DISABLEDDATE, DISABLEDTIME, DISABLEENDDATE, DISABLEENDDATEEXT, DISABLEENDTIME, ENG\_ZERO, ERRDESC, ERPPAGE, EQUIPMENT, FORMAT, FULLNAME, GROUP, HDELAY, HELP, HHDELAY, HIGH,

HIGHHIGH, HISTORIAN, ITEM, LDELAY, LLDELAY, LOCALTIMEDATE, LOGSTATE, LOW, LOWLOW, MESSAGE, MILLISEC, NAME, NATIVE\_COMMENT, NATIVE\_DESC, NATIVE\_NAME, NATIVE\_SUMDESC, OFFDATE, OFFDATEEXT, OFFMILLI, OFFTIME, OFFTIMEDATE, OFFUTC, OLD\_DESC, ONDATE, ONDATEEXT, ONMILLI, ONTIME, ONTIMEDATE, ONUTC, PAGING, PAGINGGROUP, PRIORITY, PRIV, PSI\_TYPE, RATE, RECEIPTLOCALTIMEDATE, RECEIPTDATE, RECEIPTDATEEXT, RECEIPTMILLISEC, RECEIPTTIME, RECEIPTTIMEINT, RECEIPTTIMETICKS, RESPONSE1...8, RESPONENUM, SETPOINT, STATE, STATE\_DESC, STATE\_DESC0...7, SUMDESC, SUMSTATE, SUMTYPE, TAG, TAGEX, TAGGENLINK, TIME, TIMEDATE, TIMEINT, TIMETICKS, TSQUALITY, TYPE, TYPENUM, USERDESC, USERNAME, USERLOCATION, VALUE.

See [Browse Function Field Reference](#) for more information about these fields.

*nVer:*

The version of an alarm.

If an alarm has been triggered more than once in a given period, the version lets you distinguish between different instances of the alarm's activity.

The version is used in filtering alarms for display. A query function passes a value to this parameter in order to get field information for a particular alarm.

This parameter is not needed when you use AlarmGetFieldRec() for purposes other than filtering. It will default to 0 if omitted.

*ClusterName:*

Specifies the name of the cluster in which the Alarm Server resides. This is optional if you have one cluster or are resolving the alarm server via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

The alarm field data (as a string) or empty string "".

## Related Functions

### AlarmGetOrderbyKey

Retrieves the list of key(s) that are used to determine the order of the alarm list. These keys can be set by the [AlarmSetInfo](#) function.

## Syntax

STRING **AlarmGetOrderbyKey**(*nAN*)

*nAN*:

The AN where the alarm list (with the required information) is displayed.

## Return Value

Order-by key (as a string).

## Example

```
page = AlarmGetOrderbyKey(21);
! returns the order-by key string of the alarm list at AN '21'.
```

### AlarmGetThreshold

Gets the threshold of the analog alarm where the cursor is positioned.

## Syntax

REAL **AlarmGetThreshold**(*nType*)

*nType*:

The type of threshold:

0 - High high

1 - High

2 - Low

3 - Low low

4 - Deadband

5 - Deviation

6 - Rate of change

## Return Value

The alarm threshold.

[Alarm Functions](#)

### AlarmGetThresholdRec

Gets the threshold of analog alarms by the alarm record number.

This is a blocking function. If the function is called from a foreground task that is unable to block, the return value will be -1 and a hardware alarm set. Use IsError() to retrieve the error code.

## Syntax

REAL **AlarmGetThresholdRec**(LONG *Record*, INT *Type* [, STRING *ClusterName*])

*Record*:

The alarm record number, returned from any of the following alarm functions:

- `AlarmFirstCatRec()` or `AlarmNextCatRec()` - used to search for a record by alarm category, area, and type (acknowledged, disabled, etc.).
- `AlarmFirstPriRec()` or `AlarmNextPriRec()` - used to search for a record by alarm priority, area, and type (acknowledged, disabled, etc.).
- `AlarmFirstTagRec()` or `AlarmNextTagRec()` - used to search for a record by alarm tag, name, and description.

To store this value, use data type Int in Cicode or Long for variable tags (Long needs 4 bytes).

*Type*:

The type of threshold:

0 - High high

1 - High

2 - Low

3 - Low low

4 - Deadband

5 - Deviation

6 - Rate of change

*ClusterName*:

Specifies the name of the cluster in which the Alarm Server resides. This is optional if you have one cluster or are

resolving the alarm server via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

The alarm threshold or 0.0.

## AlarmHelp

Displays the alarm help page (associated with the alarm) where the cursor is positioned. You can assign a help page to each alarm when you define it (using the Digital Alarms or the Analog Alarms database, depending on the type of alarm). You need to also define the help page in the pages database.

## Syntax

INT **AlarmHelp()**

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[PageAlarm](#)

## Example

System keyboard	
Key Sequence	AlmHelp
Command	AlarmHelp()
Comment	Display the alarm help page

[Alarm Functions](#)

### AlarmHighestPriority

Returns the alarm priority and/or state of the current highest priority alarm for the given equipment in conjunction with the selected filter criteria.

## Syntax

```
LONG AlarmHighestPriority(INT Mode [, STRING EquipmentFilter] [, STRING FilterCriteria] [, LONG KeepAliveSeconds] [, INT CachedMode] [, INT IncludingReference])
```

#### Mode

0 - return the priority of the highest priority alarm.

1 - return the alarm state of the highest priority alarm.

2 - return the results of mode 0 and 1 combined into a two-byte integer result. Use LowByte() to extract the priority of the highest priority alarm and use HighByte() to extract the alarm state of the highest priority alarm.

3 - return the current setting for the alarm server's **Highest Priority Order** field ("Priority, Alarm State" or "Alarm State, Priority").

4- Same as mode 0. Alarm Priorities where **Show on Indicator** is set to False are excepted.

5- Same as mode 1. Alarm Priorities where **Show on Indicator** is set to False are excepted.

6- Same as mode 2. Alarm Priorities where **Show on Indicator** is set to False are excepted.

For more information about the field **Show on Indicator** refer to the topic [Configure Display Properties for an Alarm Priority](#).

#### EquipmentFilter:

A comma-separated list of equipment names to filter alarms prior to applying the filter specified in the FilterCriteria argument. Each equipment name may be a part of full equipment name from the root. For example, "Region.Plant" will count alarms with equipment names literally starting with "Region.Plant" that includes "Region.PlantA" and "Region.Plant.AreaB". If it is needed to count children of a particular equipment tree only, the equipment name should end with a period('.'). A comma in between equipment expressions is regarded as an OR operator. If an empty string is specified, return Highest Priority for all Alarms.

#### FilterCriteria:

A filter name OR filter text. See the topic [Implementing Alarm Filters Using Cicode](#) for more information about filter syntax.

#### KeepAliveSeconds:

Optional length of time (in seconds) for which the count will remain in memory. Default is 30 seconds.

The *CachedMode* parameter affects the behavior of this parameter. Refer to the section below for more information.

#### CachedMode:

Optional flag that causes the current cached value to be supplied even when the value is being refreshed. This makes the function non-blocking. If the property has not yet been cached, an error is set.

0 - Do not force cached read. Cicode is blocking

1 - Force cached read. Cicode is non-blocking

Default value is 1 (true).

A priority value in the cache is accessed when its filter criteria matches the filter criteria in a subsequent call, and the priority value's *KeepAliveSeconds* duration is extended. A priority will stay in the cache for 'at least' the duration specified by *KeepAliveSeconds*, and may stay in the cache for an unspecified period of time before being discarded.

The period set for an existing priority will be overridden in the event a longer duration is set using *KeepAliveSeconds*.

A priority that is added to the cache is not immediately available for reading, so a foreground call to *AlarmHighestPriority* that causes a new count to be added will return a value of -1 and an error of 345 (Data not ready).

*IncludingReference:*

0 - Do not include alarms belonging to referenced equipment in *AlarmHighestPriority* for current equipment

1 - Include alarms belonging to referenced equipment in *AlarmHighestPriority* for current equipment.

Set to 1 by default.

*Type:*

The rule used to determine the relative priority of alarms (currently fixed to 0).

## Return Value

For Mode 0, return the priority ID of the current highest priority alarm.

For Mode 1, return the alarm state of the current highest priority alarm:

- 1 - On and Unacknowledged
- 2 - Off and Unacknowledged
- 3 - On and Acknowledged
- 4 - Disabled

For Mode 3, return the current setting for the alarm server's **Highest Priority Order** field:

- 0 - Priority, Alarm State
- 1 - Alarm State, Priority

## Example

```
INT nPriority;
INT nState;
INT nCombined;
INT nSetting;

// Priority of highest priority alarm in Plant.Area.Room* equipment and all referenced
// equipment (default non-blocking Cicode).
nPriority = AlarmHighestPriority(0, "Plant.Area.Room");

// Alarm state of highest priority alarm in Plant.Area.Room* equipment and all referenced
// equipment (default non-blocking Cicode).
```

```
nState = AlarmHighestPriority(1, "Plant.Area.Room");

// State and Priority of highest priority alarms in Plant.Area.Room*, Plant.Area.Flat*
equipment and all referenced equipment with category 10 as a two-byte integer (non-blocking
Cicode).
nCombined = AlarmHighestPriority(2, "Plant.Area.Room", Plant.Area.Flat", "Category=10", 1,
1);
nPriority = LowByte(nCombined);
nState = HighByte(nCombined);

// Current setting for the alarm server's Highest Priority Order field
nSetting = AlarmHighestPriority(3);
```

## Related Functions

[AlarmCount](#), [AlarmCountEquipment](#), [AlarmCountList](#)

## See Also

[Alarm Functions](#)

### AlarmListCreate

Creates an alarms list at a specified AN.

## Syntax

```
INT AlarmListCreate(INT nAN, INT alarm_type, INT width, INT height, INT rowheight, INT drawheader [, STRING
sCluster [, STRING sFormat [, INT hFontRow [, INT hFontHeader]]]])
```

*nAN*:

The AN number to associate with the alarms list.

*alarm\_type*:

The type of alarms to display in the alarms list:

Non-hardware alarms

0 - All active alarms, that is Types 1 and 2

1 - All unacknowledged alarms, ON and OFF

2 - All acknowledged ON alarms

3 - All disabled alarms

4 - All configured (non-hardware) alarms, that is Types 0 to 3, plus acknowledged OFF alarms.

Alarm Summary

10 - All summary alarms

15 - Sequence of events with configuration events filtered out

16 - Sequence of events

Alarm General

*11* - All ON alarms

*12* - All OFF alarms

*17* - All unacknowledged ON alarms

*18* - All unacknowledged OFF alarms

*width*:

The width of the area in which the alarms list will display (in pixels).

*height*:

The height of the area in which the alarms list will display (in pixels).

*rowheight*:

The height of each row in the alarms list (in pixels).

*drawheader*:

Determines if the alarms list includes a header row. You need to enter a value; there is no default.

*0* = no header row

*1* = include a header row

*sCluster*:

Specifies the cluster context for the alarms displayed in the list. This value is optional. If not specified, it defaults to all clusters.

*sFormat*:

The name of the display format applied to the alarms list. This determines the arrangement of columns that are presented. A customized name can be defined for a display format using the parameter [\[Format\]FormatName](#).

This value is optional. If not specified, the default format for the type of alarm specified in the *alarm\_type* parameter is used.

*hFontRow*:

The handle for the font you would like to use in the alarm list rows. This value is optional. If not specified, it defaults to *-1* (the default font).

Font handles are generated by the Cicode function [DspFont](#).

*hFontHeader*:

The handle for the font you would like to use in the alarm list header row. This value is optional. If not specified, it defaults to *-1* (the default font).

Font handles are generated by the Cicode function [DspFont](#).

## Return Value

0 (zero) if successful, otherwise an error code is returned. The error code can be obtained by calling the *IsError* Cicode function.

## Related Functions

[AlarmListDisplay](#), [AlarmListDestroy](#)

## See Also

[Alarm Functions](#)

### AlarmListDestroy

Destroys an alarms list at a specified AN.

## Syntax

**INT AlarmListDestroy(INT *nAN*)**

*nAN*:

The AN number associated with the alarms list you want to destroy.

## Return Value

0 (zero) if successful, otherwise an error code is returned. The error code can be obtained by calling the IsError Cicode function.

## Related Functions

[AlarmListDisplay](#), [AlarmListCreate](#)

## See Also

[Alarm Functions](#)

### AlarmListDisplay

Displays an alarms list at a specified AN.

## Syntax

**INT AlarmListDisplay(INT *nAN*)**

*nAN*:

The AN number associated with the alarms list you want to display.

## Return Value

0 (zero) if successful, otherwise an error code is returned. The error code can be obtained by calling the IsError Cicode function.

## Related Functions

[AlarmListCreate](#), [AlarmListDestroy](#)

[Alarm Functions](#)

### AlarmListFill

Fills an alarms list at a specified AN to be used by another routine (for example, the interlocks processing routine).

## Syntax

`INT AlarmListFill(INT nAN)`

*nAN*:

The AN number associated with the alarms list you want to use.

## Return Value

0 (zero) if successful, otherwise an error code is returned. The error code can be obtained by calling the IsError Cicode function.

## Related Functions

[AlarmListCreate](#), [AlarmListDestroy](#), [AlarmListDisplay](#)

## See Also

[Alarm Functions](#)

### AlarmNextCatRec

Searches for the next occurrence of an alarm category and type, commencing with the specified alarm record identifier (returned from the previous search through the [AlarmFirstCatRec](#) function). You can search all areas, the current area only, or specify an area to limit the search.

This function returns an alarm record identifier that you can use in other alarm functions, for example, to acknowledge, disable, or enable the alarm, or to get field data on that alarm.

This is a blocking function. If the function is called from a foreground task that is unable to block, the return value will be -1 and a hardware alarm set. Use IsError() to retrieve the error code.

## Syntax

LONG **AlarmNextCatRec**(LONG *Record*, INT *Category*, INT *Type* [, INT *Area*] [, STRING *ClusterName*] )

*Record*:

The alarm record number, returned from any of the following alarm functions:

- **AlarmFirstCatRec()** or **AlarmNextCatRec()** - used to search for a record by alarm category, area, and type (acknowledged, disabled, etc.).
- **AlarmFirstPriRec()** or **AlarmNextPriRec()** - used to search for a record by alarm priority, area, and type (acknowledged, disabled, etc.).
- **AlarmFirstTagRec()** or **AlarmNextTagRec()** - used to search for a record by alarm tag, name, and description.

*Category*:

The alarm category or group number to match. Set Category to 0 (zero) to match all alarm categories.

*nType*:

The type of alarms to display:

**Non-hardware alarms**

- 0 - All active alarms, that is Types 1 and 2
- 1 - All unacknowledged alarms, ON and OFF
- 2 - All acknowledged ON alarms
- 3 - All disabled alarms
- 4 - All configured (non-hardware) alarms, that is Types 0 to 3, plus acknowledged OFF alarms.

**Alarm General**

- 11 - All ON alarms
- 12 - All OFF alarms
- 17 - All unacknowledged ON alarms
- 18 - All unacknowledged OFF alarms

If you omit the *Type*, the default is 1.

---

**Note:** If you call this function with the *Type* argument set to an unsupported value, it may return unexpected results.

---

*Area*:

The area in which to search for alarms. If you choose to omit the area, or if you set Area to -1, only the current area will be searched.

*ClusterName*:

Specifies the name of the cluster in which the Alarm Server resides. This is optional if you have one cluster or are resolving the alarm server via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

The alarm record identifier or -1 if no match is found.

## Related Functions

[GrpOpen](#), [AlarmFirstCatRec](#), [AlarmFirstPriRec](#), [AlarmNextPriRec](#), [AlarmGetFieldRec](#), [AlarmAckRec](#),  
[AlarmDisableRec](#), [AlarmEnableRec](#), [AlarmGetThresholdRec](#), [AlarmSetThresholdRec](#)

## Example

See [AlarmAckRec](#).

## See Also

[Alarm Functions](#)

### AlarmNextPriRec

Searches for the next occurrence of an alarm of a specified priority and type, commencing with the specified alarm record identifier (returned from the previous search through the [AlarmFirstPriRec\(\)](#) function). You can search all areas, the current area only, or specify an area to limit the search.

This function returns an alarm record identifier that you can use in other alarm functions, for example, to acknowledge, disable, or enable the alarm, or to get field data on that alarm.

---

**Note:** Record numbers obtained from [AlarmGetDsp](#) are not valid for this function.

This is a blocking function. If the function is called from a foreground task that is unable to block, the return value will be -1 and a hardware alarm set. Use [IsError\(\)](#) to retrieve the error code.

## Syntax

**INT AlarmNextPriRec(LONG Record, INT Priority, INT Type [, INT Area] [, STRING ClusterName] )**

*Record:*

The alarm record number, returned from any of the following alarm functions:

- [AlarmFirstCatRec\(\)](#) or [AlarmNextCatRec\(\)](#) - used to search for a record by alarm category, area, and type (acknowledged, disabled, etc.).
- [AlarmFirstPriRec\(\)](#) or [AlarmNextPriRec\(\)](#) - used to search for a record by alarm priority, area, and type (acknowledged, disabled, etc.).
- [AlarmFirstTagRec\(\)](#) or [AlarmNextTagRec\(\)](#) - used to search for a record by alarm tag, name, and description.
- [AlarmGetDsp\(\)](#) - used to find the record that is displayed at a specified AN, for either an alarm list or alarm summary entry. Set the sField argument in [AlarmGetDsp\(\)](#) to "RecNo".

To store this value, use data type Int in Cicode or Long for variable tags (Long needs 4 bytes).

*Priority:*

The alarm Priority or group handle of a group of alarm priorities. Set Priority to 0 (zero) to match all alarm priorities.

*nType:*

The type of alarms to display:

**Non-hardware alarms**

- 0 - All active alarms, that is Types 1 and 2
- 1 - All unacknowledged alarms, ON and OFF
- 2 - All acknowledged ON alarms
- 3 - All disabled alarms
- 4 - All configured (non-hardware) alarms, that is Types 0 to 3, plus acknowledged OFF alarms.

#### Alarm General

- 11 - All ON alarms
- 12 - All OFF alarms
- 17 - All unacknowledged ON alarms
- 18 - All unacknowledged OFF alarms

If you omit the Type, the default is 1.

---

**Note:** If you call this function with the *Type* argument set to an unsupported value, it may return unexpected results.

---

#### Area:

The area in which to search for alarms. Set Area to -1 to search all areas. If you do not specify an area, only alarms in the current area on the Alarms Server are searched.

#### ClusterName:

Specifies the name of the cluster in which the Alarm Server resides. This is optional if you have one cluster or are resolving the alarm server via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

The alarm record identifier or -1 if no match is found.

## Related Functions

[GrpOpen](#), [AlarmFirstCatRec](#), [AlarmFirstPriRec](#), [AlarmNextCatRec](#), [AlarmGetFieldRec](#), [AlarmAckRec](#),  
[AlarmDisableRec](#), [AlarmEnableRec](#), [AlarmGetThresholdRec](#), [AlarmSetThresholdRec](#), [AlarmSetInfo](#)

## See Also

[Alarm Functions](#)

## AlarmNextTagRec

Searches for the next occurrence of an alarm tag, name, and description, starting with the alarm record identifier (returned from the previous search through the [AlarmFirstTagRec](#) function).

This function returns an alarm record identifier that you can use in other alarm functions, for example, to acknowledge, disable, or enable the alarm, or to get field data on that alarm.

---

**Note:** Record numbers obtained from [AlarmGetDsp](#) are not valid for this function.

This is a blocking function. If the function is called from a foreground task that is unable to block, the return value will be -1 and a hardware alarm set. Use [IsError\(\)](#) to retrieve the error code.

For complex filtering operations it is more efficient to use the alarm tag browse functions [AlmBrowseOpen](#) and [AlmBrowseNext](#).

## Syntax

**LONG AlarmNextTagRec(LONG Record, STRING Tag, STRING Name, Description [,STRING ClusterName] )**

*Record:*

The alarm record number, returned from any of the following alarm functions:

- `AlarmFirstCatRec()` or `AlarmNextCatRec()` - used to search for a record by alarm category, area, and type (acknowledged, disabled, etc.).
- `AlarmFirstPriRec()` or `AlarmNextPriRec()` - used to search for a record by alarm priority, area, and type (acknowledged, disabled, etc.).
- `AlarmFirstTagRec()` or `AlarmNextTagRec()` - used to search for a record by alarm tag, name, and description.
- `AlarmGetDsp()` - used to find the record that is displayed at a specified AN, for either an alarm list or alarm summary entry. Set the `sField` argument in `AlarmGetDsp()` to "RecNo".

To store this value, use data type Int in Cicode or Long for variable tags (Long needs 4 bytes).

*Tag:*

A string that identifies the tag to be matched. It can be one of the following:

- An alarm tag — for example, "Fire1"
- An alarm equipment item — for example, "Motor1.AlarmFire"

Specify an empty string (" ") to match all alarm tags.

*Name:*

The alarm name to be matched. Specify an empty string (" ") to match all alarm names.

*Description:*

The alarm description to be matched. Specify an empty string (" ") to match all alarm descriptions.

*ClusterName:*

Specifies the name of the cluster in which the Alarm Server resides. This is optional if you have one cluster or are resolving the alarm server via the current cluster context. The argument is enclosed in quotation marks " ".

## Return Value

The alarm record identifier or -1 if no match is found.

## Related Functions

[AlarmFirstTagRec](#), [AlarmGetFieldRec](#), [AlarmAckRec](#), [AlarmDisableRec](#), [AlarmEnableRec](#), [AlarmGetDelayRec](#),  
[AlarmGetThresholdRec](#), [AlarmSetThresholdRec](#), [AlmBrowseOpen](#), [AlmBrowseNext](#)

## Example

See [AlarmDisableRec](#).

## See Also

[Alarm Functions](#)

### AlarmNotifyVarChange

This function is used to provide time-stamped digital and time-stamped analog alarms with data. When called, it notifies the alarm server that the specified variable tag has changed.

The alarm server will then check all time-stamped digital and time-stamped analog alarms that use the variable tag to see if their alarm states need to be updated as a result of the change. Any alarm state changes that result from this check will be given the timestamp passed into this function as their time of occurrence.

**Note:** Although you can hardcode a value into the setpoint when using analog alarms, you cannot use hardcoded values with time-stamped analog alarms. If the setpoint is hardcoded, this function cannot be used to notify the alarm when the variable changes.

## Syntax

INT **AlarmNotifyVarChange**(*Tag*, *Value*, *Timestamp* [, *TimestampMS*] [, *sClusterName*] [, *bSync*] )

*Tag*:

Name of the variable tag that has changed as a string. This name may include the name of the tag's cluster in the form *cluster.tagname*. This cluster name may be different from the cluster of the alarm server indicated by *sClusterName* below.

The Tag parameter is resolved on the alarm server, so the alarm server should be configured to connect to the tag's cluster.

*Value*:

Value of the variable tag at the time of the change as a floating-point number

*Timestamp*:

Time/date at which the variable tag changed in the standard Plant SCADA time/date variable format (Seconds since 1970).

*TimestampMS*:

Millisecond portion of the time at which the variable tag changed.

*sClusterName*:

Name of the cluster of the alarm server. This is optional if you have one cluster or are resolving the alarm server via the current cluster context. The argument is enclosed in quotation marks "".

*bSync*:

An optional boolean argument that specifies whether the command is synchronous (blocking) or asynchronous (non-blocking). If it is specified as synchronous (true) the function will wait until the notification has been recorded into the alarm database before further code execution. If it is specified as asynchronous (false) the function will only return an error if no alarm server is currently available.

## Return Value

For synchronous mode, the return value will be the error that was detected when the function was called. For

asynchronous mode, the return value will be 0, unless there was no server available.

## Example

```
AlarmNotifyVarChange("LOOP_1_SP", 50.0, TimeCurrent() - 10, 550,  
"ClusterXYZ");
```

This will tell the alarm server in cluster XYZ that the value of variable tag LOOP\_1\_SP changed to 50.0 at 9.450 seconds ago.

See also [Add a Time Stamped Digital Alarm](#) and [Add a Time Stamped Analog Alarm](#).

## See Also

[Alarm Functions](#)

### AlarmQueryFirstRec

Searches for the first occurrence of an alarm category (or priority) and type. This is a wrapper function of [AlarmFirstCatRec](#) and [AlarmFirstPriRec](#).

This is a blocking function. If the function is called from a foreground task that is unable to block, the return value will be -1 and a hardware alarm set. Use [IsError\(\)](#) to retrieve the error code.

## Syntax

```
LONG AlarmQueryFirstRec(Group, nType, Area, QueryType [, sClusterName] )
```

***Group:***

Alarm category if *QueryType* is 0 or alarm priority if *QueryType* is 1.

***nType:***

The type of alarms to display:

#### Non-hardware alarms

0 - All active alarms, that is Types 1 and 2

1 - All unacknowledged alarms, ON and OFF

2 - All acknowledged ON alarms

3 - All disabled alarms

4 - All configured (non-hardware) alarms, that is Types 0 to 3, plus acknowledged OFF alarms.

#### Hardware alarms

5 - All active alarms, that is Types 6 and 7

6 - All unacknowledged alarms, ON and OFF

7 - All acknowledged ON alarms

8 - All disabled alarms

9 - All configured alarms, that is Types 5 to 8

#### Alarm Summary

*10* - All summary alarms  
*15* – Sequence of events with configuration events filtered out  
*16* - Sequence of events

#### **Alarm General**

*11* - All ON alarms  
*12* - All OFF alarms  
*13* - All ON hardware alarms  
*14* - All OFF hardware alarms  
*17* - All unacknowledged ON alarms  
*18* - All unacknowledged OFF alarms

If you omit the Type, the default is 1.

#### *Area:*

Area in which to search for alarms. Set Area to -1 to search all areas.

#### *QueryType:*

Query type.

0 - Search by category.

1 - Search by priority.

#### *sClusterName:*

Specifies the name of the cluster in which the Alarm Server resides. This is optional if you have one cluster or are resolving the alarm server via the current cluster context. The argument is enclosed in quotation marks " ".

## **Return Value**

The alarm record identifier or -1 if no match is found.

## **Related Functions**

[AlarmQueryNextRec](#)

## **See Also**

[Alarm Functions](#)

## **AlarmQueryNextRec**

Searches for the next occurrence of an alarm category (or priority) and type, commencing with the specified alarm record identifier (returned from the previous search through the alarm query functions).

This is a blocking function. If the function is called from a foreground task that is unable to block, the return value will be -1 and a hardware alarm set. Use IsError() to retrieve the error code.

This is wrapper function of [AlarmNextCatRec](#) and [AlarmNextPriRec](#).

## Syntax

LONG **AlarmQueryNextRec**(*Record*, *Group*, *nType*, *Area*, *QueryType* [, *sClusterName*] )

*Record*:

Alarm record number.

*Group*:

Alarm Category if *QueryType* is 0 or alarm priority if *QueryType* is 1.

*nType*:

The type of alarms to display:

### Non-hardware alarms

0 - All active alarms, that is Types 1 and 2

1 - All unacknowledged alarms, ON and OFF

2 - All acknowledged ON alarms

3 - All disabled alarms

4 - All configured (non-hardware) alarms, that is Types 0 to 3, plus acknowledged OFF alarms.

### Hardware alarms

5 - All active alarms, that is Types 6 and 7

6 - All unacknowledged alarms, ON and OFF

7 - All acknowledged ON alarms

8 - All disabled alarms

9 - All configured alarms, that is Types 5 to 8

### Alarm Summary

10 - All summary alarms

15 – Sequence of events with configuration events filtered out

16 - Sequence of events

### Alarm General

11 - All ON alarms

12 - All OFF alarms

13 - All ON hardware alarms

14 - All OFF hardware alarms

17 - All unacknowledged ON alarms

18 - All unacknowledged OFF alarms

If you omit the Type, the default is 1.

*Area*:

Area in which to search for alarms. Set Area to -1 to search all areas.

*QueryType*:

Query type.

0 - Search by category.

1 - Search by priority.

*sClusterName*:

Specifies the name of the cluster in which the Alarm Server resides. This is optional if you have one cluster or are resolving the alarm server via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

The alarm record identifier or -1 if no match is found.

## Related Functions

[AlarmQueryFirstRec](#)

## See Also

[Alarm Functions](#)

## AlarmSetDelay

Changes the delay setting for an alarm (that is Delay, High High Delay, Deviation Delay, etc.). This function acts on the alarm that the cursor is positioned over. Use this function during runtime to change the delay values that were specified in the alarms database. Delay changes made using this process are persistent (that is they are saved to the project).

## Syntax

INT **AlarmSetDelay**(*nType*, *Value*)

*nType*:

The type of delay:

- 0 - Delay (digital alarm/advanced alarm)
- 1 - High high delay (analog alarm)
- 2 - High delay (analog alarm)
- 3 - Low delay (analog alarm)
- 4 - Low low delay (analog alarm)
- 5 - Deviation delay (analog alarm)

*Value*:

The new value for the delay. Enter a blank value " " to remove the delay setting.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[AlarmGetDelay](#), [AlarmSetDelayRec](#), [AlarmGetDelayRec](#)

## See Also

[Alarm Functions](#)

### AlarmSetDelayRec

Changes the delay setting for an alarm (that is Delay, High High Delay, Deviation Delay, etc.) by the alarm record number. You can only call this function on an alarms server for local alarms, or on a redundant server if one has been configured.

This is a blocking function. If the function is called from a foreground task that is unable to block, an error will be returned.

## Syntax

**INT AlarmSetDelayRec(LONG Record, INT Type, INT Value, STRING ClusterName)**

*Record:*

The alarm record number, returned from any of the following alarm functions:

- `AlarmFirstCatRec()` or `AlarmNextCatRec()` - used to search for a record by alarm category, area, and type (acknowledged, disabled, etc.).
- `AlarmFirstPriRec()` or `AlarmNextPriRec()` - used to search for a record by alarm priority, area, and type (acknowledged, disabled, etc.).
- `AlarmFirstTagRec()` or `AlarmNextTagRec()` - used to search for a record by alarm tag, name, and description.
- `AlarmGetDsp()` - used to find the record that is displayed at a specified AN, for either an alarm list or alarm summary entry. Set the `sField` argument in `AlarmGetDsp()` to "RecNo".

*nType:*

The type of delay:

0 - Delay (digital alarm/advanced alarm/double point status alarm)

1 - High high delay (analog alarm)

2 - High delay (analog alarm)

3 - Low delay (analog alarm)

4 - Low low delay (analog alarm)

5 - Deviation delay (analog alarm)

*Value:*

The new value for the delay. Enter a blank value " " to remove the delay setting.

*sClusterName:*

Specifies the name of the cluster in which the Alarm Server resides. This is optional if you have one cluster or are resolving the alarm server via the current cluster context. The argument is enclosed in quotation marks "".

## Related Functions

[AlarmGetDelay](#), [AlarmNotifyVarChange](#), [AlarmGetDelayRec](#)

## See Also

[Alarm Functions](#)

### AlarmSetInfo

Controls different aspects of the alarm list displayed at a specified AN. Currently applies only to non-hardware alarm lists.

## Syntax

**INT AlarmSetInfo(INT AN, INT Type, STRING Value)**

**AN:**

The AN where the alarm list originally commenced. (AN alarm page can contain more than one alarm list). You can also specify:

-1 - Change the display parameters of all alarm lists displayed on the page.

0 - Change the display parameters of the alarm list where the cursor is positioned.

**Type:**

The type of data. The aspects and related types are listed below:

Display aspect	Types
Change display line and page offset	0, 1
Formatting of alarms in the alarm list	4, 5, 6
Filtering of alarms	2, 3, 7, 8 <b>Note:</b> If a requested alarm filter is too complex (for example, it contains too many conditions or too many nested brackets), the filter is cleared (no filter is used). The hardware alarm "Too many alarms in filters" is generated on the client components, and a tracelog error message is logged.
Sorting of alarms - to control the sorting aspect of the alarm list, type 9 and 10 should be used together.	9, 10
Linking or unlinking to a named filter.	12

0 - Alarm page number. The vertical offset (in pages) from the AN where the alarm list commenced.

1 - Alarm list offset. The vertical offset (in lines) from the AN where the alarm list commenced.

2 - Category of alarms displayed on the alarm list. To specify all categories, use a value of 0.

You can use a group handle to display a group of categories. (A group can be defined via the Security activity, or by using the GrpOpen() function.) Before you can display a group of categories, you need to first open the group using the GrpOpen() function. You would usually do this by entering the GrpOpen() function as the Page entry command for your alarm page (set using Page Properties). Be aware, however, that you should not close the group until you close the display page. If you do, the group will be lost and the group handle will become invalid. The page would then be unable to continue displaying the desired group. The handle may be reused for another group, which means the page may display a different category, or display all alarms.

You would normally close the group by entering the GrpClose() function as the Page exit command.

3 - Type of alarms displayed on the alarm list. See AlarmDsp() for a list of these types.

4 - Display all alarms according to the format and fonts specified for one category (specified in Value).

5 - The display format for all alarms specified by a format handle. All of the alarm categories will display in the same format.

6 - The display font for all user alarms specified by a font handle. All of the user alarms will appear in the same font and color.

7 - The priority of the alarms to be displayed in the alarm list. You can use a group number to display a group of priorities.

You can use a group handle to display a group of priorities. (A group can be defined using Groups - from the Project Editor System menu - or by using the GrpOpen() function.) Before you can display a group of priorities, you need to first open the group using the GrpOpen() function. You would usually do this by entering the GrpOpen() function as the Page entry command for your alarm page (set using Page Properties). Be aware, however, that you should not close the group until you close the display page. If you do, the group will be lost and the group handle will become invalid. The page would then be unable to continue displaying the desired group. You would normally close the group by entering the GrpClose() function as the Page exit command.

8 - Use the Value argument of the AlarmSetInfo() function to specify whether the display mode of the alarm list is based on Alarm Category or Priority:

- Set the Value argument to 0 (zero) to display by Category.
- Set the Value argument to 1 to display by Priority.

9 - Use the Value argument of the AlarmSetInfo() function to specify the sorting mode of the alarm list:

- Set the Value argument to 0 (zero) to display alarms sorted by ON time within their groups.
- Set the Value argument to 1 to display alarms sorted by the order-by keys. Please be aware that this option will only be meaningful if you have already called the AlarmSetInfo() function with a Type of 10 to set the order-by keys.

10 - Use the Alarm Order-by key specified in the Value argument of the AlarmSetInfo() function to determine the order in which the alarm list will be displayed.

The AlarmSetInfo() function should then be called again using a Type of 9 and a Value of 1 for Plant SCADA to sort the alarms in the order specified.

---

**Note:** It is recommended that you sort an alarm summary or SOE list using the following order-by keys (as specified in the *Value* argument):

- Alarm summary – OnDate, OnTime, OnMilliseconds
- SOE – Date, Time, Milliseconds.

If you use any other fields as an order-by key, you will have to apply a time range to your query using the Alarm Filter Functions. Otherwise, your query will not return any results and the hardware error "Invalid Argument Passed" will be generated.

---

11 – Invalid to set this field.

12 – Associate or disassociate a named filter. By setting this field to text, you associate the specified AN to a named filter which is then applied to an alarm display list. Setting this type to empty text, will unlink from any named filter, but the disassociated alarm list will retain its value, hence the filter will still be in place until a new filter is applied. If setting the *Value* to text that does not correspond to a named filter, the value read back (using *AlarmGetFilterName*) will be empty.

15 – Auto-refresh mode, where mode is:

-1 : always auto refresh

0 : auto refresh disabled

1 : auto refresh page 1, disable on all other pages.

---

**Note:** Type 15 is only in use if displaying the alarm summary (*AlarmDsp* Type 10).

---

16 – Invalid to set this field.

*Value*:

The meaning of the *Value* argument depends on the data type specified in the *Type* argument.

If you set *Type* = 0 (offset in pages) or *Type* = 1 (offset is lines), the *Value* argument must be within the range of alarm entries currently stored in the client cache, otherwise error code 569 will be returned.

If you set *Type* = 8, the *Value* argument determines whether alarms are displayed by category or priority:

0 - Alarm list displayed by Category.

1 - Alarm list displayed by Priority.

If you set *Type* = 10, the *Value* argument specifies the order-by keys to be used in sorting. Up to sixteen keys may be specified:

{KeyName [,SortDirection]}[ {KeyName [,SortDirection]}]

The Keyname argument specifies the name of the pre-defined order-by key to be used. The valid options are a subset of the alarm display fields: Tag, Name, Category, Priority, Area, Priv, Time, State, and Type.

The SortDirection argument is optional, and indicates whether the sort will be ascending or descending. Valid options are: 0 Descending (default), 1 Ascending.

For example:

{Time,0} : sorts by <Time> (descending)

{Tag,1} : sorts by <Tag> (ascending)

{Tag,1}{Time} : sorts by <Tag> (ascending), then <Time> (descending)

---

**Note:** The fields Disabled, Acknowledged and Active are hidden from the alarm list display and can only be used for filtering and sorting. If you would like to sort by Unacknowledged alarms first, followed by Acknowledged Active alarm and Date time, then you can use the following syntax:

{Acknowledged,1}{Active,0}{Time,0}

i.e. Acknowledged, ascending; Active, descending; time, descending

---

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[GrpOpen](#), [AlarmDsp](#), [AlarmGetInfo](#)

## Examples

In the following example, the alarm list is set to display in the order of the order-by key. Please be aware that this is a two-step process requiring two calls to the AlarmSetInfo() function, and that it applies only to non-hardware alarm lists.

```
! Set the order-by key.  
AlarmSetInfo(21,10,"{Time}");  
! Set the sorting mode.  
AlarmSetInfo(21,9,1);
```

Type 8 of the function is used to set the display mode to either category or priority. This is helpful when filtering based on either of these fields. In order to filter on category 2 we should use:

```
AlarmSetInfo(21, 8, 0);  
AlarmSetInfo(21, 2, 2);
```

Once we do this the alarms with category 2 will be displayed in the alarm list and remaining although active will not be displayed.

Similarly if we want to filter on priority we set the mode to priority and then use type 7. For example, to filter on priority 4 we should use:

```
AlarmSetInfo(21, 8, 1); ! priority mode  
AlarmSetInfo(21, 7, 4); ! apply filter
```

In the following examples, the display parameters of the alarm list where the cursor is positioned are changed.

```
! Change the vertical offset (pages) to 2.  
AlarmSetInfo(0,0,2);  
! Change the vertical offset (lines) to 15.  
AlarmSetInfo(0,1,15);
```

Change the alarm category to 10.

```
AlarmSetInfo(0,2,10);
```

Change the type of alarms displayed to type 5 (hardware alarms).

```
AlarmSetInfo(0,3,5);
```

In the following examples, the display parameters of the alarm list at AN 20 are changed.

```
! Display alarms with category 120 format and fonts  
AlarmSetInfo(20, 4, 120);  
! Display alarms with a new format  
hFmt=FmtOpen("MyFormat","{Name}{Desc,20}",0);  
AlarmSetInfo(20, 5, hFmt);  
! Display alarms with a new font  
hFont = DspFont("Times",-60,black,gray);  
AlarmSetInfo(20, 6, hFont);
```

The following example displays alarms with categories 1-10, 20, or 25. Before AlarmSetInfo() is run, the page entry command for the alarm display page is configured as follows:

- On page entry command: hGrp=GrpOpen("MyGrp",1); StrToGrp(hGrp,"1..10,20,25");

The page exit command for the alarm display page is configured as follows:

- On page exit command: GrpClose(hGrp); AlarmSetInfo(20, 2, hGrp);

---

**Note:** **hGrp** is defined in the variables database.

[Alarm Functions](#)

### AlarmSetThreshold

Changes the thresholds (that is High High, Low etc.) of analog alarms. This function acts on the analog alarm where the cursor is positioned. Use this function to change (at run time) the threshold values that were specified in the Analog Alarms database. Threshold changes made using this function are permanent (that is they are saved to the project). The display format currently specified for the record (in the Analog Alarms settings) will be applied to these values.

## Syntax

**INT AlarmSetThreshold(*nType*, *Value*)**

*nType*:

The type of threshold:

0 - High high

1 - High

2 - Low

3 - Low low

4 - Deadband

5 - Deviation

6 - Rate of change

*Value*:

The new value of the threshold. Enter a blank value " " to remove the threshold.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

Key Sequence	SetHighHigh ### Enter
Command	AlarmSetThreshold(0, Arg1)
Comment	Change the threshold of a high high alarm

System keyboard	
Key Sequence	SetHigh ### Enter
Command	AlarmSetThreshold(1, Arg1)
Comment	Change the threshold of a high alarm

System keyboard	
Key Sequence	SetLow ### Enter
Command	AlarmSetThreshold(2, Arg1)
Comment	Change the threshold of a low alarm

System keyboard	
Key Sequence	SetlowLow ### Enter
Command	AlarmSetThreshold(3, Arg1)
Comment	Change the threshold of a low low alarm

## See Also

[Alarm Functions](#)

### AlarmSetThresholdRec

Changes the threshold (that is High High, Low etc.) of analog alarms by the alarm record number. You can call this function only on an Alarms Server for alarms on that server, or on the redundant server (if a redundant server is configured).

Threshold changes made using this function are permanent (that is they are saved to the project). The display format currently specified for the record (in the Analog Alarms form) will be applied to these values.

**Note:** Record numbers obtained from AlarmGetDsp are not valid for this function.

This is a blocking function. If the function is called from a foreground task that is unable to block, an error will be returned.

To permanently update alarm threshold limits using AlarmSetThresholdRec, set the parameter [\[Alarm\]UseConfigLimits](#) to 1.

## Syntax

**INT AlarmSetThresholdRec (LONG Record, INT Type, STRING Value [, STRING ClusterName])**

*Record:*

The alarm record number, returned from any of the following alarm functions:

- `AlarmFirstCatRec()` or `AlarmNextCatRec()` - used to search for a record by alarm category, area, and type (acknowledged, disabled, etc.).

- `AlarmFirstPriRec()` or `AlarmNextPriRec()` - used to search for a record by alarm priority, area, and type (acknowledged, disabled, etc.).

- `AlarmFirstTagRec()` or `AlarmNextTagRec()` - used to search for a record by alarm tag, name, and description.

- `AlarmGetDsp()` - used to find the record that is displayed at a specified AN, for either an alarm list or alarm summary entry. Set the `sField` argument in `AlarmGetDsp()` to "RecNo".

To store this value, use data type Int in Cicode or Long for variable tags (Long needs 4 bytes).

*Type:*

The type of threshold:

0 - High high

1 - High

2 - Low

3 - Low low

4 - Deadband

5 - Deviation

6 - Rate of change

*Value:*

The new value of the threshold. Enter a blank value "" to remove the threshold.

*ClusterName:*

Specifies the name of the cluster in which the Alarm Server resides. This is optional if you have one cluster or are resolving the alarm server via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[AlarmSetThreshold](#)

## See Also

[Alarm Functions](#)

## AlarmSplit

Splits an alarm summary entry which has no Off time. The current entry will be given an off time equal to the time when AlarmSplit is called, and the new entry will have the same On time, with empty Off time.

If the alarm summary record has a valid Off time, the function does nothing.

You would normally call this function from a keyboard or mouse command.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**INT AlarmSplit([INT AN])**

**AN:**

Animation Number where alarm is displayed. You can:

- Set AN to where alarm is displayed which equals to AN of alarm list + Offset into the list
- Do not specify AN or set it to 0 or negative value to use current cursor value.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[AlarmSumSplit](#)

## Example

System keyboard	
Key Sequence	Split
Command	AlarmSplit()
Comment	Duplicates an alarm summary entry

## See Also

[Alarm Functions](#)

## AlarmSumAppend

Appends a new blank record to the alarm summary. Use this function to add new alarm summary entries, either for actual alarms or as special user summary entries.

If you specify a valid alarm tag in the *sTag* field, the summary entry is linked to the actual alarm. If you specify an asterisk '\*' as the first letter of the tag, the summary entry becomes a user event.

User events are not attached to alarm records, so their status will not change. Manually change the status of the user event, by calling the AlarmSumSet() function with the index returned by AlarmSumAppend(). As user events are not attached to alarms, they don't have the alarm fields - so the AlarmSumGet() function will not return any field data.

The latest entry in the Alarm summary will reflect the events of the alarm whether the alarm summary entry was appended created by an actual alarm event.

You can use user events to keep a record of logins, or control operations that you need to display in the alarm summary etc. The fields of UserEvents needs to be set immediately after creation using the AlarmSumSet() function.

To give an appended alarm summary entry the appearance of having been Acknowledged set the Acknowledge time of the summary entry. When the summary entry is linked to an actual alarm the function AlmSummaryAck() can be used to acknowledge the actual alarm linked to the summary entry. However, the AlmSummaryAck function will not directly affect the alarm summary entry.

AlarmSumAppend() can only be used if the Alarm Server is on the current machine. When the Alarm Server is not in the calling process, this function will become blocking and cannot be called from a foreground task. In this case, the return value will be undefined and a Cicode hardware alarm will be raised.

This function can only be used if the Alarm Server is on the current machine.

---

**Note:** The index passed to AlarmSum\* functions must be current,i.e. either:

- the index returned by most recent call to AlarmSumFirst/Last/Find/Next/Prev,  
OR
  - the index returned by the most recent call to AlarmSumAppend OR AlarmSumSplit
- 

The AlarmSumNext and AlarmSumPrev Cicode functions are unable to use the index returned by AlarmSumAppend.

---

**Note:** This function will only work while the record is writable which is controlled by the ArchiveAfter Parameter. Refer to the topic *Configure the Archiving Parameters* in the main help for more information.

---

**Note:** In a redundant pair scenario, this function will return an error condition and not do anything if the current server is not main. You can call this function on the primary server and the standby server so that function can succeed on one of the two servers in the specified cluster. The change will be synchronised to the other server after a short period of time (typically in 5 seconds).

---

## Syntax

**INT AlarmSumAppend(*sTag* [, *ClusterName*, *OnTime*, *OnMilli*, *bRedundant*] )**

*sTag*:

The alarm tag to append. Use an asterisk '\*' as the first letter to append a user event to the alarm summary. Please be aware that the AlarmSumAppend function returns the alarm summary index - not the error code.

*ClusterName*:

Specifies the name of the cluster in which the Alarm Server resides. This is optional if you have one cluster or are resolving the alarm server via the current cluster context. The argument is enclosed in quotation marks "".

*OnTime*:

The alarm OnTime (if omitted or is equal to 0, will default to current time, i.e. the time the function was invoked).

*OnMilli*:

Milliseconds part of the alarm's ON time

**bRedundant:(optional)**

New alarm record is created on both redundant server instances.

**Note:** This parameter has been deprecated and is always set to true.

## Return Value

The index of the alarm summary entry, or -1 if the record could not be appended.

**Note:** The index is a 32-bit integer. Storing it in a variable that is smaller than 32 bit integer (such as a 16-bit integer) may cause overflow which may result in an incorrect value.

## Example

```
! Append alarm to summary display
AlarmSumAppend("CV101");
! Append user event
iIndex = AlarmSumAppend("*MyEvent");
AlarmSumSet(iIndex, "Comment", "My event comment");
```

## See Also

[Alarm Functions](#)

### AlarmSumCommit

Commits the alarm summary entry to the Summary Device specified in the alarm category of the entry. The same alarm summary entry is unable to be committed twice. The Cicode function returns an error code if the entry has been committed by timeout (referring to [Alarm]SummaryTimeout parameter), or if AlarmSumCommit() is called twice. An entry is not committed by timeout if AlarmSumCommit() is called on this entry.

If the Alarm Server is not in the calling process, the calling process needs to run from the same machine as the alarm server.

This function can only be used if the Alarm Server is on the current machine. When the Alarm Server is not in the calling process, this function will become blocking and cannot be called from a foreground task. In this case, the return value will be undefined and a Cicode hardware alarm will be raised.

In a redundant pair scenario, this function will return an error condition and not do anything if the current server is not main. You can call this function on the primary server and the standby server so that function can succeed on one of the two servers in the specified cluster. The change will be synchronized to the other server after a short period of time (typically in 5 seconds).

**Note:** This function will only work while the record is writable which is controlled by the ArchiveAfter Parameter. Refer to the topic [Configure the Archiving Parameters](#) for more information.

## Syntax

```
INT AlarmSumCommit(Index [, ClusterName] )
```

*Index*:

The alarm summary index (returned from the `AlarmSumFirst()`, `AlarmSumNext()`, `AlarmSumLast()`, `AlarmSumPrev()`, `AlarmSumAppend()`, or `AlarmSumFind()` function).

*ClusterName*:

Specifies the name of the cluster in which the Alarm Server resides. This is optional if you have one cluster or are resolving the alarm server via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Example

```
/* This function commits alarm summary entries that match the
specified tag. */
FUNCTION
SumCommitTag(STRING sTag)
    INT Next;
    INT Index;
    STRING Name;
    Index=AlarmSumFirst();
    WHILE Index<>-1 DO
        Name=AlarmSumGet(Index, "Tag");
        Next=AlarmSumNext(Index);
        IF Name=sTag THEN
            AlarmSumCommit(Index);
        END
        Index=Next;
    END
END
```

## See Also

[Alarm Functions](#)

### AlarmSumDelete

Deletes an alarm summary entry. You identify the alarm summary entry by the *Index*, returned by one of the alarm summary search functions.

By embedding this function in a loop, you can delete a series of alarm summary entries. To start deleting from the oldest entry, call the AlarmSumFirst() function to get the index, and then call AlarmSumNext() in a loop. To delete back from the most recent entry, call AlarmSumLast() and then AlarmSumPrev() in a loop.

You can also get the *Index* from the AlarmSumFind() function, which finds an alarm summary entry by its alarm record identifier and time of activation.

This function can only be used if the Alarm Server is on the current machine. When the Alarm Server is not in the calling process, this function will become blocking and cannot be called from a foreground task. In this case, the return value will be undefined and a Cicode hardware alarm will be raised.

**Note:**

- In a redundant pair scenario, this function will return an error condition and not do anything if the current server is not main. You can call this function on the primary server and the standby server so that function can succeed on one of the two servers in the specified cluster. The change will be synchronised to the other server after a short period of time (typically in 5 seconds).
- This function will only work while the record is writable which is controlled by the ArchiveAfter parameter. Refer to the topic [Configure the Archiving Parameters](#) for more information.

## Syntax

```
INT AlarmSumDelete(Index [, ClusterName] )
```

**Index:**

The alarm summary index (returned from the AlarmSumFirst(), AlarmSumNext(), AlarmSumLast(), AlarmSumPrev(), AlarmSumAppend(), or AlarmSumFind() function).

**ClusterName:**

Specifies the name of the cluster in which the Alarm Server resides. This is optional if you have one cluster or are resolving the alarm server via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

0 (zero) if the specified alarm entry exists, otherwise an error is returned.

## Related Functions

[AlarmSumCommit](#), [AlarmSumSet](#), [AlarmSumType](#), [AlarmSumAppend](#), [AlarmDelete](#), [MsgRPC](#), [AlarmSumGet](#), [AlarmSumFirst](#), [AlarmSumNext](#), [AlarmSumLast](#), [AlarmSumPrev](#), [AlarmSumFind](#), [AlarmSplit](#), [AlarmSumSplit](#), [AlmSummaryDelete](#)

## Example

```
/* This function deletes all alarm summary entries that match the
specified tag. */
FUNCTION
SumDelTag(STRING sTag)
    INT Next;
    INT Index;
    STRING Name;
    Index=AlarmSumFirst();
    WHILE Index<>-1 DO
```

```
Name=AlarmSumGet(Index, "Tag");
Next=AlarmSumNext(Index);
IF Name=sTag THEN
    AlarmSumDelete(Index);
END
Index=Next;
END
END
```

## See Also

[Alarm Functions](#)

### AlarmSumFind

Finds the alarm summary index for an alarm that you specify by the alarm record identifier and alarm activation time (OnTime). You can use this index in the AlarmSumGet() function to get field data from an alarm record, in the AlarmSumSet() function to change the existing data in that record, or in the AlarmSumDelete() function to delete the record. If calling this function from a remote client, use the MsgRPC() function.

To work with a series of alarm summary records, call this function to get the index, and then call either AlarmSumNext() to move forwards in the summary, or AlarmSumPrev() to move backwards in the summary.

---

**Note:** Record numbers obtained from AlarmGetDsp are not valid for this function. Instead use AlarmFirstTagRec() to get the record. This should be called from the server side using MsgRPC.

This function can only be used if the Alarm Server is on the current machine. When the Alarm Server is not in the calling process, this function will become blocking and cannot be called from a foreground task. In this case, the return value will be undefined and a Cicode hardware alarm will be raised.

---

**Note:** The index passed to AlarmSum\* functions must be current. ie either:

- the index returned by most recent call to AlarmSumFirst/Last/Find/Next/Prev
  - OR
  - the index returned by the most recent call to AlarmSumAppend OR AlarmSumSplit
- 

## Syntax

INT **AlarmSumFind**(*Record*, *OnTime* [, *ClusterName*] )

*Record*:

The alarm record number, returned from any of the following alarm functions:

- AlarmFirstCatRec() or AlarmNextCatRec() - used to search for a record by alarm category, area, and type (acknowledged, disabled, etc.).
- AlarmFirstPriRec() or AlarmNextPriRec() - used to search for a record by alarm priority, area, and type (acknowledged, disabled, etc.).
- AlarmFirstTagRec() or AlarmNextTagRec() - used to search for a record by alarm tag, name, and description.

To store this value, use data type Int in Cicode or Long for variable tags (Long needs 4 bytes).

*OnTime*:

The ON time of the alarm associated with the Record, that is, the time that the alarm was activated.

AlarmSumFind() requires that the OnTime argument contains the number of seconds from Midnight, so the

formulation:

```
iOnTime = StrToTime(AlarmSumGet(iIndex, "OnTime"));
```

will NOT yield the correct result. The correct formulation for this calculation is:

```
OnTime = StrToTime(AlarmSumGet(iIndex, "OnTime")) + TimeMidnight(TimeCurrent());
```

*ClusterName*:

Specifies the name of the cluster in which the Alarm Server resides. This is optional if you have one cluster or are resolving the alarm server via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

The index of the alarm summary entry, or -1 if no alarm summary entry is found.

---

**Note:** The index is a 32-bit integer. Storing it in a variable that is smaller than 32 bit integer (such as a 16-bit integer) may cause overflow which may result in an incorrect value.

---

## Related Functions

## Example

```
/* This function sets the summary comment from the alarm record
number and the ontime of the summary event. */
FUNCTION
SumSetComment(INT AN, STRING sComment)
    INT nRecord;
    INT iOnTime;
    INT hAlarm1;
    STRING AlmTag;
    AlmTag = AlarmGetDsp(AN, "Tag");
    iOnTime = StrToDate(AlarmGetDsp(AN,"OnDate"))+StrToTime(AlarmGetDsp(AN,"OnTime"));
    hAlarm1 = MsgOpen("Alarm", 0, 0);
    MsgRPC(hAlarm1, "AlmSvrSumSetComment", "^^" + AlmTag + "^," + IntToStr(iOnTime) + ",^"
    + sComment + "^^", 1);
    MsgClose("Alarm", hAlarm1);
END
FUNCTION
AlmSvrSumSetComment(STRING AlmTag, INT iOnTime, STRING sComment)
    INT nRecord = AlarmFirstTagRec(AlmTag, "", "");
    INT Index = AlarmSumFind(nRecord, iOnTime);
    IF Index <> -1 THEN
        AlarmSumSet(Index, "Comment", sComment);
    END
END
```

## See Also

[Alarm Functions](#)

## AlarmSumFirst

Gets the index of the oldest alarm summary entry. You can use this index in the AlarmSumGet() function to get field data from an alarm record, in the AlarmSumSet() function to change the existing data in that record, or in the AlarmSumDelete() function to delete the record.

To work with a series of alarm summary records, call this function to get the index, and then call AlarmSumNext() within a loop, to move forwards in the alarm summary.

This function can only be used if the Alarm Server is on the current machine. When the Alarm Server is not in the calling process, this function will become blocking and cannot be called from a foreground task. In this case, the return value will be undefined and a Cicode hardware alarm will be raised.

---

**Note:** The index passed to AlarmSum\* functions must be current, i.e. either:

- the index returned by most recent call to AlarmSumFirst/Last/Find/Next/Prev  
OR
  - the index returned by the most recent call to AlarmSumAppend OR AlarmSumSplit.
- 

## Syntax

```
INT AlarmSumFirst( [ClusterName] )
```

*ClusterName*:

Specifies the name of the cluster in which the Alarm Server resides. This is optional if you have one cluster or are resolving the alarm server via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

The index of the oldest alarm summary entry, or -1 if no alarm summary entry is found.

---

**Note:** The index is a 32-bit integer. Storing it in a variable that is smaller than 32 bit integer (such as a 16-bit integer) may cause overflow which may result in an incorrect value.

---

[Alarm Functions](#)

### AlarmSumGet

Gets field data from an alarm summary entry. The data is returned as a string. You identify the alarm summary entry by the Index, returned by one of the alarm summary search functions. If calling this function from a remote client, use the MsgRPC function.

By embedding this function in a loop, you can get data from a series of alarm summary entries. To start from the oldest entry, call the AlarmSumFirst() function to get the index, and then call AlarmSumNext() in a loop. To work back from the most recent entry, call AlarmSumLast() and then AlarmSumPrev() in a loop.

You can also get the Index from the AlarmSumFind() function, which finds an alarm summary entry by its alarm record identifier and time of activation.

---

**Note:** Record numbers obtained from AlarmGetDsp are not valid for this function.

This function can only be used if the Alarm Server is on the current machine. When the Alarm Server is not in the calling process, this function will become blocking and cannot be called from a foreground task. In this case, the return value will be undefined and a Cicode hardware alarm will be raised.

## Syntax

INT **AlarmSumGet**(*Index*, *sField* [, *ClusterName*] )

*Index*:

The alarm summary index (returned from the AlarmSumFirst(), AlarmSumNext(), AlarmSumLast(), AlarmSumPrev(), AlarmSumAppend(), or AlarmSumFind() function).

*sField*:

The name of the field from which to extract the data:

Tag	Alarm tag
AckDate	Alarm acknowledged date
AckTime	Alarm acknowledged time
Category	Alarm category
Comment	Alarm comment
DeltaTime	Alarm active time
Desc	Alarm description

Help	Help page
Name	Alarm name
OffDate	Alarm OFF date
OffTime	Alarm OFF time
OnDate	Alarm ON date
OnTime	Alarm ON time
State	Alarm state

**ClusterName:**

Specifies the name of the cluster in which the Alarm Server resides. This is optional if you have one cluster or are resolving the alarm server via the current cluster context. The argument is enclosed in quotation marks "".

**Return Value**

Field data from the alarm summary entry (as a string).

**Related Functions**

[AlarmSumCommit](#), [AlarmSumDelete](#), [AlarmSumSet](#), [AlarmSumType](#), [AlarmSumAppend](#), [AlarmDelete](#), [MsgRPC](#), [AlarmSumFirst](#), [AlarmSumNext](#), [AlarmSumLast](#), [AlarmSumPrev](#), [AlarmSumFind](#), [AlarmSplit](#), [AlarmSumSplit](#)

**Example**

See [AlarmSumFirst](#).

**See Also**

[Alarm Functions](#)

**AlarmSumLast**

Gets the index of the most recent alarm summary entry. You can use this index in the `AlarmSumGet()` function to get field data from an alarm record, in the `AlarmSumSet()` function to change the existing data in that record, or in the `AlarmSumDelete()` function to delete the record.

To work with a series of alarm summary records, call this function to get the index, and then call `AlarmSumPrev()` within a loop, to move backwards in the alarm summary.

This function can only be used if the Alarm Server is on the current machine.

This function can only be used if the Alarm Server is on the current machine. When the Alarm Server is not in the calling process, this function will become blocking and cannot be called from a foreground task. In this case, the return value will be undefined and a Cicode hardware alarm will be raised.

---

**Note:** The index passed to AlarmSum\* functions must be current. ie either:

- the index returned by most recent call to AlarmSumFirst/Last/Find/Next/Prev
  - OR
  - the index returned by the most recent call to AlarmSumAppend OR AlarmSumSplit.
- 

## Syntax

INT AlarmSumLast( [ClusterName] )

*ClusterName:*

Specifies the name of the cluster in which the Alarm Server resides. This is optional if you have one cluster or are resolving the alarm server via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

The index of the most recent alarm summary entry, or -1 if no alarm summary entry is found.

---

**Note:** The index is a 32-bit integer. Storing it in a variable that is smaller than 32 bit integer (such as a 16-bit integer) may cause overflow which may result in an incorrect value.

---

## Related Functions

[AlarmSumCommit](#), [AlarmSumDelete](#), [AlarmSumSet](#), [AlarmSumType](#), [AlarmSumAppend](#), [AlarmDelete](#),  
[AlarmSumGet](#), [AlarmSumFirst](#), [AlarmSumNext](#), [AlarmSumPrev](#), [AlarmSumFind](#), [AlarmSplit](#), [AlarmSumSplit](#)

## Example

```
/* This function finds all alarm summary entries that match the
specified tag and sets the "OffTime" to the time specified. The
alarm entry is not acknowledged or set to the off state, the alarm
summary "OffTime" field is all that is affected. */

FUNCTION
SumSetTime(STRING sTag, INT Time)
    INT Index;
    STRING Name;
    Index=AlarmSumLast();
    WHILE Index<>-1 DO
        Name=AlarmSumGet(Index,"Tag");
        IF Name=sTag THEN
            AlarmSumSet(Index,"OffTime",Time);
        END
        Index=AlarmSumPrev(Index);
    END
END
```

## AlarmSumNext

Gets the index of the next alarm summary entry, that is, the entry that occurred later than the entry specified by Index. You can use this index in the AlarmSumGet() function to get field data from an alarm record, in the

AlarmSumSet() function to change the existing data in that record, or in the AlarmSumDelete() function to delete the record.

You can use this function to work with a series of alarm summary records. Call the AlarmSumFirst() or AlarmSumFind() function to get the index, and then call AlarmSumNext() within a loop, to move forwards in the alarm summary.

You can also get the index of an entry as soon as it displays on the alarm summary. Alarm summary entries are recorded with the most recent entry at the end of the list. Call AlarmSumLast() to get the index for the most recent entry, and then call AlarmSumNext() to get the index for the next entry that occurs.

This function can only be used if the Alarm Server is on the current machine. When the Alarm Server is not in the calling process, this function will become blocking and cannot be called from a foreground task. In this case, the return value will be undefined and a Cicode hardware alarm will be raised.

---

**Note:** The index passed to AlarmSum\* functions must be current. ie either:

- the index returned by most recent call to AlarmSumFirst/Last/Find/Next/Prev
  - OR
  - the index returned by the most recent call to AlarmSumAppend OR AlarmSumSplit.
- 

## Syntax

**INT AlarmSumNext(*Index* [, *ClusterName*] )**

*Index*:

The alarm summary index (returned from the AlarmSumFirst(), AlarmSumNext(), AlarmSumLast(), AlarmSumPrev(), or AlarmSumFind() function).

---

**Note:** If the supplied index was returned by AlarmSumAppend, AlarmSum Next and AlarmSumPrev will return -1, and an error (561, invalid index) is raised. To retrieve extended error information, call IsError().

---

*ClusterName*:

Specifies the name of the cluster in which the Alarm Server resides. This is optional if you have one cluster or are resolving the alarm server via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

The index of the next alarm summary entry or -1 if no more alarm summary entries are found.

---

**Note:** The index is a 32-bit integer. Storing it in a variable that is smaller than 32 bit integer (such as a 16-bit integer) may cause overflow which may result in an incorrect value.

---

## Example

See [AlarmSumFirst](#)

## See Also

[Alarm Functions](#)

### AlarmSumPrev

Gets the index of the previous alarm summary entry, that is, the entry that occurred before the entry specified by *Index*. You can use this index in the AlarmSumGet function to get field data from an alarm record, in the AlarmSumSet function to change the existing data in that record, or in the AlarmSumDelete function to delete the record.

You can use this function to work with a series of alarm summary records. Call the AlarmSumLast() or AlarmSumFind() function to get the index, and then call AlarmSumPrev() within a loop, to move backwards in the alarm summary.

This function can only be used if the Alarm Server is on the current machine. When the Alarm Server is not in the calling process, this function will become blocking and cannot be called from a foreground task. In this case, the return value will be undefined and a Cicode hardware alarm will be raised.

---

**Note:** The index passed to AlarmSum\* functions must be current. ie either:

- the index returned by most recent call to AlarmSumFirst/Last/Find/Next/Prev
  - OR
  - the index returned by the most recent call to AlarmSumAppend OR AlarmSumSplit.
- 

## Syntax

**INT AlarmSumPrev(*Index* [, *ClusterName*] )**

*Index*:

The alarm summary index (returned from the AlarmSumFirst(), AlarmSumNext(), AlarmSumLast(), AlarmSumPrev(), or AlarmSumFind() function).

---

**Note:** If the supplied index was returned by AlarmSumAppend, AlarmSum Next and AlarmSumPrev will return -1, and an error (561, invalid index) is raised. To get extended error information, call IsError().

---

*ClusterName*:

Specifies the name of the cluster in which the Alarm Server resides. This is optional if you have one cluster or are resolving the alarm server via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

The index of the previous alarm summary entry or -1 if no more alarm summary entries are found.

---

**Note:** The index is a 32-bit integer. Storing it in a variable that is smaller than 32 bit integer (such as a 16-bit integer) may cause overflow which may result in an incorrect value.

---

## Example

See [AlarmSumLast](#).

## See Also

[Alarm Functions](#)

## AlarmSumSet

Sets field information in an alarm summary entry. You identify the alarm summary entry by the *Index*, returned by one of the alarm summary search functions.

By embedding this function in a loop, you can change field data in a series of alarm summary entries. To start from the oldest entry, call the AlarmSumFirst function to get the index, and then call AlarmSumNext in a loop. To work back from the latest entry, call AlarmSumLast and then AlarmSumPrev in a loop.

You can also get the *Index* from the AlarmSumFind function, which finds an alarm summary entry by its alarm record identifier and time of activation.

This function can only be used if the Alarm Server is on the current machine. When the Alarm Server is not in the calling process, this function will become blocking and cannot be called from a foreground task. In this case, the return value will be undefined and a Cicode hardware alarm will be raised.

Fields of an appended alarm can only be set using this function or the replacement function AlmSummarySetField.

You can use user events to keep a record of logins, or control operations that you need to display in the alarm summary etc. The fields of UserEvents need to be set immediately after creation using this function. These entries in the Alarm Summary cannot be filtered from the summary in an AlmSummaryOpen browse session.

---

**Note:**

- In a redundant pair scenario, this function will return an error condition and not do anything if the current server is not main. You can call this function on the primary server and the standby server so that function can succeed on one of the two servers in the specified cluster. The change will be synchronised to the other server after a short period of time (typically in 5 seconds).
  - This function will only work while the record is writable which is controlled by the ArchiveAfter Parameter. Refer to the topic *Configure the Archiving Parameters* in the main help for more information.
- 

## Syntax

INT **AlarmSumSet**(*Index*, *sField*, *sData* [, *ClusterName*] )

*Index*:

The alarm summary index (returned from the AlarmSumFirst(), AlarmSumNext(), AlarmSumLast(), AlarmSumPrev(), AlarmSumAppend(), or AlarmSumFind() function).

*sField*:

The name of the field in which data is to be set:

AckTime	Alarm acknowledged time
Comment	Alarm comment

OffMilli (for time stamped alarms only)	Alarm millisecond off time
OffTime	Alarm OFF time

*sData:*

The new value of the field.

*ClusterName:*

Specifies the name of the cluster in which the Alarm Server resides. This is optional if you have one cluster or are resolving the alarm server via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

0 (zero) if the alarm summary entry exists, otherwise an error is returned.

## Related Functions

[AlarmSumCommit](#), [AlarmSumDelete](#), [AlarmSumType](#), [AlarmSumAppend](#), [AlarmDelete](#), [MsgRPC](#), [AlarmSumGet](#), [AlarmSumFirst](#), [AlarmSumNext](#), [AlarmSumLast](#), [AlarmSumPrev](#), [AlarmSumFind](#), [AlarmSplit](#), [AlarmSumSplit](#), [AlmSummarySetFieldValue](#)

## Example

See [AlarmSumFirst](#).

## See Also

[Alarm Functions](#)

## AlarmSumSplit

Splits the alarm summary entry identified by index.

On operation success, the OffTime of the current alarm summary entry is filled with specified OnTime. Meanwhile, a new alarm summary entry is raised with the specified OnTime and no OffTime.

---

**Note:** This function will only work while the record is writable which is controlled by the ArchiveAfter Parameter. Refer to the topic [Configure the Archiving Parameters](#) in the main help for more information.

The operation represents a logical split at the specified OnTime to an active alarm instance. You can use this function to add a comment related to the specified OnTime.

The alarm summary entry must not have OffTime, or the function would return -1 and do nothing.

The function is blocking and cannot be called from a foreground task. In this case, the return value will be undefined and a Cicode hardware alarm will be raised.

This function can only be used if the alarm server is on the current machine. If the Alarm Server is not in the calling process, the calling process needs to run from the same machine as the alarm server.

In a redundant pair scenario, the function would return error condition and do nothing if the current server is not main. You can call this function on both the primary server and the standby server so that function can

succeed on one of the two servers in the specified cluster. The change will be synchronized to the other server after a short period of time (typically in 5 seconds).

---

**Note:** The index passed to AlarmSum\* functions must be current. ie either:

- the index returned by most recent call to AlarmSumFirst/Last/Find/Next/Prev OR
  - the index returned by the most recent call to AlarmSumAppend OR AlarmSumSplit.
- 

## Syntax

INT **AlarmSumSplit**(*Index* [, *ClusterName*, *OnTime*, *OnMilli*, *bRedundant*] )

*Index*:

The alarm summary index (returned from the AlarmSumFirst(), AlarmSumNext(), AlarmSumLast(), AlarmSumPrev(), AlarmSumAppend(), or AlarmSumFind() function).

*ClusterName*:

Specifies the name of the cluster in which the Alarm Server resides. This is optional if you have one cluster or are resolving the alarm server via the current cluster context. The argument is enclosed in quotation marks "".

*OnTime*:

The alarm OnTime (if omitted or is equal to 0, will default to current time, i.e. the time the function was invoked).

*OnMilli*:

Milliseconds part of the alarm's ON time

*bRedundant:(optional)*

New alarm record is created on both redundant server instances. This parameter has been deprecated and is always set to true.

## Return Value

The Index of the new entry, or -1 on error.

---

**Note:** The index is a 32-bit integer. Storing it in a variable that is smaller than 32 bit integer (such as a 16-bit integer) may cause overflow which may result in an incorrect value.

---

## Example

```
/* This function finds the first alarm summary entry that matches
the specified tag, splits that entry and then adds the specified
comment to the new entry. */
FUNCTION
AlarmSplitAdd(STRING Tag, STRING Comment)
    INT Index;
    STRING Name;
```

```
Index=AlarmSumFirst();
WHILE Index<>-1 DO
    Name=AlarmSumGet(Index, "Tag");
    IF Name=sTag THEN
        AlarmSumSplit(Index);
        Index=AlarmSumFirst();
        AlarmSumSet(Index, "Comment", Comment);
        Index=-1;
    ELSE
        Index=AlarmSumNext(Index);
    END
END
END
```

## See Also

[Alarm Functions](#)

### AlarmSumType

Retrieves a value that indicates a specified alarm's type, that is whether it's a digital alarm, an analog alarm, hardware alarm, etc.

This function can only be used if the Alarm Server is on the current machine. When the Alarm Server is not in the calling process, this function will become blocking and cannot be called from a foreground task. In this case, the return value will be undefined and a Cicode hardware alarm will be raised.

## Syntax

**INT AlarmSumType(*Index* [, *ClusterName*] )**

*Index*:

The alarm summary index (returned from the AlarmSumFirst(), AlarmSumNext(), AlarmSumLast(), AlarmSumPrev(), AlarmSumAppend(), or AlarmSumFind() function).

*ClusterName*:

Specifies the name of the cluster in which the Alarm Server resides. This is optional if you have one cluster or are resolving the alarm server via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

A number that represents one of the following alarm types:

- 0 = digital alarm
- 1 = analog alarm
- 2 = advanced alarm
- 3 = Multi-Digital alarm
- 4 = Argyle analog alarm
- 5 = user-generated event

- 6 = high resolution alarm
- 8 = time-stamped digital alarm
- 9 = time-stamped analog alarm
- -1 indicates an invalid response to the request.

[AlarmSumGet](#), [AlarmSumFirst](#), [AlarmSumNext](#), [AlarmSumLast](#), [AlarmSumPrev](#), [AlarmSumFind](#), [AlarmSplit](#)

## See Also

[Alarm Functions](#)

### AlarmTagFromEquipment

Returns the first tag associated with a piece of equipment.

## Syntax

**INT AlarmTagFromEquipment(STRING Tag, [, STRING ClusterName])**

*Tag:*

A string that identifies the alarm to acknowledge. It can be one of the following:

- An alarm tag — for example, "Fire1"
- An alarm equipment item — for example, "Motor1.AlarmFire"

Specify an empty string (" ") to match all alarm tags.

*ClusterName:*

The cluster in which the tag resides

## Return Value

0 (zero) if successful, otherwise an error code will be returned

## See Also

[Alarm Functions](#)

### AlmBrowseAck

The AlmBrowseAck function acknowledges the alarm tag at the current cursor position in an active data browse session.

This function is a non-blocking function. It does not block the calling Cicode task.

## Syntax

INT AlmBrowseAck(LONG *iSession*)

*iSession*:

The handle to a browse session previously returned by a [AlmBrowseOpen](#) call.

## Return Value

0 (zero) if the alarm browse session exists, otherwise an error code is returned.

## Related Functions

[AlmBrowseDisable](#), [AlmBrowseEnable](#), [AlmBrowseClose](#), [AlmBrowseFirst](#), [AlmBrowseGetField](#), [AlmBrowseNext](#),  
[AlmBrowseNumRecords](#), [AlmBrowseOpen](#), [AlmBrowsePrev](#)

## See Also

[Alarm Functions](#)

## AlmBrowseClose

The AlmBrowseClose function terminates an active data browse session and cleans up resources associated with the session.

This function is a non-blocking function. It does not block the calling Cicode task.

## Syntax

INT AlmBrowseClose(LONG *iSession*)

*iSession*:

The handle to a browse session previously returned by a [AlmBrowseOpen](#) call.

## Return Value

0 (zero) if the alarm browse session exists, otherwise an error code is returned.

## Related Functions

[AlmBrowseAck](#), [AlmBrowseDisable](#), [AlmBrowseEnable](#), [AlmBrowseFirst](#), [AlmBrowseGetField](#), [AlmBrowseNext](#),  
[AlmBrowseNumRecords](#), [AlmBrowseOpen](#), [AlmBrowsePrev](#)

## See Also

[Alarm Functions](#)

## AlmBrowseDisable

The AlmBrowseDisable function disables the alarm tag at the current cursor position in an active data browse session.

This function is a non-blocking function. It does not block the calling Cicode task.

## Syntax

```
INT AlmBrowseDisable(INT iSession [, INT EndTime [, STRING Comment]] )
```

*iSession*:

The handle to a browse session previously returned by an [AlmBrowseOpen](#) call.

*Comment*

An optional comment limited to 200 characters explaining why the alarm is disabled. If the comment exceeds 200 characters, hardware error 274 ("Invalid argument passed") will be displayed.

## Return Value

0 (zero) if the alarm browse session exists, otherwise an error code is returned.

## Related Functions

[AlmBrowseAck](#), [AlmBrowseEnable](#), [AlmBrowseClose](#), [AlmBrowseFirst](#), [AlmBrowseGetField](#), [AlmBrowseNext](#),  
[AlmBrowseNumRecords](#), [AlmBrowseOpen](#), [AlmBrowsePrev](#)

## Examples

```
// Retrieve the handle to a browse session returned by an AlmBrowseOpen call.  
// ...  
// Disable the associated alarm for the next 60 minutes  
nEndTime = DateAdd(TimeCurrent(), 3600);  
AlmBrowseDisable(iSession, nEndTime, "Shelve alarm for 60 minutes.");  
// Retrieve the handle to a browse session returned by an AlmBrowseOpen call.  
// ...  
// Disable the associated alarm until 20 Dec 2016 6:30am local time  
nEndTime = DateAdd(StrToDate("20/12/2016"), StrToTime("6:30"));  
AlmBrowseDisable(iSession, nEndTime, "Shelve alarms until 20 Dec 2016 6:30am");
```

## See Also

[Alarm Functions](#)

## AlmBrowseEnable

The AlmBrowseEnable function enables the alarm tag at the current cursor position in an active data browse session.

This function is a non-blocking function. It does not block the calling Cicode task.

## Syntax

```
INT AlmBrowseEnable(INT iSession [, INT bAcknowledge])
```

*iSession*:

The handle to a browse session previously returned by an [AlmBrowseOpen](#) call.

*bAcknowledge*:

Forces acknowledgment of an alarm after it is enabled. The accepted values are:

0 — (default) enforced acknowledgment will not be applied.

1 — alarm will be acknowledged when enabled.

## Return Value

0 (zero) if the alarm browse session exists, otherwise an error code is returned.

## Related Functions

[AlmBrowseAck](#) [AlmBrowseDisable](#), [AlmBrowseClose](#), [AlmBrowseFirst](#), [AlmBrowseGetField](#), [AlmBrowseNext](#),  
[AlmBrowseOpen](#), [AlmBrowsePrev](#)

## Example

```
// Retrieve the handle to a browse session returned by an AlmBrowseOpen call.  
// ...  
//Enable the associated alarm and enforce acknowledgment  
AlmBrowseEnable(iSession, 1);
```

## See Also

[Alarm Functions](#)

## AlmBrowseFirst

The [AlmBrowseFirst](#) function places the data browse cursor at the first record.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

```
INT AlmBrowseFirst(LONG iSession)
```

*iSession*:

The handle to a browse session previously returned by a [AlmBrowseOpen](#) call.

## Return Value

0 (zero) if the alarm browse session exists, otherwise an error code is returned.

## Related Functions

[AlmBrowseAck](#), [AlmBrowseDisable](#), [AlmBrowseEnable](#), [AlmBrowseClose](#), [AlmBrowseGetField](#), [AlmBrowseNext](#), [AlmBrowseNumRecords](#), [AlmBrowseOpen](#), [AlmBrowsePrev](#)

## See Also

[Alarm Functions](#)

### AlmBrowseGetField

The AlmBrowseGetField function retrieves the value of the specified field from the record the data browse cursor is currently referencing.

This function is a non-blocking function. It does not block the calling Cicode task.

## Syntax

STRING **AlmBrowseGetField**(LONG *iSession*, STRING *FieldName*)

*iSession*:

The handle to a browse session previously returned by a [AlmBrowseOpen](#) call.

*sFieldName*:

The name of the field that references the value to be returned. Supported fields are:

ACKDATE, ACKDATEEXT, ACKTIME, ACQERROR, ALARMTYPE, ALMCOMMENT, AREA, CATEGORY, CAUSE1, CAUSE2, CAUSE3, CAUSE4, CAUSE5, CAUSE6, CAUSE7, CAUSE8, CLUSTER, COMMENT, CONSEQUENCE1, CONSEQUENCE2, CONSEQUENCE3, CONSEQUENCE4, CONSEQUENCE5, CONSEQUENCE6, CONSEQUENCE7, CONSEQUENCE8, CUSTOM1, CUSTOM2, CUSTOM3, CUSTOM4, CUSTOM5, CUSTOM6, CUSTOM7, CUSTOM8, DATE, DATEEXT, DEADBAND, DELTATIME, DESC, DEVDELAY, DEVIATION, DISABLEENDDATE, DISABLEENDDATEEXT, DISABLEENDTIME, DISABLECOMMENT, ERRDESC, ERRPAGE, EQUIPMENT, FORMAT, GROUP, HDELAY, HELP, HHDELAY, HIGH, HIGHHIGH, LDELAY, LEVEL, LLDELAY, LOCALTIMEDATE, LOGSTATE, LOW, LOWLOW, MILLISEC, NAME, NATIVE\_COMMENT, NATIVE\_DESC, NATIVE\_NAME, NATIVE\_SUMDESC, OFFDATE, OFFDATEEXT, OFFMILLI, OFFTIME, OFFTIMEDATE, OLD\_DESC, ONDATE, ONDATEEXT, ONMILLI, ONTIME, ONTIMEDATE, PAGING, PAGINGGROUP, PRIORITY, PRIV, QUALITY, RATE, RECEIPTLOCALTIMEDATE, RECEIPTDATE, RESPONSE1, RESPONSE2, RESPONSE3, RESPONSE4, RESPONSE5, RESPONSE6, RESPONSE7, RESPONSE8, RESPONSENUM, RESPTIME1, RESPTIME2, RESPTIME3, RESPTIME4, RESPTIME5, RESPTIME6, RESPTIME7, RESPTIME8, STATE, STATE\_DESC, STATE\_DESC0, STATE\_DESC1, STATE\_DESC2, STATE\_DESC3, STATE\_DESC4, STATE\_DESC5, STATE\_DESC6, STATE\_DESC7, SUMDESC, SUMSTATE, SUMTYPE, TAG, TAGEX, TIME, TIMEDATE, TYPE, TYPENUM, USERNAME, VALUE.

See [Browse Function Field Reference](#) for information about fields.

## Return Value

The value of the specified field as a string. An empty string may or may not be an indication that an error has been detected. The last error should be checked in this instance to determine if an error has actually occurred.

## Related Functions

[AlmBrowseAck](#), [AlmBrowseDisable](#), [AlmBrowseEnable](#), [AlmBrowseClose](#), [AlmBrowseFirst](#), [AlmBrowseNext](#),  
[AlmBrowseNumRecords](#), [AlmBrowseOpen](#), [AlmBrowsePrev](#)

## Example

```
STRING fieldValue = "";
STRING fieldName = "TYPE";
INT errorCode = 0;
...
fieldValue = AlmBrowseGetField(iSession, sFieldName);
IF fieldValue <> "" THEN
    // Successful case
ELSE
    // Function returned an error
END
...
```

## AlmBrowseNext

The AlmBrowseNext function moves the data browse cursor forward one record. If you call this function after you have reached the end of the records, error 412 is returned (Databrowse session EOF).

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

INT **AlmBrowseNext**(LONG *iSession*)

*iSession*:

The handle to a browse session previously returned by a [AlmBrowseOpen](#) call.

## Return Value

0 (zero) if the browse has successfully been moved to the next record, otherwise an error code is returned.

## Related Functions

[AlmBrowseAck](#), [AlmBrowseDisable](#), [AlmBrowseEnable](#), [AlmBrowseClose](#), [AlmBrowseFirst](#), [AlmBrowseGetField](#),  
[AlmBrowseNumRecords](#), [AlmBrowseOpen](#), [AlmBrowsePrev](#)

## See Also

[Alarm Functions](#)

## AlmBrowseNumRecords

The AlmBrowseNumRecords function returns the number of records that match the filter criteria.

This function is a non-blocking function. It does not block the calling Cicode task.

## Syntax

```
LONG AlmBrowseNumRecords(LONG iSession)
```

*iSession*:

The handle to a browse session previously returned by a AlmBrowseOpen call.

## Return Value

The number of records that have matched the filter criteria. A value of 0 denotes that no records have matched. A value of -1 denotes that the browse session is unable to provide a fixed number. This may be the case if the data being browsed changed during the browse session.

## Related Functions

[AlmBrowseAck](#), [AlmBrowseDisable](#), [AlmBrowseEnable](#), [AlmBrowseClose](#), [AlmBrowseFirst](#), [AlmBrowseGetField](#),  
[AlmBrowseNext](#), [AlmBrowseOpen](#), [AlmBrowsePrev](#)

## Example

```
INT numRecords = 0;  
...  
numRecords = AlmBrowseNumRecords(iSession);  
IF numRecords <> 0 THEN  
    // Have records  
ELSE  
    // No records  
END  
...
```

## See Also

[Alarm Functions](#)

## AlmBrowseOpen

The AlmBrowseOpen function initiates a new browse session and returns a handle to the new session that can be used in subsequent data browse function calls. Use this function to browse all configured alarms.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

**Note:** After calling AlmBrowseOpen() it is necessary to call AlmBrowseFirst() in order to place the cursor at the beginning of the browse session, otherwise a hardware alarm is invoked.

## Syntax

```
LONG AlmBrowseOpen( Filter, STRING Fields [, STRING Clusters [,INT AutoCloseMode]] )
```

### *Filter:*

A filter expression specifying the records to return during the browse. An empty string indicates that all records will be returned. Where a fieldname is not specified in the filter, it is assumed to be tagname. For example, the filter "AAA" is equivalent to "Tag=AAA". Multiple filters separated by semicolons are supported.

---

**Note:** When using Date/Time fields specify in the number of seconds since 1970. For example,  
LOCALTIMEDATE>=1348723732.

See the topic [Implementing Alarm Filters Using Cicode](#) for more information about filter syntax.

### *Fields:*

Specifies via a comma delimited string the columns to be returned during the browse. An empty string indicates that the server will return all available columns. Supported fields are:

ACKDATE, ACKDATEEXT, ACKMILLI, ACKTIME, ACKUTC, ACQDESC, ACQERROR, ALARMTYPE, ALMCOMMENT, AREA, ARR\_SIZE, CATEGORY, CAUSE1...8, CLASSIFICATION, CLUSTER, COMMENT, CONSEQUENCE1...8, CUSTOM1...8, DATE, DATEEXT, DEADBAND, DELAY, DELTAMILLI, DELTATIME, DESC, DEVDELAY, DEVIATION, DISABLECOMMENT, DISABLEDDATE, DISABLEDTIME, DISABLEENDDATE, DISABLEENDDATEEXT, DISABLEENDTIME, ENG\_ZERO, ERRDESC,ERRPAGE, EQUIPMENT, FORMAT, FULLNAME, GROUP, HDELAY, HELP, HHDELAY, HIGH, HIGHHIGH, HISTORIAN, ITEM, LDELAY, LLDELAY, LOCALTIMEDATE, LOGSTATE, LOW, LOWLOW, MESSAGE, MILLSEC, NAME, NATIVE\_COMMENT, NATIVE\_DESC, NATIVE\_NAME, NATIVE\_SUMDESC, OFFDATE, OFFDATEEXT, OFFMILLI, OFFTIME, OFFTIMEDATE, OFFUTC, OLD\_DESC, ONDATE, ONDATEEXT, ONMILLI, ONTIME, ONTIMEDATE, ONUTC, PAGING, PAGINGGROUP, PRIORITY, PRIV, PSI\_TYPE, RATE, RECEIPTLOCALTIMEDATE, RECEIPTDATE, RECEIPTDATEEXT, RECEIPTMILLISEC, RECEIPTTIME, RECEIPTTIMEINT, RECEIPTTIMETICKS, RESPONSE1...8, RESPONSENUM, SETPOINT, STATE, STATE\_DESC, STATE\_DESCO...7, SUMDESC, SUMSTATE, SUMTYPE, TAG, TAGEX, TAGGENLINK, TIME, TIMEDATE, TIMEINT, TIMETICKS, TSQUALITY, TYPE, TYPENUM, USERDESC, USERNAME, USERLOCATION, VALUE.

See [Browse Function Field Reference](#) for information about fields.

### *Clusters:*

An optional parameter that specifies via a comma delimited string the subset of the clusters to browse. An empty string indicates that the connected clusters will be browsed.

### *AutoCloseMode*

An optional parameter to automatically close the browsing session at page navigation.

0 - (Default) Will not automatically close the browsing session. Use AlmBrowseClose to close the session manually.

1 - The browsing session will be closed when the page is changed or otherwise closed.

---

**Note:** All other modes are reserved.

## Return Value

Returns an integer handle to the browse session. Returns -1 when an error is detected.

The returned entries will be ordered alphabetically by name.

## Related Functions

[AlmBrowseNext](#), [AlmBrowseNumRecords](#), [AlmBrowsePrev](#)

## Example

```
INT iSession;
...
iSession = AlmBrowseOpen("NAME=ABC*", "NAME,TYPE",
"ClusterA,ClusterB");
IF iSession <> -1 THEN
    // Successful case
ELSE
    // Function returned an error
END
...
```

## See Also

[Alarm Functions](#)

### AlmBrowsePrev

The AlmBrowsePrev function moves the data browse cursor back one record. If you call this function after you have reached the beginning of the records, error 412 is returned (Databrowse session EOF).

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

INT **AlmBrowsePrev**(LONG *iSession*)

*iSession*:

The handle to a browse session previously returned by a AlmBrowseOpen call.

## Return Value

0 (zero) if the alarm browse session exists, otherwise an error code is returned.

## Related Functions

[AlmBrowseAck](#), [AlmBrowseDisable](#), [AlmBrowseEnable](#), [AlmBrowseClose](#), [AlmBrowseFirst](#), [AlmBrowseGetField](#),  
[AlmBrowseNext](#), [AlmBrowseNumRecords](#), [AlmBrowseOpen](#)

## See Also

[Alarm Functions](#)

## AlmSummaryAck

The AlmSummaryAck function acknowledges the alarm in the active alarm list which is linked to the current entry of the alarm summary browse session.

If the current alarm summary browse session entry is a user event the function will have no effect.

This function is a non-blocking function. It does not block the calling Cicode task.

## Syntax

**INT AlmSummaryAck(LONG Session)**

*Session:*

The handle to a browse session previously returned by a AlmSummaryOpen call.

## Return Value

0 (zero) if the alarm browse session exists, otherwise an error code is returned.

## Related Functions

[AlmSummaryClear](#), [AlmSummaryClose](#), [AlmSummaryDelete](#), [AlmSummaryDeleteAll](#), [AlmSummaryDisable](#),  
[AlmSummaryEnable](#), [AlmSummaryFirst](#), [AlmSummaryGetField](#), [AlmSummaryLast](#), [AlmSummaryNext](#),  
[AlmSummaryOpen](#), [AlmSummaryPrev](#), [AlmSummaryNumRecords](#)

## See Also

[Alarm Functions](#)

## AlmSummaryCommit

The AlmSummaryCommit function triggers the actual write of the value for the field previously specified by AlmSummarySetFieldValue.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

---

**Note:** This function will only work while the record is writable which is controlled by the [Alarm]ArchiveAfter parameter. Refer to the topic [Configure the Archiving Parameters](#) for more information.

---

## Syntax

**AlmSummaryCommit**(*iSession*)

*iSession:*

The handle to a browse session previously returned by a AlmSummaryOpen call.

## Return Value

0 (zero) if the alarm browse session exists, otherwise an error is returned.

## Related Functions

[AlmSummaryAck](#) [AlmSummaryClear](#), [AlmSummaryClose](#), [AlmSummaryDelete](#), [AlmSummaryDeleteAll](#),

[AlmSummaryNext](#), [AlmSummaryOpen](#), [AlmSummaryPrev](#), [AlmSummarySetFieldValue](#)

## Example

```
INT errorCode = 0;  
...  
errorCode = AlmSummaryCommit(iSession);  
IF errorCode = 0 THEN  
    // Successful case  
ELSE  
    // Function returned an error  
END  
...
```

## See Also

[Alarm Functions](#)

## AlmSummaryClear

The AlmSummaryClear function clears the latched alarm at the current cursor position in an active data browse session. A latched alarm is an alarm which is OFF and acknowledged when [Alarm]AckHold is set to 1. The function does nothing if the alarm summary entry at the cursor is not linked to a latched alarm.

This function is a non-blocking function. It does not block the calling Cicode task.

## Syntax

INT **AlmSummaryClear**(LONG Session)

*Session:*

The handle to a browse session previously returned by a AlmSummaryOpen call.

## Return Value

0 (zero) if the alarm browse session exists, otherwise an error code is returned.

## Related Functions

[AlmSummaryPrev](#), [AlmSummaryNumRecords](#)

## See Also

[Alarm Functions](#)

### AlmSummaryClose

The AlmSummaryClose function terminates an active data browse session and cleans up all resources associated with the session.

This function is a non-blocking function. It does not block the calling Cicode task.

## Syntax

INT **AlmSummaryClose**(LONG *iSession*)

*iSession*

The handle to a browse session previously returned by a AlmSummaryOpen call.

## Return Value

0 (zero) if the alarm browse session exists, otherwise an error code is returned.

## Related Functions

[AlmSummaryAck](#), [AlmSummaryClear](#), [AlmSummaryDelete](#), [AlmSummaryDeleteAll](#), [AlmSummaryDisable](#),

[AlmSummaryOpen](#), [AlmSummaryPrev](#), [AlmSummaryNumRecords](#)

## See Also

[Alarm Functions](#)

### AlmSummaryDelete

The AlmSummaryDelete function deletes the record in the filtered list that the cursor is currently referencing. The cursor moves to the next available entry in the data browse session after the current alarm summary is deleted.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

---

**Note:** This function will only work while the record is writable which is controlled by the ArchiveAfter parameter. Refer to the topic [Configure the Archiving Parameters](#) for more information.

## Syntax

```
INT AlmSummaryDelete(LONG iSession)
```

*iSession:*

The handle to a filtered list previously returned by a AlmSummaryOpen call.

## Return Value

0 (zero) if the alarm browse session exists, otherwise an error code is returned.

## Related Functions

[AlmSummaryAck](#), [AlmSummaryClear](#), [AlmSummaryClose](#), [AlmSummaryDeleteAll](#) [AlmSummaryDisable](#),  
[AlmSummaryEnable](#), [AlmSummaryFirst](#), [AlmSummaryGetField](#), [AlmSummaryLast](#), [AlmSummaryNext](#),  
[AlmSummaryOpen](#), [AlmSummaryPrev](#), [AlmSummaryNumRecords](#)

## Example

```
INT errorCode = 0;  
...  
errorCode = AlmSummaryDelete(iSession);  
IF errorCode = 0 THEN  
// Successful case  
ELSE  
// Function returned an error  
END  
...
```

## See Also

[Alarm Functions](#)

### AlmSummaryDeleteAll

The AlmSummaryDeleteAll function deletes every record from the filtered list source.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

**Note:** This function will only work while the record is writable which is controlled by the ArchiveAfter parameter. Refer to the topic [Configure the Archiving Parameters](#) for more information.

## Syntax

```
INT AlmSummaryDeleteAll(LONG iSession)
```

*iSession:*

The handle to a filtered list previously returned by a AlmSummaryOpen call.

## Return Value

0 (zero) if the alarm filtered list session exists, otherwise an error code is returned.

## Related Functions

[AlmSummaryAck](#), [AlmSummaryClear](#), [AlmSummaryClose](#), [AlmSummaryDelete](#), [AlmSummaryDisable](#),  
[AlmSummaryEnable](#), [AlmSummaryFirst](#), [AlmSummaryGetField](#), [AlmSummaryLast](#), [AlmSummaryNext](#),  
[AlmSummaryOpen](#), [AlmSummaryPrev](#), [AlmSummaryNumRecords](#)

## Example

```
INT errorCode = 0;
...
errorCode = AlmSummaryDeleteAll(iSession);
IF errorCode = 0 THEN
    // Successful case
ELSE
    // Function returned an error
END
```

## See Also

[Alarm Functions](#)

## AlmSummaryDisable

The AlmSummaryDisable function disables the alarm at the current cursor position in an active data browse session.

This function is a non-blocking function. It does not block the calling Cicode task.

## Syntax

INT **AlmSummaryDisable**(INT *iSession* [, INT *EndTime* [, STRING *Comment*]] )

*iSession*:

The handle to a browse session previously returned by an [AlmSummaryOpen](#) call.

*EndTime*:

A date/time variable that indicates when the alarm will no longer be disabled. If this parameter is omitted or set to 0, the alarm will be disabled indefinitely.

*Comment*:

An optional comment limited to 200 characters explaining why the alarm is disabled. If the comment exceeds 200 characters, hardware error 274 ("Invalid argument passed") will be displayed.

## Return Value

0 (zero) if the alarm browse session exists, otherwise an error code is returned.

## Related Functions

[AlmSummaryEnable](#), [AlmSummaryFirst](#), [AlmSummaryGetField](#), [AlmSummaryLast](#), [AlmSummaryNext](#),  
[AlmSummaryOpen](#), [AlmSummaryPrev](#), [AlmSummaryNumRecords](#)

## Examples

```
// Retrieve the handle to a browse session returned by an AlmSummaryOpen call.  
// ...  
// Disable the associated alarm for the next 60 minutes  
nEndTime = DateAdd(TimeCurrent(), 3600);  
AlmSummaryDisable(iSession, nEndTime, "Shelve alarm for 60 minutes.");  
// Retrieve the handle to a browse session returned by an AlmSummaryOpen call.  
// ...  
// Disable the associated alarm until 20 Dec 2016 6:30am local time  
nEndTime = DateAdd(StrToDate("20/12/2016"), StrToTime("6:30"));  
AlmSummaryDisable(iSession, nEndTime, "Shelve alarms until 20 Dec 2016 6:30am");
```

## AlmSummaryEnable

The AlmSummaryEnable function enables the alarm at the current cursor position in an active data browse session.

This function is a non-blocking function. It does not block the calling Cicode task.

## Syntax

INT **AlmSummaryEnable**(INT *iSession* [, INT *bAcknowledge*])

*iSession*:

The handle to a browse session previously returned by an [AlmSummaryOpen](#) call.

*bAcknowledge*:

Forces acknowledgment of an alarm after it is enabled. The accepted values are:

0 — (default) enforced acknowledgment will not be applied.

1 — alarm will be acknowledged when enabled.

## Return Value

0 (zero) if the alarm browse session exists, otherwise an error code is returned.

## Related Functions

[AlmSummaryAck](#), [AlmSummaryClear](#), [AlmSummaryClose](#), [AlmSummaryDelete](#), [AlmSummaryDeleteAll](#),  
[AlmSummaryDisable](#), [AlmSummaryFirst](#), [AlmSummaryGetField](#), [AlmSummaryLast](#), [AlmSummaryNext](#),  
[AlmSummaryOpen](#), [AlmSummaryPrev](#), [AlmSummaryNumRecords](#)

## Example

```
// Retrieve the handle to a browse session returned by an AlmSummaryOpen call.  
// ...  
//Enable the associated alarm and enforce acknowledgment  
AlmSummaryEnable(iSession, 1);
```

## See Also

[Alarm Functions](#)

### AlmSummaryFirst

The AlmSummaryFirst function places the data browse cursor at the first record.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

INT **AlmSummaryFirst**(LONG *iSession*)

*iSession*:

The handle to a browse session previously returned by a AlmSummaryOpen call.

## Return Value

0 (zero) if the alarm browse session exists, otherwise an error code is returned.

## Related Functions

[AlmSummaryAck](#), [AlmSummaryClear](#), [AlmSummaryDelete](#), [AlmSummaryDeleteAll](#), [AlmSummaryDisable](#),  
[AlmSummaryEnable](#), [AlmSummaryGetField](#), [AlmSummaryLast](#), [AlmSummaryNext](#), [AlmSummaryOpen](#),  
[AlmSummaryPrev](#), [AlmSummaryNumRecords](#)

[Alarm Functions](#)

### AlmSummaryGetField

The AlmSummaryGetField function retrieves the value of the specified field from the record the data browse

cursor is currently referencing.

This function is a non-blocking function. It does not block the calling Cicode task.

## Syntax

```
STRING AlmSummaryGetField(LONG iSession, STRING sFieldName)
```

*iSession*:

The handle to a browse session previously returned by a AlmSummaryOpen call.

*sFieldName*:

The name of the field that references the value to be returned. Supported fields are:

ACKDATE, ACKDATEEXT, ACKTIME, ACQERROR, ALARMTYPE, ALMCOMMENT, AREA, CATEGORY, CLUSTER, COMMENT, CUSTOM1, CUSTOM2, CUSTOM3, CUSTOM4, CUSTOM5, CUSTOM6, CUSTOM7, CUSTOM8, DATE, DATEEXT, DEADBAND, DELTATIME, DESC, DEVIATION, ERRDESC, ERPPAGE, EQUIPMENT, FORMAT, FULLNAME, GROUP, HELP, HIGH, HIGHHIGH, LOCALTIMEDATE, LOGSTATE, LOW, LOWLOW, MILLISEC, NAME, NATIVE\_COMMENT, NATIVE\_DESC, NATIVE\_NAME, NATIVE\_SUMDESC, NODE, OFFDATE, OFFDATEEXT, OFFMILLI, OFFTIME, OFFTIMEDATE, OLD\_DESC, ONDATE, ONDATEEXT, ONMILLI, ONTIME, ONTIMEDATE, PAGING, PAGINGGROUP, PRIORITY, PRIV, QUALITY, RATE, STATE, STATE\_DESC, STATE\_DESC0, STATE\_DESC1, STATE\_DESC2, STATE\_DESC3, STATE\_DESC4, STATE\_DESC5, STATE\_DESC6, STATE\_DESC7, SUMDESC, SUMSTATE, SUMTYPE, TAG, TAGEX, TIME, TIMEDATE, TYPE, TYPENUM, USERNAME, VALUE.

See [Browse Function Field Reference](#) for information about fields.

## Return Value

The value of the specified field as a string. An empty string may or may not be an indication that an error has been detected. The last error should be checked in this instance to determine if an error has actually occurred.

## Related Functions

[AlmSummaryAck](#), [AlmSummaryClear](#), [AlmSummaryClose](#), [AlmSummaryDelete](#), [AlmSummaryDeleteAll](#),  
[AlmSummaryDisable](#), [AlmSummaryEnable](#), [AlmSummaryFirst](#), [AlmSummaryLast](#), [AlmSummaryNext](#),  
[AlmSummaryOpen](#), [AlmSummaryPrev](#), [AlmSummaryNumRecords](#)

## Example

```
STRING fieldValue = "";
STRING fieldName = "TYPE";
INT errorCode = 0;
...
fieldValue = AlmSummaryGetField(iSession, sFieldName);
IF fieldValue <> "" THEN
    // Successful case
ELSE
    // Function returned an error
END
...
```

## See Also

[Alarm Functions](#)

### AlmSummaryLast

The AlmSummaryLast function places the data browse cursor at the most recent summary record from the last cluster of the available browsing cluster list.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**INT AlmSummaryLast(LONG *iSession*)**

*iSession*:

The handle to a browse session previously returned by a [AlmSummaryOpen](#) call.

## Return Value

0 (zero) if the alarm browse session exists, otherwise an error code is returned.

## Related Functions

[AlmSummaryAck](#), [AlmSummaryClear](#), [AlmSummaryClose](#), [AlmSummaryDelete](#), [AlmSummaryDeleteAll](#),  
[AlmSummaryDisable](#), [AlmSummaryEnable](#), [AlmSummaryFirst](#), [AlmSummaryGetField](#), [AlmSummaryNext](#),  
[AlmSummaryOpen](#), [AlmSummaryPrev](#), [AlmSummaryNumRecords](#)

## See Also

[Alarm Functions](#)

### AlmSummaryNext

The AlmSummaryNext function moves the data browse cursor forward one record. If you call this function after you have reached the end of a summary, error 412 is returned (Databrowse session EOF).

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**INT AlmSummaryNext(LONG *iSession*)**

*iSession*:

The handle to a browse session previously returned by a [AlmSummaryOpen](#) call.

## Return Value

0 (zero) if the alarm browse session exists, otherwise an error code is returned.

## Related Functions

[AlmSummaryAck](#), [AlmSummaryClose](#), [AlmSummaryDelete](#), [AlmSummaryDeleteAll](#), [AlmSummaryDisable](#),  
[AlmSummaryEnable](#), [AlmSummaryFirst](#), [AlmSummaryGetField](#), [AlmSummaryLast](#), [AlmSummaryOpen](#),  
[AlmSummaryPrev](#), [AlmSummaryNumRecords](#)

## See Also

[Alarm Functions](#)

## AlmSummaryNumRecords

The AlmSummaryNumRecords function retrieves the number of records in an alarm summary browse session. This function is a non-blocking function. It does not block the calling Cicode task.

## Syntax

LONG **AlmSummaryNumRecords**(LONG *iSession*)

*iSession*:

The handle to a browse session previously returned by a [AlmSummaryOpen](#) call.

## Return Value

The number of records that have matched the filter criteria. A value of 0 denotes that no records have matched. A value of -1 denotes that the browse session is unable to provide a fixed number. This may be the case if the data being browsed changed during the browse session.

## Related Functions

[AlmSummaryAck](#), [AlmSummaryClear](#), [AlmSummaryClose](#), [AlmSummaryDelete](#), [AlmSummaryDeleteAll](#),  
[AlmSummaryDisable](#), [AlmSummaryEnable](#), [AlmSummaryFirst](#), [AlmSummaryGetField](#), [AlmSummaryLast](#),  
[AlmSummaryNext](#), [AlmSummaryPrev](#)

## Example

```
INT numRecords = 0;  
...  
numRecords = AlmSummaryNumRecords(iSession);  
IF numRecords <> 0 THEN  
    // Have records  
ELSE  
    // No records
```

```
END  
...
```

## See Also

[Alarm Functions](#)

### AlmSummaryOpen

The AlmSummaryOpen function initiates a new browse session and returns a handle to the new session that can be used in subsequent data browse function calls.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

The AlarmSummaryOpen function allows direct, successful subsequent execution of [AlmSummaryNext](#) and [AlmSummaryPrev](#) functions.

The AlmSummaryNext function executed directly after AlmSummaryOpen will place the data browse cursor at the earliest summary record.

The AlmSummaryPrev function executed directly after AlmSummaryOpen will place the cursor at the most recent summary record.

---

**Note:** Performance may be affected when using the AlmSummaryOpen browse functions in a system which has accumulated large volumes of alarm summary entries.

---

To improve performance:

- Specify only the required fields in the Fields parameter of the AlmSummaryOpen Cicode function. By default the parameter is empty and the browse will retrieve all available fields. Refer to Example 1.
- Specify a small OnTime filter for the alarm when calling the Cicode function. Confirm that the AlmSummaryClose is called for each browse session that has been opened using AlmSummaryOpen. Refer to Example 2.
- Specify a small row limit in the RowLimit parameter of the AlmSummaryOpen function. The default value is -1 which will use the default row limit specified in the Citect.ini parameter [Alarm]QueryRowLimit. Refer to Example 3.

## Syntax

LONG **AlmSummaryOpen**(STRING *Filter*, STRING *Fields* [, STRING *Clusters* [, INT *RowLimit*, [,INT *AutoCloseMode*]]]])

*Filter:*

A filter expression specifying the records to return during the browse. An empty string indicates that all records will be returned. Where a fieldname is not specified in the filter, it is assumed to be tagname. For example, the filter "AAA" is equivalent to "TAG=AAA".

*Fields:*

Specifies via a comma delimited string the columns to be returned during the browse. An empty string indicates that the server will return all available columns. Supported fields are:

ACKDATE, ACKDATEEXT, ACKMILLI, ACKTIME, ACKUTC, ACQDESC, ACQERROR, ALARMTYPE, ALMCOMMENT, AREA, ARR\_SIZE, CATEGORY, CAUSE1...8, CLASSIFICATION, CLUSTER, COMMENT, CONSEQUENCE1...8,

CUSTOM1...8, DATE, DATEEXT, DEADBAND, DELAY, DELTAMILLI, DELTATIME, DESC, DEVDELAY, DEVIATION, DISABLECOMMENT, DISABLEDDATE, DISABLEDTIME, DISABLEENDDATE, DISABLEENDDATEEXT, DISABLEENDTIME, ENG\_ZERO, ERRDESC,ERRPAGE, EQUIPMENT, FORMAT, FULLNAME, GROUP, HDELAY, HELP, HHDELAY, HIGH, HIGHHIGH, HISTORIAN, ITEM, LDELAY, LLDELAY, LOCALTIMEDATE, LOGSTATE, LOW, LOWLOW, MESSAGE, MILLISEC, NAME, NATIVE\_COMMENT, NATIVE\_DESC, NATIVE\_NAME, NATIVE\_SUMDESC, OFFDATE, OFFDATEEXT, OFFMILLI, OFFTIME, OFFTIMEDATE, OFFUTC, OLD\_DESC, ONDATE, ONDATEEXT, ONMILLI, ONTIME, ONTIMEDATE, ONUTC, PAGING, PAGINGGROUP, PRIORITY, PRIV, PSI\_TYPE, RATE, RECEIPTLOCALTIMEDATE, RECEIPTDATE, RECEIPTDATEEXT, RECEIPTMILLISEC, RECEIPTTIME, RECEIPTTIMEINT, RECEIPTTIMETICKS, RESPONSE1...8, RESPONENUM, SETPOINT, STATE, STATE\_DESC, STATE\_DESCO...7, SUMDESC, SUMSTATE, SUMTYPE, TAG, TAGEX, TAGGENLINK, TIME, TIMEDATE, TIMEINT, TIMETICKS, TSQUALITY, TYPE, TYPENUM, USERDESC, USERNAME, USERLOCATION, VALUE.

See [Browse Function Field Reference](#) for information about fields.

#### *Clusters:*

An optional parameter that specifies via a comma delimited string the subset of the clusters to browse. An empty string indicates that the connected clusters will be browsed.

#### *RowLimit:*

The default value of iRowLimit is -1. This will cause the browse session to use the default global maximum row limit (configured by the INI parameter [\[Alarm\]BrowseRowLimit](#)), or the default value of the INI parameter if not specified.

Specifying a small iRowLimit can reduce the round-trip time and the memory usage of AlmSummaryOpen Cicode function in a system with large alarm summary history.

#### *AutoCloseMode*

Optional parameter to close session at page navigation.

0 - Will not automatically close the browsing session. Use AlmSummaryClose to close the session manually.

1 - The browsing session will be closed when the page is changed or otherwise closed.

## Return Value

Returns an integer handle to the browse session. Returns -1 on error.

## Related Functions

[AlmSummaryAck](#), [AlmSummaryClear](#), [AlmSummaryClose](#), [AlmSummaryDelete](#), [AlmSummaryDeleteAll](#), [AlmSummaryDisable](#), [AlmSummaryEnable](#), [AlmSummaryFirst](#), [AlmSummaryGetField](#), [AlmSummaryLast](#), [AlmSummaryNext](#), [AlmSummaryPrev](#), [AlmSummaryNumRecords](#)

## Example

```
Example 1 - Specifying the fields
INT iSession;
...
iSession = AlmSummaryOpen("NAME=ABC*", "NAME,TYPE",
"ClusterA,ClusterB");
IF iSession <> -1 THEN
// Successful case
```

```
ELSE
// Function returned an error
END
...
Example 2 - Specifying the time range for multiple incremental browse sessions
INT session;
STRING t0 ;
STRING t1;
// Below is an example of browsing alarm summary records incrementally in small time ranges
// of 20 minutes interval over an hour from 10:00am TO 11:00am on 9th March 2015 local
time.
// 10:00 ~ 10:20
t0 = IntToStr(TimestampToInt(TimestampCreate(2015,03,09,10,00,00,000)));
t1 = IntToStr(TimestampToInt(TimestampCreate(2015,03,09,10,20,00,000)));
session = AlmSummaryOpen("OnTime >= " + t0 + " AND OnTime < " + t1, "");
IF (session >= 0) THEN
    AlmSummaryFirst(session);
    // Do something with the browse session
    // ...
    AlmSummaryClose(session);
END

// 10:20 ~ 10:40
t0 = IntToStr(TimestampToInt(TimestampCreate(2015,03,09,10,20,00,000)));
t1 = IntToStr(TimestampToInt(TimestampCreate(2015,03,09,10,40,00,000)));
session = AlmSummaryOpen("OnTime >= " + t0 + " AND OnTime < " + t1, "");
IF (session >= 0) THEN
    AlmSummaryFirst(session);
    // Do something with the browse session
    // ...
    AlmSummaryClose(session);
END

// 10:40 ~ 11:00
t0 = IntToStr(TimestampToInt(TimestampCreate(2015,03,09,10,40,00,000)));
t1 = IntToStr(TimestampToInt(TimestampCreate(2015,03,09,11,00,00,000)));
session = AlmSummaryOpen("OnTime >= " + t0 + " AND OnTime < " + t1, "");
IF (session >= 0) THEN
    AlmSummaryFirst(session);
    // Do something with the browse session
    // ...
    AlmSummaryClose(session);
END
...

Example 3 - Specify RowLimit for multiple incremental browse sessions
INT session;
INT rowLimit = 500;
STRING continuationFilter;
REAL ts;
STRING lastOnTime;

// Below is an example of browsing alarm summary records incrementally in small row limit
// of 50
// The OnTime and Tag of the last record is used as the continuation for the next
incremental session.
```

```
// First session
session = AlmSummaryOpen("", "", "Cluster1", rowLimit);
IF (session < 0) THEN
    RETURN;
END

AlmSummaryFirst(session);
// Do something with the browse session, and call AlmSummaryNext(session) to iterate
// ...

// Capture the timestamp of the last record for browse continuation with a next session.
AlmSummaryLast(session);
ts = (StrToReal(AlmSummaryGetField(session, "OnMilli")) / 1000) +
    StrToDate(AlmSummaryGetField(session, "OnDate")) +
    StrToTime(AlmSummaryGetField(session, "OnTime"));
lastOnTime = RealToStr(ts, 0, 3);
AlmSummaryClose(session);

// Continue browsing using small row limit.
continuationFilter = "OnTime > " + lastOnTime;
session = AlmSummaryOpen(continuationFilter, "", "Cluster1", rowLimit);
IF (session < 0) THEN
    RETURN;
END

IF AlmSummaryFirst(session) <> 0 THEN
    AlmSummaryClose(session);
    RETURN;
END

// Do something with the browse session, and call AlmSummaryNext(session) to iterate
// ...

// Capture the timestamp of the last record for browse continuation with a next session.
AlmSummaryLast(session);
ts = (StrToReal(AlmSummaryGetField(session, "OnMilli")) / 1000) +
    StrToDate(AlmSummaryGetField(session, "OnDate")) +
    StrToTime(AlmSummaryGetField(session, "OnTime"));
lastOnTime = RealToStr(ts, 0, 3);
AlmSummaryClose(session);
...
```

### AlmSummaryPrev

The AlmSummaryPrev function moves the data browse cursor back one record. If you call this function after you have reached the beginning of a summary, error 412 is returned (Databrowse session EOF).

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**INT AlmSummaryPrev(LONG Session)**

*iSession:*

The handle to a browse session previously returned by a AlmSummaryOpen call.

## Return Value

0 (zero) if the alarm browse session exists, otherwise an error code is returned.

## Related Functions

[Alarm Functions](#)

## AlmSummarySetFieldValue

The AlmSummarySetFieldValue function sets a new value for the specified field for the record the data browse cursor is currently referencing. The value is not committed until a call to AlmSummaryCommit is made.

The new values are discarded if the cursor is moved away from the current alarm summary entry before AlmSummaryCommit is made in the data browse session

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

---

**Note:** This function will only work while the record is writable which is controlled by the [\[Alarm\]ArchiveAfter](#) parameter. Refer to the topic [Configure the Archiving Parameters](#) for more information.

---

## Syntax

**LONG AlmSummarySetFieldValue(*iSession*, *sFieldname*, *sFieldValue*)**

*iSession:*

The handle to a browse session previously returned by a AlmSummaryOpen call.

*sFieldName:*

The name of the field whose value is to be updated. Supported fields are:

AckTime	Alarm acknowledged time
Comment	Alarm Comment
OffMilli (for time stamped alarms only)	Alarm millisecond off time

OffTime	Alarm OFF time
---------	----------------

See [Browse Function Field Reference](#) for additional information about fields.

*sFieldValue:*

The field value to update.

## Return Value

0 (zero) if the alarm browse session exists, otherwise an error code is returned.

## Related Functions

[AlmSummaryAck](#), [AlmSummaryClear](#), [AlmSummaryClose](#), [AlmSummaryCommit](#), [AlmSummaryDelete](#), [AlmSummaryDeleteAll](#), [AlmSummaryDisable](#), [AlmSummaryEnable](#), [AlmSummaryFirst](#), [AlmSummaryGetField](#), [AlmSummaryLast](#), [AlmSummaryNext](#), [AlmSummaryOpen](#), [AlmSummaryNumRecords](#)

## Example

```
STRING sFieldValue = "NEW_COMMENT";
STRING sFieldName = "COMMENT";
INT errorCode = 0;
...
errorCode = AlmSummarySetFieldValue(iSession, sFieldName,
    sFieldValue);
IF errorCode = 0 THEN
    // Successful case
ELSE
    // Function returned an error
END
...
```

## See Also

[Alarm Functions](#)

## AlmTagsAck

---

**Note:** This command is now deprecated. Use [AlmBrowseAck](#) function instead.

The AlmTagsAck function acknowledges the alarm tag at the current cursor position in an active data browse session.

This function is a non-blocking function. It does not block the calling Cicode task.

## Syntax

INT **AlmTagsAck**(*iSession*)

*iSession:*

The handle to a browse session previously returned by a AlmTagsOpen call.

## Return Value

0 (zero) if the alarm browse session exists, otherwise an error code is returned.

## Related Functions

[AlmTagsClear](#), [AlmTagsDisable](#), [AlmTagsEnable](#), [AlmTagsClose](#), [AlmTagsFirst](#), [AlmTagsGetField](#), [AlmTagsNext](#), [AlmTagsNumRecords](#), [AlmTagsOpen](#), [AlmTagsPrev](#)

## AlmTagsClear

---

**Note:** This command is now deprecated.

The AlmTagsClear function clears the alarm tag at the current cursor position in an active data browse session. This function is a non-blocking function. It does not block the calling Cicode task.

## Syntax

INT **AlmTagsClear**(*iSession*)

*iSession*:

The handle to a browse session previously returned by a AlmTagsOpen call.

## Return Value

0 (zero) if the alarm browse session exists, otherwise an error code is returned.

## Related Functions

[AlmTagsAck](#), [AlmTagsDisable](#), [AlmTagsEnable](#), [AlmTagsClose](#), [AlmTagsFirst](#), [AlmTagsGetField](#), [AlmTagsNext](#), [AlmTagsNumRecords](#), [AlmTagsOpen](#), [AlmTagsPrev](#)

## See Also

[Alarm Functions](#)

## AlmTagsClose

---

**Note:** This command is now deprecated. Use [AlmBrowseClose](#) function instead.

The AlmTagsClose function terminates an active data browse session and cleans up all resources associated with the session.

This function is a non-blocking function. It does not block the calling Cicode task.

## Syntax

INT AlmTagsClose(*iSession*)

*iSession*:

The handle to a browse session previously returned by a AlmTagsOpen call.

## Return Value

0 (zero) if the alarm browse session exists, otherwise an error code is returned.

## Related Functions

## See Also

[Alarm Functions](#)

## AlmTagsDisable

---

**Note:** This command is now deprecated. Use [AlmBrowseDisable](#) function instead.

The AlmTagsDisable function disables the alarm tag at the current cursor position in an active data browse session.

This function is a non-blocking function. It does not block the calling Cicode task.

## Syntax

INT AlmTagsDisable([INT *iSession* [, INT *EndTime* [, STRING *Comment*] ] )

*iSession*:

The handle to a browse session previously returned by a AlmTagsOpen call.

*EndTime*:

A date/time variable that indicates when the alarm will no longer be disabled. If this parameter is omitted or set to 0, the alarm will be disabled indefinitely.

*Comment*:

An optional comment limited to 200 characters explaining why the alarm is disabled. If the comment exceeds 200 characters, hardware error 274 ("Invalid argument passed") will be displayed.

## Return Value

0 (zero) if the alarm browse session exists, otherwise an error code is returned.

## Related Functions

[AlmTagsAck](#), [AlmTagsClear](#), [AlmTagsDisable](#), [AlmTagsClose](#), [AlmTagsFirst](#), [AlmTagsGetField](#), [AlmTagsNext](#),  
[AlmTagsNumRecords](#), [AlmTagsOpen](#), [AlmTagsPrev](#)

## See Also

[Alarm Functions](#)

### AlmTagsEnable

---

**Note:** This command is now deprecated. Use [AlmBrowseEnable](#) function instead.

---

The AlmTagsEnable function enables the alarm tag at the current cursor position in an active data browse session.

This function is a non-blocking function. It does not block the calling Cicode task.

## Syntax

INT **AlmTagsEnable**(INT *iSession* [, INT *bAcknowledge*])

*iSession*:

The handle to a browse session previously returned by a AlmTagsOpen call.

*bAcknowledge*:

Forces acknowledgment of an alarm after it is enabled. The accepted values are:

0 — (default) enforced acknowledgment will not be applied.

1 — alarm will be acknowledged when enabled.

## Return Value

0 (zero) if the alarm browse session exists, otherwise an error code is returned.

## Related Functions

[AlmTagsAck](#), [AlmTagsClear](#), [AlmTagsDisable](#), [AlmTagsClose](#), [AlmTagsFirst](#), [AlmTagsGetField](#), [AlmTagsNext](#),

## See Also

[Alarm Functions](#)

### AlmTagsFirst

---

**Note:** This command is now deprecated. Use [AlmBrowseFirst](#) function instead.

---

The AlmTagsFirst function places the data browse cursor at the first record.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**INT AlmTagsFirst(*iSession*)**

*iSession*:

The handle to a browse session previously returned by a AlmTagsOpen call.

## Return Value

0 (zero) if the alarm browse session exists, otherwise an error code is returned.

## Related Functions

[AlmTagsAck](#), [AlmTagsClear](#), [AlmTagsDisable](#), [AlmTagsClose](#), [AlmTagsEnable](#), [AlmTagsGetField](#),  
[AlmTagsNumRecords](#), [AlmTagsOpen](#), [AlmTagsPrev](#)

## See Also

[Alarm Functions](#)

## AlmTagsGetField

---

**Note:** This command is now deprecated. Use [AlmBrowseGetField](#) function instead.

---

The AlmTagsGetField function retrieves the value of the specified field from the record the data browse cursor is currently referencing.

This function is a non-blocking function. It does not block the calling Cicode task.

## Syntax

**STRING AlmTagsGetField(*iSession*, *sFieldName*)**

*iSession*:

The handle to a browse session previously returned by a AlmTagsOpen call.

*sFieldName*:

The name of the field that references the value to be returned. Supported fields are:

ACKDATE, ACKDATEEXT, ACKTIME, ACQERROR, ALARMTYPE, ALMCOMMENT, AREA, CATEGORY, CAUSE1, CAUSE2, CAUSE3, CAUSE4, CAUSE5, CAUSE6, CAUSE7, CAUSE8, CLUSTER, COMMENT, CONSEQUENCE1, CONSEQUENCE2, CONSEQUENCE3, CONSEQUENCE4, CONSEQUENCE5, CONSEQUENCE6, CONSEQUENCE7, CONSEQUENCE8, CUSTOM1, CUSTOM2, CUSTOM3, CUSTOM4, CUSTOM5, CUSTOM6, CUSTOM7, CUSTOM8, DATE, DATEEXT, DEADBAND, DELTATIME, DESC, DEVIATION, DISABLEENDDATE, DISABLEENDDATEEXT, DISABLEENDTIME, DISABLECOMMENT, ERRDESC, ERRPAGE, EQUIPMENT, FORMAT, GROUP, HELP, HIGH, HIGHHIGH, LEVEL, LOCALTIMEDATE, LOGSTATE, LOW, LOWLOW, MILLISEC, NAME, NATIVE\_COMMENT, NATIVE\_DESC, NATIVE\_NAME, NATIVE\_SUMDESC, OFFDATE, OFFDATEEXT, OFFMILLI, OFFTIME, OFFTIMEDATE, OLD\_DESC, ONDATE, ONDATEEXT, ONMILLI, ONTIME, ONTIMEDATE, PAGING, PAGINGGROUP, PRIORITY, PRIV, QUALITY, RATE,

RECEIPTLOCALTIMEDATE, RECEIPTDATE, RESPONSE1, RESPONSE2, RESPONSE3, RESPONSE4, RESPONSE5, RESPONSE6, RESPONSE7, RESPONSE8, RESPONSENUM, RESPTIME1, RESPTIME2, RESPTIME3, RESPTIME4, RESPTIME5, RESPTIME6, RESPTIME7, RESPTIME8, STATE, STATE\_DESC, STATE\_DESC0, STATE\_DESC1, STATE\_DESC2, STATE\_DESC3, STATE\_DESC4, STATE\_DESC5, STATE\_DESC6, STATE\_DESC7, SUMDESC, SUMSTATE, SUMTYPE, TAG, TAGEX, TIME, TIMEDATE, TYPE, TYPENUM, USERNAME, VALUE.

See [Browse Function Field Reference](#) for information about fields.

## Return Value

The value of the specified field as a string. An empty string may or may not be an indication that an error has been detected. The last error should be checked in this instance to determine if an error has actually occurred.

## Related Functions

[AlmTagsAck](#), [AlmTagsClear](#), [AlmTagsDisable](#), [AlmTagsEnable](#), [AlmTagsClose](#), [AlmTagsFirst](#), [AlmTagsNext](#), [AlmTagsNumRecords](#), [AlmTagsOpen](#),

## Example

```
STRING fieldValue = "";
STRING fieldName = "TYPE";
INT errorCode = 0;
...
fieldValue = AlmTagsGetField(iSession, sFieldName);
IF fieldValue <> "" THEN
    // Successful case
ELSE
    // Function returned an error
END
...
```

## See Also

[Alarm Functions](#)

## AlmTagsNext

---

**Note:** This command is now deprecated. Use [AlmBrowseNext](#) function instead.

The AlmTagsNext function moves the data browse cursor forward one record. If you call this function after you have reached the end of the records, error 412 is returned (Databrowse session EOF).

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

INT **AlmTagsNext**(*iSession*)

*iSession*:

The handle to a browse session previously returned by a AlmTagsOpen call.

## Return Value

0 (zero) if the browse has successfully been moved to the next record, otherwise an error code is returned.

## Related Functions

[AlmTagsAck](#), [AlmTagsClear](#), [AlmTagsEnable](#), [AlmTagsClose](#), [AlmTagsFirst](#), [AlmTagsGetField](#), [AlmTagsNumRecords](#),  
[AlmTagsOpen](#), [AlmTagsPrev](#)

## See Also

[Alarm Functions](#)

## AlmTagsNumRecords

---

**Note:** This command is now deprecated. Use [AlmBrowseNumRecords](#) function instead.

---

The AlmTagsNumRecords function returns the number of records that match the filter criteria.

This function is a non-blocking function. It does not block the calling Cicode task.

## Syntax

LONG **AlmTagsNumRecords**(*iSession*)

*iSession*:

The handle to a browse session previously returned by a AlmTagsOpen call.

## Return Value

The number of records that have matched the filter criteria. A value of 0 denotes that no records have matched. A value of -1 denotes that the browse session is unable to provide a fixed number. This may be the case if the data being browsed changed during the browse session.

## Related Functions

[AlmTagsAck](#), [AlmTagsClear](#), [AlmTagsDisable](#), [AlmTagsEnable](#), [AlmTagsClose](#), [AlmTagsFirst](#), [AlmTagsGetField](#),  
[AlmTagsNext](#), [AlmTagsOpen](#), [AlmTagsPrev](#)

## Example

```
INT numRecords = 0;  
...  
numRecords = AlmTagsNumRecords(iSession);  
IF numRecords <> 0 THEN  
    // Have records
```

```
ELSE
    // No records
END
...
```

## AlmTagsOpen

**Note:** This command is now deprecated. Use [AlmBrowseOpen](#) function instead.

The AlmTagsOpen function initiates a new browse session and returns a handle to the new session that can be used in subsequent data browse function calls.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

**Note:** After calling AlmTagsOpen() it is necessary to call AlmTagsFirst() in order to place the cursor at the beginning of the browse session, otherwise a hardware alarm is invoked.

## Syntax

```
LONG AlmTagsOpen(sFilter, sFields [, sClusters] )
```

*sFilter*:

A filter expression specifying the records to return during the browse. An empty string indicates that all records will be returned. Where a fieldname is not specified in the filter, it is assumed to be tagname. For example, the filter "AAA" is equivalent to "Tag=AAA".

*sFields*:

Specifies via a comma delimited string the columns to be returned during the browse. An empty string indicates that the server will return all available columns. Supported fields are:

ACKDATE, ACKDATEEXT, ACKTIME, ACQERROR, ALARMTYPE, ALMCOMMENT, AREA, CATEGORY, CLUSTER, COMMENT, CUSTOM1, CUSTOM2, CUSTOM3, CUSTOM4, CUSTOM5, CUSTOM6, CUSTOM7, CUSTOM8, DATE, DATEEXT, DEADBAND, DELTATIME, DESC, DEVIATION, DISABLEENDTIME, ERRDESC, ERPPAGE, EQUIPMENT, FORMAT, GROUP, HELP, HIGH, HIGHHIGH, ITEM, LEVEL, LOCALTIMEDATE, LOGSTATE, LOW, LOWLOW, MILLISEC, NAME, NATIVE\_COMMENT, NATIVE\_DESC, NATIVE\_NAME, NATIVE\_SUMDESC, OFFDATE, OFFDATEEXT, OFFMILLI, OFFTIME, OFFTIMEDATE, OLD\_DESC, ONDATE, ONDATEEXT, ONMILLI, ONTIME, ONTIMEDATE, PAGING, PAGINGGROUP, PRIORITY, PRIV, QUALITY, RATE, RECEIPTLOCALTIMEDATE, RECEIPTDATE, STATE, STATE\_DESC, STATE\_DESC0, STATE\_DESC1, STATE\_DESC2, STATE\_DESC3, STATE\_DESC4, STATE\_DESC5, STATE\_DESC6, STATE\_DESC7, SUMDESC, SUMSTATE, SUMTYPE, TAG, TAGEX, TIME, TIMEDATE, TYPE, TYPENUM, USERNAME, VALUE.

See [Browse Function Field Reference](#) for information about fields.

*sClusters*:

An optional parameter that specifies via a comma delimited string the subset of the clusters to browse. An empty string indicates that the connected clusters will be browsed.

## Return Value

Returns an integer handle to the browse session. Returns -1 when an error is detected.

The returned entries will be ordered alphabetically by name.

## Related Functions

[AlmTagsAck](#), [AlmTagsClear](#), [AlmTagsDisable](#), [AlmTagsEnable](#), [AlmTagsClose](#), [AlmTagsFirst](#), [AlmTagsGetField](#), [AlmTagsNext](#), [AlmTagsNumRecords](#), [AlmTagsPrev](#)

## Example

```
INT iSession;  
...  
iSession = AlmTagsOpen("NAME=ABC*", "NAME,TYPE",  
"ClusterA,ClusterB");  
IF iSession <> -1 THEN  
// Successful case  
ELSE  
// Function returned an error  
END  
...
```

## See Also

[Alarm Functions](#)

## AlmTagsPrev

---

**Note:** This command is now deprecated. Use [AlmBrowsePrev](#) function instead.

The AlmTagsPrev function moves the data browse cursor back one record. If you call this function after you have reached the beginning of the records, error 412 is returned (Databrowse session EOF).

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

INT **AlmTagsPrev**(*iSession*)

*iSession*:

The handle to a browse session previously returned by a AlmTagsOpen call.

## Return Value

0 (zero) if the alarm browse session exists, otherwise an error code is returned.

## Related Functions

[AlmTagsAck](#), [AlmTagsClear](#), [AlmTagsDisable](#), [AlmTagsEnable](#), [AlmTagsClose](#), [AlmTagsFirst](#), [AlmTagsGetField](#), [AlmTagsNext](#), [AlmTagsNumRecords](#), [AlmTagsOpen](#)

## See Also

[Alarm Functions](#)

### HwAlarmQue

Returns the handle of the hardware alarm queue. The Alarms Server writes hardware alarm information into this queue as each hardware alarm occurs. To read events from this queue, use the QueRead or QuePeek functions. The data written into the queue is the hardware alarm format, and is stored in the Str field.

To use this function, you need to enable the hardware alarm queue by specifying the [\[Alarm\]HwAlarmQueMax](#) parameter. This parameter specifies the maximum length that the queue can grow to. The [\[Alarm\]HwAlarmFmt](#) parameter defines the format of the data placed into the string field. If HwAlarmFmt is not specified then the format defaults to "Time: {Time,12} Date:{Date,11} Desc:{Desc,40}" .

The following format fields are relevant to hardware alarms:

- {Tag,n}
- {TagEx,n}
- {Cluster,n}
- {Name,n}
- {State,n}
- {Time,n}
- {Date,n}
- {Desc,n}
- {ErrDesc,n}
- {ErrPage,n}

For a description of the fields see the "Alarm Display Fields" help page.

The number of buffers available for user queues is controlled by the [\[Code\]Queue](#) parameter. Each entry in any user queue consumes one buffer. When all buffers have been used the alarms server will not be able to add new hardware alarms to the queue, and the error message "Out Of Buffers Usr.Que" will be written to syslog.dat.

---

**Note:** When similar hardware alarms are triggered, for example "Tag not found" alarms, the hardware alarm page and hardware alarm queue show the last invalid entry. The previous entry of the same description is overwritten.

---

## Syntax

**HwAlarmQue( )**

## Return Value

The handle of the hardware alarm queue, or -1 if the queue cannot be opened.

## Related Functions

[QueRead](#), [QuePeek](#)

## Example

```
hQue = HwAlarmQue()
WHILE TRUE DO
    QueRead(hQue, nAlarmType, sHwAlarmString, 1);
    /* do whatever with the alarm information */
    ....
    Sleep(0);
END
```

## Alarm Filter Functions

The following Cicode functions relate to alarm filters.

<a href="#">AlarmFilterClose</a>	Removes the session from memory.
<a href="#">AlarmFilterEditAppend</a>	Appends the provided expression to the current filter session content without any validation.
<a href="#">AlarmFilterEditAppendEquipment</a>	Appends the provided expression that includes equipment names or category to the current filter session content without any validation.
<a href="#">AlarmFilterEditClose</a>	Removes the session from the memory.
<a href="#">AlarmFilterEditCommit</a>	Validates the filter built in this session and, if valid, applies the filter to the list associated with the session.
<a href="#">AlarmFilterEditFirst</a>	Retrieves the first part of the filter.
<a href="#">AlarmFilterEditLast</a>	Retrieves the last part of the filter.
<a href="#">AlarmFilterEditNext</a>	Retrieves the next part of the filter.
<a href="#">AlarmFilterEditOpen</a>	Creates a session for the historical list associated with the provided animation number (aN) or FilterName.
<a href="#">AlarmFilterEditPrev</a>	Retrieves the previous part of the filter.
<a href="#">AlarmFilterEditSet</a>	It replaces the current filter session content by the

	provided expression without any validation.
<a href="#">AlarmFilterForm</a>	Available when using the Legacy Filter Form. Use to display an alarm form to specify filter criteria for an alarm list or a named filter.
<a href="#">AlarmFilterOpen</a>	Creates a new named filter.
<a href="#">AlarmGetFilterName</a>	Retrieves the name of the filter for the AN.
<a href="#">AlarmResetQuery</a>	Use when using the AlarmFilterForm(). Clears the filter of the specified filter source.
<a href="#">LibAlarmFilterForm</a>	Displays a generic alarm filter popup for specifying filter criteria for either an alarm list or named filter. Only available if 'Lib_controls' project is included in main project.

**Note:** If a requested filter is too complex (for example, it contains too many conditions or too many nested brackets), the filter is cleared (no filter is used). The hardware alarm "Too many alarms in filters" is generated on the client components, and a tracelog error message is logged.

## See Also

[Cicode Function Categories](#)

[Using Cicode Functions](#)

## AlarmFilterClose

This function removes the named filter from memory.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**INT AlarmFilterClose(STRING *FilterName*)**

*FilterName*

Name of the filter

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Example

```
// This example shows how to open and close the named filter "Myfilter"
// nothing of interest is done with the filter in this example.
INT nOpenModeOld = 0;
```

```
INT nOpenModeNew = 1;
INT nOpenModeAny = 2;
INT nCloseModeManual = 0;
INT nCloseModePageChanged = 1;
INT nError;
nError = AlarmFilterOpen("MyFilter", nOpenModeNew, nCloseModeManual);
IF nError = 0 THEN
    nError = AlarmFilterClose("MyFilter");
END
```

## Related Functions

[AlarmFilterOpen](#)

## See Also

[Alarm Filter Functions](#)

### AlarmFilterEditAppend

The **AlarmFilterEditAppend** function takes a session handle and a filter expression as parameters. It appends the provided expression to the current filter session content without any validation. This does not apply to all filters on the list (see [AlarmFilterEditCommit](#)).

## Syntax

```
INT AlarmFilterEditAppend(INT hSession, STRING FilterCriteria)
```

*hSession*:

Session handle for the historical list previously returned by the function [AlarmFilterEditOpen](#).

*FilterCriteria*:

Filter expression as a string. For example: "(Tag=A) OR (TAG=B)"

See the topic [Implementing Alarm Filters Using Cicode](#) for more information about filter syntax.

---

**Note:** If a requested filter is too complex (for example, it contains too many conditions or too many nested brackets), the filter is cleared (no filter is used). The hardware alarm "Too many alarms in filters" is generated on the client components, and a tracelog error message is logged.

---

## Return Value

0 (zero) if the alarm filter session exists, otherwise an error code is returned.

## Example

```
// This example shows how to update an edit session.
// This example requires that the edit session hEdit exists.
// This example shows how you would split the parts of the filter
// to avoid an overflow error when handling strings.
INT nError;
```

```
nError = AlarmFilterEditSet(hEdit, "Tag");
nError = AlarmFilterEditAppend(hEdit, "=");
nError = AlarmFilterEditAppend(hEdit, "Dig*");
nError = AlarmFilterEditCommit(hEdit);
sRet = AlarmFilterEditFirst(iHndl); // Tag=Dig*;
```

## Related Functions

[AlarmFilterEditSet](#)

## See Also

[Alarm Filter Functions](#)

### AlarmFilterEditAppendEquipment

Appends the provided expression that can include equipment names to the current filter session content without validation.

## Syntax

**INT AlarmFilterEditAppendEquipment(INT *hSession*, STRING *EquipmentFilter*, STRING *Ref*)**

*hSession*:

Session handle for the historical list previously returned by the function [AlarmFilterEditOpen](#).

*EquipmentFilter*:

A comma-separated list of equipment names to filter alarms prior to applying the other filter specified on the FilterCriteria argument. This field has been extended to support wildcards, and hence accept partial filter strings.

Expression has been extended to allow:

"EQUIPMENT=XYZ" (this may have an asterisk as the last character, this is interpreted as a wildcard)

What this means is:

- "XYZ" becomes "EQUIPMENT=XYZ\*"
- "EQUIPMENT=XYZ" stays as "EQUIPMENT=XYZ"

---

**Note:** Filters that take the form "XYZ" should no longer be used. It is recommended you use the "EQUIPMENT=XYZ" form, further "XYZ" can now be expressed as "EQUIPMENT=XYZ,EQUIPMENT=XYZ.\*" as this will include all items on the "XYZ" equipment and all items on sub-equipment of the "XYZ" equipment.

*Ref*:

0 - Do not include alarms belonging to referenced equipment in Filter

1 - Include alarms belonging to referenced equipment in Filter

## Return Value

0 (zero) if the alarm filter session exists, otherwise an error code is returned.

## Example

```
// This example shows how to update an edit session.  
// This example requires that the edit session hEdit exists.  
// This example assumes that the ExampleEquipment has references to  
// RefEquipment.RefItem1 and RefEquipment.RefItem2.  
INT nError;  
nError = AlarmFilterEditSet(hEdit, "");  
nError = AlarmFilterEditAppendEquipment(hEdit, "EQUIPMENT=ExampleEquipment", 1);  
nError = AlarmFilterEditCommit(hEdit);  
sRet = AlarmFilterEditFirst(hEdit); // "((Cluster=Cluster1 AND Equipment=ExampleEquipment)  
OR (Cluster=Cluster1 AND Equipment=RefEquipment AND  
(ITEM=RefItem1 OR ITEM=RefItem2))"
```

## Related Functions

[AlarmFilterEditSet](#)

## See Also

[Alarm Filter Functions](#)

## AlarmFilterEditClose

The AlmFilterEditClose function removes the session from the memory. The filter is not reset and is valid until a new filter is created and applied.

## Syntax

INT **AlarmFilterEditClose**(INT *hSession*)

*Session*

Session handle for the historical list previously returned by the function [AlarmFilterEditOpen](#).

## Return Value

0 (zero) if the alarm filter session exists, otherwise an error code is returned.

## Example

```
iHndl = AlarmFilterEditOpen(iAN);  
iRet = AlarmFilterEditSet(iHndl, "Tag=Dig*;Category=1;Area=1;");  
iRet = AlarmFilterEditAppend(iHndl, "Priority<20");  
sRet = AlarmFilterEditFirst(iHndl); // Tag=Dig*;  
sRet = AlarmFilterEditNext(iHndl); // Category=1;  
sRet = AlarmFilterEditLast(iHndl); // Priority<20;  
sRet = AlarmFilterEditPrev(iHndl); // Area=1;  
iRet = AlarmFilterEditClose(iHndl);
```

## Related Functions

[AlarmFilterEditOpen](#)

[Alarm Filter Functions](#)

### AlarmFilterEditCommit

The AlarmFilterEditCommit function takes a session handle as parameter. It validate the filter created in this session and, if valid, applies this filter to the list associated with the session.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**INT AlarmFilterEditCommit(INT *hSession*)**

*hSession*:

Session handle for the historical list previously returned by the function [AlarmFilterEditOpen](#).

## Return Value

0 (zero) if the alarm filter session exists, otherwise an error code is returned.

## Example

```
// This example requires that the edit session hEdit exists.  
INT nError;  
nError = AlarmFilterEditSet(hEdit,"tag=Dig*;Category=1;");  
nError = AlarmFilterEditCommit(hEdit);
```

## Related Functions

[AlarmFilterEditSet](#), [AlarmFilterEditAppend](#)

## See Also

[Alarm Filter Functions](#)

### AlarmFilterEditFirst

This function takes a session handle parameter. It gets the first part of the filter. Each part is either:

- A filter expression delimited with ";"
- A partial filter expression truncated at 254 character (if no ";" found before)

## Syntax

```
STRING AlarmFilterEditFirst(INT hSession)
```

*hSession*

Session handle for the historical list previously returned by the function [AlarmFilterEditOpen](#).

## Return Value

First part of filter or if does not exist an empty string "".

## Example

```
iHndl = AlarmFilterEditOpen(iAN);
iRet = AlarmFilterEditSet(iHndl,"Tag=Dig*;Category=1;Area=1;");
iRet = AlarmFilterEditAppend(iHndl, "Priority<20");
sRet = AlarmFilterEditFirst(iHndl); // Tag=Dig*;
sRet = AlarmFilterEditNext(iHndl); // Category=1;
sRet = AlarmFilterEditLast(iHndl); // Priority<20;
sRet = AlarmFilterEditPrev(iHndl); // Area=1;
iRet = AlarmFilterEditClose(iHndl);
```

## Related Functions

[AlarmFilterEditNext](#), [AlarmFilterEditPrev](#)

## See Also

[Alarm Filter Functions](#)

## AlarmFilterEditLast

This function takes a session handle parameter. It gets the last part of the filter. Each part is either:

- A filter expression delimited with ";"
- A partial filter expression truncated at 254 character (if no ";" found before).

## Syntax

```
STRING AlarmFilterEditLast(hSession)
```

*hSession*

Session handle for the historical list previously returned by the function [AlarmFilterEditOpen](#).

## Return Value

First part of filter or if does not exist an empty string "".

## Example

```
iHndl = AlarmFilterEditOpen(iAN);
iRet = AlarmFilterEditSet(iHndl,"Tag=Dig*;Category=1;Area=1;");
iRet = AlarmFilterEditAppend(iHndl, "Priority<20");
sRet = AlarmFilterEditFirst(iHndl); // Tag=Dig*;
sRet = AlarmFilterEditNext(iHndl); // Category=1;
sRet = AlarmFilterEditLast(iHndl); // Priority<20;
sRet = AlarmFilterEditPrev(iHndl); // Area=1;
iRet = AlarmFilterEditClose(iHndl);
```

## Related Functions

[AlarmFilterEditPrev](#)

## See Also

[Alarm Filter Functions](#)

### AlarmFilterEditNext

This function takes a session handle parameter. It gets the next part of the filter. Each part is either:

- A filter expression delimited with ";"
- A partial filter expression truncated at 254 character (if no ";" found before)

## Syntax

**INT AlarmFilterEditNext(INT *hSession*)**

*hSession*:

Session handle for the historical list previously returned by the function [AlarmFilterEditOpen](#).

## Return Value

Next part of filter or if does not exist an empty string "".

## Example

```
iHndl = AlarmFilterEditOpen(iAN);
iRet = AlarmFilterEditSet(iHndl,"Tag=Dig*;Category=1;Area=1;");
iRet = AlarmFilterEditAppend(iHndl, "Priority<20");
sRet = AlarmFilterEditFirst(iHndl); // Tag=Dig*;
sRet = AlarmFilterEditNext(iHndl); // Category=1;
sRet = AlarmFilterEditLast(iHndl); // Priority<20;
sRet = AlarmFilterEditPrev(iHndl); // Area=1;
iRet = AlarmFilterEditClose(iHndl);
```

## Related Functions

[AlarmFilterEditFirst](#), [AlarmFilterEditPrev](#)

## See Also

[Alarm Filter Functions](#)

### AlarmFilterEditOpen

The AlmFilterEditOpen function creates a session for the historical list (or lists) associated with the provided animation number (AN) or FilterName or all alarm lists displayed on the page via (-1) option. This session is initialised with the current filter applied on the lists.

It returns a session handle which will be used as parameter in all other functions to reference the session or -1 if the parameter is not a valid animation number or if this animation number is not linked to an historical list.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

INT **AlarmFilterEditOpen**(STRING *FilterName* or INT *AN* or INT -1 [, INT *AutoCloseMode*])

*FilterName*

Name of Filter

*AN*

Animation Number, for example 21 or 11

-1

Change the display parameters of all alarm lists displayed on the page

*AutoCloseMode*

Values for AutoCloseMode are bit flags.

The values for the bits are:

- 0 bit - Will not automatically close filter. Use [AlarmFilterEditClose](#).
- 1 bit - When set, the named filter will be closed when the page is changed or otherwise closed.

---

**Note:** All other modes are reserved.

---

## Return Value

Returns a session handle to the filter browse session. Returns -1 when an error is detected.

## Example

```
iHndl = AlarmFilterEditOpen(iAN);
iRet = AlarmFilterEditSet(iHndl,"Tag=Dig*;Category=1;Area=1;");
iRet = AlarmFilterEditAppend(iHndl, "Priority<20");
sRet = AlarmFilterEditFirst(iHndl); // Tag=Dig*;
```

```
sRet = AlarmFilterEditNext(iHndl); // Category=1;
sRet = AlarmFilterEditLast(iHndl); // Priority<20;
sRet = AlarmFilterEditPrev(iHndl); // Area=1;
iRet = AlarmFilterEditClose(iHndl);
```

## Related Functions

[AlarmFilterEditClose](#)

## See Also

[Alarm Filter Functions](#)

### AlarmFilterEditPrev

This function takes a session handle parameter. It gets the previous part of the filter. Each part is either:

- A filter expression delimited with ";"
- A partial filter expression truncated at 254 character (if no ";" found before)

## Syntax

```
STRING AlarmFilterEditPrev(INT hSession)
```

*hSession:*

Session handle for the historical list previously returned by the function [AlarmFilterEditOpen](#).

## Return Value

Previous part of filter or if does not exist an empty string "".

## Example

```
iHndl = AlarmFilterEditOpen(iAN);
iRet = AlarmFilterEditSet(iHndl, "Tag=Dig*;Category=1;Area=1;");
iRet = AlarmFilterEditAppend(iHndl, "Priority<20");
sRet = AlarmFilterEditFirst(iHndl); // Tag=Dig*;
sRet = AlarmFilterEditNext(iHndl); // Category=1;
sRet = AlarmFilterEditLast(iHndl); // Priority<20;
sRet = AlarmFilterEditPrev(iHndl); // Area=1;
iRet = AlarmFilterEditClose(iHndl);
```

## Related Functions

[AlarmFilterEditFirst](#), [AlarmFilterEditNext](#), [AlarmFilterEditLast](#)

## See Also

[Alarm Filter Functions](#)

### AlarmFilterEditSet

The AlarmFilterEditSet function takes a session handle and a filter expression as parameters. It replaces the current filter session content by the provided expression without any validation. This does not apply to all filters on the list (see [AlarmFilterEditCommit](#)).

## Syntax

**INT AlarmFilterEditSet(INT *hSession*, STRING *FilterCriteria*)**

*hSession*:

Session handle for the historical list previously returned by the function [AlarmFilterEditOpen](#).

*FilterCriteria*:

Filter expression as a string. For example:"(Tag=A) OR (TAG=B)"

See the topic [Implementing Alarm Filters Using Cicode](#) for more information about filter syntax.

Expression has been extended to allow:

- "REFCAT=XYZ" (this may have an asterisk as the first and/or last character, these are interpreted as wildcards)
- "PAGE=XYZ" (this is an exact literal match only)

What this means is:

- "PAGE=PageXYZ" becomes "EQUIPMENT=..." that includes all the equipment that have "PageXYZ" in the PAGE field in the Equipment table
- "REFCAT=\*XYZ\*" becomes "EQUIPMENT=..." that includes all the equipment defined in the Equipment References table that matches the supplied pattern and the CATEGORY field in that table. This value MAY contain an asterisk as the first, and or the last character, but the content between any bounding asterisks is treated as literal including an asterisk.

---

**Note:** If a requested filter is too complex (for example, it contains too many conditions or too many nested brackets), the filter is cleared (no filter is used). The hardware alarm "Too many alarms in filters" is generated on the client components, and a tracelog error message is logged.

---

## Return Value

0 (zero) if the alarm filter session exists, otherwise an error code is returned.

## Example

```
iHndl = AlarmFilterEditOpen(iAN);
iRet = AlarmFilterEditSet(iHndl,"Tag=Dig*;Category=1;Area=1;");
iRet = AlarmFilterEditAppend(iHndl, "Priority<20");
sRet = AlarmFilterEditFirst(iHndl); // Tag=Dig*;
sRet = AlarmFilterEditNext(iHndl); // Category=1;
sRet = AlarmFilterEditLast(iHndl); // Priority<20;
sRet = AlarmFilterEditPrev(iHndl); // Area=1;
```

```
iRet = AlarmFilterEditClose(iHndl);
```

## Related Functions

## See Also

[Alarm Filter Functions](#)

### AlarmFilterEditHasField

The `AlarmFilterEditHasField` function checks whether an alarm field name or any field in a set of field names is used in the filter specified in an alarm filter edit session.

## Syntax

```
INT AlarmFilterEditHasField(INT hSession, STRING sFieldName)
```

*Session:*

Session handle for the historical list previously returned by the function [AlarmFilterEditOpen](#).

*sFieldName*

The alarm field name or names separated by comma (no space) to be checked if it is used in filter criteria.

## Return Value

1 (TRUE) if the filter criteria is valid and alarm field name is used, otherwise 0 (FALSE) is returned.

## Example

```
iHndl = AlarmFilterEditOpen(iAN);
iRet = AlarmFilterEditSet(iHndl, "Tag=Dig*;Category=1;Area=1");
iRet = AlarmFilterEditHasField(iHndl, "Tag"); // 1 as Tag field is used
iRet = AlarmFilterEditHasField(iHndl, "Desc"); // 0 as Desc field is not used
iRet = AlarmFilterEditSet(iHndl, "NewCar=Fantastic;");
iRet = AlarmFilterEditHasField(iHndl, "NewCar"); // 0 as filter criteria is invalid
```

## Related Functions

[AlarmFilterEditSet](#)

## See Also

[Alarm Filter Functions](#)

## AlarmFilterForm

Displays a form for specifying filtering criteria for either an alarm list or a named filter. This function uses the AlarmFilterEdit family of Cicode functions to set the filter.

**Note:** If the user passes in the Animation number of an alarm list as its FilterSrc argument, the filter set by this function will override the filter set by function [AlarmSetInfo](#) as both functions modify the internal filter associated with the alarm list.

## Syntax

```
INT AlarmFilterForm(INT nIndex, INT nMode = 0, INT nDebug = 0, STRING nFilterSrc = "-1")
```

*nIndex*

0 - Active Alarm form

1- Summary Alarm form

2 – Disabled alarms

3 – Sequence of events (SOE)

-1 – auto-detection, only works if argument sFilterSrc is AN of an alarm list

*nMode*

0 is for form having datetime as drop list and no shift interface;

1 is for form having datetime as droplets and shift interface;

2 is for form having datetime as field and no shift interface;

3 is for form having datetime as field and shift interface

*nDebug*

For debugging filter values; 1 will write filter parameters to file - filter.txt in the [run] folder

*nFilterSrc*

The source where the filter will be applied to. It can either be the Animation Number (AN) of an alarm list or the name of a filter created via the [AlarmFilterOpen](#) Cicode function. If it is not specified, it is defaulted to -1 which refers to all alarm lists on the current page.

## Return Value

1 if filter has been applied, 0 if filter has been cleared, or -1 if no change is made.

## Related Functions

[AlarmResetQuery](#), [AlarmFilterOpen](#)

**Note:** The Alarm Filter Help is available when using the Legacy Alarm Filter Form at Runtime.

## See Also

[Alarm Filter Functions](#)

## AlarmFilterOpen

This function creates a named filter. The filter is initialized with empty content (matches all alarms). If unable to open the named filter an error code is returned.

See the topic *About Named Filters* in the main Plant SCADA help for more information about filter syntax.

---

**Note:** If a requested filter is too complex (for example, it contains too many conditions or too many nested brackets), the filter is cleared (no filter is used). The hardware alarm "Too many alarms in filters" is generated on the client components, and a tracelog error message is logged.

---

## Syntax

```
INT AlarmFilterOpen(STRING FilterName, INT OpenMode [, INT AutoCloseMode])
```

*FilterName*

Name of the filter.

*OpenMode*

The values for *OpenMode* are:

0 - Open an existing named filter.

1- Create a new named filter.

2- Attempts to open an existing named filter. If the named filter does not exist, a new named filter is created.

*AutoCloseMode*

Values for *AutoCloseMode* are bit flags.

The values for the bits are:

- 0 bit - Will not automatically close filter. Use [AlarmFilterClose](#).

- 1 bit - When set, the named filter will be closed when the page is changed or otherwise closed.

---

**Note:** All other modes are reserved.

---

## Return Value

0 (zero) if the filter was opened or created or an error if unsuccessful.

## Example

```
// This example shows how to open and close the named filter "Myfilter"
// nothing of interest is done with the filter in this example.
INT nOpenModeOld = 0;
INT nOpenModeNew = 1;
INT nOpenModeAny = 2;
INT nCloseModeManual = 0;
INT nCloseModePageChanged = 1;
INT nError;
nError = AlarmFilterOpen("MyFilter", nOpenModeNew, nCloseModeManual);
IF nError = 0 THEN
nError = AlarmFilterClose("MyFilter");
END
```

## Related Functions

[AlarmFilterClose](#), [AlarmSetInfo](#)

## See Also

[Alarm Filter Functions](#)

### AlarmGetFilterName

Retrieves the name of the linked named filter for the supplied An. If empty text, there is currently no linked named filter.

## Syntax

STRING **AlarmGetFilterName**(INT *An*)

*An*

Animation number

## Return Value

Name of linked filter or " ".

## Example

```
// This example shows how to link, unlink and check the linking of a
// named filter to an alarm list (by its animation number)
// This example requires that the named filter "Myfilter" exists.
STRING sName;
INT nError;
INT nAnimationNumber=21;
INT nSetInfoFilterName=12;
nError = AlarmSetInfo(nAnimationNumber, nSetInfoFilterName, "MyFilter");
IF nError = 0 THEN
    sName = AlarmGetFilterName(nAnimationNumber); //MyFilter"
END
nError = AlarmSetInfo(nAnimationNumber, nSetInfoFilterName, "");
IF nError = 0 THEN
    sName = AlarmGetFilterName(nAnimationNumber); //"
END
```

## Related Functions

[AlarmFilterOpen](#)

## See Also

[Alarm Filter Functions](#)

### AlarmResetQuery

Clears the filter of the specified filter source. Used to reset the filter set up by the Cicode function [AlarmFilterForm](#). This function uses the AlarmFilterEdit family of Cicode functions, to reset the filter.

**Note:** If the user passes in the Animation number of an alarm list as its FitlerSrc argument, the filter set by this function will override the filter set by function [AlarmSetInfo](#) as both functions modify the internal filter associated with the alarm list.

## Syntax

**AlarmResetQuery(STRING FilterSrc)**

*FilterSrc*

The source where the filter will be applied to. It can either be the Animation Number (AN) of an alarm list or the name of a filter created via the [AlarmFilterOpen](#) Cicode function. If it is not specified, it is defaulted to -1 which refers to all alarm lists on the current page.

## Return Value

None

## Related Functions

[AlarmFilterForm](#)

**Note:** The Alarm Filter Help is available when using the Legacy Alarm Filter Form at Runtime.

## See Also

[Alarm Filter Functions](#)

### LibAlarmFilterForm

**Note:** This function is only available if the Lib\_Controls project is included in the user project.

Displays a generic alarm filter pop-up for specifying filtering criteria for either an alarm list or a named filter. This function uses the AlarmFilterEdit family of Cicode functions to set the filter.

**Note:** If the user passes in the Animation number of an alarm list as its FitlerSrc argument, the filter set by this function will override the filter set by function [AlarmSetInfo\(\)](#) as both functions modify the internal filter associated with the alarm list.

## Syntax

`INT LibAlarmFilterForm([INT FormType [, STRING FilterSrc [, STRING Title [, INT Mode [, STRING AppliedCallbackFn]]]]])`

### *FormType*

Type of alarm filter form:

-1 – (Default) auto detect if the FilterSrc is set to a valid alarm list AN

0 – active alarm

1 – alarm summary

2 – disabled alarms

3 – sequence of events (SOE)

### *sFilterSrc*

The source where the filter will be applied to. It can either be the Animation Number (AN) of an alarm list or the name of a filter created via the AlarmFilterOpen() Cicode function. If it is not specified, it is defaulted to -1 which refers to all alarm lists on the current page. If the FilterSrc cannot be opened, it will prompt the user to create the filter source.

### *sTitle*

The title for the filter form. If it is not specified or left blank, the title is determined by the form type:

0 – Active Alarm Filter

1 – Summary Alarm Filter

2 – Disabled Alarm Filter

3 – SOE Filter

Any other value – (<FilterSrc> - Alarm Filter)

### *nMode*

The mode of the form:

0 – (Default) Displays form in synchronous mode. The function waits for the user to close the form before returning. Under this mode, the "Apply" button is not shown on the form.

1 – Display form in asynchronous mode. The function does not wait for the user to close the form and returns immediately. Under this mode, the "Apply" button is shown on the form. Using this button, the user can apply filter to the alarm list(s) multiple times without closing the form.

### *sAppliedCallbackFn*

The callback function statement to be called when the criteria (rules) specified in the form is applied either via the OK or Apply buttons. Like other callback functions available to other library controls genie. The callback function supports keyword substitutions during callback:

#Filter - The FilterSrc specified when showing the form

#Result – The result of the filter application. See return value for details.

## Return Value

1 if filter has been applied, 0 if filter has been cleared, or -1 if no change is made.

## Related Functions

[AlarmResetQuery](#)

**Note:** The Alarm Filter Help is available when using the Legacy Alarm Filter Form at Runtime.

## Array Functions

Plant SCADA supports the following array functions:

<a href="#">ArrayCopy</a>	Makes a copy of an array.
<a href="#">ArrayCreate</a>	Creates an array.
<a href="#">ArrayCreateByAn</a>	Creates an array at a specified AN.
<a href="#">ArrayDestroy</a>	Destroys an array.
<a href="#">ArrayDestroyByAn</a>	Destroys an array associated with the specified AN.
<a href="#">ArrayExists</a>	Determines if an array with a specified handle exists.
<a href="#">ArrayExistsByAn</a>	Determines if an array associated with a specified AN exists.
<a href="#">ArrayFillFromAlarmDataByAn</a>	This function is used to fill an array with information from internal alarm record caches.
<a href="#">ArrayGetArrayByAn</a>	Retrieves an array associated with a specified AN.
<a href="#">ArrayGetInfo</a>	Retrieves the size of the x-, y-, or z-dimension for an array.
<a href="#">ArrayGetInt</a>	Retrieves an integer value from an array.
<a href="#">ArrayGetInt</a>	Retrieves an integer value from an array associated with a specified AN.
<a href="#">ArrayGetMapName</a>	Retrieves the name of the map associated with an array.
<a href="#">ArrayGetMapNameByAn</a>	Retrieves the name of the map for an array associated with a specified AN.
<a href="#">ArrayGetString</a>	Retrieves a string from an array.
<a href="#">ArrayGetStringByAn</a>	Retrieves a string from an array associated with a

	specified AN.
<a href="#">ArrayIsDirty</a>	Determines if an array is 'dirty' (information in the array has changed).
<a href="#">ArraySetInt</a>	Sets an integer value within an array.
<a href="#">ArraySetIntByAn</a>	Sets an integer value in an array associated with a specified AN.
<a href="#">ArraySetIsDirty</a>	Allows you to indicate that an array is dirty (meaning the information in the array has changed).
<a href="#">ArraySetString</a>	Sets a string value in an array.
<a href="#">ArraySetStringByAn</a>	Sets a string value in an array associated with a specified AN.
<a href="#">ArraySwap</a>	Swaps the contents of two arrays.
<a href="#">DspArrayByAn</a>	Displays an alarm list associated with a specified AN at the location of that AN.

## See Also

[Cicode Function Categories](#)

[Using Cicode Functions](#)

## ArrayCopy

Makes a copy of an array.

## Syntax

**INT ArrayCopy(INT hArray)**

*hArray:*

The handle of the array you want to copy.

## Return Value

The handle of the created copy. If unsuccessful, -1 is returned. The error code can be obtained by calling the IsError Cicode function.

## Related Functions

[ArraySetIntByAn](#), [ArraySetIsDirty](#), [ArraySetString](#), [ArraySetStringByAn](#), [ArraySwap](#), [DspArrayByAn](#)

## Example

```
...
hArray2 = ArrayCopy(hArray1);
...
```

## See Also

[Array Functions](#)

## ArrayCreate

Creates an array. An array can include up to 2,097,153 elements, but each dimension needs to have less than 32765.

A Plant SCADA project will only support up to 32765 arrays.

**Note:** Very large arrays may require a lot of memory. You need to calculate how much memory will be used by an array. For example, an array of 100 x 100 x 100 storing a 100 character string value in each cell will use approximately 100,000,000 bytes of memory.

## Syntax

**INT ArrayCreate(STRING sArrayName, INT x [, INT y [, INT z]])**

*sArrayName*:

The name of the array.

*x*:

The size of the array's x–dimension (from 1 to 32765).

*y*:

The size of the array's y–dimension (from 1 to 32765). This value is optional. If not specified, it defaults to 1.

*z*:

The size of the array's z–dimension (from 1 to 32765). This value is optional. If not specified, it defaults to 1.

## Return Value

The handle of the array. If unsuccessful, –1 is returned. The error code can be obtained by calling the IsError Cicode function.

**Note:** Any arrays that are created in custom Cicode should also be destroyed in custom Cicode, otherwise the program may eventually consume all available memory (see [ArrayDestroy](#)).

## Related Functions

[ArraySetIntByAn](#), [ArraySetIsDirty](#), [ArraySetString](#), [ArraySetStringByAn](#), [ArraySwap](#), [DspArrayByAn](#)

## Example

```
...  
  
hArray = ArrayCreate("TestArray", 128, 128, 128);  
err0 = IsError(); // error = 0 - number of elements 2,097,152  
  
hArray = ArrayCreate("TestArray", 129, 128, 128);  
err1 = IsError(); // error = 272 out of memory  
  
hArray = ArrayCreate("TestArray", 128, 128, 129);  
err2 = IsError(); // error = 272 out of memory  
  
hArray = ArrayCreate("TestArray", 32765, 1, 1);  
err3 = IsError(); // error = 0  
  
hArray = ArrayCreate("TestArray", 32765, 10, 5);  
err4 = IsError(); // error = 0 - number of elements 1,638,250  
  
hArray = ArrayCreate("TestArray", 32766, 1, 1);  
err5 = IsError(); // error = 257 - value is out of range  
  
hArray = ArrayCreate("TestArray", 1, 32766, 1);  
err6 = IsError(); // error = 257 - value is out of range  
  
hArray = ArrayCreate("TestArray", 1, 1, 32766);  
err7 = IsError(); // error = 257 - value is out of range  
  
hArray = ArrayCreate("TestArray", 32765);  
err8 = IsError(); // error = 0  
  
...
```

## See Also

[Array Functions](#)

### ArrayCreateByAn

Creates an array at a specified AN. An array can include up to 2,097,153 elements, but each dimension needs to have less than 32765.

A Plant SCADA project will only support up to 32765 arrays.

**Note:** Very large arrays may require a lot of memory. You need to calculate how much memory will be used by an array. For example, an array of 100 x 100 x 100 storing a 100 character string value in each cell will use approximately 100,000,000 bytes of memory.

## Syntax

```
INTArrayCreateByAn(INT nAN, INT x [, INT y [, INT z]])
```

*nAN*:

The AN number to associate with the array.

Elements in a Genie can access array cell values associated with a particular AN number without having the array handle. The Genie creates the array and associates it with the AN of one of the items in the Genie when it is initialized or the page is created. Other items in the Genie can then get or set values in that array. The List View Genie uses this 'ByAn' array feature.

*x*:

The size of the array's x–dimension (from 1 to 32765).

*y*:

The size of the array's y–dimension (from 1 to 32765). This value is optional. If not specified, it defaults to 1.

*z*:

The size of the array's z–dimension (from 1 to 32765). This value is optional. If not specified, it defaults to 1.

## Return Value

The handle of the array. If unsuccessful, –1 is returned. The error code can be obtained by calling the IsError Cicode function.

**Note:** Any arrays that are created in custom Cicode should also be destroyed in custom Cicode, otherwise the program may eventually consume all available memory (see [ArrayDestroyByAn](#)).

[ArraySetIntByAn](#), [ArraySetIsDirty](#), [ArraySetString](#), [ArraySetStringByAn](#), [ArraySwap](#), [DspArrayByAn](#)

## Example

```
...  
  
hArray = ArrayCreateByAn(hAn, 128, 128, 128);  
err0 = IsError(); // error = 0 - number of elements 2,097,152  
  
hArray = ArrayCreateByAn(hAn, 129, 128, 128);  
err1 = IsError(); // error = 272 out of memory  
  
hArray = ArrayCreateByAn(hAn, 128, 128, 129);  
err2 = IsError(); // error = 272 out of memory  
  
hArray = ArrayCreateByAn(hAn, 32765, 1, 1);  
err3 = IsError(); // error = 0  
  
hArray = ArrayCreateByAn(hAn, 32765, 10, 5);
```

```
err4 = IsError(); // error = 0 - number of elements 1,638,250

hArray = ArrayCreateByAn(hAn, 32766, 1, 1);
err5 = IsError(); // error = 257 - value is out of range

hArray = ArrayCreateByAn(hAn, 1, 32766, 1);
err6 = IsError(); // error = 257 - value is out of range

hArray = ArrayCreateByAn(hAn, 1, 1, 32766);
err7 = IsError(); // error = 257 - value is out of range

hArray = ArrayCreateByAn(hAn, 3, 3, 3);
err8 = IsError(); // error = 0

...
```

[ArraySetIntByAn](#), [ArraySetIsDirty](#), [ArraySetString](#), [ArraySetStringByAn](#), [ArraySwap](#), [DspArrayByAn](#)

### Example

```
error1 = ArrayDestroyByAn(nAn);
```

### See Also

[Array Functions](#)

## ArrayExists

Determines if an array with a specified handle exists.

### Syntax

**INT ArrayExists(INT hArray)**

*hArray:*

The handle of the array.

### Return Value

TRUE if the array exists. FALSE if the array does not exist.

## Related Functions

[ArrayCopy](#), [ArrayCreate](#), [ArrayCreateByAn](#), [ArrayDestroy](#), [ArrayDestroyByAn](#), [ArrayExistsByAn](#),  
[ArrayFillFromAlarmDataByAn](#), [ArrayGetArrayByAn](#), [ArrayGetInfo](#), [ArrayGetInt](#), [ArrayGetIntByAn](#),  
[ArrayGetMapName](#), [ArrayGetMapNameByAn](#), [ArrayGetString](#), [ArrayGetStringByAn](#), [ArrayIsDirty](#), [ArraySetInt](#),  
[ArraySetIntByAn](#), [ArraySetIsDirty](#), [ArraySetString](#), [ArraySetStringByAn](#), [ArraySwap](#), [DspArrayByAn](#)

## Example

```
...
IF (ArrayExists(hArray1)) THEN
    MapName = ArrayGetMapName(hArray1);
END
...
```

## See Also

[Array Functions](#)

## ArrayExistsByAn

Determines if an array associated with a specified AN exists.

## Syntax

INT **ArrayExistsByAn(INT nAN)**

*nAN:*

The AN associated with an array.

## Return Value

TRUE if the array exists. FALSE if the array does not exist.

## Related Functions

[ArrayCopy](#), [ArrayCreate](#), [ArrayCreateByAn](#), [ArrayDestroy](#), [ArrayDestroyByAn](#), [ArrayExists](#),  
[ArrayFillFromAlarmDataByAn](#), [ArrayGetArrayByAn](#), [ArrayGetInfo](#), [ArrayGetInt](#), [ArrayGetIntByAn](#),

### ArrayFillFromAlarmDataByAn

This function is used to fill an array with information from internal alarm record caches. It is used by alarm page Genies to obtain the alarm record information to be displayed on the page.

## Syntax

**INT ArrayFillFromAlarmDataByAn(INT *hAN*)**

*hAN*:

The AN number for the alarm list you want to use to fill the array.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[ArrayCopy](#), [ArrayCreate](#), [ArrayCreateByAn](#), [ArrayDestroy](#), [ArrayDestroyByAn](#), [ArrayExists](#), [ArrayExistsByAn](#),  
[ArrayGetArrayByAn](#), [ArrayGetInfo](#), [ArrayGetInt](#), [ArrayGetIntByAn](#), [ArrayGetMapName](#), [ArrayGetMapNameByAn](#),

[ArraySetStringByAn](#), [ArraySwap](#), [DspArrayByAn](#)

## Example

```
error1 = ArrayFillFromAlarmDataByAn(600);
```

## See Also

[Array Functions](#)

### ArrayGetArrayByAn

Retrieves an array associated with a specified AN.

## Syntax

**INT ArrayGetArrayByAn(INT *nAN*)**

*nAN*:

The AN number associated with the array that will be retrieved.

## Return Value

The handle of the array. If unsuccessful, -1 is returned. The error code can be obtained by calling the [IsError](#) Cicode function.

## Related Functions

[ArrayCopy](#), [ArrayCreate](#), [ArrayCreateByAn](#), [ArrayDestroy](#), [ArrayDestroyByAn](#), [ArrayExists](#), [ArrayExistsByAn](#), [ArrayFillFromAlarmDataByAn](#), [ArrayGetInfo](#), [ArrayGetInt](#), [ArrayGetIntByAn](#), [ArrayGetMapName](#), [ArrayGetMapNameByAn](#), [ArrayGetString](#), [ArrayGetStringByAn](#), [ArrayIsDirty](#), [ArraySetInt](#), [ArraySetIntByAn](#), [ArraySetIsDirty](#), [ArraySetString](#), [ArraySetStringByAn](#), [ArraySwap](#), [DspArrayByAn](#)

## Example

```
hArray = ArrayGetArrayByAn(hAn);
```

## See Also

[Array Functions](#)

## ArrayGetInfo

Retrieves the size of the x-, y-, or z-dimension for an array.

## Syntax

**INT ArrayGetInfo(INT hArray, INT nType)**

*hArray:*

The handle of the array.

*nType:*

0 = the array's x-dimension

1 = the array's y-dimension

2 = the array's z-dimension

## Return Value

The size of the x-, y-, or z-dimension, if successful. If unsuccessful, -1 is returned. The error code can be obtained by calling the [IsError](#) Cicode function.

## Related Functions

[ArrayCopy](#), [ArrayCreate](#), [ArrayCreateByAn](#), [ArrayDestroy](#), [ArrayDestroyByAn](#), [ArrayExists](#), [ArrayExistsByAn](#), [ArrayFillFromAlarmDataByAn](#), [ArrayGetArrayByAn](#), [ArrayGetInt](#), [ArrayGetIntByAn](#), [ArrayGetMapName](#), [ArrayGetMapNameByAn](#), [ArrayGetString](#), [ArrayGetStringByAn](#), [ArrayIsDirty](#), [ArraySetInt](#), [ArraySetIntByAn](#), [ArraySetIsDirty](#), [ArraySetString](#), [ArraySetStringByAn](#)

[ArraySetIsDirty](#), [ArraySetString](#), [ArraySetStringByAn](#), [ArraySwap](#), [DspArrayByAn](#)

## Example

```
...
hArray = ArrayCreate("TestArray", 3, 4, 5);
x=ArrayGetInfo(hArray,0); //x-dimension expected = 3
y=ArrayGetInfo(hArray,1); //y-dimension expected = 4
z=ArrayGetInfo(hArray,2); //z-dimension expected = 5
```

## See Also

[Array Functions](#)

## ArrayGetInt

Retrieves an integer value from an array.

## Syntax

**INT ArrayGetInt(INT *hArray*, INT *x* [, INT *y* [, INT *z*]])**

*hArray*:

The handle of the array.

*x*:

The index for the x–dimension.

*y*:

The index for the y–dimension.

*z*:

The index for the z–dimension.

## Return Value

The requested integer, if successful. If unsuccessful, the error code can be obtained by calling the [IsError](#) Cicode function.

## Related Functions

[ArrayCopy](#), [ArrayCreate](#), [ArrayCreateByAn](#), [ArrayDestroy](#), [ArrayDestroyByAn](#), [ArrayExists](#), [ArrayExistsByAn](#), [ArrayFillFromAlarmDataByAn](#), [ArrayGetArrayByAn](#), [ArrayGetInfo](#), [ArrayGetIntByAn](#), [ArrayGetMapName](#), [ArrayGetMapNameByAn](#), [ArrayGetString](#), [ArrayGetStringByAn](#), [ArrayIsDirty](#), [ArraySetInt](#), [ArraySetIntByAn](#), [ArraySetIsDirty](#), [ArraySetString](#), [ArraySetStringByAn](#), [ArraySwap](#), [DspArrayByAn](#)

## Example

```
...
```

```
// Set the integer value at Array(1,2,3) to be 444
ArraySetInt(hArray, 444, 1, 2, 3);
// Get the integer value at Array(1,2,3)
value = ArrayGetInt(hArray, 1, 2, 3);
// value = 444
...
```

## See Also

[Array Functions](#)

### ArrayGetIntByAn

Retrieves an integer value from an array associated with a specified AN.

## Syntax

```
INT ArrayGetIntByAn(INT nAN, INT x [, INT y [, INT z]])
```

*nAN*:

The AN number.

*x*:

The index for the x–dimension.

*y*:

The index for the y–dimension.

*z*:

The index for the z–dimension.

## Return Value

The requested integer, if successful. If unsuccessful, –1 is returned. The error code can be obtained by calling the [IsError](#) Cicode function.

## Related Functions

[ArrayCopy](#), [ArrayCreate](#), [ArrayCreateByAn](#), [ArrayDestroy](#), [ArrayDestroyByAn](#), [ArrayExists](#), [ArrayExistsByAn](#), [ArrayFillFromAlarmDataByAn](#), [ArrayGetArrayByAn](#), [ArrayGetInfo](#), [ArrayGetInt](#), [ArrayGetMapName](#), [ArrayGetMapNameByAn](#), [ArrayGetString](#), [ArrayGetStringByAn](#), [ArrayIsDirty](#), [ArraySetInt](#), [ArraySetIntByAn](#), [ArraySetIsDirty](#), [ArraySetString](#), [ArraySetStringByAn](#), [ArraySwap](#), [DspArrayByAn](#)

## Example

```
...
// Set the integer value at (1,2,3) of the array associated with hAn to be 444
ArraySetIntByAn(hAn, 444, 1, 2, 3);
// Get the integer value at (1,2,3) of the array associated with hAn
value = ArrayGetIntByAn(hAn, 1, 2, 3);
```

```
// value = 444
...
```

[Array Functions](#)

### ArrayGetMapName

Retrieves the name of the map associated with an array.

## Syntax

```
STRING ArrayGetMapName(INT hArray)
```

*hArray*:

The handle of the array.

## Return Value

If successful, the requested map name as a string. If unsuccessful, " " is returned. The error code can be obtained by calling the [IsError](#) Cicode function.

## Related Functions

[ArrayCopy](#), [ArrayCreate](#), [ArrayCreateByAn](#), [ArrayDestroy](#), [ArrayDestroyByAn](#), [ArrayExists](#), [ArrayExistsByAn](#),

[ArraySetIsDirty](#), [ArraySetString](#), [ArraySetStringByAn](#), [ArraySwap](#), [DspArrayByAn](#)

## Example

```
MapName = ArrayGetMapName(hArray1);
```

## See Also

[Array Functions](#)

### ArrayGetMapNameByAn

Retrieves the name of the map for an array associated with a specified AN.

## Syntax

```
STRING ArrayGetMapNameByAn(INT nAN)
```

*nAN*:

The AN associated with the array.

## Return Value

If successful, the requested map name as a string. If unsuccessful, " " is returned. The error code can be obtained by calling the [IsError](#) Cicode function.

## Related Functions

[ArrayCopy](#), [ArrayCreate](#), [ArrayCreateByAn](#), [ArrayDestroy](#), [ArrayDestroyByAn](#), [ArrayExists](#), [ArrayExistsByAn](#),  
[ArrayFillFromAlarmDataByAn](#), [ArrayGetArrayByAn](#), [ArrayGetInfo](#), [ArrayGetInt](#), [ArrayGetIntByAn](#), [ArrayGetString](#),  
[ArrayGetStringByAn](#), [ArrayIsDirty](#), [ArraySetInt](#), [ArraySetIntByAn](#), [ArraySetIsDirty](#), [ArraySetString](#),  
[ArraySetStringByAn](#), [ArraySwap](#), [DspArrayByAn](#)

## Example

```
MapName = ArrayGetMapNameByAn(hAn);
```

## See Also

[Array Functions](#)

## ArrayGetString

Retrieves a string from an array.

## Syntax

```
STRING ArrayGetString(INT hArray, INT x [, INT y [, INT z]])
```

*hArray*:

The handle of the array.

*x*:

The index for the x-dimension.

*y*:

The index for the y-dimension.

*z*:

The index for the z-dimension.

## Return Value

The requested string, if successful. If unsuccessful, " " is returned. The error code can be obtained by calling the [IsError](#) Cicode function.

## Related Functions

[ArrayCopy](#), [ArrayCreate](#), [ArrayCreateByAn](#), [ArrayDestroy](#), [ArrayDestroyByAn](#), [ArrayExists](#), [ArrayExistsByAn](#),

[ArrayIsDirty](#), [ArraySetString](#), [ArrayGetStringByAn](#), [ArraySwap](#), [DspArrayByAn](#)

## Example

```
// Set the string value at Array(1,2,3) to be "abc"  
ArraySetString(hArray, "abc", 1, 2, 3);  
// Get the integer value at Array(1,2,3)  
value = ArrayGetString(hArray, 1, 2, 3);  
// value = "abc"  
...
```

## See Also

[Array Functions](#)

## ArrayGetStringByAn

Retrieves a string value from an array associated with a specified AN.

## Syntax

STRING **ArrayGetStringByAn**(INT *nAN*, INT *x* [, INT *y* [, INT *z*]])

*nAN*:

The AN associated with array.

*x*:

The index for the x–dimension.

*y*:

The index for the y–dimension.

*z*:

The index for the z–dimension.

## Return Value

The requested string, otherwise an error is returned.

## Related Functions

[ArrayGetMapName](#), [ArrayGetMapNameByAn](#), [ArrayGetString](#), [ArrayIsDirty](#), [ArraySetInt](#), [ArraySetIntByAn](#),

[ArraySetIsDirty](#), [ArraySetString](#), [ArraySetStringByAn](#), [ArraySwap](#), [DspArrayByAn](#)

## Example

```
// Set the integer value at (1,2,3) of the array associated with hAn to be "abc"
ArraySetStringByAn(hAn, "abc", 1, 2, 3);
// Get the integer value at (1,2,3) of the array associated with hAn
value = ArrayGetStringByAn(hAn, 1, 2, 3);
// value = "abc"
...
```

## See Also

[Array Functions](#)

## ArrayIsDirty

Determines if an array is ‘dirty’ (information in the array has changed). When any array element is changed, the ‘Dirty’ flag of the array is set to be TRUE.

## Syntax

**INT ArrayIsDirty(INT hArray)**

*hArray:*

The handle of the array.

## Return Value

1 if true (is dirty), or 0 if false (is not dirty). An error is not returned by this function.

## Related Functions

[ArrayCopy](#), [ArrayCreate](#), [ArrayCreateByAn](#), [ArrayDestroy](#), [ArrayDestroyByAn](#), [ArrayExists](#), [ArrayExistsByAn](#),  
[ArrayFillFromAlarmDataByAn](#), [ArrayGetArrayByAn](#), [ArrayGetInfo](#), [ArrayGetInt](#), [ArrayGetIntByAn](#),  
[ArrayGetMapName](#), [ArrayGetMapNameByAn](#), [ArrayGetString](#), [ArrayGetStringByAn](#), [ArraySetInt](#),  
[ArraySetIntByAn](#), [ArraySetIsDirty](#), [ArraySetString](#), [ArraySetStringByAn](#), [ArraySwap](#), [DspArrayByAn](#)

## Example

```
hArray = ArrayCreate("TestArray", 3, 3, 3);
error1 = ArraySetIsDirty(hArray, 0); // reset is dirty
intig1 = ArrayIsDirty(hArray); // intig1 = 0 -> reset
ArraySetInt(hArray, 444, 1, 2, 3); // Change a value
intig1 = ArrayIsDirty(hArray) ; // intig1 = 1 -> set
```

## See Also

[Array Functions](#)

### ArraySetInt

Sets an integer value within an array.

## Syntax

**INTArraySetInt(INT hArray, INT nValue, INT x [, INT y [, INT z]])**

*hArray:*

The handle of the array.

*nValue:*

The value you would like to set.

*x:*

The index for the x–dimension.

*y:*

The index for the y–dimension.

*z:*

The index for the z–dimension.

## Return Value

If unsuccessful, an error code will be returned by the [IsError](#) Cicode function.

## Related Functions

[ArrayCopy](#), [ArrayCreate](#), [ArrayCreateByAn](#), [ArrayDestroy](#), [ArrayDestroyByAn](#), [ArrayExists](#), [ArrayExistsByAn](#),

[ArraySetIntByAn](#), [ArraySetIsDirty](#), [ArraySetString](#), [ArraySetStringByAn](#), [ArraySwap](#), [DspArrayByAn](#)

## Example

```
...
error1= ArraySetInt(hArray, IntToStr(i), 0, 0, 0);
value1= ArrayGetInt(hArray, 0, 0, 0);
...
```

## See Also

[Array Functions](#)

## ArraySetIntByAn

Sets an integer value in an array associated with a specified AN.

## Syntax

**INTArraySetIntByAn(INT *nAN*, INT *nValue*, INT *x* [, INT *y* [, INT *z*]])**

*nAN*:

The AN associated with the array.

*nValue*:

The value you would like to set.

*x*:

The index for the x–dimension.

*y*:

The index for the y–dimension.

*z*:

The index for the z–dimension.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[ArrayCopy](#), [ArrayCreate](#), [ArrayCreateByAn](#), [ArrayDestroy](#), [ArrayDestroyByAn](#), [ArrayExists](#), [ArrayExistsByAn](#),

[ArraySetIsDirty](#), [ArraySetString](#), [ArraySetStringByAn](#), [ArraySwap](#), [DspArrayByAn](#)

## Example

```
...
// Set the integer value at (1,2,3) of the array associated with hAn to be 444
ArraySetIntByAn(hAn, 444, 1, 2, 3);
// Get the integer value at (1,2,3) of the array associated with hAn
value = ArrayGetIntByAn(hAn, 1, 2, 3);
// value = 444
...
```

## See Also

[Array Functions](#)

## ArraySetIsDirty

Allows you to indicate that an array is dirty (meaning the information in the array has changed), or not dirty (the information in the array has not been changed).

## Syntax

**ArraySetIsDirty(INT hArray, INT IsDirty)**

*hArray*:

The handle of the array.

*IsDirty*:

0= False

1 = True

## Return Value

If unsuccessful, an error code will be returned by the [IsError](#) Cicode function.

## Related Functions

[Array Functions](#)

## ArraySetString

Sets a string value in an array.

## Syntax

**INTArraySetString(INT hArray, STRING sValue, INT x [, INT y [, INT z]])**

*hArray*:

The handle of the array.

*sValue*:

The string value you would like to set.

*x*:

The index for the x-dimension.

*y*:

The index for the y-dimension.

*z*:

The index for the z-dimension.

## Return Value

If unsuccessful, an error code will be returned by the [IsError](#) Cicode function.

## Related Functions

## ArraySetStringByAn

Sets a string value in an array associated with a specified AN.

## Syntax

**INTArraySetStringByAn(INT *nAN*, STRING *sValue*, INT *x* [, INT *y* [, INT *z*]])**

*nAN*:

The AN associated with the array.

*sValue*:

The string value you would like to set.

*x*:

The index for the x–dimension.

*y*:

The index for the y–dimension.

*z*:

The index for the z–dimension.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## ArraySwap

Swaps the contents of two arrays.

## Syntax

**INT ArraySwap(INT *hArray1*, INT *hArray2*)**

*hArray1*:

The handle of the array that you would like to swap with *hArray2*.

*hArray2*:

The handle of the array that you would like to swap with *hArray1*.

## Return Value

If unsuccessful, an error code will be returned by the [IsError](#) Cicode function.

## Related Functions

[Array Functions](#)

## DspArrayByAn

Displays an alarm list associated with a specified AN at the location of that AN. The array associated with the AN contains the alarm data. It is typically used as part of an alarm list or generic list Genie.

## Syntax

**INTDspArrayByAn(INT nAN)**

*nAN:*

The AN associated the array that contains alarm data.

## Return Value

0 (zero). If there is an error, the error code can be obtained by calling the [IsError](#) Cicode function.

## Related Functions

## Clipboard Functions

Following are functions relating to the Windows clipboard:

<a href="#">ClipCopy</a>	Copies a string to the Windows clipboard.
<a href="#">ClipPaste</a>	Pastes a string from the Windows clipboard.
<a href="#">ClipReadLn</a>	Reads a line of text from the Windows clipboard.
<a href="#">ClipSetMode</a>	Sets the format of data sent to the Windows clipboard.
<a href="#">ClipWriteLn</a>	Writes a line of text to the Windows clipboard.

## See Also

[Cicode Function Categories](#)

[Using Cicode Functions](#)

## ClipCopy

Copies a string to the Windows clipboard. When the string is in the clipboard, you can paste it to any Windows program.

## Syntax

**ClipCopy**(*sText*[, *bAppendNewLine*])

*sText*:

The string to copy to the clipboard.

*bAppendNewLine*:

Determines if new line characters (carriage return + line feed) are appended to text when it is added to the clipboard. You can set this argument to FALSE if you need to paste text into a field that does not accept these characters.

TRUE (default) = new line characters are included.

FALSE = new line characters are not included.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[ClipWriteLn](#)

## Example

```
ClipCopy("put this in clipboard");
```

See Also

[Clipboard Functions](#)

## ClipPaste

Pastes a string from the Windows clipboard.

## Syntax

**ClipPaste()**

## Return Value

The contents of the clipboard (as a string). If the clipboard is empty, an empty string is returned.

## Related Functions

[ClipReadLn](#), [ClipCopy](#)

## Example

```
/* Get string from clipboard into sText. */  
sText = ClipPaste();
```

See Also

[Clipboard Functions](#)

## ClipReadLn

Reads a single line of text from the Windows clipboard. With this function, you can read a block of text from the clipboard - line by line. Call the function once to read each line of text from the clipboard. When the end of the clipboard is reached, an empty string is returned.

## Syntax

**ClipReadLn()**

## Return Value

One line of text from the clipboard (as a string). If the clipboard is empty, an empty string is returned.

## Related Functions

[ClipPaste](#)

## Example

```
/* Get first line of text from clipboard. */  
sText = ClipReadLn();  
WHILE StrLength(sText) > 0 DO  
! Do something with text  
...  
! Read next line of clipboard  
sText = ClipReadLn();  
END
```

### See Also

[Clipboard Functions](#)

## ClipSetMode

Sets the format of data sent to the Windows clipboard.

## Syntax

**ClipSetMode(*nMode*)**

*nMode*:

The mode of the data:

1 - ASCII Text

2 - CSV (Comma separated values) format

You can select multiple modes by adding modes together.

## Return Value

The value of the previous mode.

## Related Functions

[ClipCopy](#), [ClipWriteLn](#)

## Example

```
/* Set the clipboard to CSV mode, write two values, and reset the
```

```
clipboard to the original mode. */
nOldMode = ClipSetMode(2);
ClipCopy("100,200");
ClipSetMode(nOldMode);
```

## ClipWriteLn

Writes a line of text to the Windows clipboard. With this function, you can write any amount of text to the clipboard. Call this function once for each line of text. To terminate the block of text, call this function and pass an empty string.

### Syntax

**ClipWriteLn(*sText*)**

*sText*:

The line of text to write to the clipboard, or an empty string (" ") to end the write operation.

### Return Value

0 (zero) if successful, otherwise an error code is returned.

### Related Functions

[ClipCopy](#)

### Example

```
ClipWriteLn("first line of text");
ClipWriteLn("second line of text");
ClipWriteLn(""); ! End of write operation
```

## Cluster Functions

Following are functions relating to clusters:

<a href="#">ClusterActivate</a>	Allows the user to activate an inactive cluster.
<a href="#">ClusterDeactivate</a>	Allows the user to deactivate an active cluster.
<a href="#">ClusterFirst</a>	Allows the user to retrieve the first configured cluster in the project.

<a href="#">ClusterGetName</a>	Deprecated in this version
<a href="#">ClusterIsActive</a>	Allows the user to determine if a cluster is active.
<a href="#">ClusterNext</a>	Allows the user to retrieve the next configured cluster in the project.
<a href="#">ClusterServerTypes</a>	Allows the user to determine which servers are defined for a given cluster.
<a href="#">ClusterSetName</a>	Deprecated in this version
<a href="#">ClusterStatus</a>	Allows the user to determine the connection status from the client to a server on a cluster.
<a href="#">ClusterSwapActive</a>	Allows the user to deactivate an active cluster at the same time as activating a deactive cluster.

## See Also

[Cicode Function Categories](#)

[Using Cicode Functions](#)

## ClusterActivate

This function allows the user to activate an inactive cluster. When a cluster is made active, all data associated with that cluster is available to the client, and hardware alarms will occur if no connections can be made to the servers in the cluster.

## Syntax

**ClusterActivate(*sClusterName*)**

*sClusterName*:

The name of the cluster to activate enclosed in quotation marks "".

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[ClusterDeactivate](#), [ClusterFirst](#), [ClusterIsActive](#), [ClusterNext](#), [ClusterServerTypes](#), [ClusterStatus](#), [ClusterSwapActive](#), [TaskCluster](#)

## See Also

[Cluster Functions](#)

### ClusterDeactivate

This function allows the user to deactivate an active cluster. When a cluster is made inactive, no data associated with that cluster is available to the client, and hardware alarms will not occur if no connections can be made to the servers in the cluster.

## Syntax

**ClusterDeactivate(*sClusterName*)**

*sClusterName*:

The name of the cluster to deactivate enclosed in quotation marks "".

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[ClusterActivate](#), [ClusterFirst](#), [ClusterIsActive](#), [ClusterNext](#), [ClusterServerTypes](#), [ClusterStatus](#), [ClusterSwapActive](#), [TaskCluster](#)

## See Also

[Cluster Functions](#)

### ClusterFirst

This function allows the user to retrieve the first configured cluster in the project.

## Syntax

**ClusterFirst()**

## Return Value

The name of the first configured cluster.

## Related Functions

[ClusterActivate](#), [ClusterDeactivate](#), [ClusterIsActive](#), [ClusterNext](#), [ClusterServerTypes](#), [ClusterStatus](#),

[ClusterSwapActive](#), [TaskCluster](#)

## See Also

[Cluster Functions](#)

### ClusterGetName

ClusterGetName is deprecated in this version of Plant SCADA.

## Syntax

**ClusterGetName(*sPrimary*, *sStandby*, *nMode*)**

*sPrimary*:

The name of the cluster's primary server (that is that which was set as sPrimary using the ClusterSetName() function). Must be a String type variable.

*sStandby*:

The name of the cluster's standby server (that is that which was set as sStandby using the ClusterSetName() function). Must be a String type variable.

*nMode*:

The mode is for future expansion of the function - set to 0 (zero).

## Return Value

The status of the get name.

## Related Functions

[ClusterSetName](#)

## Example

```
// Return and display the server names.//  
ClusterGetName(sPrimary, sStandby, 0);  
Prompt("Name of Cluster" + sPrimary);
```

## See Also

[Cluster Functions](#)

### ClusterIsActive

This function allows the user to determine if a cluster is active.

## Syntax

**ClusterIsActive(ClusterName)**

*sClusterName*:

The name of the cluster to query enclosed in quotation marks " ".

## Return Value

TRUE if active, FALSE otherwise. If the cluster name was invalid, this function will return FALSE and a hardware alarm will be generated.

## Related Functions

[ClusterActivate](#), [ClusterDeactivate](#), [ClusterFirst](#), [ClusterNext](#), [ClusterServerTypes](#), [ClusterStatus](#),  
[ClusterSwapActive](#), [TaskCluster](#)

## See Also

[Cluster Functions](#)

## ClusterNext

This function allows the user to retrieve the next configured cluster in the project.

## Syntax

**ClusterNext(ClusterName)**

*sClusterName*:

Any configured cluster name enclosed in quotation marks "", this will usually be the name of the previous cluster as returned from [ClusterFirst](#), or a previous call to ClusterNext.

## Return Value

The name of the next configured cluster or an empty string if there is no more clusters.

## Related Functions

[ClusterActivate](#), [ClusterDeactivate](#), [ClusterFirst](#), [ClusterIsActive](#), [ClusterServerTypes](#), [ClusterStatus](#),  
[ClusterSwapActive](#), [TaskCluster](#)

## See Also

[Cluster Functions](#)

## ClusterServerTypes

This function allows the user to determine which servers are defined for a given cluster.

## Syntax

**ClusterServerTypes(ClusterName)**

*sClusterName:*

The name of the cluster to query enclosed in quotation marks "".

## Return Value

Logical OR of the following server flags:

- 0001 - 1st bit set means an Alarm Server is configured
- 0010 - 2nd bit set means a Trend Server is configured
- 0100 - 3rd bit set means a Report Server is configured
- 1000 - 4th bit set means an IO Server is configured

For example, a return value of 14 indicates an I/O Server, a Report Server, and a Trend Server are configured.

## Related Functions

[ClusterActivate](#), [ClusterDeactivate](#), [ClusterFirst](#), [ClusterIsActive](#), [ClusterNext](#), [ClusterStatus](#), [ClusterSwapActive](#), [TaskCluster](#)

## See Also

[Cluster Functions](#)

## ClusterSetName

ClusterSetName is deprecated in this version of Plant SCADA.

## Syntax

**ClusterSetName(*sPrimary*, *sStandby*, *nMode*)**

*sPrimary:*

The name of the cluster's primary server (Reports Server, Alarms Server etc.), as defined using the Computer Setup Wizard. When the ClusterSetName() function is used, Plant SCADA will attempt to connect to this server.

*sStandby:*

The name of the cluster's standby server (Reports Server, Alarms Server etc.), as defined using the Computer Setup Wizard. If the *sPrimary* server is unavailable when the ClusterSetName() function is used, Plant SCADA will attempt to connect to this server.

If there is no standby server, enter an empty string for *sStandby*.

*nMode*:

The mode of the connection:

0 - If you select this mode, Plant SCADA will renew the last connection. If it was connected to the *sPrimary* server, when this function was last used, it will attempt to connect to it again. If it was last connected to the *sStandby* server, it will attempt to connect to it again. This mode is useful when a server is known to be unavailable, as it facilitates faster cluster switching.

1 - Plant SCADA will attempt to connect to the *sPrimary* server first, each time this function is used. If the *sPrimary* server is unavailable, Plant SCADA will try the *sStandby* server.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[ClusterGetName](#)

## Example

```
// Connect to Cluster A, with server CITECTA1 as primary server,  
and CITECTA2 as standby.//  
ClusterSetName("CITECTA1", "CITECTA2", 0);  
// Display the menu page for Cluster A Project.//  
PageDisplay("MenuA");
```

## See Also

[Cluster Functions](#)

## ClusterStatus

This function allows the user to determine the connection status from the client to a server on a cluster.

## Syntax

**ClusterStatus**(*clusterName*, *serverType*)

*clusterName*:

The name of the cluster to query enclosed in quotation marks "".

*serverType*:

The type of server (not a bit mask):

1 - Alarm Server

2 - Trend Server

4 - Report Server

## 8 - IO Server

### Return Value

One of the following values:

- -1 - if the cluster does not contain a server of the given type.
- -2 - if the cluster does not exist"
- 0 - if the cluster contains the server but the cluster is inactive.
- 1 - if the cluster is active but the connection to the server is offline.
- 2 - if the cluster is active and the connection to the server is online.

### Related Functions

[ClusterSwapActive](#), [TaskCluster](#)

### See Also

[Cluster Functions](#)

### ClusterSwapActive

This function allows the user to deactivate an active cluster at the same time as activating an inactive cluster. The arguments may be passed in any order, but one cluster needs to be active and the other needs to be inactive.

### Syntax

**ClusterSwapActive**(*clusterNameA*, *clusterNameB*)

*clusterNameA*:

The name of the cluster to activate or deactivate enclosed in quotation marks "".

*clusterNameB*:

The name of the cluster to activate or deactivate enclosed in quotation marks "".

### Return Value

0 (zero) if successful, otherwise an error code is returned.

### Related Functions

[ClusterActivate](#), [ClusterDeactivate](#), [ClusterFirst](#), [ClusterIsActive](#), [ClusterNext](#), [ClusterServerTypes](#), [ClusterStatus](#),  
[TaskCluster](#)

## Color Functions

Following are functions relating to colors:

<a href="#">CitectColourToPackedRGB</a>	Converts a Plant SCADA color into a packed RGB color value that can be used by an ActiveX object.
<a href="#">GetBlueValue</a>	Returns the Blue component of a packed RGB color.
<a href="#">GetGreenValue</a>	Returns the Green component of a packed RGB color.
<a href="#">GetRedValue</a>	Returns the Red component of a packed RGB color.
<a href="#">MakeColour</a>	Creates a color from red, green and blue component parts.
<a href="#">PackedRGB</a>	Returns a packed RGB color based on specified red, green, and blue values.
<a href="#">PackedRGBToCitectColour</a>	Converts a packed RGB color into the nearest equivalent Plant SCADA color.

## See Also

[Cicode Function Categories](#)

[Using Cicode Functions](#)

### CitectColourToPackedRGB

Converts a Plant SCADA color value into a packed RGB color value that can be understood by an ActiveX object.

## Syntax

**CitectColourToPackedRGB(*nCitectColor*)**

*nCitectColor*:

The Plant SCADA color value to be converted into a packed RGB color. Plant SCADA colors are defined in the labels database, or calculated by the function [MakeColour](#).

## Return Value

The packed RGB color value - if successful, otherwise an error code is returned.

## Related Functions

[PackedRGBToCitectColour](#)

## See Also

[Color Functions](#)

### GetBlueValue

Returns the blue component of a packed RGB color.

## Syntax

**GetBlueValue(*nPackedRGB*)**

*nPackedRGB*:

The packed RGB color.

## Return Value

The red value (0-255) - if successful, otherwise an error is returned.

## Related Functions

[GetRedValue](#), [GetGreenValue](#)

## See Also

[Color Functions](#)

### GetGreenValue

Returns the green component of a packed RGB color.

## Syntax

**GetGreenValue(*nPackedRGB*)**

*nPackedRGB*:

The packed RGB color.

## Return Value

The red value (0-255) - if successful, otherwise an error is returned.

## Related Functions

[GetRedValue](#), [GetBlueValue](#)

## See Also

[Color Functions](#)

### GetRedValue

Returns the red component of a packed RGB color.

## Syntax

**GetRedValue(*nPackedRGB*)**

*nPackedRGB*:

The packed RGB color.

## Return Value

The red value (0-255) - if successful, otherwise an error is returned.

## Related Functions

[GetGreenValue](#), [GetBlueValue](#)

## See Also

[Color Functions](#)

### MakeColour

Creates a color from red, green and blue component parts.

---

**Note:** To define a transparent color, use the label TRANSPARENT.

---

## Syntax

**MakeColour(*nRed*,*nGreen*,*nBlue*)**

*nRed*:

The color value for red, from 0-255

*nGreen*:

The color value for green, from 0-255

*nBlue*:

The color value for blue, from 0-255

## Return Value

An integer that is an encoded representation of the color created.

## Examples

```
! creates the color red
MakeColour(255,0,0)
! creates the color white
MakeColour(255,255,255)
```

**Note:** For backwards compatibility, you can refer to this function using the alias "MakeCitectColour".

## See Also

[Color Functions](#)

## PackedRGB

Returns a packed RGB color based on specified red, green, and blue values.

## Syntax

**PackedRGB(*nRed*, *nGreen*, *nBlue*)**

*nRed*:

The red component of the desired packed RGB color.

*nGreen*:

The green component of the desired packed RGB color.

*nBlue*:

The blue component of the desired packed RGB color.

## Return Value

The packed RGB color value - if successful, otherwise an error is returned.

## Related Functions

[CitectColourToPackedRGB](#)

## See Also

[Color Functions](#)

## PackedRGBToCitectColour

Converts a packed RGB color into a calculated Plant SCADA color value.

## Syntax

**PackedRGBToCitectColour(*nPackedRGB*)**

*nPackedRGB*:

The packed RGB color.

## Return Value

The Plant SCADA color value if successful; otherwise an error is returned.

## Related Functions

[CitectColourToPackedRGB](#)

## See Also

[Color Functions](#)

## Communication Functions

Following are functions relating to communications:

<a href="#">ComClose</a>	Closes a communication port.
<a href="#">ComOpen</a>	Opens a communication port for access.
<a href="#">ComRead</a>	Reads characters from a communication port.
<a href="#">ComReset</a>	Resets the communication port.
<a href="#">ComWrite</a>	Writes characters to a communication port.
<a href="#">SerialKey</a>	Redirects serial characters from a port to the keyboard.

## See Also

[Cicode Function Categories](#)

[Using Cicode Functions](#)

## ComClose

This function flags a port for close and reopen when the next ComOpen (Port mode 0) or driver open occurs. It does not actually close the port when called. Any Cicode tasks that are waiting for a read or write operation to complete (or that are retrying to read or write) return with a range error.

Plant SCADA automatically closes all communication ports at shutdown.

This function can only be called from an I/O server.

## Syntax

**ComClose(*hPort*)**

*hPort*:

The communication port handle, returned from the [ComOpen](#) function. This handle identifies the table where all data on the associated communication port is stored.

## Return Value

0 if the port is successfully closed, or an error if the port is already closed or if the port number is invalid.

## Related Functions

[ComOpen](#), [ComRead](#), [ComWrite](#)

## Example

See [ComOpen](#).

## See Also

[Communication Functions](#)

## ComOpen

Opens a communication port for access. The board and port need to both be defined in the database (using the Boards and Ports settings).

If you try to open the same COM port twice with [ComOpen](#), the second open will not succeed and return -1. If this is passed without checking other Com functions, the COM port may not do anything. For this reason, do not open COM ports twice, and always check the return value from ComOpen.

The communication system should be used for low speed communications only. You should not use the communication functions to communicate with high speed PLCs - the performance may not be adequate.

It is highly recommended that you only use ComOpen in the context where no existing driver is using the same port.

For slower connections where latency might exist, it is recommended that a sleep is configured after ComOpen(). This delay will ensure that ComRead or ComWrite do not execute before the device is connected. The sleep

should be twice as long as the time it takes for communication to reach its destination and return (for example, ping time for TCPIP ports). For local serial ports, a sleep will not be needed.

This function can only be called from an I/O server.

## Syntax

**ComOpen(*sPort*, *nMode*)**

*sPort*:

The port name as specified in the Ports database.

*nMode*:

The mode of the open:

0 - Take control of the port from Plant SCADA. In this non-shared mode, you have complete access to the port - Plant SCADA cannot use the port. Communication will be restored when the port is closed. In this mode, fresh port opens will occur each call.

1 - Share the port with Plant SCADA. In this mode, you can write to the port, and Plant SCADA can also use it. Please be aware that ComRead will be unreliable if the communication port is opened as shared. In this mode, if the port is found to be connected, a reconnect does not occur. If not connected, then the port is connected.

It is recommended that mode 1 be used where possible.

## Return Value

A communication port handle if the communication system is opened successfully, otherwise -1 is returned. The handle identifies the table where all data on the associated port is stored. You can use the handle in the other communication functions, to send and receive characters from the port.

## Related Functions

[ComClose](#), [ComRead](#), [ComWrite](#)

## Example

```
INT
FUNCTION
StartSerial(STRING sPort)
    INT hPort;
    hPort = ComOpen(sPort, 0);
    IF hPort < 0 THEN
        Prompt("Cannot open port " + sPort);
        RETURN -1;
    END
    TaskNew("SerialRead", hPort, 0);
    TaskNew("SerialWrite", hPort, 0);
    ComClose(hPort);
    RETURN 0;
END
INT
FUNCTION
```

```
SerialWrite(INT hPort)
    STRING buffer;
    INT SerialWriteError;
    INT length;
    INT error;
    WHILE 1 DO
        ! put data into buffer and set length
        .
        .
        ErrSet(1);
        SerialWriteError = ComWrite(hPort, buffer, length, 1);
        error = IsError() // if 7 then a timeout occurred
        IF SerialWriteError THEN
            Prompt("Error Writing port");
            ComReset(hPort);
        END
    END
    RETURN 0;
END
INT
FUNCTION
SerialRead(INT hPort)
    STRING buffer;
    INT length;
    INT total;
    INT SerialReadError;
    total = 0;
    WHILE 1 DO
        length = 128; ! need to set length as read modifies
        SerialReadError = ComRead(hPort, buffer, length, 1);
        IF SerialReadError THEN
            // Only flag error if data expected
            Prompt("Error from port " + SerialReadError : #####);
            ComReset(hPort);
        ELSE
            ! get data from buffer, length is set to number read
            .
            .
        END
    END
    RETURN 0;
END
```

## See Also

[Communication Functions](#)

## ComRead

Reads characters from a communication port. The characters are read from the communication port into a string buffer. If no characters have arrived after the specified timeout, the function returns with a timeout error. If the timeout is 0, the function gets any characters that have arrived from the last call, and returns immediately.

You use the *iLength* variable to specify the length of the buffer, or the maximum number of characters to read

when ComRead is called. When ComRead returns, *iLength* is set to the actual number of characters read. Because *iLength* is modified by this function, you need to reset it before each call.

You should not treat the string buffer as a normal string - it has no string terminator. Use the StrGetChar function to extract characters from the buffer.

ComRead should not be used if the port is in use by an existing driver.

For high speed transports like TCPIP, it is recommended that timeout be set to 0.

It is strongly recommended not to call ComRead while another ComRead is still pending on the same port, because it can produce unexpected results.

## **WARNING**

### **UNINTENDED EQUIPMENT OPERATION**

Do not call ComRead() if another instance of ComRead() is still pending on the same port.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

This function is a blocking function. It blocks the calling Cicode task until the operation is complete. This function can only be called from an I/O Server.

## Syntax

**ComRead(*hPort*, *sBuffer*, *iLength*, *iTimeOut*)**

*hPort*:

The communication port handle, returned from the ComOpen() function. This handle identifies the table where the data on the associated communication port is stored.

*sBuffer*:

The buffer into which to put the characters. The actual number of characters read is returned in *iLength*. Must be a String type variable.

*iLength*:

The number of characters to read into the buffer. The maximum length you may read in one call is 128 characters. When the function returns, this variable is set to the actual number of characters read. Must be a Long type variable.

*iTimeOut*:

The timeout for the read to complete in seconds:

- If *iTimeOut* = 0 (zero), the function checks for characters in the buffer and returns.
- If *iTimeOut* > 0, the function returns after this number of seconds in Port mode 0 (and sets error 7 which is the task timeout code), or as soon as bytes are read in Port mode 1. In mode 1 if the read occurred before the timeout, there will be no error.
- If *iTimeOut* < 0, the function waits forever for characters.

## Return Value

0 (zero) if the read is successful, otherwise an error code is returned.

## Related Functions

[ComOpen](#), [ComClose](#), [ComWrite](#), [StrGetChar](#)

## Example

See [ComOpen](#).

### See Also

[Communication Functions](#)

## ComReset

Resets the communication port. This function can only be called from an I/O Server.

## Syntax

**ComReset(*hPort*)**

*hPort*:

The communication port handle, returned from the [ComOpen](#) function. This handle identifies the table where all data on the associated communication port is stored.

## Return Value

0 (zero) if the write is successful, otherwise an error code is returned.

## Related Functions

[ComOpen](#), [ComClose](#), [ComRead](#), [StrGetChar](#)

## Example

See [ComOpen](#).

### See Also

[Communication Functions](#)

## ComWrite

Writes characters to a communication port. The characters are written from the string buffer to the port. If the characters have not been transmitted after the specified timeout, the function returns with a timeout error. If the timeout is 0, the function returns immediately and the characters are transmitted in the background.

ComWrite does not treat the buffer as a true string, but rather as an array of characters of the length specified - you can send any character to the communication port. Use the StrSetChar function to build the buffer. Do not

call ComWrite while another ComWrite is still pending on the same port, because it can produce unexpected results.

You use the *iLength* variable to specify the length of the buffer, or the maximum number of characters to write when ComWrite is called. When ComWrite returns, *iLength* is reset to zero.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

It is highly recommended that you only use ComWrite in the context where no existing driver is using the same port.

For high speed transports like TCPIP, it is recommended that timeout be set to 0.

This function can only be called from an I/O server.

## Syntax

**ComWrite(*hPort*, *sBuffer*, *iLength*, *iTimeOut*)**

*hPort*:

The communication port handle, returned from the ComOpen() function. This handle identifies the table where all data on the associated communication port is stored.

*sBuffer*:

The buffer from which to write the characters. Must be a String type variable.

*iLength*:

The number of characters to write from the buffer. The maximum number of characters you can write is 128. Must be a Long type variable.

*iTimeOut*:

The timeout for the write to complete in seconds.

- If *iTimeOut* = 0 (zero), the characters are copied to the communication buffer and the function returns immediately - the characters are transmitted in the background.
- If *iTimeOut* > 0, the function returns after this number of seconds in Port mode 0 (and sets error 7 which is the task timeout code), or as soon as the write occurs in Port mode 1. In mode 1 if the write occurred, there will be no error.
- If *iTimeOut* < 0, the function waits forever to transmit the characters.

## Return Value

0 (zero) if the write is successful, otherwise an error code is returned.

## Related Functions

[ComOpen](#), [ComClose](#), [ComRead](#), [StrGetChar](#)

## Example

See [ComOpen](#).

## See Also

[Communication Functions](#)

### SerialKey

Redirects all serial characters from a port to the keyboard. If using a keyboard attached to a serial port, you should call this function at startup, so that Plant SCADA copies all characters (read from the port) to the keyboard. The Port needs to be defined in the Ports database.

If the port is not on an I/O server, you need to create a dummy I/O server record (for example, name the server DServer1). Complete the Boards and Ports records. Set the following parameters in the CITECT.INI file:

[IOServer]Name to the server name (for example, DServer1)  
[IOServer]Server to 0

This method enables the port without making the computer an I/O server. (If the I/O server is enabled (and not required as an I/O server), extra overhead and memory are used.)

This function can only be called from an I/O server.

## Syntax

**SerialKey(*sPort*)**

*sPort*:

The name of the port connected to the serial keyboard.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[ComOpen](#)

## Example

```
SerialKey("Port1"); ! enable the serial keyboard
```

## Dynamic Data Exchange Functions

Following are functions relating to Dynamic Data Exchange:

DDEExec	Executes a command in an external DDE compliant
---------	---

	Windows application.
DDEPost	Makes a Plant SCADA variable available for DDE linking by other DDE compliant Windows applications.
DDERead	Reads a variable from a DDE compliant Windows application.
DDEWrite	Writes a variable to a DDE compliant Windows application.
DDEhExecute	Executes a command in an external DDE compliant Windows application.
DDEhGetLastError	Gets the latest Windows DDE error code.
DDEhInitiate	Starts a DDE conversation with an external DDE compliant Windows application.
DDEhPoke	Writes data to a DDE compliant Windows application.
DDEhReadLn	Reads a line of text from a DDE Conversion.
DDEhRequest	Requests data from a DDE compliant Windows application.
DDEhSetMode	Set the mode of a DDE conversation.
DDEhTerminate	Closes a DDE conversation with a Windows application.
DDEhWriteLn	Writes a line of text to the DDE conversation.

## See Also

[Cicode Function Categories](#)

[Using Cicode Functions](#)

## DDEExec

Executes a command in an external Windows application running on the same computer. With this function, you can control other applications that support DDE. Refer to the documentation provided with the external Windows application to determine if DDE is supported and what functions can be called.

You cannot use DDEExec() to call macros on a remote computer or to call Access SQLs. For these calls, Network DDE needs to pass the *sDocument* argument, so you need to use the *DDEh...* functions, passing *sDocument* in the DDEhInitiate() function.

## Syntax

**DDEExec(*sApplication*, *sCommand*)**

*sApplication*:

Application name (.EXE filename), for example, "WinWord".

*sCommand*:

The command that the application will execute.

## Return Value

1 (one) if successful, otherwise an error code is returned.

## Related Functions

[DDEPost](#), [DDERead](#), [DDEWrite](#), [DDEhExecute](#)

## Example

```
/* Instruct the Excel application to recalculate its spreadsheet
immediately. */
DDEExec("Excel", "[Calculate.Now()]");
```

## See Also

[Dynamic Data Exchange Functions](#)

## DDEhExecute

Executes a command in an external Windows application. You need to first start a conversation with the DDEhInitiate function, and use the handle returned by that function to identify the conversation.

With this function, you can control other applications that support DDE. Refer to the documentation provided with your other Windows application to determine if DDE is supported and what functions can be called.

This function is a blocking function. It will block the calling Cicode task until the operation is complete.

## Syntax

**DDEhExecute(*Handle*, *sCommand*)**

*Handle*:

The integer handle that identifies the DDE conversation, returned from the DDEhInitiate function.

*sCommand*:

The command that the application will execute.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[DDEhInitiate](#), [DDEhRequest](#), [DDEhPoke](#), [DDEhTerminate](#), [DDEhGetLastError](#)

## Example

See [DDEhInitiate](#).

## See Also

[Dynamic Data Exchange Functions](#)

## DDEhGetLastError

Gets the latest error code issued from Windows for the conversation identified by the handle.

## Syntax

**DDEhGetLastError(Handle)**

*Handle*:

The integer handle that identifies the DDE conversation, returned from the [DDEhInitiate](#) function.

## Return Value

The error code last issued from Windows DDEML (for that conversation):

DMLERR_ADVACKTIMEOUT	0x4000
DMLERR_BUSY	0x4001
DMLERR_DATAACKTIMEOUT	0x4002
DMLERR_DLL_NOT_INITIALIZED	0x4003
DMLERR_DLL_USAGE	0x4004
DMLERR_EXECACKTIMEOUT	0x4005
DMLERR_INVALIDPARAMETER	0x4006
DMLERR_LOW_MEMORY	0x4007
DMLERR_MEMORY_ERROR	0x4008

DMLERR_NOTPROCESSED	0x4009
DMLERR_NO_CONV_ESTABLISHED	0x400a
DMLERR_POKEACKTIMEOUT	0x400b
DMLERR_POSTMSG_FAILED	0x400c
DMLERR_REENTRANCY	0x400d
DMLERR_SERVER_DIED	0x400e
DMLERR_SYS_ERROR	0x400f
DMLERR_UNADVACKTIMEOUT	0x4010
DMLERR_UNFOUND_QUEUE_ID	0x4011

## Related Functions

[DDEhInitiate](#), [DDEhRequest](#), [DDEhPoke](#), [DDEhTerminate](#)

## Example

See [DDEhInitiate](#).

## See Also

[Dynamic Data Exchange Functions](#)

## DDEhInitiate

Starts a conversation with an external Windows application. When the data exchange is complete, you should terminate the conversation to free system resources.

## Syntax

**DDEhInitiate(*sApplication*, *sDocument*)**

*sApplication*:

The application name (.EXE filename), for example, "WinWord".

*sDocument*:

The document, topic, or file name.

## Return Value

An integer handle for the conversation between Plant SCADA and the other application, or -1 if the conversation

is not started successfully. The handle is used by the other *DDEh...* functions, to identify the conversation.

## Related Functions

[DDEhExecute](#), [DDEhRequest](#), [DDEhPoke](#), [DDEhTerminate](#), [DDEhGetLastError](#)

## Example

```
! Read from Excel spreadsheet
STRING FUNCTION GetExcelData();
    INT hChannel;
    STRING sData;
    hChannel = DDEhInitiate("EXCEL", "DATA.XLS");
    IF hChannel > -1 THEN
        sData = DDEhRequest(hChannel, "R1C1");
        DDEhTerminate(hChannel);
        hChannel = -1;
    END;
    RETURN sData;
END

! Write to Excel spreadsheet
FUNCTION SetExcelData(STRING sData);
    INT hChannel;
    hChannel = DDEhInitiate("EXCEL", "DATA.XLS");
    IF hChannel > -1 THEN
        DDEhPoke(hChannel, "R1C1", sData);
        DDEhTerminate(hChannel);
        hChannel = -1;
    END;
END

! Execute Excel Macro
FUNCTION DoExcelMacro();
    INT hChannel;
    hChannel = DDEhInitiate("EXCEL", "DATA.XLS");
    IF hChannel > -1 THEN
        DDEhExecute(hChannel, "[RUN(^"TestMacro^")]");
        DDEhTerminate(hChannel);
        hChannel = -1;
    END;
END
```

## See Also

[Dynamic Data Exchange Functions](#)

### DDEhPoke

Writes a value to an external Windows application, for example, an Excel spreadsheet. The value is written once to the application. (To write the value dynamically, you need to call this function at the rate at which the data needs to be updated.)

You need to first start a conversation with the [DDEhInitiate](#) function, and use the handle returned by that

function to identify the conversation.

This function is a blocking function. It will block the calling Cicode task until the operation is complete.

## Syntax

**DDEhPoke**(*Handle*, *sItem*, *sValue*)

*Handle*:

The integer handle that identifies the DDE conversation, returned from the [DDEhInitiate](#) function.

*sItem*:

A unique name for the item; for example, the variable name, field name, or spreadsheet cell position.

*sValue*:

The value of the item.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[DDEhInitiate](#), [DDEhExecute](#), [DDEhRequest](#), [DDEhTerminate](#), [DDEhGetLastError](#)

## Example

See [DDEhInitiate](#).

## See Also

[Dynamic Data Exchange Functions](#)

## DDEhReadLn

Reads a line of text from a DDE Conversion, for example, from an Excel spreadsheet. You need to first start a conversation with the [DDEhInitiate](#) function, and use the handle returned by that function to identify the conversation. This function allows you to read a large amount of data via DDE. Keep calling the function until an empty string is returned to verify that all the data has been read.

This function is a blocking function. It will block the calling Cicode task until the operation is complete.

## Syntax

**DDEhReadLn**(*Handle*, *sTopic*)

*Handle*:

The integer handle that identifies the DDE conversation, returned from the [DDEhInitiate](#) function.

*sTopic*:

A unique topic name for the item; for example, the variable name, field name, or spreadsheet cell position.

## Return Value

A line of data, or an empty string when all data has been read.

## Related Functions

[DDEhSetMode](#), [DDEhWriteLn](#), [DDEhInitiate](#), [DDEhExecute](#), [DDEhRequest](#), [DDEhTerminate](#), [DDEhGetLastError](#)

## Example

See [DDEhWriteLn](#).

## See Also

[Dynamic Data Exchange Functions](#)

## DDEhRequest

Reads a value from an external Windows application, for example, from an Excel spreadsheet. You need to first start a conversation with the [DDEhInitiate](#) function, and use the handle returned by that function to identify the conversation.

This function is a blocking function. It will block the calling Cicode task until the operation is complete.

## Syntax

**DDEhRequest**(*Handle*, *sItem*)

*Handle*:

The integer handle that identifies the DDE conversation, returned from the [DDEhInitiate](#) function.

*sItem*:

A unique name for the item; for example, the variable name, field name, or spreadsheet cell position.

## Return Value

A string of data, or an empty string if the function cannot read the value.

## Related Functions

[DDEhInitiate](#), [DDEhExecute](#), [DDEhPoke](#), [DDEhTerminate](#), [DDEhGetLastError](#)

## Example

See [DDEhInitiate](#).

## See Also

[Dynamic Data Exchange Functions](#)

### DDEhSetMode

Set the mode of the DDE conversation. The default mode of a DDE conversation is to use TEXT data format - a simple string of data. This function allows you to set the mode to CSV (Comma Separated Values). Some Windows applications support this mode of data as it helps them to separate the data. For example, when you send CSV format to Excel, each value will be placed into a unique cell. If you use TEXT mode all the data will be placed into the same cell.

## Syntax

**DDEhSetMode**(*Handle*, *sMode*)

*Handle*:

The integer handle that identifies the DDE conversation, returned from the DDEhInitiate function.

*sMode*:

The mode of the DDE conversation:

1 - Text (default)

2 - CSV

## Return Value

The error code.

## Related Functions

[DDEhInitiate](#), [DDEhExecute](#), [DDEhRequest](#), [DDEhTerminate](#), [DDEhPoke](#), [DDEhReadLn](#), [DDEhWriteLn](#), [DDEhSetMode](#)

## Example

See [DDEhWriteLn](#).

## See Also

[Dynamic Data Exchange Functions](#)

### DDEhTerminate

Closes the conversation identified by the handle, and frees the resources associated with that conversation. After you call this function, the handle is no longer valid.

With Network DDE, you might need to terminate and re-initiate a conversation. For example, if you delete rows

on an MS Access sheet, the deleted rows display as #DELETED until you terminate and re-initiate the conversation.

## Syntax

**DDEhTerminate(*Handle*)**

*Handle*:

The integer handle that identifies the DDE conversation, returned from the [DDEhInitiate](#) function.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[DDEhInitiate](#), [DDEhExecute](#), [DDEhPoke](#), [DDEhRequest](#),

## Example

See [DDEhInitiate](#).

## See Also

[Dynamic Data Exchange Functions](#)

## DDEhWriteLn

Writes a line of text to the DDE conversation. With this function, you can write any amount of text to the DDE conversation. Call this function once for each line of text. To terminate the block of text, call this function and pass an empty string.

## Syntax

**DDEhWriteLn(*Handle*, *sTopic*, *sData*)**

*Handle*:

The integer handle that identifies the DDE conversation, returned from the [DDEhInitiate](#) function.

*sTopic*:

A unique name for the topic the data will be written to; for example, the spreadsheet cell position. The topic is only used when you complete the write by passing an empty string for data.

*sData*:

The line of data to write. To terminate the data and make Plant SCADA send the data, set the data to an empty string.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[DDEhInitiate](#), [DDEhExecute](#), [DDEhRequest](#), [DDEhTerminate](#), [DDEhGetLastError](#), [DDEhPoke](#), [DDEhReadLn](#),  
[DDEhWriteLn](#), [DDEhSetMode](#)

## Example

```
! Write to Excel spreadsheet
! write the numbers 1..8 into 8 unique cells in Excel.
FUNCTION WriteExcelData(STRING sData);
    INT hChannel;
    hChannel = DDEhInitiate("EXCEL", "DATA.XLS");
    IF hChannel > -1 THEN
        // set to CSV mode so EXCEL will put each value in a cell
        DDEhSetMode(hChannel, 2);
        DDEhWriteLn(hChannel, "", "1,2,3,4");
        DDEhWriteLn(hChannel, "R1C1:R2C4", "5,6,7,8");
        DDEhWriteLn(hChannel,"R1C1:R2C4","");
        DDEhTerminate(hChannel);
        hChannel = -1;
    END;
END
```

## See Also

[Dynamic Data Exchange Functions](#)

## DDEPost

Makes a Plant SCADA variable value available for DDE linking (which means it posts a DDE link so that it can be read by other DDE compliant applications running on the same computer). This sets up Plant SCADA to behave as a DDE Server for this DDE channel.

**Note:** This function is disabled unless the parameter [DDE]Enable is set to 1 in the Citect.ini file.

After a value is posted, other Windows applications running on the same computer can read the value by using their own DDE Client functions. If the value of the posted variable changes, any linked applications are informed of the new value.

To link to this value from any DDE Client applications running on the same computer, they need to appropriately use the DDE Client syntax with:

- "Citect" as the **<DDE Server application name>**
- "Data" as the **<DDE Topic name>**
- The name used for the first parameter **sItem** in this DDEPost() function as the **<DDE data item name>**.

Unlike the DDERead() and DDEWrite() Cicode functions which are static, the DDEPost() function can be used to

create a dynamic DDE link, providing the DDE Client applications appropriately set their side of the DDE channel to be automatically updated.

## Syntax

**DDEPost(*sItem*, *sValue*)**

*sItem*:

A unique name for the item; for example, the variable name, field name, or spreadsheet cell position.

*sValue*:

The value of the item.

## Return Value

The value that is posted, or empty string if the function does not succeed in posting the link.

## Related Functions

[DDEExec](#), , [DDEWrite](#)

## Example

```
! In Cicode, post a string "PV1" for external DDE
applications to connect with DDEPost("TAGONE",PV1);
/* To link to this posted tag from a cell in Excel, set the cell to
=Citect|Data!TAGONE. This will set the value of the Excel cell to the string "PV1". */
/* To link to this posted tag from a field in Word, set the field
to{DDEAuto Citect Data TAGONE}. This will set the value of the
field link to the string "PV1". */
```

### See Also

[Dynamic Data Exchange Functions](#)

## DDERead

Reads values from an external DDE compliant Windows application running on the same computer, (for example, from an Excel spreadsheet cell or a Word document).

This is a one-way static communication which is read once from the application per call. To read the value dynamically, call this function at the rate at which the data is required to be updated.

Use this function when you want precise control over exactly what you want from the DDE exchange.

## Syntax

**DDERead(*sApplication*, *sDocument*, *sItem* [, *Mode*] )**

*sApplication*:

The application name (.EXE filename), for example, "WinWord".

*sDocument:*

The document, topic, or file name.

*sItem:*

A unique name for the item; for example, the variable name, field name, or spreadsheet cell position.

*Mode:*

A flag that tells the application whether or not to set up an advise loop:

0 - Do not set up advise loop.

1 - Set up advise loop (default).

## Return Value

The value (from the external application) as a string, or an empty string if the function cannot read the desired values.

## Related Functions

[DDEExec](#), [DDEPost](#), [DDEWrite](#)

## Example

```
/* Read the value from R1C1 (Row1,Column1) of an Excel spreadsheet
named "Sheet1". */
DDERead("Excel","Sheet1","R1C1");
/* Read the value from the Item1 bookmark of the Word document
named "Recipes.doc". */
DDERead("Winword","Recipes","Item1");
```

## See Also

[Dynamic Data Exchange Functions](#)

## DDEWrite

Writes a value to an external Windows application, for example, to an Excel spreadsheet. The value is written once to the application. To write the value dynamically, you need to call this function at the rate at which the data needs to be updated.

Use DDEWrite() to cause Plant SCADA runtime to initiate the DDE conversation with a DDE compliant application running on the same computer.

## Syntax

**DDEWrite(*sApplication*, *sDocument*, *sItem*, *sValue*)**

*sApplication:*

The application name (.EXE filename), for example, "WinWord".

*sDocument:*

The document, topic, or file name.

*sItem:*

A unique name for the item; for example, the variable name, field name, or spreadsheet cell position.

*sValue:*

The value of the item.

## Return Value

The value that is sent to the other application, or an empty string if the function does not successfully write the value.

## Related Functions

[DDEExec](#), [DDEPost](#)

## Example

```
/* Write the value of a Plant SCADA variable named
TAGONE to R1C1 (Row1,Column1) of an Excel spreadsheet named
"Sheet1". The value is in string format. */
DDEWrite("Excel","Sheet1","R1C1",TAGONE);
```

## Device Functions

Following are functions relating to devices:

<a href="#">DevAppend</a>	Appends a blank record to the end of a device.
<a href="#">DevClose</a>	Closes a device.
<a href="#">DevControl</a>	Controls a dBASE or SQL device.
<a href="#">DevCurr</a>	Gets the current device number.
<a href="#">DevDelete</a>	Deletes the current record in a database device.
<a href="#">DevDisable</a>	Disables (and re-enables) a device from any access.
<a href="#">DevEOF</a>	Checks for the end of a file.
<a href="#">DevFind</a>	Finds a record in a device.

<a href="#">DevFirst</a>	Finds the first record in a device.
<a href="#">DevFlush</a>	Flushes buffered data to a device.
<a href="#">DevGetField</a>	Gets field data from the current record.
<a href="#">DevHistory</a>	Renames a device file and any subsequent history files.
<a href="#">DevInfo</a>	Gets device information.
<a href="#">DevModify</a>	Modifies the attributes of a device.
<a href="#">DevNext</a>	Gets the next record in a device.
<a href="#">DevOpen</a>	Opens a device for access.
<a href="#">DevOpenGrp</a>	This function has been deprecated.
<a href="#">DevPrev</a>	Gets the previous record in a device.
<a href="#">DevPrint</a>	Prints free-format data to a group of devices.
<a href="#">DevRead</a>	Reads characters from a device.
<a href="#">DevReadLn</a>	Reads a line of characters from a device.
<a href="#">DevRecNo</a>	Gets the current record number of a device.
<a href="#">DevSeek</a>	Moves to any record in a device.
<a href="#">DevSetField</a>	Sets new field data in the current record.
<a href="#">DevSize</a>	Gets the size of a device.
<a href="#">DevWrite</a>	Writes a string to a device.
<a href="#">DevWriteLn</a>	Writes a string with a newline character to a device.
<a href="#">DevZap</a>	Zaps a device.
<a href="#">Print</a>	Prints a string in a report.
<a href="#">PrintLn</a>	Prints a string with a newline character in a report.
<a href="#">PrintFont</a>	Changes the printing font on the current device.

## See Also

[Cicode Function Categories](#)[Using Cicode Functions](#)

## DevAppend

Appends a blank record to the end of a device. After the record is appended, you can use the [DevSetField](#) function to add data to fields in the record.

**Note:** For SQL devices this function is a blocking Cicode function. Data should be added to all requested fields in the row via the Cicode function [DevSetField](#) before [DevAppend](#) is applied.

You need to first call the [DevOpen](#) function to get the device handle (hDev).

## Syntax

**DevAppend(hDev)**

*hDev*:

The device handle, returned from the [DevOpen](#) function. The device handle identifies the table where all data on the associated device is stored.

## Return Value

0 (zero) if the record is successfully appended, otherwise an error code is returned.

## Related Functions

[DevOpen](#), [DevSetField](#)

## Example

```
INT FUNCTION WriteAlarmCount( INT hDevice, STRING sAlarm, INT iCount, INT iTime )
    DevAppend(hDevice);
    DevSetField(hDevice, "ALARM", sAlarm);
    DevSetField(hDevice, "TIME", IntToStr(iTime));
    DevSetField(hDevice, "COUNT", IntToStr(iCount));
END
```

For SQL devices the above example will not work. Instead use the following example:

```
INT FUNCTION WriteAlarmCount( INT hSqlDevice, STRING sAlarm, INT iCount, INT iTime )
    DevSetField(hSqlDevice, "ALARM", sAlarm);
    DevSetField(hSqlDevice, "TIME", IntToStr(iTime));
    DevSetField(hSqlDevice, "COUNT", IntToStr(iCount));
    DevAppend(hSqlDevice);
END
```

## See Also

[Device Functions](#)

## DevClose

Closes a device. Any data in the buffer is flushed to the device before it is closed. After a device is closed, its

device handle becomes invalid and cannot be used.

For SQL devices, this function is a blocking Cicode function.

## Syntax

**DevClose(*hDev*, *Mode*)**

*hDev*:

The device handle, returned from the [DevOpen](#) function. The device handle identifies the table where data on the associated device is stored.

*Mode*:

The mode of the close:

0 - Close the device in user mode - the default mode if none is specified. A device opened by Cicode function DevOpen need to be closed in this mode.

1 - Close the device in remove logging mode - under this mode, the current device will be rolled over to history files immediately. You should only use this mode in a report.

2 - Close the device in keep logging mode - under this mode, the current device will not be rolled over to history files. This allows subsequent messages to be written to the same file. This mode is used internally in a report written in rich text format (rtf).

---

**Note:** Do not call DevClose to the current device in an rtf report. This may make the output file unreadable.

---

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[DevOpen](#)

## Example

```
DevClose(hDev);
```

## See Also

[Device Functions](#)

## DevControl

Controls a dBASE or SQL device. You can pack a dBASE device to physically remove deleted records, or re-index a dBASE device to regenerate the keys. You can issue queries to an SQL device, or get the error status of the last SQL query.

For SQL devices, this function is a blocking Cicode function.

## Syntax

**DevControl(*hDev*, *Type* [, *sData*])**

*hDev*:

The device handle, returned from the [DevOpen](#) function. The device handle identifies the table where all data on the associated device is stored.

*nType*:

The type of command:

0 - Re-index the device based on the key defined in the device record (dBASE devices only).

1 - Pack the database file - all deleted records are removed (dBASE devices only).

2 - Issue a direct SQL query to the device (SQL devices only).

3 - Get error status of the last SQL query (SQL devices only).

---

**Note:** ASCII files and printers are not supported.

---

*sData*:

The command data, that is the SQL query to be issued. Used only for Type 2 commands.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[DevOpen](#), [DevZap](#)

## Example

```
! pack a dBASE file device
DevControl(hDev, 1, "");
```

## See Also

[Device Functions](#)

## DevCurr

Gets the current device handle. You can only call this function in a report, to get the handle of the device where the report is logging. You can then use the other device functions (for example, [DevPrint](#)) to access that logging device. (To get the handle of a device other than a logging device, you need to use the [DevOpen](#) function.)

If the report is logging to a group of devices, this function will return the group handle. However, not all device functions support group handles, for example, you cannot read from a group of devices.

## Syntax

**DevCurr()**

## Return Value

The current device handle or group handle.

If no device is configured, -1 is returned.

## Related Functions

[DevOpen](#), [DevPrint](#)

## Example

```
! Get the report device number.  
hDev=DevCurr();
```

## See Also

[Device Functions](#)

## DevDelete

Deletes the current record in a dBASE database device. The record is not physically deleted, but is marked for deletion. You can physically delete the record by packing the database with the [DevControl](#) function.

For SQL devices, this function is a blocking Cicode function.

## Syntax

**DevDelete(*hDev*)**

*hDev*:

The device handle, returned from the [DevOpen](#) function. The device handle identifies the table where all data on the associated device is stored.

## Return Value

0 (zero) if the record is successfully deleted, otherwise an error code is returned.

## Related Functions

[DevOpen](#), [DevClose](#), [DevControl](#)

## Example

```
! Delete the current record.  
DevDelete(hDev);
```

## See Also

[Device Functions](#)

### DevDisable

Disables (and re-enables) a device from all access, and discards any data written to the device. When a device is disabled, it cannot be opened, and data cannot be read from the device. Use this function to disable logging to a database or printer.

The *State* argument is a toggle. A *State* of 1 disables the device(s), but you can then re-enable the device(s) by repeating the function with *State* = 0.

## Syntax

**DevDisable(*sName*, *State*)**

*sName*:

The device name, or \* (asterisk) for all devices.

*State*:

The disable state:

0 - Enable the device.

1 - Disable the device.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[DevOpen](#)

## Example

```
! Disable the AlarmLog device.  
DevDisable("AlarmLog",1);  
:  
DevDisable("AlarmLog",0); ! Re-enable the device.
```

## See Also

[Device Functions](#)

## DevEOF

Gets the status of the end of file (EOF) flag for a device. When you use the [DevPrev](#), [DevNext](#), or [DevSeek](#) function, the start or end of the device will eventually be reached, and the EOF flag will be set. Use this function to test the EOF flag.

## Syntax

**DevEOF(*hDev*)**

*hDev*:

The device handle, returned from the [DevOpen\(\)](#) function. The device handle identifies the table where all data on the associated device is stored.

## Return Value

1 if the EOF flag has been set, otherwise 0 (zero).

## Related Functions

[DevOpen](#), [DevPrev](#), [DevNext](#), [DevSeek](#), [DevReadLn](#)

## Example

```
hDev = DevOpen("Log", 0);
WHILE NOT DevEOF(hDev) DO
    Prompt(DevGetField(hDev, "Tag"));
    DevNext(hDev);
END
DevClose(hDev);
```

## See Also

[Device Functions](#)

## DevFind

Searches a device for a record that contains specified data in a specified field. The search starts at the current record and continues forward until the matched data is found or the end of the database is reached. If the file has a keyed index, an indexed search is used.

For SQL devices, this function is a blocking Cicode function.

## Syntax

**DevFind(*hDev*, *sFind*, *sField*)**

*hDev*:

The device handle, returned from the DevOpen() function. The device handle identifies the table where all data on the associated device is stored.

*sFind:*

The data to find in *sField*, as a string.

For SQL devices: The DevFind() function can distinguish between numbers, strings, and dates, so you do not need to enclose the data in quote marks. Dates and times need to be in the correct format:

- Date: YYYY-MM-DD
- Time: HH:MM:SS
- DateTime: YYYY-MM-DD HH:MM:SS[.F...] (The fraction .F... is optional.)

*sField:*

The field name to match.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[DevOpen](#), [DevSeek](#)

## Example

```
! Find the Ice cream recipe.  
DevNotFound=DevFind(hDev,"Ice cream","Recipe");  
IF DevNotFound=0 THEN  
    ! Get the recipe values.  
    ..  
ELSE  
    Prompt("Ice cream not found");  
END
```

## See Also

[Device Functions](#)

## DevFirst

Finds the first record in a device.

For SQL devices, this function is a blocking Cicode function.

## Syntax

**DevFirst(*hDev*)**

*hDev:*

The device handle, returned from the [DevOpen](#) function. The device handle identifies the table where all data on the associated device is stored.

## Return Value

The first indexed record (if the device is an indexed database), otherwise the first record in the device.

## Related Functions

[DevOpen](#), [DevClose](#)

## Example

```
! Find the first record.  
FirstRec = DevFirst(hDev);
```

### See Also

[Device Functions](#)

## DevFlush

Flushes buffered data to the physical device. Plant SCADA normally optimizes the writing of data for maximum performance, so use this function only if it is really necessary.

## Syntax

**DevFlush(*hDev*)**

*hDev*:

The device handle, returned from the [DevOpen](#) function. The device handle identifies the table where data on the associated device is stored.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[DevOpen](#), [DevClose](#)

## Example

```
! Flush device to disk.  
DevFlush(hDev);
```

## See Also

[Device Functions](#)

### DevGetField

Gets field data from the current record in a device.

## Syntax

**DevGetField(*hDev*, *sField*)**

*hDev*:

The device handle, returned from the [DevOpen](#) function. The device handle identifies the table where all data on the associated device is stored.

*sField*:

The field name, as a string of up to 10 characters. (The dBASE file format limits all field names to a maximum of 10 characters.)

## Return Value

The field data (as a string). If the field is not found an empty string is returned.

## Related Functions

[DevOpen](#), [DevSetField](#)

## Example

```
INT
FUNCTION
GetRecipe(STRING sName)
    INT hDev;
    hDev = DevOpen("Recipe", 0);
    IF hDev >= 0 THEN
        DevSeek(hDev, 1);
        IF DevFind(hDev, sName, "NAME") = 0 THEN
            PLC_FLOUR = DevGetField(hDev, "FLOUR");
            PLC_WATER = DevGetField(hDev, "WATER");
            PLC_SALT = DevGetField(hDev, "SALT");
            PLC_MILK = DevGetField(hDev, "MILK");
        ELSE
            DspError("Cannot Find Recipe " + sName);
        END
        DevClose(hDev);
    ELSE
        DspError("Cannot open recipe database");
    END
END
```

## See Also

[Device Functions](#)

### DevHistory

Renames a device file and any subsequent history files. The current device is closed and renamed as the first history file. For example, the device file 'Templog.txt' is renamed as 'Templog.001'. If a history file 'Templog.001' already exists, it is renamed as 'Templog.002', and so on. The next time data is written to the device, a new device file is created.

---

**Note:** If the device file has not been created (that is data has not been written to the device), only existing history files are renamed. Use this function for direct control of the device history process.

The DevHistory function does not support SQL devices.

## Syntax

**DevHistory(*hDev*)**

*hDev*:

The device handle, returned from the [DevOpen](#) function. The device handle identifies the table where all data on the associated device is stored.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[DevOpen](#), [DevControl](#)

## Example

```
! Create history file
DevHistory(hDev);
```

## See Also

[Device Functions](#)

### DevInfo

Gets information on a device.

## Syntax

**DevInfo(*hDev*, *nType*)**

*hDev*:

The device handle, returned from the [DevOpen](#) function. The device handle identifies the table where all data on the associated device is stored.

*nType*:

Type of information:

-*n*: Name of field *n* (where *n* is any number up to the total number of fields). For example, if there are 10 fields, -7 will return the name of field 7.

- (*Total no. of fields + n*): Length of field *n* (where *n* is any number up to the total number of fields). For example, if there are 10 fields, -15 will return the length of field 5.

0: Device Name

1: Format

2: Header

3: File Name

4: Number of history files

5: Form length

6: Number of fields

7: Disable flag

8: Device type

9: Record size

10: Format number

11: Type of history schedule:

- 0: Event triggered
- 1: Daily
- 2: Weekly
- 3: Monthly
- 4: Yearly

12: The history period, in seconds, or week day, month or year, for example, if history is weekly then this is the day of the week, that is 1 to 7

13: Synchronisation time of day of the history in seconds, for example, 36000 (that is, 10:00:00)

14: The time the next history file will be created in seconds

## Return Value

The device information as a string if successful, otherwise an empty string is returned.

## Related Functions

[DevControl](#)

## Example

```
! Get the number of fields in a device.  
NoFields=DevInfo(hDev,6);  
FOR I=1 TO NoFields DO  
    ! Get and display the name of each field.  
    sField=DevInfo(hDev,-I);  
    nLength=DevInfo(hDev,-I - NoFields);  
    Prompt("Field Name "+sField + "Length " + nLength:##);  
END
```

## See Also

[Device Functions](#)

### DevModify

Modifies the attributes of a device. The device needs to be closed before you can modify a device.

This function allows you to dynamically change the file name or other attributes of a device at run time. You can use a single device to access many files. For example, you can create a device called Temp with a file name of TEMP.DBF. Using this function you could dynamically change the file name to access any dBASE file.

This function is useful in conjunction with the FormOpenFile or FormSaveAsFile functions. (These functions allow the operator to select file names easily.)

When using this function, you should be careful that no other Cicode function is already using the same device. Check the return value of this function before opening the device or you will destroy the data in the device to which it is already attached. If the device is already open, calling DevModify will return an error (and raise a hardware alarm to notify user).

If DevModify returns error, it means it has not modified the device and the device parameters will remain as they were before the call to DevModify.

Use a semaphore to help protect your Cicode.

For SQL devices, this function is a blocking Cicode function.

## Syntax

**DevModify(*sName*, *Format*, *Header*, *FileName*, *nType*)**

*Name:*

The name of the device.

*Format:*

A new format for the device or "\*" to use the existing format. See Format Templates for more information.

*Header:*

A new header for the device or "\*" to use the existing header.

*FileName:*

A new file name for the device or "\*" (asterisk) to use the existing filename.

*nType:*

A new device type, or -1 to use the existing device type.

Device Type	Device
ASCII_DEV	ASCII file
PRINTER_DEV	Printer
dBASE_DEV	dBASE file
SQL_DEV	SQL database

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[DevOpen](#), [DevClose](#), [DevSetField](#), [DevInfo](#), [DevAppend](#), [FormOpenFile](#)

## Example

```
! change the file name of MyDev
DevModify("MyDev", "*", "*", "c:\data\newfile.dbf", -1);
! change the fields and file name of MyDev
DevModify("MyDev", "{time}{date}{tags}", "*",
"C:\DATA\OLDFILE.DBF", -1);
! change the device to TXT file
DevModify("MyDev", "*", "*", "C:\DATA\OLDFILE.TXT", ASCII_DEV);
```

## See Also

[Device Functions](#)

## DevNext

Gets the next record in a device. If the end of the database is reached, the EOF flag is set and an error code is returned.

For SQL devices, this function is a blocking Cicode function.

## Syntax

**DevNext(*hDev*)**

*hDev*:

The device handle, returned from the [DevOpen](#) function. The device handle identifies the table where all data on the associated device is stored.

## Return Value

0 if the next record is read, or an error if the end of the database is reached.

## Related Functions

[DevEOF](#), [DevPrev](#)

## Example

```
Status=0;  
I = 0;  
hDev = DevOpen("Log", 0);  
WHILE Status = 0 DO  
    DspText(20 + I, 0, DevGetField(hDev,"Tag"));  
    I = I + 1;  
    Status = DevNext(hDev);  
END  
DevClose(hDev);
```

## See Also

[Device Functions](#)

## DevOpen

Opens a device and returns the device handle. The device needs to be defined in the Plant SCADA database. If the device cannot be opened, and user error checking is not enabled, the current Cicode task is halted.

You can use this function to return the handle of a device that is already open. The DevOpen function does not physically open another device - it returns the same device handle as when the device was opened. The mode of the second open call is ignored. To re-open an open device in a different mode, you need to first close the device and then re-open it in the new mode.

For SQL devices, this function is a blocking Cicode function. When using an ODBC driver to connect to an SQL server or database, experience has shown that connecting only once on startup and not closing the device yields the best performance. ODBC connection is slow and if used on demand may affect your system's performance. Also, some ODBC drivers may leak memory on each connection and may cause errors after a number of re-connects.

---

**Note:** If you are opening a database device in indexed mode (nMode=2), an index file will automatically be created by Plant SCADA if one does not already exist. If you feel a device index has become corrupt, delete the existing index file and a new one will be created the next time the DevOpen function is run.

---

## Syntax

**DevOpen(sName [, nMode] )**

*Name:*

The name of the device.

***nMode:***

The mode of the open:

0 - Open the device in shared mode - the default mode when opening a device if none is specified.

1 - Open the device in exclusive mode. In this mode only one user can have the device open. The open will return an error if another user has the device open in shared or exclusive mode.

2 - Open the device in indexed mode. In this mode the device will be accessed in index order. This mode is only valid if the device is a database device and has an index configured in the Header field at the Devices form. Please be aware that specifying mode 2 when opening an ASCII device is ignored internally.

4 - Open the device in 'SQL not select' mode. If opened in this mode, you need to not attempt to read from an SQL device.

8 - Open the device in logging mode. In this mode the history files will be created automatically.

16 - Open the device in read only mode. In this mode data can be viewed, but not written. This mode is supported only by DBF and ASCII files - it is ignored by printers and SQL/ODBC databases.

## Return Value

The device handle. If the device cannot be opened, -1 is returned. The device handle identifies the table where all data on the associated device is stored.

## Related Functions

[DevClose](#)

## Example

```
FUNCTION
PrintRecipe(STRING sCategory)
    STRING sRecipe;
    INT hRecipe, hPrinter;
    ErrSet(1); ! enable user error checking
    hRecipe = DevOpen("Recipe", 0);
    IF hRecipe = -1 THEN
        DspError("Cannot open recipe");
        RETURN FALSE;
    END
    hPrinter = DevOpen("Printer1", 0);
    IF hPrinter = -1 THEN
        DspError("Cannot open printer");
        RETURN FALSE;
    END
    ErrSet(0); ! disable user error checking
    WHILE NOT DevEof(hRecipe) DO
        sRecipe = DevReadLn(hRecipe);
        DevWriteLn(hPrinter, sRecipe);
    END
    DevClose(hRecipe);
    DevClose(hPrinter);
    RETURN TRUE;
END
```

## See Also

[Device Functions](#)

### DevPrev

Gets the previous record in a device. If the start of the database is reached, the EOF flag is set and an error code is returned.

## Syntax

**DevPrev(*hDev*)**

*hDev*:

The device handle, returned from the [DevOpen](#) function. The device handle identifies the table where all data on the associated device is stored.

## Return Value

0 if the record is read successfully, or an error code if the start of the database is reached.

## Related Functions

[DevOpen](#), [DevEOF](#), [DevNext](#)

## Example

```
Status=0;
I = 0;
hDev = DevOpen("Log", 0);
iError = DevSeek(hDev, DevSize(hDev)); ! seek to end
WHILE iError = 0 DO
    DspText(20 + I, 0, DevGetField(hDev,"Tag"));
    I = I + 1;
    iError = DevPrev(hDev);
END
DevClose(hDev);
```

## See Also

[Device Functions](#)

### DevPrint

Prints free-format data to groups of devices. Using this function, you can write data to many devices at the same time. You would normally use this function in a report.

## Syntax

**DevPrint(*hGrp*, *sData*, *NewLine*)**

*hGrp*:

The device handle, or the group handle for a group of devices.

*sData*:

The data to print to the group of devices.

*NewLine*:

The newline flag:

0 - Do not insert a newline character.

1 - Insert a newline character.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[DevWriteLn](#), [DevCurr](#)

## Example

```
! Get the report device number or group number (for a group of
devices).
hGrp=DevCurr();
! Print PV123 to a group of devices.
DevPrint(hGrp,"PV123="+PV123:###,1);
```

## See Also

[Device Functions](#)

## DevRead

Reads characters from a device. If the device is record-based, the current field is read. If the device is free-format, the specified number of characters is read. If the number of characters specified is greater than the number of characters remaining in the device, only the remaining characters are read.

The DevRead function does not support SQL devices. Use the [DevGetField](#) function for these devices.

## Syntax

**DevRead(*hDev*, *Length*)**

*hDev*:

The device handle, returned from the [DevOpen](#) function. The device handle identifies the table where all data on

the associated device is stored.

*Length:*

The number of characters to read.

## Return Value

The data (in string format). If the end of the device is found, an empty string is returned.

## Related Functions

[DevOpen](#), [DevReadLn](#), [DevFind](#)

## Example

```
! Read 20 characters from a device.  
Str=DevRead(hDev,20);
```

## See Also

[Device Functions](#)

## DevReadLn

Reads data from the current record of a device until the end of the line, or end of the record. If the device is record-based, the record number is incremented. The carriage return and newline characters are not returned.

The DevReadLn function does not support SQL devices. Use the [DevGetField](#) function for these devices.

## Syntax

**DevReadLn(*hDev*)**

*hDev:*

The device handle, returned from the [DevOpen](#) function. The device handle identifies the table where all data on the associated device is stored.

## Return Value

The data (in string format). If the end of the device is found, an empty string is returned and the EOF flag is set.

## Related Functions

[DevOpen](#), [DevRead](#), [DevEOF](#), [DevFind](#)

## Example

```
Str=DevReadLn(hDev);
```

## See Also

[Device Functions](#)

### DevRecNo

Gets the current record number of a device. If the device is record-based, the record number ranges from 1 to the maximum size of the file. If the device is free-format, the record number ranges from 0 to the maximum byte size -1.

The DevRecNo function does not support SQL devices. For these devices -1 is returned.

## Syntax

**DevRecNo(*hDev*)**

*hDev*:

The device handle, returned from the [DevOpen](#) function. The device handle identifies the table where all data on the associated device is stored.

## Return Value

The record number. If an error is detected while getting the record number, -1 is returned.

## Related Functions

[DevOpen](#), [DevSeek](#)

## Example

```
! Get the current record number.  
Rec=DevRecNo(hDev);
```

## See Also

[Device Functions](#)

### DevSeek

Moves the device pointer to a specified position in the device. If the device is a database, and it is opened in indexed mode, DevSeek will seek to the record number - not through the index. To locate the first record in an indexed device, call the [DevFirst](#) function.

## Syntax

**DevSeek(*hDev*, *Offset*)**

*hDev*:

The device handle, returned from the DevOpen() function. The device handle identifies the table where all data on the associated device is stored.

*Offset*:

The offset in the device. If the device is a database device, the offset is the record number. If the device is a binary device, the offset is in bytes (from 0 to the maximum file size -1).

**Note:** If offset causes a seek past the end of the file, DevSeek returns no error, but sets the EOF flag (that is, a subsequent DevEOF call will return true). For SQL devices, the function can use only either 0 or 1 offset (beginning of the table).

---

## Return Value

0 (zero) if the seek was successful, otherwise an error code is returned.

## Related Functions

[DevOpen](#), [DevEOF](#), [DevRecNo](#), [DevFirst](#)

## Example

```
hDev=DevOpen("Log", 0);
DevSeek(hDev,100);
DevGetField(hDev,"Tag");
! Gets the value of the "Tag" field at record 100.
```

## See Also

[Device Functions](#)

## DevSetField

Sets new field data in the current record in a device.

## Syntax

**DevSetField(*hDev*, *sField*, *sData*)**

*hDev*:

The device handle, returned from the [DevOpen](#) function. The device handle identifies the table where all data on the associated device is stored.

*sField*:

The field name, as a string of up to 10 characters. (The dBASE file format limits all field names to a maximum of

10 characters.)

*sData:*

New field data, in string format. Plant SCADA converts any other data type into a string before setting the data.

## Return Value

0 (zero) if the data is successfully set, otherwise an error code is returned.

## Related Functions

[DevOpen](#), [DevAppend](#), [DevGetField](#)

## Example

```
! Set the fields in the "Recipe" device.  
hDev=DevOpen("Recipe", 0);  
DevSeek(hDev, 1);  
DevSetField(hDev, "Name", "WhiteBread");  
DevSetField(hDev, "Flour", IntToStr(iFlour));  
DevSetField(hDev, "Water", iWater:####);  
DevSetField(hDev, "Salt", iSalt);  
DevClose(hDev);
```

## See Also

[Device Functions](#)

## DevSize

Gets the size of a physical device.

The DevSize function does not support SQL devices. For these devices -1 will be returned.

## Syntax

**DevSize(*hDev*)**

*hDev:*

The device handle, returned from the [DevOpen](#) function. The device handle identifies the table where all data on the associated device is stored.

## Return Value

If the device is a database device, the number of records is returned. If the device is a binary device, the number of bytes in the file is returned. If an error is detected, -1 is returned.

## Related Functions

[DevRecNo](#), [DevSeek](#)

## Example

```
INT NoRec;  
NoRec=DevSize(hDev);  
! Seek to the last record.  
DevSeek(hDev,NoRec);
```

## See Also

[Device Functions](#)

## DevWrite

Writes a string to a device. If the device is free-format, the data is written to the device as specified. If the device is record-based, the data is written to the current field, and the field pointer is moved to the next field.

Writing to a DBF device appends the data to the device.

Writing to a SQL device appends the data to the device only when all fields of the row have been written.

## Syntax

**DevWrite(*hDev, sData*)**

*hDev*:

The device handle, returned from the [DevOpen](#) function. The device handle identifies the table where all data on the associated device is stored.

*sData*:

The data to write, as a string.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DevOpen](#), [DevWriteLn](#)

## Example

```
! Write PV123 to the device.  
DevWrite(hDev,"PV123="+PV123:###.#);
```

For SQL devices: The DevWrite function can distinguish between numbers, strings, and dates, so you do not need to enclose the data in quote marks. Dates and times need to be in the correct format:

- Date: YYYY-MM-DD
- Time: HH:MM:SS
- DateTime: YYYY-MM-DD HH:MM:SS[.F...] (The fraction .F... is optional.)

## See Also

[Device Functions](#)

### DevWriteLn

Writes a string to a device. If the device is free-format, the data is written to the device, followed by a newline character. If the device is record-based, a new record is appended to the device and the data is written to this record. The record pointer is then moved to the next record.

## Syntax

**DevWriteLn(*hDev*, *sData*)**

*hDev*:

The device handle, returned from the [DevOpen](#) function. The device handle identifies the table where all data on the associated device is stored.

*sData*:

The data to write, as a string.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DevOpen](#), [DevWrite](#)

## Example

```
/* Write PV123 to the device followed by a newline character */
DevWriteLn(hDev, "PV123="+PV123:###.#);
```

## See Also

[Device Functions](#)

### DevZap

Zaps a device. If a database device is zapped, all records are deleted. If an ASCII file is zapped, the file is truncated to 0 (zero) length. Use this function when you want to delete all records in a database or file without

deleting the actual file.

For SQL devices, this function is a blocking Cicode function.

## Syntax

**DevZap(*hDev*)**

*hDev*:

The device handle, returned from the [DevOpen](#) function. The device handle identifies the table where all data on the associated device is stored.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DevDelete](#)

## Example

```
! Delete all records in the alarm log database.  
hDev = DevOpen("AlarmLog", 0);  
DevZap(hDev);
```

## See Also

[Device Functions](#)

## Print

Prints a string on the current device. You should call this function only in a report. The output is sent to the device (or group of devices) defined in the Reports database (in the output device field).

---

**Note:** To print a new line in an RTF report, use the "\par" special character. For example, Print("String" + "\par").

---

## Syntax

**Print(*String*)**

*String*:

The string (data) to print.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[PrintLn](#), [DevCurr](#), [DevPrint](#), [DevWrite](#)

## Example

```
! Print "Testvar" and stay on the same line.  
Print("Value of Testvar="+Testvar:##.#);
```

## See Also

[Device Functions](#)

## PrintFont

Changes the printing font on the current device. You should call this function only in a report. It will change the font style for the device (or group of devices) defined in the Reports database (output device field). It has effect only on reports being printed to a PRINTER\_DEV - it has no effect on other types of devices, such as ASCII\_DEV and dBASE\_DEV.

## Syntax

**PrintFont(*Font*)**

*Font*:

The Plant SCADA font (defined in the Fonts database).

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[Print](#)

## Example

The following report file...

```
{! example.rpt }  
-----  
AN example Report  
-----  
{CICODE}  
PrintFont("HeadingFont");  
{END}  
Plant Area 1  
{CICODE}
```

```
PrintFont("ReportFont");
{END}
{Time(1) } {Date(2) }
PV_1 {PV_1:#####.##}
PV_2 {PV_2:#####.##}
-----End of Report-----
...will print as...
-----
AN example Report
-----
Plant Area 1
04:41:56 19-10-93
PV_1 49.00
PV_2 65.00
-----End of Report-----
```

## See Also

[Device Functions](#)

## PrintLn

Prints a string on the current device, followed by a newline character. You should call this function only in a report. The output will be sent to the device or group of devices defined in the Reports database (in the output device field).

**Note:** To print a new line in an RTF report, use the "\par" special character. For example, PrintLn("String" + "\par").

## Syntax

**PrintLn(*String*)**

*String*:

The string (data) to print.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[Print](#), [DevCurr](#), [DevPrint](#), [DevWrite](#)

## Example

```
! Print "Testvar" followed by a new line.
PrintLn("Value of Testvar="+Testvar:##.#);
```

## See Also

## Display Functions

Following are functions relating to the display of graphics pages and objects:

<a href="#">DspAnCreateControlObject</a>	Creates a new instance of an ActiveX object. If the object already exists for the given Animation Point Number, then that object will be used (a new object is not created).
<a href="#">DspAnFree</a>	Frees (removes) an AN from the current page.
<a href="#">DspAnGetArea</a>	Gets the area configured for an object at a specific AN (animation-point number).
<a href="#">DspAnGetMetadata</a>	Retrieves the field value of the specified metadata entry.
<a href="#">DspAnGetMetadataAt</a>	Retrieves metadata information at the specified index.
<a href="#">DspAnGetPos</a>	Gets the x and y coordinates of an AN (animation-point number).
<a href="#">DspAnGetPrivilege</a>	Gets the privileges configured for an object at a specific AN (animation-point number).
<a href="#">DspAnInfo</a>	Gets information on the state of the animation at an AN.
<a href="#">DspAnInRgn</a>	Checks if an AN is within a specified region.
<a href="#">DspAnMove</a>	Moves an AN.
<a href="#">DspAnMoveRel</a>	Moves an AN relative to its current position.
<a href="#">DspAnSetName</a>	Sets the animation name using a valid AN and Name.
<a href="#">DspAnNew</a>	Creates an AN at the specified x and y coordinates.
<a href="#">DspAnNewRel</a>	Creates an AN relative to another AN.
<a href="#">DspAnSetMetadata</a>	Non-blocking function, that sets the value of the specified metadata entry.
<a href="#">DspAnSetMetadataAt</a>	Sets the value of a metadata entry.
<a href="#">DspBar</a>	Displays a bar graph at an AN.

DspBmp	Displays a bitmap at a specified AN.
DspButton	Displays a button at an AN and puts a key into the key command line (when the button is selected).
DspButtonFn	Displays a button at an AN and calls a function when the button is selected.
DspClearClip	Clears any previously specified clip rectangle for an AN.
DspChart	Displays a chart at an AN.
DspCol	DspCol is deprecated in this version.
DspDel	Deletes the objects at an AN.
DspDelayRenderBegin	Delays screen updating until DspDelayRenderEnd() is called.
DspDelayRenderEnd	Ends the screen update delay set by DspDelayRenderBegin().
DspDirty	Forces an update to an AN.
DspError	Displays an error message at the prompt AN.
DspFile	Defines the screen attributes for displaying a text file.
DspFileGetInfo	Gets the attributes of a file to screen display.
DspFileGetName	Gets the name of the file being displayed in the display "window".
DspFileScroll	Scrolls a file (displayed in the display "window") by a number of characters.
DspFileSetName	Sets the name of the file to display in the display "window".
DspFont	Creates a font.
DspFontHnd	Gets a font handle.
DspFullScreen	Enables or disables the fullscreen mode of the active window.
DspGetAnBottom	Gets the bottom extent of the object at the specified AN.
DspGetAnCur	Gets the current AN.

DspGetAnExtent	Gets the extent of the object at a specified AN.
DspGetAnFirst	Returns the first AN on the current page.
DspGetAnFromName	Returns the AN for an object using a valid name.
DspGetAnFromNameRelative	Name used to retrieve the AN of an object on the page relative to a given AN.
DspGetAnFromPoint	Gets the AN of the object at a specified set of screen coordinates.
DspGetAnHeight	Gets the height of the object at a specified AN.
DspGetAnLeft	Gets the left extent of the object at the specified AN.
DspGetAnNext	Returns the AN following a specified AN.
DspGetAnRight	Gets the right extent of the object at the specified AN.
DspGetAnTop	Gets the top extent of the object at the specified AN.
DspGetAnWidth	Gets the width of the object at a specified AN.
DspGetEnv	Gets a page environment variable.
DspGetMetadataFromName	Name used to retrieve the metadata of an object on the page.
DspGetMetadataFromNameRelative	Name used to retrieve the metadata of an object on the page relative to a given AN.
DspGetMouse	Gets the mouse position.
DspGetMouseOver	Determines if the mouse is within the boundaries of a given AN.
DspGetNameFromAn	Retrieves the Animation name of an object using a valid AN.
DspGetNearestAn	Gets the nearest AN.
DspGetParentAn	Gets the parent animation number (if any), for the specified AN.
DspGetSlider	Gets the current position (value) of a slider at an AN.
DspGetTip	Gets the tool tip text associated with an AN.
DspGrayButton	Greys and disables a button.
DspInfo	Gets object display information from an AN.

DspInfoDestroy	Deletes an object information block created by DspInfoNew().
DspInfoField	Gets stored and real-time data for a variable tag.
DspInfoNew	Creates an object information block for an AN.
DspInfoValid	Checks if an object information block is still valid.
DspIsButtonGray	Gets the current status of a button.
DspKernel	Displays the Kernel window.
DspMarkerMove	Moves a trend or chart marker to a specified position.
DspMarkerNew	Creates a new trend marker.
DspMCI	Controls a multimedia device.
DspPlaySound	Plays a waveform (sound).
DspPopupConfigMenu	Displays the contents of a menu node as a pop-up (context) menu, and runs the command associated with the selected menu item.
DspPopupMenu	Creates a menu consisting of a number of menu items.
DspRichText	Creates a Rich Text object at the animation point.
DspRichTextEdit	Enables/disables editing of the contents of a rich text object.
DspRichTextEnable	Enables/disables a rich text object.
DspRichTextGetInfo	Returns size information about a rich text object.
DspRichTextLoad	Loads a copy of a rich text file into a rich text object.
DspRichTextPgScroll	Scrolls the contents of a rich text object by one page length.
DspRichTextPrint	Prints the contents of a rich text object.
DspRichTextSave	Saves the contents of a rich text object to a file.
DspRichTextScroll	Scrolls the contents of a rich text object by a user defined amount.
DspRubEnd	Ends a rubber band selection.
DspRubMove	Moves a rubber band selection to the new position.
DspRubSetClip	Sets the clipping region for the rubber band display.

DspRubSetColor	Sets the color of the rubber band tool that is used to select a section within a trend object.
DspRubStart	Starts a rubber band selection (used to rescale a trend with the mouse).
DspSetClip	Sets the clip rectangle for an AN.
DspSetCurColor	Sets the color of the focus rectangle.
DspSetMetadataFromName	Name used to set the metadata of an object on the page.
DspSetMetadataFromNameRelative	Name used to set the metadata of an object on the page relative to the given AN.
DspSetPopupMenuFont	Sets the font for the text of the popup menu.
DspSetSlider	Sets the current position of a slider at the specified AN.
DspSetTip	Sets tool tip text associated with an AN.
DspSetTooltipFont	Sets the font for tool tip text.
DspStatus	Sets the communication status error for a specified animation number.
DspStr	Displays a string at an AN.
DspSym	Displays a symbol at an AN.
DspSymAnm	Displays a series of animated symbols at an AN.
DspSymAnmEx	Displays a series of animated symbols at an AN.
DspSymAtSize	Displays a symbol at a scale and offset from an AN.
DspText	Displays text at an AN.
DspTipMode	Switches the display of tool tips on or off.
DspTrend	Displays a trend at an AN.
DspTrendInfo	Gets information on a trend definition.
DspWebContentGetURL	Gets the current URL for a Web Content control on a graphics page.
DspWebContentSetURL	Sets the URL for a Web Content control on a graphics page.

[Cicode Function Categories](#)

[Using Cicode Functions](#)

### DspAnCreateControlObject

Creates a new instance of an ActiveX object. If the object already exists for the given Animation Point Number, then that object will be used, that is a new object will not be created, the existing object will merely be refreshed.

AN object created using this function remains in existence until the page is closed or the associated Cicode Object is deleted.

## Syntax

**DspAnCreateControlObject(*nAN, sClass, Width, Height [, sEventClass]*)**

*nAN*:

The animation-point number.

*sClass*:

The class of the object. You can use the object's human readable name, its program ID, or its GUID. If the class does not exist, the function will return an error.

For example:

- "Calendar Control 8.0" - human readable name
- "MSCAL.Calendar.7" - Program ID
- "{8E27C92B-1264-101C-8A2F-040224009C02}" - GUID

*Width*:

The width of the ActiveX object.

*Height*:

The height of the ActiveX object.

*sEventClass*:

The string you would like to use as the event class for the object.

## Return Value

The newly created object, if successful, otherwise an error is generated.

## Related Functions

[CreateObject](#), [CreateControlObject](#)

## Example

See [CreateControlObject](#).

## See Also

[Display Functions](#)

### DspAnFree

Frees (removes) an AN from the current page. If an animation exists at the animation number, it is deleted before the AN is freed. Use this function to free existing ANs or ANs created with the DspAnNew() function. Please be aware that the ANs are only freed in memory - the change is not persistent. The next time the page is opened it will display the AN.

---

**Note:** This function was designed to only be used on Cicode objects, or the animation point object from the version 3.xx/4.xx toolbox.

---

## Syntax

**DspAnFree(*nAN*)**

*nAN*:

The animation-point number.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DspAnNew](#)

## Example

```
/* Remove AN20 from the current page. */
DspAnFree(20);
```

## See Also

[Display Functions](#)

### DspAnGetArea

Gets the area configured for an object at a specific AN (animation-point number). The area is returned as an integer.

---

**Note:** This function does not return the areas of keyboard commands associated with the object.

---

## Syntax

**DspAnGetArea(*nAN*)**

*nAN*:

The animation-point number.

## Return Value

The area if successful, otherwise an error is returned. If the object is configured with 'Same area as page' checked, the area of the page will be returned. AN area of 0 (zero) means no areas are configured for the object.

## Related Functions

[DspAnGetPrivilege](#)

## Example

```
/* Get the area configured for the object at AN60. /
DspAnGetArea(60);
```

## See Also

[Display Functions](#)

## DspAnGetMetadata

Retrieves the field value of the specified metadata entry.

## Syntax

**DspAnGetMetadata(*nAN*, *sMetaName*)**

*nAN*:

An animation number that uniquely identifies an object. This object contains the list of metadata definitions that will be used to perform the association operations. When -2 is specified, it is equivalent to using DspGetAnCur(). (See for usage and limitations.)

*sMetaName*:

The name of the metadata entry for which to search.

---

**Note:** Before calling this function, it may be worthwhile to call ErrSet(1) to disable error checking as this function will generate a hardware error for any object that does not have a metadata entry 'sMetaName', and the cicode task will stop executing.

---

## Return Value

Value for the specified metadata. Returns empty string if a matching metadata entry is not defined and error code if unsuccessful.

## Related Functions

[DspAnGetMetadataAt](#), [DspAnSetMetadata](#), [DspAnSetMetadataAt](#)

## See Also

[Display Functions](#)

### DspAnGetMetadataAt

Retrieves metadata information at the specified index.

## Syntax

**DspAnGetMetadataAt(*nAN*, *nIndex* ,*sField*)**

*nAn*:

An animation number that uniquely identifies an object. This object contains the list of metadata definitions that will be used to perform the association operations. When -2 is specified, it is equivalent to using DspGetAnCur. (See [DspGetAnCur](#) for usage and limitations.)

*nIndex*:

The index of the metadata in the animation point. The index is 0-based; i.e. the first metadata entry has an index of 0, the next 1, and so on.

*sField*:

The name of the field from which to retrieve the information for the metadata. Supported fields are:

- Name
- Value

## Return Value

The field value string. If there is an error, an empty string is returned. The error code can be obtained by calling the IsError Cicode function.

## Related Functions

[DspAnGetMetadata](#), [DspAnSetMetadata](#), [DspAnSetMetadataAt](#)

[Display Functions](#)

## DspAnGetPos

Gets the x and y coordinates of an AN, in pixels, relative to the top-left corner of the window.

## Syntax

**DspAnGetPos(*nAN*, *X*, *Y* [, *nMode*])**

*nAN*:

The animation-point number.

*X*, *Y*:

Variables used to store the x and y pixel coordinates of the AN, returned from this function.

*nMode*:

0 – (Default mode) Gets coordinates of an AN on the page. If the AN has not been displayed yet, e.g. default visibility state is hidden, (0, 0) is returned from calling the function.

1 – Gets coordinates of an AN from its configuration. i.e. page coordinates at which the object was originally inserted in Graphics Builder is returned from calling the function.

## Return Value

0 (zero) if successful, otherwise an error is returned. The *X* and *Y* variables are set to the AN's position if successful, or to -1 if an error has been detected.

## Related Functions

[DspAnMove](#), [DspAnInRgn](#), [DspGetAnCur](#), [DspGetMouse](#), [DspGetNearestAn](#), [PageTransformCoords](#)

## Example

```
/* Get the position of AN20 into X and Y. /
DspAnGetPos(20,X,Y);
```

## See Also

[Display Functions](#)

## DspAnGetPrivilege

Gets the privileges configured for an object at a specific AN (animation-point number). The privilege is returned as an integer.

**Note:** This function does not return the privileges of keyboard commands associated with the object.

## Syntax

**DspAnGetPrivilege(*nAN*)**

*nAN:*

The animation-point number.

## Return Value

The privilege if successful, otherwise an error is returned. A privilege of 0 (zero) means no privileges are configured for the object.

## Related Functions

[DspAnGetArea](#)

## Example

```
/* Get the privileges of the object at AN45. /
DspAnGetPrivilege(45);
```

## See Also

[Display Functions](#)

## DspAnInfo

Gets information on an AN - the type or state of the animation that is currently displayed.

## Syntax

**DspAnInfo(*nAN*, *nType*)**

*nAN:*

The animation-point number.

*nType:*

The type of information:

**0** - The type of animation currently displayed at the AN. The following is returned:

- **0** - No animation is displayed.
- **1** - Color is displayed.
- **2** - A bar graph is displayed.
- **3** - Text is displayed.
- **4** - A symbol is displayed.
- **5** - AN animation symbol is displayed.
- **6** - A trend is displayed.
- **7** - A button is displayed.
- **8** - A slider is displayed.

- 9 - A plot is displayed.

1 - The state of the animation currently displayed. If color is displayed, the color is returned. If a bar graph, trend, or symbol is displayed, the bar, trend, or symbol name is returned. If text is displayed, the font handle is returned.

2 - The value of the text or the name of a button at the given AN point is returned.

3 - The type of animation currently displayed at the AN for Mode 0 plus the following:

- 10 - Rich Edit
- 11 - Bitmap
- 12 - Straight Line
- 13 - Free hand Line
- 14 - Rectangle
- 15 - Ellipse
- 16 - Spark
- 17 - Group
- 18 - Windows Meta File
- 19 - Poly Line
- 20 - Dynamic object
- 21 - Pipe
- 22 - Symbol Set
- 23 - OCX
- 24 - Basic AN
- 25 - Number
- 26 - Advanced AN
- 27 - Keyboard AN
- 28 - Sizemove AN
- 29 - Touch AN

## Return Value

The animation information, which depends on the type passed argument, as described above, as a string.

## Related Functions

[DspGetAnCur](#)

## Example

```
IF DspAnInfo(25,0) = "1" THEN
    /* If color on AN 25, then get the color */
    col = DspAnInfo(25,1);
END
```

## See Also

[Display Functions](#)

### DspAnInRgn

Checks if an AN is within a region bounded by two ANs.

Will return False if any of the specified ANs are completely clipped. A partially clipped AN is treated as being fully visible.

## Syntax

**pAnInRgn(nAN, One, Two)**

*nAN*:

The animation-point number.

*One, Two*:

One - the AN at a corner of the region; two - the AN at the opposite corner of the region.

## Return Value

1 if the AN is within the region, or 0 (zero) if it is not.

## Example

```
DspGetMouse(X,Y);
DspAnMove(250,X,Y);
IF DspAnInRgn(250,20,30) THEN
    Prompt("Mouse in region bounded by AN20 and AN30");
ELSE
    Prompt("Mouse not in region");
END
```

## See Also

[Display Functions](#)

### DspAnMove

Moves an AN to a new position. Any animation at this AN is also moved.

---

**Note:** This function was designed to only be used on Cicode objects, or the animation point object from the version 3.xx/4.xx toolbox.

---

## Syntax

**DspAnMove(nAN, X, Y)**

*nAN:*

The animation-point number.

*X:*

The x pixel coordinates of the new position.

*Y:*

The y pixel coordinates of the new position.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DspAnMoveRel](#)

## Example

```
DspAnMove(25,100,200);  
! Moves AN25 to pixel location 100,200.
```

## See Also

[Display Functions](#)

## DspAnMoveRel

Moves an AN relative to its current position. Any animation at this AN is also moved.

---

**Note:** This function was designed to only be used on Cicode objects, or the animation point object from the version 3.xx/4.xx toolbox.

---

## Syntax

**DspAnMoveRel(*nAN*, *X*, *Y*)**

*nAN:*

The animation-point number.

*X:*

The number of pixels to move the AN in the x plane.

*Y:*

The number of pixels to move the AN in the y plane.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DspAnMove](#)

## Example

```
DspAnMoveRel(25,10,20);
/* Moves AN25 by 10 pixels to the right and 20 pixels downward,
relative to its current position. */
```

## See Also

[Display Functions](#)

## DspAnNew

Creates an AN at the specified x and y coordinates.

## Syntax

**DspAnNew(X, Y)**

X:

The x pixel coordinate where the new AN is created.

Y:

The y pixel coordinate where the new AN is created.

## Return Value

If successful, the new AN is returned. If the AN cannot be created, -1 is returned. If an AN already exists at this location, that AN is returned.

## Related Functions

[DspAnNewRel](#), [DspAnFree](#)

## Example

```
AN=DspAnNew(100,200);
DspSym(AN,20);
/* Displays symbol 20 at pixel location 100,200 */
```

## See Also

[Display Functions](#)

### DspAnNewRel

Creates an AN at a distance of x,y pixels from a specified AN.

**Note:** This function was designed to only be used on Cicode objects, or the animation point object from the version 3.xx/4.xx toolbox.

## Syntax

**DspAnNewRel(*nAN*, *X*, *Y*)**

*nAN*:

The AN used as a reference for the new AN.

*X*:

The distance in the x plane (in pixels) from the reference AN to the new AN.

*Y*:

The distance in the y plane (in pixels) from the reference AN to the new AN.

## Return Value

If successful, the new AN is returned. If the AN cannot be created, -1 is returned. If an AN already exists at this location, that AN is returned.

## Related Functions

[DspAnNew](#), [DspGetAnCur](#)

## Example

```
AN=DspAnNewRel(20,100,200);
/* Creates an AN at 100x and 200y pixels from AN20 */
```

## See Also

[Display Functions](#)

### DspAnSetName

Using a valid AN set the name of an animation object.

## Syntax

**DspAnSetName(*hAN*, *sName*)**

*hAN*:

The AN used as a reference for the new Animation Name.

*sName*

Animation Name to be set

## Return Value

Returns an error if given name is already in use.

## Related Functions

[DspGetAnFromName](#), [DspGetNameFromAn](#)

## See Also

[Display Functions](#)

## DspAnSetMetadata

Non-blocking function, that sets the value of the specified metadata entry.

---

**Note:** Metadata items can only be set using Cicode if the name is configured in the object properties -metadata tab and saved with the page.

---

## Syntax

**DspAnSetMetadata(*nAn*, *sMetaName*, *sValue*)**

*nAn*:

An animation number that uniquely identifies an object. This object contains the list of metadata definitions that will be used to perform the association operations. When -2 is specified, it is equivalent to using DspGetAnCur(). (See [DspGetAnCur](#) for usage and limitations.)

*sMetaName*:

The name of metadata entry for which to search.

*sValue*:

The value for the metadata to be set.

---

**Note:** Before calling this function, it may be worthwhile to call ErrSet(1) to disable error checking as this function will generate a hardware error for any object that does not have a metadata entry called '*sMetaName*', and the cicode task will stop executing

---

## Return Value

0 if successful, error code if unsuccessful

## Related Functions

[DspAnSetMetadataAt](#), [DspAnGetMetadata](#), [DspAnGetMetadataAt](#)

## See Also

[Display Functions](#)

### DspAnSetMetadataAt

Non-blocking function, that sets the value of a metadata entry.

**Note:** Metadata items can only be set using Cicode if the name is configured in the object properties -metadata tab and saved with the page.

## Syntax

**DspAnSetMetadataAt(*nAN*, *nIndex*, *sField*, *sFieldValue*)**

*nAn*:

An animation number that uniquely identifies an object. This object contains the list of metadata definitions that will be used to perform the association operations. When -2 is specified, it is equivalent to using DspGetAnCur(). (See [DspGetAnCur](#) for usage and limitations.)

*nIndex*:

The index of the metadata in the animation point.

*sField*:

The name of the field in which to set the information for the metadata. Supported fields are:

- Name
- Value

*sFieldValue*:

The value to set in the specified field of the metadata entry.

**Note:** Clusters should be configured either directly by specifying a full tag name such as C1.TagA or indirectly via the function calls (such as WinNewAt(...)) or via the page configuration parameter.

## Return Value

0 if successful, error code if unsuccessful

## Related Functions

[DspAnSetMetadata](#), [DspAnGetMetadata](#), [DspAnGetMetadataAt](#)

## See Also

[Display Functions](#)

### DspBar

Displays a bar graph (on a graphics page) at a specified AN. To scale a tag into the correct range, use the EngToGeneric() function.

**Note:** This function was designed to only be used on Cicode objects, or the animation point object from the version 3.xx/4.xx toolbox.

## Syntax

**DspBar(*nAN*, *Bar*, *Value*)**

*nAN*:

The AN where the bar graph will be displayed.

*Bar*:

The name of the bar graph to display in the format <[LibName.]BarName>. If you do not specify the library name, a bar graph from the Global library displays (if it exists). To display a Version 1.xx bar graph, specify the bar definition (1 to 255). For example, if you specify bar 1, Plant SCADA displays the bar graph Global.Bar001.

*Value*:

The value to display on the bar graph. The value needs to be from 0 to 32000 to give 0 to full-scale range on the bar.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[EngToGeneric](#)

## Example

```
DspBar(25,"Bars.Loops",320);
/* Displays a value of 320 (that is 10%) on the loops bar (from the
bars library) at AN25. */
DspBar(25,3,320);
/* Displays a value of 320 (that is 10%) on bar definition 3
(Plant SCADA Version 1.xx) at AN25. */
DspBar(26,"Loops_Bar",EngToGeneric(Tag1,0,100));
/* Displays Tag1 on the loops_bar (from the global library) at
AN26. Tag1 has an engineering scale of 0 to 100. */
```

## See Also

[Display Functions](#)

### DspBmp

Displays a bitmap at a specified AN. This function allows you to display any bitmap file at run time. (You can get a new bitmap file from operator input or from the plant, and display it dynamically.)

**Note:** This function was designed to only be used on Cicode objects, or the animation point object from the version 3.xx/4.xx toolbox.

## Syntax

**DspBmp(*nAN*, *sFile*, *Mode*)**

*nAN*:

The animation-point number.

*sFile*:

The name of the bitmap (.BMP) file. The file needs to be in the user project path. (Only .bmp files are supported. Other image formats like .png or .jpg are not supported.)

*Mode*:

The mode of bitmap display:

0 - Erase the existing bitmap and display this bitmap.

1 - Do not erase the existing bitmap, just draw the new bitmap. (This mode provides smoother animation than Mode 0, but the bitmaps needs to be the same size).

2 - Do not erase the existing bitmap, just draw the new bitmap. This mode is similar to mode 1, but it displays the bitmap about 3 times faster. However, the bitmap should not contain any transparent color, or it will display as a random color. Use this mode for fast, smooth animation.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DspDel](#)

## Example

```
// Display the bitmap "MyImage.bmp" at AN 60
DspBMP(60, "MyImage.bmp", 0)
```

## See Also

[Display Functions](#)

## DspButton

Displays a button at a specified AN. When the button is selected, the key definition is put into the key command line. The font, width, height, and down and repeat keys of the button are optional. If you do not specify a width and height, the button adjusts to the size of the button *sName*.

---

**Note:** This function was designed to only be used on Cicode objects, or the animation point object from the version 3.xx/4.xx toolbox.

---

## Syntax

**DspButton(*nAN*, *UpKey*, *Name* [, *hFont*] [, *Width*] [, *Height*] [, *DownKey*] [, *RepeatKey*] [, *Style*])**

*nAN*:

The animation-point number.

*UpKey*:

The key generated when the command button is selected (when the mouse button is released after being clicked down). This is the default operation for commands activated by a button.

*Name*:

The name to display on the button.

*hFont*:

The handle of the font used to display the button name. Use the DspFont() function to create a new font and return the font handle. Use the DspFontHnd() function to return the font handle of an existing font. The Windows button font is used if the font is omitted or is not defined in the database.

*Width*:

The width of the button in pixels.

*Height*:

The height of the button in pixels.

*DownKey*:

The key generated when the mouse button is clicked down (over the command button). Normally this parameter is not used, because most buttons are configured to activate a command when the mouse button is released (returning to the 'up' position).

*RepeatKey*:

The key generated repetitively, while the mouse button is being held down (over the command button).

*Style*:

A number indicating the visibility style of the button:

0 - NORMAL: The button appears as a standard button.

1 - BORDER\_3D: The button is drawn with only the 3-D border (transparent face).

2 - BORDER: The button is drawn with only a thin line border.

3 - TARGET: The button is totally transparent - this constitutes a screen target.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DspButtonFn](#), [KeySetSeq](#), [DspFont](#), [DspFontHnd](#)

## Example

```
/* Display a self-sizing button at AN20 using the default font.  
The button is named "Help". When selected, the Key Code "KEY_F1"  
is put into the key command line. */  
DspButton(20,KEY_F1,"Help");  
/* Display the same button at AN20, but in an existing font called  
"BigFont". */  
DspButton(20,KEY_F1,"Help",DspFontHnd("BigFont"));
```

## See Also

[Display Functions](#)

## DspButtonFn

Displays a button at a specified AN. When the button is selected, a user function is called. If the width and height are 0 (zero), then the button adjusts to the size of the button *sName*.

---

**Note:** This function was designed to only be used on Cicode objects, or the animation point object from the version 3.xx/4.xx toolbox.

---

## Syntax

**DspButtonFn(*nAN*, *UpFunction*, *Name* [, *hFont*] [, *Width*] [, *Height*] [, *DownFunction*] [, *RepeatFunction*] )**

*nAN*:

The animation-point number.

*UpFunction*:

The user function called when the command button is selected (when the mouse button is released after being clicked down). This is the default operation for commands activated by a button. This callback function can have no arguments, so specify the function with no parentheses (). The callback function needs to return INT as its return data type. You cannot specify a Plant SCADA built-in function for this argument.

*Name*:

The name to display on the button.

*hFont*:

The handle of the font used to display the button name. Use the DspFont() function to create a new font and return the font handle. Use the DspFontHnd() function to return the font handle of an existing font. The Windows button font is used if the font is omitted or is not defined in the database.

**Width:**

The width of the button in pixels.

**Height:**

The height of the button in pixels.

**DownFunction:**

The user function called when the mouse button is clicked down (over the command button). Normally this parameter is not used, because most buttons are configured to activate when the mouse button is released (returning to the 'up' position). The callback function needs to have no arguments, so specify the function with no parentheses (). The callback function needs to return INT as its return data type. You cannot specify a Plant SCADA built-in function for this argument.

**RepeatFunction:**

The user function called repetitively, while the mouse button is being held down (over the command button). The callback function needs to have no arguments, so specify the function with no parentheses (). The callback function needs to return INT as its return data type. You cannot specify a Plant SCADA built-in function for this argument.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DspButton](#), [DspFont](#), [DspFontHnd](#)

## Example

```
DspButtonFn(20,MyFunc,"Help",0,50,10);
! Call this function when the button is selected.
INT
FUNCTION
MyFunc()
    PageDisplay("Help");
    RETURN 0;
END
```

## See Also

[Display Functions](#)

## DspChart

Displays a chart at an AN. Charts are trend lines with markers on them. Values are plotted on the chart pens. You need to specify *Value1*, but *Value2* to *Value8* are optional.

If more values (than the configured pens) are specified, the additional values are ignored. If fewer values (than the configured pens) are specified, the pens that have no values are not displayed.

You should use this function only if you want to control the display of charts directly.

**Note:** This function was designed to only be used on Cicode objects, or the animation point object from the version 3.xx/4.xx toolbox.

## Syntax

**DspChart(*nAN*, *Chart*, *Value1* [, *Value2* ... *Value8*] )**

*nAN*:

The AN where the chart will be displayed.

*Chart*:

The chart to display.

*Value1*:

The value to display on Pen 1 of the chart.

*Value2* ... *8*:

The values to display on Pen 2...Pen 8 of the chart. These values are optional.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DspDel](#), [DspTrend](#)

## Example

```
/* Using chart definition 5 at AN25, display a value of 10 on
Pen1, 20 on Pen2, 30 on Pen3 and 40 on Pen4 of the chart. */
DspChart(25,5,10,20,30,40);
/* Using chart definition 6 at AN26, display a value of 100 on Pen1
and 500 on Pen2 of the chart. */
DspChart(26,6,100,500);
```

[Display Functions](#)

## DspClearClip

Clears the clipping rectangle surrounding the object or group of objects.

## Syntax

**DspClearClip(INT nAN)**

*nAn:*

The animation-point number of the object or groups within the clipping rectangle.

## Return Value

If nAN is invalid will return 0

When cleared will return 0 and change co-ordinates for clipping rectangle to 0.

## Example

```
DspClearClip(17)
```

## See Also

[Display Functions](#)

## DspCol

DspCol is deprecated in this version of Plant SCADA.

## Syntax

**DspCol(nAN, Color)**

*nAN:*

The animation-point number.

*Color:*

The color to display at the AN.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DspDel](#)

## Example

```
DspCol(25,RED);  
/* Displays the color red at AN25. */
```

## See Also

[Display Functions](#)

### DspDel

Deletes all objects from a specified AN.

**Note:** This function was designed to only be used on Cicode objects, or the animation point object from the version 3.xx/4.xx toolbox.

## Syntax

**DspDel(*nAN*)**

*nAN*:

The animation-point number.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DspDirty](#)

## Example

```
DspDel(25);
! Deletes all animation at AN25.
```

## See Also

[Display Functions](#)

### DspDelayRenderBegin

Delays screen updating until DspDelayRenderEnd is called. This function should be used with DspDelayRenderEnd() to "sandwich" Cicode that will modify the appearance of a page. The code should be preceded by DspDelayRenderBegin(), and followed by DspDelayRenderEnd(). This will reduce screen update times, because the modifying code is given time to execute before the page is updated with the changes, and the changes are all made in a single re-draw.

**Note:** If you have not changed the [Page]DelayRenderAll parameter from its default (TRUE), then you do not need to use this function.

You can call this function as many times in a row as you like, as long as each is ended with a call to DspDelayRenderEnd.

Because your display will stop updating while the "sandwiched" code runs, you should try to make that code as efficient as possible. Do not call Sleep() or any other Cicode functions that will take a long time to run.

Do not call WinSelect within the "sandwiched" code. Do not call this function directly from the Kernel.

## Syntax

**DspDelayRenderBegin()**

## Related Functions

[DspDelayRenderEnd](#)

## Example

```
/* Begin delay so the following code can be executed before the
images are re-drawn. */
DspDelayRenderBegin();
DspBMP(50, "Image1.bmp", 0) ! Display the bitmap "Image1.bmp"
at AN 50
DspBMP(100, "Image2.bmp", 0) ! Display the bitmap "Image2.bmp"
at AN 100
DspBMP(150, "Image3.bmp", 0) ! Display the bitmap "Image3.bmp"
at AN 150
DspBMP(200, "Image4.bmp", 0) ! Display the bitmap "Image4.bmp"
at AN 200
DspBMP(250, "Image5.bmp", 0) ! Display the bitmap "Image5.bmp"
at AN 250
/* End delay so the images can be re-drawn. */
DspDelayRenderEnd();
```

## See Also

[Display Functions](#)

## DspDelayRenderEnd

Ends the screen update delay set by DspDelayRenderBegin. This function should be used with DspDelayRenderBegin() to "sandwich" Cicode that will modify the appearance of a page. The code should be preceded by DspDelayRenderBegin(), and followed by DspDelayRenderEnd(). This will reduce screen update times, because the modifying code is given time to execute before the page is updated with the changes, and the changes are all made in a single re-draw.

Because your display will stop updating while the "sandwiched" code runs, you should try to make that code as efficient as possible. Do not call Sleep() or any other Cicode functions that will take a long time to run.

Do not call WinSelect within the "sandwiched" code. Do not call this function directly from the Kernel.

---

**Note:** If you have not changed the [\[Page\]DelayRenderAll](#) parameter from its default (TRUE), then you do not need to use this function.

## Syntax

```
DspDelayRenderEnd()
```

## Return Value

No value is returned.

## Related Functions

[DspDelayRenderBegin](#)

## Example

```
/* Begin delay so the following code can be executed before the
images are re-drawn. */
DspDelayRenderBegin();
DspBMP(50, "Image1.bmp", 0) ! Display the bitmap "Image1.bmp"
at AN 50
DspBMP(100, "Image2.bmp", 0) ! Display the bitmap "Image2.bmp"
at AN 100
DspBMP(150, "Image3.bmp", 0) ! Display the bitmap "Image3.bmp"
at AN 150
DspBMP(200, "Image4.bmp", 0) ! Display the bitmap "Image4.bmp"
at AN 200
DspBMP(250, "Image5.bmp", 0) ! Display the bitmap "Image5.bmp"
at AN 250
/* End delay so the images can be re-drawn. */
DspDelayRenderEnd();
```

## See Also

[Display Functions](#)

## DspDirty

Forces Plant SCADA to update an AN. Normally, Plant SCADA updates the animation on the AN only if the data has changed. This function tells Plant SCADA to update the AN the next time it animates the AN - even if the data has not changed.

Use this function when you have complex animations that overlap. If two or more animations overlap, you should use the DspDel() or DspDirty() function on their ANs, and then display them in the same order (when they need to be updated).

---

**Note:** This function was designed to only be used on Cicode objects, or the animation point object from the version 3.xx/4.xx toolbox.

## Syntax

**DspDirty(*nAN*)**

*nAN*:

The animation-point number.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DspDel](#)

## Example

```
DspDirty(20);  
! Forces an update of AN20.
```

## See Also

[Display Functions](#)

## DspError

Displays an error message at the prompt AN on the operator's computer. You can disable the error message display (of this function) by setting the Cicode execution mode in the CodeSetMode() function.

## Syntax

**DspError(*String*)**

*String*:

The message to be displayed.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[CodeSetMode](#), [Prompt](#)

## Example

```
DspError("Error found");
! Displays "Error found" at the prompt AN.
```

## See Also

[Display Functions](#)

## DspFile

Defines the screen attributes for displaying a text file. This function defines a "window" where the file will be displayed. You should call this function before any file-to-screen function.

You need to define sequential ANs for each line of text in the display. The file is displayed starting at the specified AN, then the next (highest) AN, and so on. You should not use proportionally-spaced fonts, because the columns of text might not be aligned.

You would normally call this function as the entry function for a graphics page. Use the DspFileSetName() function to specify the file to be displayed. This function is a low level animation function - it controls exactly how the file is to display. If you just want to display a file, use the PageFile() function.

## Syntax

**DspFile**(*nAN, hFont, Height, Width*)

*nAN*:

The AN where the file display window will be positioned.

*hFont*:

The handle for the font that is used to display the file, returned from the DspFont() or DspFontHnd() function. The font handle identifies the table where data on the associated font is stored.

*Height*:

The maximum number of lines to display on one page of the file display window.

*Width*:

The width of the file display window, in characters.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[PageFile](#), [DspFileGetInfo](#), [DspFileGetName](#), [DspFileScroll](#), [DspFileSetName](#), [DspFont](#), [DspFontHnd](#)

## Example

```
DspFile(20,0,20,80);
/* Defines the attributes of a screen display to start at AN20,
using the default font, with a window size of 20 lines x 80
columns. */
```

## See Also

[Display Functions](#)

### DspFileGetInfo

Gets the attributes of a file-to-screen display (used for displaying text files).

## Syntax

**DspFileGetInfo(*nAN*, *Type*)**

*nAN*:

The AN where the file display window will be located. This AN needs to be the same as the AN specified with the DspFile() function.

*nType*:

The type of data required:

0 - The width of the file display window, in characters.

1 - The maximum number of lines that can display in one page of the file display window.

2 - The file-to-screen row offset number.

3 - The file-to-screen column offset number.

4 - The number of lines in the displayed file.

## Return Value

The attributes of the "window" as an integer. If an incorrect AN is specified, an error is returned.

## Related Functions

[DspFile](#), [DspFileGetName](#), [DspFileScroll](#), [DspFileSetName](#)

## Example

```
! Display the page number of the file display.
PageNumber=IntToStr(DspFileGetInfo(20,2)/DspFileGetInfo(20,1)+1);
DspText(12,0,"Page No "+PageNumber);
```

## See Also

[Display Functions](#)

### DspFileGetName

Gets the name of the file being displayed in the display "window". You can use this function to display the file name on the screen.

## Syntax

**DspFileGetName(*nAN*)**

*nAN*:

The animation-point number.

## Return Value

The name of the file (as a string). If an incorrect AN is specified, an error is returned.

## Related Functions

[DspFile](#), [DspFileGetInfo](#), [DspFileScroll](#), [DspFileSetName](#)

## Example

```
DspText(11,0,DspFileGetName(20));  
! Displays the name of the file displayed at AN20.
```

## See Also

[Display Functions](#)

### DspFileScroll

Scrolls a file (displayed in the display "window") by a number of characters.

## Syntax

**DspFileScroll(*nAN, Direction, Characters*)**

*nAN*:

The animation-point number.

*Direction*:

The direction in which to scroll:

1 - Left

2 - Right

3 - Up

4 - Down

*Characters:*

The number of characters to scroll. To page up or page down through the file, scroll by the height of the file-to-screen window (returned by DspFileGetInfo(AN, 1)).

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DspFile](#), [DspFileGetInfo](#), [DspFileSetName](#), [DspFileGetName](#)

## Example

### Page Keyboard

Key Sequence	PgUp
Command	DspFileScroll(20,3,10)
Comment	Scroll up 10 lines

## See Also

[Display Functions](#)

## DspFileSetName

Sets the name of the file to display in the display "window". You should call the DspFile() function first (as the entry function for a graphics page) to define the attributes of the display. You can then use the DspFileSetName() function (as a keyboard command) to display a user-specified file. When you call this function, the specified file name is read from disk and displayed on the screen.

## Syntax

**DspFileSetName(*nAN*, *sName*)**

*nAN*:

The animation-point number.

*sName*:

The name of the file to display.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DspFile](#), [DspFileGetInfo](#), [DspFileGetName](#), [DspFileScroll](#)

## Example

### Pages

Page Name	FilePage
Entry Command	DspFile(20,0,20,80)
Comment	Defines a file to screen display to commence at AN20

### Page keyboard

Key Sequence	##### Enter
Command	DspFileSetName(20, Arg1)
Comment	Displays a specified file on the page

```
DspFile(20,0,20,80);
/* Defines the file-to-screen display to commence at AN20 using
the default font, with a window size of 20 lines x 80 columns. */
DspFileSetName(20,"C:\AUTOEXEC.BAT");
! Displays file C:\AUTOEXEC.BAT.
```

## See Also

[Display Functions](#)

## DspFont

Creates a font and returns a font handle. If the requested font already exists, its font handle is returned. You can use this font handle in the functions that display text, buttons, and text files.

If the exact font size does not exist, the closest font size is used.

## Syntax

**DspFont**(*FontType*, *PixelSize*, *ForeOnColor*, *BackOnColor* [, *ForeOffColor*] [, *BackOffColor*] )

*FontType*:

The font type, for example, "Helv".

***PixelSize:***

The font size, as a positive number for pixels, or a negative number for points.

***ForeOnColor:***

The foreground color used for the text. If implementing flashing color, this is the initial color that will be used. Select a color from the list of Predefined Color Names and Codes or create an RGB-based color using the function MakeColour.

***BackOnColor:***

The color used for the background of text. If implementing flashing color, this is the initial color that will be used. Select a color from the list of Predefined Color Names and Codes or create an RGB-based color using the function MakeColour.

***ForeOffColor:***

An optional argument only required if implementing flashing color for the font foreground. It represents the secondary color used. Select a color from the list of Predefined Color Names and Codes or create an RGB-based color using the function MakeColour.

***BackOffColor:***

An optional argument only required if implementing flashing color for the font background. It represents the secondary color used. Select a color from the list of Predefined Color Names and Codes or create an RGB-based color using the function MakeColour.

## Return Value

The font handle as an integer. If the font cannot be created, -1 is returned. The font handle identifies the table where all data on the associated font is stored.

## Related Functions

[DspFontHnd](#), [DspText](#), [DspButton](#), [DspButtonFn](#), [DspFile](#), [DspSetFontPopupMenuFont](#)

## Example

```
Font = DspFont("Helv", -12, White, Red);
DspText(20, Font, "Text in Helv Font");
/* Displays "Text in Helv Font" in 12-point Helvetica font in
white on red at AN20. */
Font = DspFont("Helv", 24, White, Red, Black);
DspText(20, Font, "Text in Helv Font");
/* Displays "Text in Helv Font" in 24 pixel Helvetica font in
flashing black and white on red at AN20. */
```

## See Also

[Display Functions](#)

## DspFontHnd

Gets the font handle of a font that is defined in the Fonts database. You can use this font handle in the functions that display text, buttons, and text files.

## Syntax

**DspFontHnd(*sName*)**

*Name:*

The font name in the fonts database.

## Return Value

The font handle as an integer. If the font cannot be found, -1 is returned. The font handle identifies the table where the data on the associated font is stored.

## Related Functions

[DspFont](#), [DspText](#), [DspButton](#), [DspButtonFn](#), [DspFile](#), [DspSetPopupMenuFont](#)

## Example

Font Name	BigFont
Font Type	Helv
Pixel Size	24
Foreground Color	Blue
Background Color	-1
Comment	Defines a font

```
hBigFont=DspFontHnd("BigFont");
DspText(20,hBigFont,"Text in Big Font");
/* Displays "Text in Big Font" in 24-point Helvetica font in blue
on an unchanged background at AN20. */
```

## See Also

[Display Functions](#)

## DspFullScreen

Disables or enables the fullscreen mode of the currently active window. This function does not resize the

window when it is called; it merely sets the mode flag. The next time the window is displayed, its size (on screen) changes to reflect the setting of the flag. This function overrides the [Animator]FullScreen parameter setting.

If [Page]DynamicSizing is turned on, a page in fullscreen state takes up the entire display area (assuming this does not affect its aspect ratio), and it cannot be resized. Also, a fullscreen page will display without a title bar unless **Title Bar** is checked in Page Properties (or was checked when the page was created). Resizing pages can result in lower picture quality. If this is unacceptable, you should re-design the page using the desired resolution.

If [Page]DynamicSizing is turned off, fullscreen will have the same limitations as it had in versions of Plant SCADA prior to V5.10. In other words, for a page to be displayed in fullscreen, the size of the page needs to be the same size as the display (or bigger). If the page is smaller than the display, the title bar will still display even if fullscreen mode is enabled. Check the size of the graphic pages in CtDraw Tools | Page Attributes Dialog to verify that it is the same as the display resolution. For example 640x480 for VGA, 800x600 for SVGA and 1024x768 for XGA.

## Syntax

**DspFullScreen(*Mode*)**

*Mode*:

Fullscreen mode:

0 - Disable fullscreen mode.

1 - Enable fullscreen mode without title bar

2 – Enable fullscreen mode with title bar.

Return Value

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[WinMode](#)

## Example

```
/*Minimize the Window, Enable fullscreen mode and then maximize  
the window.*/  
WinMode(6);  
DspFullScreen(1);  
WinMode(3);
```

## See Also

[Display Functions](#)

## DspGetAnBottom

Gets the bottom extent of the object at the specified AN.

### Syntax

**DspGetAnBottom(*nAN*)**

*nAN*:

The animation-point number.

### Return Value

The y coordinate of the bottom extent of the object at the AN. If no object exists at the AN, -1 is returned.

### Related Functions

[DspGetAnBottom](#), [DspGetAnWidth](#), [DspGetAnHeight](#), [DspGetAnLeft](#), [DspGetAnRight](#), [DspGetAnTop](#),  
[DspGetAnNext](#), [DspGetAnExtent](#)

### Example

```
nBottom = DspGetAnBottom(30);
```

### See Also

[Display Functions](#)

## DspGetAnCur

Gets the AN of the current graphics object. This function should only be used by expressions or Cicode functions called from the condition fields of a graphics object, excluding input/command fields. If you need to know the AN that triggered the input/command, the [KeyGetCursor](#) function may be used as it returns the AN where the cursor is currently positioned.

You cannot call this function from the Button or Keyboard forms.

### Syntax

**DspGetAnCur()**

### Return Value

The AN associated with the current graphics object. If this function is called outside the page animation system or from an input/command field, -1 will be returned.

## Example

### Numbers

AN	20
Expression	MyFunc(PV_10)
Comment	Display the value of PV_10 at AN20

```
/* Function displays a number at the current AN and returns the
value supplied in the call */
INT
FUNCTION
MyFunc(INT value)
    INT AN, hNew;
    AN = DspGetAnCur();
    hNew = DspAnNewRel(AN, 0, 20);
    DspStr(hNew, "Default", VALUE:###.#);
    RETURN value;
END
```

## See Also

[Display Functions](#)

### DspGetAnExtent

Gts the extent (the page co-ordinates) of the object at the specified AN.

## Syntax

**DspGetAnExtent(*nAN, Top, Left, Bottom, Right*)**

*nAN*:

The AN at which the object is positioned.

*Top*:

A buffer that contains the top-most extent of the object.

*Left*:

A buffer that contains the left-most extent of the object.

*Bottom*:

A buffer that contains the bottom-most extent of the object.

*Right*:

A buffer that contains the right-most extent of the object.

## Return Value

0 (zero) if successful, otherwise an error is returned. The *Top*, *Left*, *Bottom*, and *Right* arguments contain the

extents of the object, in pixels.

## Related Functions

[DspGetAnRawExtent](#), [DspGetAnWidth](#), , [DspGetAnLeft](#), [DspGetAnRight](#), [DspGetAnBottom](#), [DspGetAnTop](#),  
[PageTransformCoords](#)

## Example

```
// Get extents at AN 25.  
DspGetAnExtent(25, Top, Left, Bottom, Right);
```

## See Also

[Display Functions](#)

### DspGetAnRawExtent

Gets the extent of the object from the graphics page at the specified AN. The extent represents the page coordinates at which the object was originally inserted.

**Note:** If the object has movement configured, use the [DspGetAnExtent](#) function to get the extent of the object.

## Syntax

**DspGetAnRawExtent(*nAN*, *Top*, *Left*, *Bottom*, *Right*)**

*nAN*:

The AN at which the object is positioned.

*Top*:

A buffer that contains the top-most extent of the object.

*Left*:

A buffer that contains the left-most extent of the object.

*Bottom*:

A buffer that contains the bottom-most extent of the object.

*Right*:

A buffer that contains the right-most extent of the object.

## Return Value

0 (zero) if successful, otherwise an error is returned. The *Top*, *Left*, *Bottom*, and *Right* arguments contain the extents of the object, in pixels.

## Related Functions

[DspGetAnExtent](#), [DspGetAnWidth](#), [DspGetAnHeight](#), [DspGetAnLeft](#), [DspGetAnRight](#), [DspGetAnBottom](#),  
[DspGetAnTop](#), [PageTransformCoords](#)

## Example

```
// Get extents at AN 25.  
DspGetAnRawExtent(25, Top, Left, Bottom, Right);
```

## See Also

[Display Functions](#)

### DspGetAnFirst

Gets the first AN on the current page, based on the order in which the ANs were stored by Graphics Builder.

## Syntax

`DspGetAnFirst()`

## Return Value

The value for the first AN, otherwise an error is returned.

## Related Functions

[DspGetAnNext](#)

## See Also

[Display Functions](#)

### DspGetAnFromName

Name used to retrieve the AN of an object on the page. Use the following relative path syntax:

[RelativePath].[Group].[Group].Control

This will browse the group hierarchy to a specific starting point, and then drill down to other groups to find the named control or object.

If you do not use a relative path the system will first look for an object within the groups specified relative to the object the cicode is running on, and if the name is not found, it will then search the page for the first existence of the object name. See [Referencing an object using a name at runtime](#) for more information.

**Note:** When retrieving the AN for an object within a genie or super genie you need to use a relative path.

## Syntax

**DspGetAnFromName(*sName*)**

*sName*

The Name of the object used as a reference for the AN.

## Return Value

AN of object or -1 if not found.

## Related Functions

[DspAnSetName](#), [DspGetNameFromAn](#)

## Example

```
// Example of relative pathing syntax
// Reference from a current group, symbol or genie
DspGetAnFromName("./Object1")
// Navigate three levels up and from the root level search for Object1.
DspGetAnFromName("../..\\Object1")
```

## See Also

[Display Functions](#)

## DspGetAnFromNameRelative

Name used to retrieve the animation number (AN) of an object on the page relative to a given Animation Number(AN). Use the following syntax:

[RelativePath].[Group].[Group].Control

This will browse the group hierarchy to a specific starting point, and then drill down to other groups to find the named control or object.

See [Referencing an Object using a Name at Runtime](#) more information on the relative path syntax.

**Note:** When retrieving the AN for an object within a genie or super genie you need to use a relative path.

## Syntax

**DspGetAnFromNameRelative(*hAN*, *sName*)**

*hAN*

AN used as the starting point for the search.

*sName*

The Name used as a reference for the AN.

**Note:** With an AN you can start the search from any level and not just the group you are in.

## Return Value

AN of object or -1 if not found.

## Related Functions

[DspAnSetName](#), [DspGetNameFromAn](#)

## Example

```
// example of relative pathing syntax
DspGetAnFromNameRelative(625, "..\..\..\Object1")
//Using another AN as browse starting point
DspGetAnFromNameRelative(639, "..\..\Object1")
```

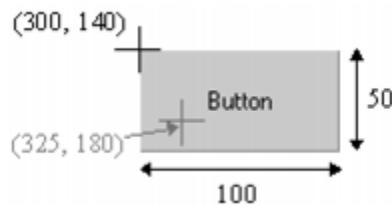

## See Also

[Display Functions](#)

### DspGetAnFromPoint

Gets the AN of the object at a specified set of screen coordinates. If the X and Y coordinates given are within the extents of an object, then the AN number of the object will be returned.

For example, if there is a button at coordinates (300, 140), and it is 100 wide, 50 high, this function would return the AN if it uses X between 300 & 400 and Y between 140 and 190, such as DspGetAnFromPoint(325,180).

If you are using groups and the specified coordinates point to an object that is part of a group, the AN of the object is returned, not the AN of the group.

## Syntax

**DspGetAnFromPoint(X, Y [, PrevAN] )**

**X:**

The x coordinate of the screen point.

**Y:**

The y coordinate of the screen point.

**PrevAN:**

Retrieves the previous AN (in z-order) in situations where a number of objects overlap at the specified point. The default of 0 (zero) specifies no previous AN. A non-zero value should only ever be passed if it is the result of a

previous call to DspGetAnFromPoint.

## Return Value

The AN or 0 (zero) if no object exists at the point.

For clipped objects the AN will not be returned if the mouse is over the clipped region.

## Example

```
DspGetMouse(X,Y);
// GetMouse position
AN = DspGetAnFromPoint(X,Y);
// Gets AN if mouse is over the object
Prompt("AN of object =" + nAN:###);
!Displays the object's AN at the prompt line
```

If several objects overlap each other at the specified point, the PrevAN argument can be used to produce a list of the associated ANs. This is achieved by using PrevAN to pass the previous result into another call of the function until a zero return is given.

```
INT nAn;
nAn = DspGetAnFromPoint(100,100)
WHILE nAn <> 0 DO
    //Do Something
    nAn = DspGetAnFromPoint(100,100,nAn);
END
```

## See Also

[Display Functions](#)

## DspGetAnHeight

Gets the height of the object at a specified AN.

## Syntax

**DspGetAnHeight(*nAN*)**

*nAN*:

The animation-point number.

## Return Value

The height of the object (in pixels). If no object exists at the AN, -1 is returned.

## Related Functions

[DspGetAnWidth](#), [DspGetAnLeft](#), [DspGetAnRight](#), [DspGetAnTop](#)

## Example

```
nHeight = DspGetAnHeight(30);
```

## See Also

[Display Functions](#)

### DspGetAnLeft

Gets the left extent of the object at the specified AN.

## Syntax

**DspGetAnLeft(*nAN*)**

*nAN*:

The animation-point number.

## Return Value

The x coordinate of the left extent of the object at the AN. If no object exists at the AN, -1 is returned.

## Related Functions

[DspGetAnWidth](#), [DspGetAnHeight](#), [DspGetAnRight](#), [DspGetAnBottom](#), [DspGetAnTop](#), [DspGetAnExtent](#)

## Example

```
nLeft = DspGetAnLeft(30);
```

## See Also

[Display Functions](#)

### DspGetAnNext

Returns the AN that follows the specified AN, based on the order in which the ANs were stored on a page by Graphics Builder.

## Syntax

**DspGetAnNext(*nAN*)**

*nAN*:

The animation-point number.

## Return Value

The value for the next AN. If -1 is returned, it means the specified AN is invalid or it is the last AN on the page.

## Related Functions

[DspGetAnFirst](#)

## See Also

[Display Functions](#)

## DspGetAnRight

Gets the right extent of the object at the specified AN.

## Syntax

**DspGetAnRight(*nAN*)**

*nAN*:

The animation-point number.

## Return Value

The x coordinate of the right extent of the object at the AN. If no object exists at the AN, -1 is returned.

## Related Functions

## Example

```
nRight = DspGetAnRight(30);
```

## See Also

[Display Functions](#)

## DspGetAnTop

Gets the top extent of the object at the specified AN.

## Syntax

**DspGetAnTop(*nAN*)**

*nAN*:

The animation-point number.

## Return Value

The y coordinate of the top extent of the object at the AN. If no object exists at the AN, -1 is returned.

## Related Functions

[DspGetAnWidth](#), [DspGetAnHeight](#), [DspGetAnLeft](#), [DspGetAnRight](#), [DspGetAnBottom](#), [DspGetAnExtent](#)

### DspGetEnv

Gets a page environment variable.

## Syntax

**DspGetEnv(*sName*)**

*sName*:

The name of the variable (set using the page environment dialog).

**Note:** Page environment variables are case sensitive.

## Return Value

The value of the variable (as a string).

## Example

```
FUNCTION
PageGroup()
    PageDisplay(DspGetEnv("GroupMenu"));
END
```

## See Also

[Display Functions](#)

### DspGetMetadataFromName

Name used to retrieve the metadata of an object on the page. Use the following relative path syntax:

[RelativePath].[Group].[Group].Control

This will browse the group hierarchy to a specific starting point, and then drill down to other groups to find the named control or object and metadata. See [Referencing an Object using a Name at Runtime](#) for more information.

## Syntax

**DspGetMetadataFromName(*sName*, *sMetaName*)**

*sName*

The Name used as a reference for the object.

*sMetaName*

The name of the metadata to be returned.

The name belonging to the metadata name/value pair defined in the object's properties metadata tab. See the topic Metadata in the main help for more information.

## Return Value

The value of the metadata or blank.

## Related Functions

[DspSetMetadataFromName](#)

## Example

```
// example of relative pathing syntax
// Relative pathing varies according to the starting point of the search
DspGetMetadataFromName("Object1", "Pump")
DspGetMetadataFromName(".\Object1", "Pump")
DspGetMetadataFromName("../..\..\Object1", "Pump")
```

## See Also

[Display Functions](#)

## DspGetMetadataFromNameRelative

Name used to retrieve the metadata of an object on the page relative to a given Animation Number (AN). Use the following syntax:

[RelativePath].[Group].[Group].Control

This will browse the group hierarchy from the given AN, and then drill down to other groups to find the named control or object. See Referencing an Object using a Name at Runtime for more information.

## Syntax

**DspGetMetadataFromNameRelative(*hAN*, *sName*, *sMetaName*)**

*hAN*

AN used as the starting point for the search.

With an AN you can start the search from any level and not just the group you are in.

***sName***

The name of the AN used as a reference for the object.

***sMetaName***

The name of the metadata to be returned.

The name belonging to the metadata name/value pair defined in the object's properties metadata tab. See the topic **Metadata** in the main help for more information.

## Return Value

The value of the metadata or blank.

## Related Functions

[DspSetMetadataFromNameRelative](#)

## Example

```
// example of relative pathing syntax
DspGetMetadataFromNameRelative(639, "..\..\Object1", "Pump")
//Using another AN as browse starting point
DspGetMetadataFromNameRelative(625, "..\..\..\Object1", "Pump")
```

## See Also

[Display Functions](#)

## DspGetMouse

Gets the x and y coordinates of the mouse position, relative to the top left corner of the window.

## Syntax

**DspGetMouse(X, Y)**

X:

A locally declared variable used to store the x pixel coordinate of the mouse position, returned from this function.

Y:

A locally declared variable used to store the y pixel coordinate of the mouse position, returned from this function.

---

**Note:** Locally declared Cicode variables need to be used for X and Y, otherwise an "Incompatible Type" compile error may be generated.

## Return Value

0 (zero) if successful, otherwise an error is returned. The X and Y variables are set to the mouse position.

## Related Functions

[DspAnGetPos](#), [DspGetMouseOver](#), [DspGetNearestAn](#), [PageTransformCoords](#)

## Example

```
! If the mouse cursor is at x,y pixel coordinate 43,20;  
DspGetMouse(X,Y);  
! Sets X to 43 and Y to 20.
```

## See Also

[Display Functions](#)

## DspGetMouseOver

Determines if the mouse is within the boundaries of a given AN.

## Syntax

**DspGetMouseOver(*nAN*)**

*nAN*

The AN of the animation you wish to check, or -1 for the current AN. Defaults to -1.

## Return Value

1 if within the specified AN, 0 if not.

Will return False if the mouse is over the clipped part of an AN.

## Related Functions

[KeyGetCursor](#), [DspAnGetPos](#), [DspGetMouse](#), [DspGetNearestAn](#)

## See Also

[Display Functions](#)

## DspGetNameFromAn

Using a valid animation number (AN) the animation name of the object is returned.

## Syntax

**DspGetNameFromAn(*hAN*)**

*hAN*:

The AN used as a reference for the name of the object.

## Return Value

The animation name of the object, or blank

## Related Functions

[DspGetAnFromName](#), [DspAnSetName](#)

## See Also

[Display Functions](#)

## DspGetNearestAn

Gets the AN nearest to a specified x,y pixel location.

If using groups and the nearest object to the specified coordinates is part of a group, the AN of the object is returned, not the AN of the group.

If using clipping objects completely clipped ANs will be ignored when determining the nearest AN to the specified x, y pixel location. Partially clipped ANs are treated as being fully visible.

## Syntax

**DspGetNearestAn(*X, Y*)**

*X*:

The x coordinate (in pixels).

*Y*:

The y coordinate (in pixels).

## Return Value

The animation point number (AN). A value of -1 is returned if no AN is found.

## Related Functions

[DspGetMouse](#), [DspAnGetPos](#), [DspGetAnFromPoint](#)

## Example

```
DspGetMouse(X,Y);
! Gets mouse position.
AN=DspGetNearestAn(X,Y);
! Gets AN nearest to the mouse.
Prompt("Mouse At AN"+nAN:###);
! Displays AN nearest to the mouse.
```

## See Also

[Display Functions](#)

### DspGetParentAn

Gets the parent animation number (if any), for the specified animation number. AN animation point will have a parent animation point if it corresponds to an object in a group.

## Syntax

**DspGetParentAn(*nAN*)**

*AN:*

The animation-point number.

## Return Value

The parent animation point number (AN). If no parent animation exists or an invalid animation number is passed, 0 (zero) is returned.

## Related Functions

[DspGetAnCur](#)

## Example

```
// Get the parent animation for object 89 (part of a symbol set)
AN = DspGetParentAn(89);
```

## See Also

[Display Functions](#)

### DspGetSlider

Gets the current position (value) of a slider at an AN. You can call this function in the slider event to find the new

position of the slider.

**Note:** This function was designed to only be used on Cicode objects, or the animation point object from the version 3.xx/4.xx toolbox.

## Syntax

**DspGetSlider(*nAN*)**

*nAN*:

The animation-point number.

## Return Value

The value of the slider from 0 to 32000. If no animation exists at the AN, -1 is returned.

## Related Functions

[DspSetSlider](#)

## Example

```
// Get the position of the slider at AN 30
nPos = DspGetSlider(30);
```

## See Also

[Display Functions](#)

## DspGetTip

Gets the tool tip text associated with an AN.

## Syntax

**DspGetTip(*nAN*, *Mode*)**

*nAN*:

The AN from which to get the tool tip text. If no object is configured at the AN, the function will return an empty string.

*Mode*:

0 - Tool tips from all animation records configured at the AN. Tips are concatenated with a newline character between each string. (This mode is only used for V3.xx and V4.xx animations, and has been subsequently superseded.)

1 - The tool tip from the object configured at the AN.

## Return Value

The tool tip text (as a string). If no user tip is available, an empty string is returned.

## Related Functions

[DspSetTip](#), [DspTipMode](#)

## Example

```
!Display the tool tip text on AN19
DspText(19, 0, DspGetTip(KeyGetCursor(), 1));
```

## See Also

[Display Functions](#)

## DspGrayButton

Grays and disables a button. If the button is a symbol, the symbol is overwritten with a gray mask. (When a button is grayed, it cannot be selected.) If the **Disabled** field in the Buttons database is blank, the button is enabled unless you use this function. If the **Disabled** field in the Buttons database contains an expression, this function will not override the expression.

---

**Note:** This function was designed to only be used on Cicode objects, or the animation point object from the version 3.xx/4.xx toolbox.

---

## Syntax

**DspGrayButton(*nAN*, *nMode*)**

*nAN*:

The AN where the button is located.

*nMode*:

The mode of the operation:

0 - Ungray the button.

1 - (GRAY\_SUNK) Recess the text or symbol (the text or symbol on the button is recessed and shadowed).

2 - (GRAY\_PART) This mode is now obsolete - it now has the same effect as GRAY\_ALL.

3 - (GRAY\_ALL) - Mask the entire button (a gray mask displays over the face of the button).

## Return Value

0 (zero) if successful, otherwise, -1 (if no AN is found).

## Related Functions

[DspButton](#), [DspButtonFn](#), [DsplsButtonGray](#)

## Example

```
! Disable button at AN21
DspGrayButton(21, GRAY_SUNK);
```

## See Also

[Display Functions](#)

## DsplInfo

Extracts individual pieces of object information from an AN. Each AN can have multiple expressions associated with it, and each expression can have multiple variables associated with it. You use an index to refer to each individual expressions or variables. Typically, you would query the number of expressions, then the number of variables in a given expression, then the details of a given variable tag.

**Note:** Before calling this function you need to first use **DsplInfoNew()** to create a handle to the information block from which you want to extract information.

## Syntax

**DsplInfo(*hInfo*, *Type*, *Index*)**

*hInfo*:

The object information block handle, as returned by **DsplInfoNew()**. This handle identifies the table (or block) where all object data is stored.

*nType*:

The type of data to extract:

0 - Object title (the name of the object type)

1 - Object expression text

2 - Object expression result text

3 - The variable tag name

4 - Not supported.

5 - The engineering value associated with the variable

6 - The Cicode context. Calling **DsplInfo** with this Type will return a string describing the context in which the Cicode expression is contained. For example, if it appears on the horizontal movement tab it would return "Move X".

7 - The number of Cicode expressions. Calling **DsplInfo** with this Type will return the number of Cicode expressions associated with this animation point.

8 - The number of tags in the expression. Calling **DsplInfo** with this Type will return the number of tags that appear in the given Cicode expression.

9 - Name of the cluster in which the variable tag resides.

10 - Full name of the variable tag in the form *cluster.tagname*.

*Index:*

An index to the variable within the information block. The required index changes according to the Type as follows:

- For Types 0 to 2, 6 and 8, the index needs to be set to the index of the expression that you wish to query.
- For Types 3 to 5, the index needs to be set to the index of the tag that you wish to query. When one of these types is used, DsplInfo will query the tag in the most recently queried expression (otherwise expression 0).
- For Type 7, the index is ignored.

---

**Note:** Getting the raw value using DsplInfo is no longer supported. To get the raw value of a tag, use the TagSubscribe function, specifying a value of "Raw" for the *sScaleMode* parameter. When using TagSubscribe, you can either call SubscriptionGetAttribute to obtain the value whenever required or register a callback Cicode function to run when the value changes. See [TagSubscribe](#) for more details.

---

## Return Value

The object information (as a string). A blank string is returned if you specify a non-existent expression or variable.

## Related Functions

[DsplInfoNew](#), [DsplInfoField](#), [DsplInfoDestroy](#), [TagSubscribe](#), [SubscriptionAddCallback](#), [SubscriptionGetAttribute](#)

## Example

```
INT hInfo;
INT iEngineeringValue;
INT iNumberOfExpressions;
INT iNumberOfTags;
INT iExpressionIndex;
INT iTagIndex;
STRING sObjectType;
STRING sExpressionText;
STRING sExpressionResult;
STRING sExpressionContext;
STRING sTagName;
hInfo = DsplInfoNew(AN);
IF (hInfo > -1) THEN
    sObjectType = DsplInfo(hInfo, 0, 0);
    iNumberOfExpressions = StrToInt(DsplInfo(hInfo, 7, 0));
    FOR iExpressionIndex = 0 TO iExpressionIndex < iNumberOfExpressions DO
        sExpressionText = DsplInfo(hInfo, 1, iExpressionIndex);
        sExpressionResult = DsplInfo(hInfo, 2, iExpressionIndex);
        sExpressionContext = DsplInfo(hInfo, 6, iExpressionIndex);
        iNumberOfTags = StrToInt(DsplInfo(hInfo, 8, iExpressionIndex));
        FOR iTagIndex = 0 TO iTagIndex < iNumberOfTags DO
            sTagName = DsplInfo(hInfo, 3, iTagIndex);
            iEngineeringValue = StrToInt(DsplInfo(hInfo, 5, iTagIndex));
        ..
    END
```

```
    ..  
END  
END
```

### DspInfoDestroy

Destroys an object information block created by DspInfoNew(). You should destroy an object information block when you no longer need it, to free Plant SCADA resources.

When the page (with which the object is associated) is closed, Plant SCADA automatically destroys the object information block.

## Syntax

**DspInfoDestroy(*hInfo*)**

*hInfo*:

The object information block handle, as returned by DspInfoNew(). This handle identifies the table (or block) where all object data is stored.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DspInfo](#), [DspInfoNew](#), [DspInfoField](#), [DspInfoValid](#)

## Example

```
hInfo=DspInfoNew(20);  
! Do animation operation  
DspInfoDestroy(hInfo);
```

## See Also

[Display Functions](#)

### DspInfoField

Obtains static and real-time data from a variable tag. You get static data from the Variable Tags database. The additional field "Eng\_Value", returns dynamic real-time data for the variable tag. To get this real-time data, you need to first call the DspInfoNew() function to get the information block handle *hInfo*.

Getting the raw value of a variable tag using `DspInfoField` is no longer supported. To get the raw value of a tag, use the `TagSubscribe` function, specifying a value of "Raw" for the `sScaleMode` parameter. When using `TagSubscribe`, you can either call `SubscriptionGetAttribute` to obtain the value whenever required or register callback cicode function to run when the value changes. See `TagSubscribe` for more details.

## Syntax

`DspInfoField(hInfo, sTag, sField [, sClusterName] )`

*hInfo*:

The object information block handle, as returned by `DspInfoNew()`. This handle identifies the table (or block) where data on the object is stored. Set this handle to 0 (zero) if you do not require real-time data.

*sTag*:

The name of the variable tag. The name of the tag can be prefixed by the name of the cluster that is "ClusterName.Tag". This argument does not support arrays. If array syntax is used, the information will be retrieved for only the tag name.

*sField*:

The name of the field from which to extract the data:

- *Cluster* - Name of the cluster in which the Tag resides
- *Comment* - Variable tag comment
- *Eng\_Full* - Engineering Full Scale
- *Eng\_Zero* - Engineering Zero Scale
- *Eng\_Units* - Engineering Units
- *Eng\_Value* - Scaled engineering value - Dynamic
- *Field* - Description
- *FullName* - Full name of the tag in the form *cluster.tagname*.
- *Name* - Variable Tag Name
- *Type* - Data Type
- *Unit* - I/O Device Name

*sClusterName*:

Specifies the name of the cluster in which the Tag resides. This is optional if you have one cluster or are resolving the tag via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

The data (as a string).

## Related Functions

[DspInfo](#), [DspInfoNew](#), [DspInfoDestroy](#), [SubscriptionGetAttribute](#), [SubscriptionAddCallback](#), [TagSubscribe](#)

## Example

```
! Get the I/O device that Variable Tag "PV123" belongs to.  
IODev=DspInfoField(0,"PV123","Unit");  
! Get the real-time engineering value of a tag.  
hInfo=DspInfoNew(20);  
sTag=DspInfo(hInfo,3,0);  
EngValue=DspInfoField(hInfo,sTag,"Eng_Value");
```

## See Also

[Display Functions](#)

### DspInfoNew

Creates an object information block. Use this function with the associated low-level animation information functions to get and process object information on an AN.

---

**Note:** When you have finished with the object information block, you need to destroy it with the DspInfoDestroy() function. There are limited number of info 383 blocks that can be allocated, if they are not freed properly DspInfoNew will return -1.

---

If you need simple animation help, use the InfoForm() or the InfoFormAn() functions.

---

**Note:** DspInfoNew, InfoForm and InfoFormAn will not work if the parameter[General]SymbolicInfo = 0.

---

## Syntax

**DspInfoNew(*nAN*)**

*nAN*:

The AN for which object information is provided.

## Return Value

The object information block handle. If no object data is available, then -1 is returned.

## Related Functions

[DspInfo](#), [DspInfoField](#), [InfoForm](#), [InfoFormAn](#)

## Example

```
/*This example creates a form, with the title "Tag Info" and a  
size of 25 x 5 characters. It creates an information block for the  
AN closest to the mouse cursor and then extracts the name, I/O  
device, and engineering value for the first tag in the object  
expression.*/  
INT hInfo;  
STRING sTag;
```

```
hInfo=DspInfoNew(DspGetNearestAN());
IF hInfo>-1 THEN
    FormNew("Tag Info",25,5,2);
    sTag=DspInfo(hInfo,3,0);
    FormPrompt(0,0,sTag);
    FormPrompt(0,16,DspInfoField(hInfo,sTag,"Unit"));
    FormPrompt(0,32,DspInfoField(hInfo,sTag,"Eng_Value"));
    FormRead(0);
    DspInfoDestroy(hInfo);
END
```

## See Also

[Display Functions](#)

### DspInfoValid

Checks if an object information block handle is valid. An object information block handle becomes invalid after it is destroyed, or if the user closes the page it is associated with. Use this function if background Cicode is using the object information block, and the operator closes the page.

## Syntax

**DspInfoValid(*hInfo*)**

*hInfo*:

The object information block handle, as returned by DspInfoNew(). This handle identifies the table (or block) where all object data is stored.

## Return Value

1 if the information block handle is valid, otherwise 0 (zero).

## Related Functions

[DspInfoNew](#), [DspInfoField](#), [DsplInfoDestroy](#)

## Example

```
IF DspInfoValid(hInfo) THEN
    EngValue=DspInfoField(hInfo,sTag,"Eng_Value");
END
```

## See Also

[Display Functions](#)

## DspIsButtonGray

Gets the current status of a button.

**Note:** This function was designed to only be used on Cicode objects, or the animation point object from the version 3.xx/4.xx toolbox.

## Syntax

**DspIsButtonGray(nAN)**

*nAN*:

The AN for which object information is provided.

## Return Value

The current mode of the button:

- 0 - The button is active (not grayed).
- 1 - (SUNK\_GRAY) The button is inactive (the text or symbol on the button is recessed).
- 2 - (PART\_GRAY) This mode is now obsolete. The button will be inactive even if part\_gray is returned.
- 3 - (ALL\_GRAY) The button is inactive (the entire button is masked).

## Related Functions

[DspButton](#), [DspButtonFn](#), [DspGrayButton](#)

## Example

```
! Check the status of the button at AN21
status = DspIsButtonGray(21);
```

## See Also

[Display Functions](#)

## DspKernel

Displays the Kernel window.

To display the Kernel window, the user that is currently logged in needs to be assigned to a Role that has the **Kernel Access** property set to "Full Access" or "Read Only". A Read Only user can access the Kernel, but cannot perform some privileged commands like running Cicode. See [Display the Kernel Window](#).

**Note:** The special Kernel user that enabled Kernel access in versions prior to Plant SCADA 2023 R2 no longer has default access to the Kernel window.

Kernel access should be restricted to authorised personnel only as once they are in the Kernel, they can execute any Cicode function without further privilege restrictions and therefore have total control of Plant SCADA (and

subsequently the plant and equipment). Please be aware that you can also open the Kernel by setting the [Debug]Menu parameter to 1 and, when your system is running, selecting **Kernel** from the system menu.

You should be experienced with Plant SCADA and Cicode before attempting to use the Kernel as these facilities are powerful, and if used incorrectly, can corrupt your system.

**Note:**

- You should only use the Kernel for diagnostics and debugging purposes, and not for normal Plant SCADA operation.
- Kernel access should be restricted to authorised personnel only as once they are in the Kernel, they can execute any Cicode function without further privilege restrictions and therefore have total control of Plant SCADA (and subsequently the plant and equipment).

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

- Do not use the Kernel for normal Plant SCADA operation. The Kernel is only for diagnostics and debugging purposes.
- Configure your security so that only approved personnel can view or use the Kernel.
- Do not view or use the Kernel unless you are an expert user of Plant SCADA and Cicode, or are under the direct guidance of AVEVA Support.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

## Syntax

**DspKernel(*nMode*)**

*nMode*:

The display mode of Kernel:

1 - Display the Kernel. If the Kernel is already displayed and *nMode*=1, the keyboard focus is changed to the Kernel.

0 - Hide the Kernel

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[KerCmd](#), [TraceMsg](#)

## Example

```
DspKernel(1);  
!Display the Runtime Kernel window
```

## See Also

### DspMarkerMove

Moves a trend or chart marker to a specified position.

## Syntax

**DspMarkerMove(*nAN*, *hMarker*, *Offset*)**

*nAN*:

The AN where the trend or chart is positioned.

*hMarker*:

The marker handle, as returned from the DspMarkerNew() function. The marker handle identifies the table where all data on the associated marker is stored.

*Offset*:

The offset by which to move the marker. Vertical markers have an offset from 0 (zero) to the maximum number of samples in the trend. Horizontal markers have a offset of 0 (zero) to 32000.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DspMarkerNew](#), [OnEvent](#)

## Example

See [DspMarkerNew](#).

## See Also

[Display Functions](#)

### DspMarkerNew

Creates a new trend marker. A trend marker is used to show cursor values or limits on a trend. You can use up to 10 markers on a single trend or chart.

If you add markers to a trend or chart that Plant SCADA is animating, you need to repaint them using the trend paint event (OnEvent(Window,22)). (Otherwise Plant SCADA will delete any markers displayed when the trend is updated.)

## Syntax

**DspMarkerNew(*nAN*, *Mode*, *Color*)**

*nAN*:

The animation-point number.

*Mode*:

The mode of the marker:

*0* - A vertical marker

*1* - A horizontal marker

*Color*:

The color of the marker (flashing color not supported). Select a color from the list of [Predefined Color Names and Codes](#) or create an RGB color using the function [MakeColour](#).

## Return Value

The marker handle, or -1 if the function is unsuccessful. The marker handle identifies the table where data on the associated marker is stored.

## Related Functions

[DspMarkerMove](#), [OnEvent](#)

## Example

```
INT offset; ! offset of marker
INT hMarker; ! marker handle
hMarker = DspMarkerNew(40, 0, WHITE);
! create a new marker, vertical WHITE
offset = 100;
DspMarkerMove(40, hMarker, offset);
! Moves marker to offset 100
OnEvent(22, MyTrendPaint);
! set trend paint event, needs to stop event when change pages
! this function is called when Plant SCADA updates the trend
INT
FUNCTION
MyTrendPaint()
    DspMarkerMove(40, hMarker, offset);
    RETURN 0;
END
```

## See Also

[Display Functions](#)

## DspMCI

Controls a multimedia device. The Media Control Interface (MCI) is a high-level command interface to multimedia devices and resource files. MCI provides applications with device-independent capabilities for controlling audio and visual peripherals (for example, for playing multimedia devices and recording multimedia resource files).

Using this function, you can control multimedia devices by using simple commands like open, play, and close. MCI commands are a generic interface to multimedia devices. You can control any supported multimedia device, including audio playback and recording. For a full overview of MCI, see the Windows *Multimedia Programmer's Guide*.

## Syntax

**DspMCI(*sCommand*)**

*sCommand*:

The MCI command. See Microsoft Windows documentation for details.

## Return Value

A string message with the status of the MCI command.

## Related Functions

[DspPlaySound](#)

## Example

```
DspMCI("open cdaudio")
DspMCI("set cdaudio time format tmsf")
DspMCI("play cdaudio from 6 to 7")
DspMCI("close cdaudio")
/*Plays track 6 of an audio CD*/
DspMCI("open c:\mmdata\purplefi.wav type waveaudio alias finch")
DspMCI("set finch time format samples")
DspMCI("play finch from 1 to 10000")
DspMCI("close finch")
/*Plays the first 10,000 samples of a waveform audio file*/
```

## See Also

[Display Functions](#)

## DspPlaySound

Plays a waveform (sound). Wave form sound files \*.wav are provided with Windows and by third-party developers, or you can record them yourself to play long (and complex) sound sequences.

**⚠ WARNING****LOSS OF CONTROL**

- Do not use Plant SCADA's alarming system as the primary alert mechanism for safety-related alarms or notifications (that is, those classified as critical to process safety, the protection of the plant and equipment, or the protection of human life).
- Do not use Plant SCADA's audible alarm functionality as a replacement for safety-related warning systems critical to process safety, the protection of the plant and equipment or the protection of human life.
- Safety-related alarms and notifications should be independent and separate from the process control system. They should be implemented in the form of a stand-alone physical alarm system driving individual discrete alarm annunciators.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

When the *sSoundname* is a sound file path and "Mode" is "0", this function loads the .wav file from the specified path (Sound Files) and plays the associated waveform. If the specified sound file is not available in the mentioned path, an error message will be returned and a hardware alarm will be reported. Use of a system sound in this mode is not supported and will result in an error message and a hardware alarm.

When the *sSoundname* is a system sound name and *nMode* is "1", this function searches the system for the entry with the specified name and plays the associated waveform. If the name cannot be found, there is no error message indicated as either a return value or hardware alarm. For this reason, the use of mode 0 with waveform files is recommended over mode 1 with system sounds. Further, use of a valid wave form sound file in this mode instead of mode "0" will result in an error message and a hardware alarm informing the wrong mode is in use.

## Syntax

**DspPlaySound(*sSoundname*, *nMode*)**

*sSoundname*:

Sound File Path: Sound file to be played from the specified path.

System Sound Name: The predefined system waveform to be played. Examples of predefined sounds include:

- SystemAsterisk
- SystemExclamation
- SystemQuestion
- SystemDefault
- SystemHand
- SystemExit
- SystemStart

*nMode*:

- Mode 0: For use when the "*sSoundname*" is a sound file path.
- Mode 1: For use when the "*sSoundname*" is a system sound name.

## Return Value

TRUE if successful, otherwise FALSE (if an error is detected).

## Related Functions

[Beep](#)

## Example

```
DspPlaySound("C:\WINNT\MEDIA\Notify.wav",0);
DspPlaySound("SystemStart",1);
```

[Display Functions](#)

## DspPopupConfigMenu

Displays the contents of a menu node as a pop-up (context) menu, and run the command associated with the selected menu item. You can specify the contents of a menu using the menu configuration dialog at design time, or using the Menu family of Cicode functions at runtime.

## Syntax

**DspPopupConfigMenu(*hParent*, [, *bNonRecursive* [, *XPos* [, *YPos*]]])**

*hParent*

The parent node of the menu tree returned from any of the following functions:

- [MenuGetGenericNode\(\)](#), [MenuGetPageNode\(\)](#) or [MenuGetWindowNode\(\)](#) - used to get the parent node of menu tree for a page.
- [MenuGetFirstChild\(\)](#), [MenuGetNextChild\(\)](#), [MenuGetPrevChild\(\)](#), [MenuGetParent\(\)](#) - used to traverse to other nodes in a menu tree

*bNonRecursive*

Whether not to recursively transverse child tree nodes and list them as sub-menus in the pop-up menu. This parameter is optional. If it is left unspecified, its value will be defaulted to 0 (recursive). When it is set to 1, only the immediate child nodes of the specified menu handle will be listed. In this mode, tree nodes will be listed as normal menu items (instead of submenus) in the pop-up menu.

*XPos*

The x-coordinate (relative to the page) at which the menu will be displayed. This parameter is optional. If it is left unspecified, the menu will display at the cursor's current position.

*YPos*

The y-coordinate (relative to the page) at which the menu will be displayed. This parameter is optional. If it is left unspecified, the menu will display at the cursor's current position.

## Return Value

0 if the selected menu command is run or error code if menu command cannot run.

## See Also

[Display Functions](#)

### DspPopupMenu

Creates a popup menu consisting of a number of menu items. Multiple calls to this function enable you to add new items and create sub menus, building a system of linked, Windows-style menus.

Menu items can be displayed as checked and/or disabled. You can also specify a bitmap to display as a menu icon.

This function is first called to build the menu's items and links, and then called again to display it on the screen. In this final call, you have the option to specify the coordinates at which the menu will display, or let it default to the current cursor position.

## Syntax

**DspPopupMenu(*iMenuNumber*, *sMenuItems* [, *XPos*] [, *YPos*] )**

*iMenuNumber*:

An integer representing the menu you are adding items to. The first menu created is Menu 0. If left unspecified, this parameter defaults to -1, causing the menu to be displayed on the screen.

Multiple function calls with the same *iMenuNumber* allow you to build up entries in a particular menu. For example, the following four function calls with *iMenuNumber* = 1 build up 8 entries in Menu 1:

- DspPopupMenu(1, "Selection A>2, Selection B>3");
- DspPopupMenu(1, "Selection C>2, Selection D");
- DspPopupMenu(1, "Selection E>2, Selection F>3");
- DspPopupMenu(1, "Selection G>2, Selection H");

*sMenuItems*:

A comma-separated string defining the items in each menu. The default value for this parameter is an empty string, which will get passed to the function in the call to display the menu.

The (!), (~), and (,) symbols control display options for menu items.

For example, !Item1 disables Item1; ~Item2 checks Item2; and ,Item3 inserts a separator above Item3. To insert a link from a menu item to a sub menu, use the (>) symbol. For example, : Item4>1 means Item4 links to menu 1.

To insert a bitmap to the left of a menu item as its icon, use the following notation: [Icon]Item5 Inserts the bitmap Icon.BMP to the left of Item5. [Icon] needs to be placed before the Item name, but after any disable (!) or check (~) symbols you may wish to specify.

Bitmap files used for menu icons need to be saved in the project directory so that they can be found by Plant SCADA.

*XPos*:

The x-coordinate (relative to the page) at which the menu will be displayed. This parameter is optional. If it is left

unspecified, the menu will display at the cursor's current position.

*YPos:*

The y-coordinate (relative to the page) at which the menu will be displayed. This parameter is optional. If it is left unspecified, the menu will display at the cursor's current position.

## Return Value

The selected menu item as an integer. This comprises the menu number (return value div 100), and the position of the item in the menu (return value mod 100). For example, a return value of 201 indicates that the first item in Menu 2 was selected, and a return value of 3 indicates that the third item in Menu 0 was selected.

The return value is limited to a maximum of 65535, that is 655 menus and 35 items on the menu. Above this limit the function returns 0.

**Note:** Links to sub menus are not counted as menu items. For example, if your menu consists of 10 links and one unlinked item, the function will return only when the unlinked item is selected.

## Example 1

```
!Example 1 illustrates one menu with three menu items.  
FUNCTION BuildPopupMenu()  
    INT iSelection;  
    DspPopupMenu(0, "Item 1,!Item 2,~Item 3");  
    iSelection = DspPopupMenu(-1, "", 150, 300);  
    ! The above builds a menu with three items:  
    ! 'Item 1' will be shown as normal, 'Item 2' will be shown as disabled,  
    ! and 'Item 3' will be shown as checked.  
    ! The menu will be displayed at position (150, 300).  
END
```

## Example 2

```
!Example 2 illustrates the creation of two menus which are linked.  
FUNCTION BuildLinkedPopupMenu()  
    INT iSelection;  
    DspPopupMenu(0, "Item A,Item B>1,Item C");  
    DspPopupMenu(1, "Item B1,,[Trend]Item B2,,Item B3");  
    iSelection = DspPopupMenu();  
    ! The above will build two menus - Menu 0 and Menu 1  
    ! Item B on Menu 0 links to Menu 1.  
    ! 'Item B2' will be shown with Trend.BMP at its left.  
    ! The menu will be displayed at the cursor's position.  
    ! If 'Item A' is selected, iSelection will equal 1  
    ! If 'Item C' is selected, iSelection will equal 2  
    ! If 'Item B1' is selected, iSelection will equal 101  
    ! If 'Item B2' is selected, iSelection will equal 102  
    ! If 'Item B3' is selected, iSelection will equal 103  
END
```

[Display Functions](#)

## DspRichText

Creates a Rich Text object of the given dimensions at the animation point *nAN*. This object can then be used to display an RTF file (like an RTF report) called using the DspRichTextLoad function.

## Syntax

**DspRichText(*nAN*, *iHeight*, *iWidth*, *nMode*)**

*nAN*:

The AN at which the rich text object will display when the DspRichText command is run.

*iHeight*:

The height of the rich text object in pixels. The height is established by measuring down from the animation point.

*iWidth*:

The width of the rich text object in pixels. The width is established by measuring across to the right from the animation point.

*nMode*:

The display mode for the rich text object. The mode can be any combination of:

0 - **Disabled** - should be used if the rich text object is to be used for display purposes only.

1 - **Enabled** - allows you to select and copy the contents of the RTF object (for instance an RTF report), but you will not be able to make changes.

2 - **Read/Write** - allows you to edit the contents of the RTF object. Remember, however, that the object needs to be enabled before it can be edited. If it has already been enabled, you can just enter Mode 2 as your argument. If it is not already enabled, you will need to enable it. By combining Mode 1 and Mode 2 in your argument (3), you can enable the object, and make it read/write at the same time.

Because the content of the rich text object is just a copy of the original file, changes will not affect the actual file, until saved using the [DspRichTextSave](#) function.

## Return Value

0 if successful, otherwise an error is returned.

## Related Functions

[DspRichTextLoad](#), [PageRichTextFile](#)

## Example

```
//This will produce a rich text object at animation point 57,  
which is 200 pixels high, and 200 pixels wide. This object will be  
for display purposes only (that is read only)//  
DspRichText(57,200,200,0);
```

## See Also

[Display Functions](#)

### DspRichTextEdit

Enables editing of the contents of the rich text object at *nAN* if *nEdit* = TRUE, and disables editing if *nEdit* = FALSE.

## Syntax

**DspRichTextEdit(*nAN*, *bEdit*)**

*nAN*:

The reference AN for the rich text object.

*bEdit*:

The value of this argument determines whether you will be able to edit the contents of the rich text object at AN. Enter TRUE to enable editing, or enter FALSE to make the contents read-only.

Changes made to the contents of the object will not be saved until the DspRichTextSave function is used.

## Return Value

0 if successful, otherwise an error is returned.

## Related Functions

[PageRichTextFile](#), [DspRichTextEnable](#), [DspRichTextSave](#)

## Example

```
// Enables editing of the rich text object at AN 25 - if one
exists. Otherwise an error will be returned to iResult //
iResult = DspRichTextEdit(25,TRUE);
```

## See Also

[Display Functions](#)

### DspRichTextEnable

Enables the rich text object at *nAN* if *nEnable* = TRUE, and disables the object if *nEnable* = FALSE. When the object is disabled, its contents cannot be selected or copied etc.

## Syntax

**DspRichTextEnable(*nAN*, *bEnable*)**

*nAN*:

The reference AN for the rich text object.

*bEnable*:

The value of this argument determines whether the rich text object at AN will be enabled or disabled. Enter TRUE to enable the object (that is you can select and copy the contents of the RTF object, but you can't make changes). Enter FALSE to disable the object (that is make it display only).

## Return Value

0 if successful, otherwise an error is returned.

## Related Functions

[DspRichTextEdit](#)

## Example

```
// This line disables the rich text object at AN 25 - if one
// exists. Otherwise an error will be returned to iResult //
iResult = DspRichTextEnable(25,FALSE);
```

## See Also

[Display Functions](#)

## DspRichTextGetInfo

Retrieves size information about the rich text object at animation point *nAN*.

## Syntax

**DspRichTextGetInfo(*nAN*, *iType*)**

*nAN*:

The reference AN for the rich text object.

*iType*:

The following size information (in pixels) can be returned about the specified rich text object:

- 0 - Height
- 1 - Width

## Return Value

The requested information as a string (units = pixels).

## Related Functions

[PageRichTextFile](#)

## Example

```
! Gets the height of the rich text object at AN 25 - if one exists.  
iHeight = DspRichTextGetInfo(25,0);  
! Gets the width of the rich text object at AN 423.  
iWidth = DspRichTextGetInfo(423,1);
```

## See Also

[Display Functions](#)

## DspRichTextLoad

Loads a copy of the file *Filename* into the rich text object) at animation point *nAN*. (The rich text object may have been created using either the DspRichTextLoad function or the PageRichTextFile function.)

## Syntax

**DspRichTextLoad(*nAN*, *sFilename*)**

*nAN*:

The animation point at which a copy of the rich text file (for example, an RTF report) will display. This AN needs to match that of a rich text object (created using either the DspRichText function, or the PageRichTextFile function), or the copy of the file will not be loaded into anything, and will not display.

*sFilename*:

The name of the file to be copied and loaded into the rich text object at the specified animation point. The filename needs to be entered in quotation marks "".

The maximum file size that can be loaded is 512kb.

If you are loading a copy of an RTF report, the report needs to already have been run and saved to a file. Remember that the filename for the saved report comes from the File Name field in the Devices form. The location of the saved file needs to also be included as part of the filename. For example, if the filename in the Devices form listed [Data];RepDev.rtf, then you would need to enter "[Data]\repdev.rtf" as your argument. Alternatively, you can manually enter the path, for example, "c:\MyApplication\data\repdev.rtf".

If you are keeping a number of history files for the report, instead of using the extension rtf, you need to change it to reflect the number of the desired history file, for example, 001.

## Return Value

0 if successful, otherwise an error is returned.

## Related Functions

[DspRichText](#), [PageRichTextFile](#)

## Example

```
// This will look in the [Data] path (as specified in the
Citect.ini file), and load a copy of the file DayRep.rtf into the
rich text object at animation point 57. //
DspRichTextLoad(57, "[Data]\DayRep.rtf");
// This will look in the [Data] path (as specified in the
Citect.ini file), and load a copy of the history file DayRep.003
into the rich text object at animation point 908. //
DspRichTextLoad(908, "[Data]\DayRep.003");
// This will load a copy of the history file
f:\MyApplication\data\DayRep.006, into the rich text object at animation
point 908. //
DspRichTextLoad(908, "f:\MyApplication\data\DayRep.006");
```

## See Also

[Display Functions](#)

## DspRichTextPgScroll

Scrolls the contents of the rich text object displayed at *nAN*, by one page length in the direction given in *direction*.

## Syntax

**DspRichTextPgScroll(*nAN*, *iDirection*)**

*nAN*:

The reference AN for the rich text object.

*iDirection*:

The direction in which you want to scroll each time this function is run. You can choose from the following:

1 - Left

2 - Right

3 - Up

4 - Down

8 - Scroll to top

16 - Scroll to bottom

## Return Value

0 if successful, otherwise an error is returned.

## Related Functions

[PageRichTextFile](#), [DspRichTextEdit](#), [DspRichTextScroll](#)

## Example

```
// This line scrolls the contents of the rich text object at AN 25
// down one page. Otherwise an error will be returned to iResult //
iResult = DspRichTextPgScroll(25,4);
// This line scrolls the contents of the rich text object at AN 423
// right one page. Otherwise an error will be returned to iResult //
iResult = DspRichTextPgScroll(423,2);
```

## See Also

[Display Functions](#)

## DspRichTextPrint

Prints the contents of the rich text object at animation point *nAN*, to the port *PortName*.

## Syntax

**DspRichTextPrint(*nAN*, *sPortName*)**

*nAN*:

The reference AN for the rich text object.

*sPortName*:

The name of the printer port to which the contents of the rich text object will be printed. This name needs to be enclosed within quotation marks "". For example "LPT1", to print to the local printer, or "\\Pserver\canon1" using UNC to print to a network printer.

## Return Value

0 if successful, otherwise an error is returned.

## Related Functions

[DspRichText](#), [FileRichTextPrint](#)

## Example

```
! This lines prints
DspRichTextPrint(25,"LPT1:");
```

## See Also

[Display Functions](#)

### DspRichTextSave

Saves the contents of the rich text object at animation point *nAN*, to the file *Filename*.

## Syntax

**DspRichTextSave(*nAN*, *sFilename*)**

*nAN*:

The reference AN for the rich text object.

*sFilename*:

The name under which the contents of the rich text object will be saved. This name needs to be enclosed within quotation marks "", and needs to include the destination path. For example "[Data]\saved.rtf".

## Return Value

0 if successful, otherwise an error is returned.

## Related Functions

[DspRichText](#), [PageRichTextFile](#), [DspRichTextLoad](#), [DspRichTextEdit](#)

## Example

```
// These lines show two different ways of saving the contents of
// the rich text object (at AN 25) to file DayRep.rtf//
DspRichTextSave(25,"[Data]\DayRep.rtf");
DspRichTextSave(25,"c:\MyApplication\data\DayRep.rtf");
```

## See Also

[Display Functions](#)

### DspRichTextScroll

Scrolls the contents of the rich text object displayed at *nAN*, in the direction given in *direction*, by the number of

lines/units given in *amount*. Remember that the height of a line varies according to the font used, therefore if you need to scroll absolute distances, it might be advisable to use the DspRichTextPgScroll function.

## Syntax

**DspRichTextScroll(*nAN*, *iDirection*, *iAmount*)**

*nAN*:

The reference AN for the rich text object.

*iDirection*:

The direction in which you want to scroll each time this function is run. You can choose from the following:

1 - Left

2 - Right

3 - Up

4 - Down

8 - Scroll to top

16 - Scroll to bottom

*iAmount*:

The amount by which you would like to scroll each time this function is run. Enter the number of lines (for a vertical direction) or units (for a horizontal direction) by which you would like to scroll.

## Return Value

0 if successful, otherwise an error is returned.

## Related Functions

[PageRichTextFile](#), [DspRichTextEdit](#), [DspRichTextPgScroll](#)

## Example

```
DspRichTextScroll(25,4,8);
DspRichTextScroll(423,2,1);
```

## See Also

[Display Functions](#)

## DspRubEnd

Ends the rubber band selection, and returns the coordinates of the rubber band selection. The meaning of the *cx* and *cy* values depend on the *nMode* you specify in the DspRubStart() function.

## Syntax

**DspRubEnd(x, y, cx, cy)**

*x,y:*

The x and y coordinates of the start position. Must be a Long type variable.

*cx,cy:*

The x and y coordinates of the end position. Must be a Long type variable.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DspRubStart](#), [DspRubMove](#), [DspRubSetClip](#)

## Example

See [DspRubStart](#).

## See Also

[Display Functions](#)

## DspRubMove

Moves the rubber band selection to the new position. You need to first have defined a rubber band selection using the DspRubStart() and DspRubEnd() functions.

This function will erase the existing rubber band and then redraw it in the new position. You would normally move the rubber band by mouse input, but you can get input from the keyboard or any other Cicode to control the rubber band.

## Syntax

**DspRubMove(x, y)**

*x,y:*

The x and y coordinates of the current position.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DspRubStart](#), [DspRubEnd](#), [DspRubSetClip](#)

## Example

See [DspRubStart](#).

## See Also

[Display Functions](#)

## DspRubSetClip

Sets the clipping region for the rubber band display. If you enable the clipping region, the rubber band will not move outside of the clip region. This allows you to restrict the rubber band to within some constrained region. (For example, to prevent an operator from dragging the rubber band outside of the trend display when zooming the trend.)

You need to call this function (to enable the clipping region) before you can start the rubber band selection (with the DspRubStart() function).

## Syntax

**DspRubSetClip(x1, y1, x2, y2)**

*x1,y1,x2,y2:*

The x and y coordinates of the clipping region.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DspRubStart](#), [DspRubEnd](#), [DspRubMove](#)

## Example

```
// Set the clipping region to a rectangle starting at 100, 100 to
// 200, 300
DspRubSetClip(100, 100, 200, 300);
// Start the rubber band display with clipping mode on
DspRubStart(x, y, 4);
```

## See Also

[Display Functions](#)

### DspRubSetColor

Sets the color of the rubber band tool that is used to select a section within a trend object.

## Syntax

**DspRubSetColor(INT Color)**

*Color:*

An integer representing the color to use for the rubber band. The default value is white (0xFFFFFFFF).

There are a set of labels available in the Include project that you can use:

BLACK — 0x00000000

BLUE — 0x00000080

GREEN — 0x00008000

CYAN — 0x00008080

RED — 0x00800000

MAGENTA — 0x00800080

BROWN — 0x00808000

GREY — 0x00BFBFBF

DARK\_GREY — 0x007F7F7F

LIGHT\_BLUE — 0x000000FF

LIGHT\_GREEN — 0x0000FF00

LIGHT\_CYAN — 0x0000FFFF

LIGHT\_RED — 0x00FF0000

LIGHT\_MAGENTA — 0x00FF00FF

YELLOW — 0x00FFFF00

WHITE — 0x00FFFFFF

---

**Note:** If your project is based on the Situational Awareness Starter Project, this value will be overwritten by the color theme setting specified for the project.

---

## Return Value

The previous rubber band color as an integer.

## Example

```
DspRubSetColor(WHITE); // The rubber band will be white (the default)
DspRubSetColor(MakeColour(221, 221, 221)); // The rubber band will be grey
```

```
DspRubSetColor(MakeColour(255, 0, 0)); // The rubber band will be red
DspRubSetColor(MakeColour(0, 255, 0)); // The rubber band will be green
DspRubSetColor(MakeColour(0, 0, 255)); // The rubber band will be blue
```

## See Also

[Display Functions](#)

### DspRubStart

Starts the rubber band selection. Call this function when the left mouse button is pressed - the rubber band is displayed at the starting position. Call the DspRubEnd() function to end the selection, when the mouse button is released. The DspRubMove() function moves the selection to the new position.

This function is used by the trend templates for the trend zoom function. Use the rubber band functions whenever you want the operator to select a region on the screen or display a dynamic rectangle on the screen.

You can only display one rubber band per page. If you display a second rubber band, the first rubber band is erased. To move a rubber band with the mouse, use the OnEvent() function to get notification of the mouse movement, and then the DspRubMove() function. Because these are generic rubber-band display functions, you can get input from the keyboard, Cicode variables, the I/O device, and the mouse.

## Syntax

**DspRubStart(*x*, *y*, *nMode*)**

*x,y*:

The x and y coordinates of the current position.

*nMode*:

The mode of the rubber banding operation:

0 - cx,cy as absolute pixel positions

1 - cx,cy in pixels relative to x,y

2 - (x,y) the distance from top left to (cx,cy)

4 - enable the rubber band selection using the clipping region defined by DspRubSetClip().

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DspRubEnd](#), [DspRubMove](#), [DspRubSetClip](#), [OnEvent](#)

## Example

See also the ZOOM.CI file in the Include project for details.

```
INT xRub, yRub, cxRub, cyRub;
```

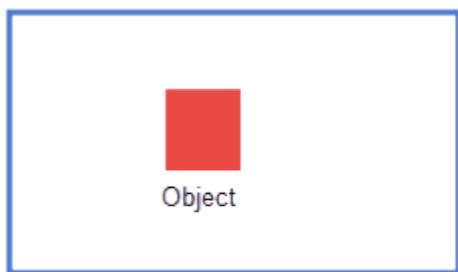

```
/* Call this function on left mouse button down. */
FUNCTION
StartSelection()
    INT x,y;
    DspGetMouse(x,y); ! Get the current mouse position
    DspRubStart(x,y,0); ! Start the rubber banding
    OnEvent(0,MouseEvent); ! Attach mouse move event
END
/* Call this function on left mouse button up. */
FUNCTION
EndSelection()
    ! Stop the rubber banding and get sizes into the ..Rub variables
    DspRubEnd(xRub,yRub,cxRub,cyRub);
    OnEvent(0,0); ! Stop mouse move event
END
INT
FUNCTION
MouseEvent()
    INT x,y;
    DspGetMouse(x,y); ! Get mouse position
    DspRubMove(x,y); ! Move the rubber band
    RETURN 0
END
```

## See Also

[Display Functions](#)

### DspSetClip

Sets the clip rectangle for the AN of an object or group of objects, defined by the top, left, right and bottom coordinates.

Clipping Rectangle

Object is not rendered outside clipping rectangle

If an AN has a clip rectangle specified, then any part (object) of the AN that is outside of the rectangle will not be rendered. You can use a clip rectangle for "control" type genies like treeviews that have scrollbars, to clip the contents of the control to the control's area when the scrollbar is moved.

A clip rectangle can be set for a group which will affect all the children of the group (and their children).

A clip rectangle set on a child will override the clip set on the group (this also applies to nested groups).

When an AN is clipped (i.e. it is outside the clip rectangle) then it will not respond to mouse input i.e. touch commands will not be invoked, tooltips will not be displayed, and the kobject will not be given the focus rectangle for keyboard input. If it is partially clipped, then this only applies to the clipped part, the visible part still responds as normal.

## Syntax

**DspSetClip(INT nAN, INT nLeft, INT nTop, INT nRight, INT nBottom)**

*nAN:*

The animation-point number of the object or group of objects inside the clipping region.

*nLeft:*

The x coordinate of the left side of the clipping boundary

*nTop:*

The x coordinate of the top of the clipping boundary

*nRight:*

The y co-ordinate of the right side of the clip rectangle.

*nBottom:*

The y co-ordinate of the bottom of the clip rectangle.

## Return Value

It returns an error if nAN is invalid, or the specified rectangle is invalid i.e. nLeft >= nRight or nTop >= nBottom.

---

**Note:** Will return an error if nAN specifies an ActiveX control.

---

## Example

```
DspSetClip(17, 200, 200, 800, 500);
```

## See Also

[Display Functions](#)

## DspSetCurColor

Sets the color of the focus rectangle. The focus rectangle is used to highlight a selectable object, tab or list item as the mouse moves over it.

## Syntax

**DspSetCurColor(INT Color)**

**Color:**

An integer representing the color to use for the focus rectangle. The default value is white (0x00FFFFFF).

There are a set of labels available in the Include project that you can use:

BLACK — 0x00000000  
BLUE — 0x00000080  
GREEN — 0x00008000  
CYAN — 0x00008080  
RED — 0x00800000  
MAGENTA — 0x00800080  
BROWN — 0x00808000  
GREY — 0x00BFBFBF  
DARK\_GREY — 0x007F7F7F  
LIGHT\_BLUE — 0x000000FF  
LIGHT\_GREEN — 0x0000FF00  
LIGHT\_CYAN — 0x0000FFFF  
LIGHT\_RED — 0x00FF0000  
LIGHT\_MAGENTA — 0x00FF00FF  
YELLOW — 0x00FFFF00  
WHITE — 0x00FFFFFF  
TRANSPARENT - 0xFF000000

---

**Note:** If your project is based on the Situational Awareness Starter Project, this value will be overwritten by the color theme setting specified for the project.

---

## Return Value

The previous focus rectangle color as an integer.

## Example

```
DspSetCurColor(WHITE); // The focus rectangle will be white (the default)
DspSetCurColor(MakeCitectColour(221, 221, 221)); // The focus rectangle will be grey
DspSetCurColor(MakeCitectColour(255, 0, 0)); // The focus rectangle will be red
DspSetCurColor(MakeCitectColour(0, 255, 0)); // The focus rectangle will be green
DspSetCurColor(MakeCitectColour(0, 0, 255)); // The focus rectangle will be blue
```

### DspSetMetadataFromName

Name used to set the metadata of an object on the page. Use the following syntax:

[RelativePath].[Group].[Group].Control

## Syntax

**DspSetMetadataFromName(*sName*, *sMetaName*, *sValue*)**

*sName*

The Name used as a reference for the object.

*sMetaName*

The Name of the metadata to be returned.

*sValue*

The value of the metadata to be returned.

## Return Value

The value of the metadata or error code.

## Related Functions

[DspSetMetadataFromName](#)

## See Also

[Display Functions](#)

## DspSetMetadataFromNameRelative

Name used to set the metadata of an object on the page relative to the given AN. Use the following syntax:

[RelativePath].[Group].[Group].Control

This will browse the group hierarchy to the given AN, and then drill down to other groups to find the named control or object.

See [Referencing an Object Using a Name at Runtime](#) for more information.

## Syntax

**DspSetMetadataFromNameRelative(*hAN*, *sName*, *sMetaName*, *sValue*)**

*hAN*

AN used as the starting point for the search of the object name.

*sName*

The Name used as a reference for the object.

*sMetaName*

The Name of the metadata to be returned.

*sValue*

The Name of the metadata to be returned.

## Return Value

The value of the metadata or error code

## Related Functions

[DspGetMetadataFromNameRelative](#)

## DspSetFont

Allows you to set the font and font size for text that appears in popup menus at runtime. For example, you can use this function to adjust the size of the text that appears in context menus to suit a particular screen resolution.

**Note:** Background color and foreground color properties are not supported on popup menus.

## Syntax

**DspSetFont(*hFont*)**

*hFont*:

The handle of font to be used.

## Return Value

No return value.

## Related Functions

[DspSetTooltipFont](#), [DspFont](#), [DspFontHnd](#)

## Example

```
IF (StrEndsWith(sPage, "_HD1080") = TRUE) THEN
    hFont = DspFontHnd("SA_Menu");
ELSE
    IF (StrEndsWith(sPage, "_UHD4K") = TRUE) THEN
        hFont = DspFontHnd("SA_Menu4K");
END
IF (hFont <> -1) THEN
    DspSetFont(hFont);
END
```

## See Also

[Display Functions](#)

### DspSetSlider

Sets the current position of a slider at the specified AN. You can use this function to move a slider, and adjust the value of the variable associated with the slider.

**Note:** This function was designed to only be used on Cicode objects, or the animation point object from the version 3.xx/4.xx toolbox.

## Syntax

**DspSetSlider(*nAN*, *nPos*)**

*nAN*:

The animation-point number.

*nPos*:

The position of the slider from 0 to 32000 where 0 is the zero position of the slider and 32000 if full position of the slider.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DspGetSlider](#)

## Example

```
// Set the position of the slider at AN 30 to 1/2 scale
DspSetSlider(30, 16000);
```

## See Also

[Display Functions](#)

### DspSetTip

Sets tool tip text associated with an AN. Any existing text associated with the AN will be replaced with the new text.

## Syntax

**DspSetTip(*nAN*, *sText*)**

*nAN*:

The animation-point number.

*sText*:

The tool tip text to set for the AN.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DspGetTip](#), [DspTipMode](#)

## Example

```
!Set a tool tip for AN19
DspSetTip(19, "Start Slurry Pump");
```

## See Also

[Display Functions](#)

## DspSetTooltipFont

Sets the font for tool tip text.

The parameter [Animator]TooltipFont also specifies the tool tip font. The parameter is checked at startup, and if it is set, the font is set accordingly. You can then use DspSetTooltipFont() to override the parameter until the next time you start Plant SCADA.

## Syntax

**DspSetTooltipFont(*sName* [, *nPointSize*] [, *sAttribs*] )**

*sName*:

The name of the Windows font to be used, enclosed by quotation marks ". A value for this parameter is required, however specifying an empty string "" will set the tooltip font to the default of MS Sans Serif.

*nPointSize*:

The size of the font in points. If you do not specify a value, the point size defaults to 12.

*sAttribs*:

A string specifying the format of the font. Use one or all of the following, enclosed by quotation marks " ":

- *B* to specify Bold
- *I* to specify Italics
- *U* to specify Underline

If you don't specify a value for this parameter, it will default to an empty string and no formatting will be applied.

## Return Value

No return value.

## Related Functions

[DspGetTip](#), [DspTipMode](#), [DspSetPopupMenuFont](#)

## Example

```
!Set the tool tip font to Bold, Italic, Times New Roman, with a
point size of 12
DspSetTooltipFont("Times New Roman", 12, "BI");
```

## See Also

[Display Functions](#)

## DspStatus

Determines whether the object at the specified AN will be grayed (hatch pattern) in the event communication attempts are unsuccessful.

## Syntax

**DspStatus**(*nAN*, *nMode*)

*nAN*:

The animation-point number.

*nMode*:

0 - Normal display when communication attempts are unsuccessful

1 - Gray the object (with a hatch pattern) when communication attempts are unsuccessful

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Example

```
DspStatus(67, 1)
```

```
// Disable the animation at AN 67
```

## See Also

[Display Functions](#)

### DspStr

Displays a string at a specified AN.

**Note:** This function was designed to only be used on Cicode objects, or the animation point object from the version 3.xx/4.xx toolbox.

## Syntax

**DspStr(*nAN*, *sFont*, *sText* [, *iLength*] [, *iAlignMode*] [, *iLengthMode*] [, *bTooltip*])**

*nAN*:

The AN where the text will be displayed.

*sFont*:

The name of the font that is used to display the text. The Font Name needs to be defined in the Fonts database. If the font is not found, the default font is used.

*sText*:

The text to display.

*iLength*:

Length of the text to display, either in characters or pixels depending on Mode (default -1, no truncation)

*iAlignMode*:

The alignment of the text string:

0 - Left Justified (default)

1 - Right Justified.

2 - Center Justified.

*iLengthMode*:

The length mode of the text string:

0 - Length as pixels truncated (default)

1 - Length as pixels truncated with ellipsis

2 - Length interpreted as characters.

*bTooltip*:

Determines if the original text is provided as tool tip when the displayed text becomes truncated.

0 - Tool tip is not available (default).

1 - Tool tip is available.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DspText](#)

## Example

```
DspStr(25,"RedFont","Display this text");
/* Displays "Display this text" using "RedFont" at AN25. "RedFont"
needs to be defined in the Fonts database. */
```

## See Also

[Display Functions](#)

## DspSym

Displays a symbol or a Genie at a specified AN. This dynamically displayed object will disappear at page navigation.

To display a Genie, the Genie should be configured to be used with this function. See "Create a New Genie" topic for more information.

## Syntax

**DspSym**(*iAN*, *sSymbol* [, *iMode*] [, *iType*] )

*iAN*:

The AN where the symbol will be displayed.

*sSymbol*:

The name of the symbol to display in the format <[LibName.]SymName>. If you do not specify the library name, a symbol from the Global library will display (if it exists).

*iMode*:

Not used. The mode is always set to 1, which means do not erase the existing symbol, just draw the new symbol.

*iType*:

Symbol Type:

0 - Symbol. *sSymbol* parameter is interpreted as a symbol. If you do not specify the library name, a symbol from the Global library will display (if it exists).

1 - Dynamic Genie, *sSymbol* parameter is interpreted as a Genie.

2 - Priority Genie. *sSymbol* is interpreted as a priority which is a numeric key in the alarm priority table and the function selects "Library Name.Genie Name" from the table.

3 - Priority Genie Thumbnail. *sSymbol* is interpreted as a priority which is a numeric key in the alarm priority

table and the function selects "Library Name.Thumbnail Name" from the table.

4 - Mode Genie. sSymbol is interpreted as a mode which is a display name in the alarm mode table. The function selects "Library Genie Name" from the table.

5 - .Mode Genie Thumbnail. sSymbol is interpreted as a mode which is a display name in the alarm mode table. The function selects "Library Genie Name" from the table.

---

**Note:** Type 0 symbols do not erase existing objects whilst type 1, 2, 3, 4, 5 symbols erase existing objects at the AN.

---

## Return Value

0 (zero) if successful, otherwise one of the following errors will be returned. A hardware alarm is also raised against DspSym when there is an error message.

- If an invalid type is passed, for example, DspSym(600, "lib1.genie1", 1, 99), the error 274 "Invalid Argument Passed" is returned.
- If a genie name which does not exist is passed, or, the option "I want to use this Genie with the Cicode function DspSym" is not selected in the Graphics Builder, the error 350 "RDB file not found" is returned.
- If an invalid animation number is passed, for example, DspSym(-99, "lib1.genie1", 1, 1), the error 274 "Invalid Argument Passed" is returned.
- If an animation number which does not exist is passed, the error 303 "Invalid animation number" is returned.
- If the AN where the genie will be displayed is a part (child) of the genie that was dynamically created, the error 408 "Databrowse not supported" is returned.
- For other runtime errors, for example, it did not create an animation for one of the objects of the genie, the error 272 "Out of memory" is returned.

iResult = DspSym(iAn4, "Shelved / Disabled", 1, 4);  
! Display the genie specified in the record of "Shelved / Disabled" on Alarm Modes table,  
specified by Library Name and Thumbnail Name fields, at an animation number indicated by  
iAn7.  
iResult = DspSym(iAn7, "Shelved / Disabled", 1, 5);
```

## See Also

[Display Functions](#)

### DspSymAnm

Animates a series of symbols at an AN. *Sym1* displays first, then *Sym2*, *Sym3* . . . *Sym8* and then *Sym1* displays again, etc. When the next symbol in the sequence is displayed, the current symbol is not erased, but is overwritten to provide a smoother animation. The symbols should all be the same size.

The frequency of changing the symbols is determined by the [Page]AnmDelay parameter.

You only need to call this function once to keep the animation going. To stop the animation call the DspDel() function, or call this function again with different symbols (to change the animation).

---

**Note:** This function was designed to only be used on Cicode objects, or the animation point object from the version 3.xx/4.xx toolbox.

---

## Syntax

**DspSymAnm(*nAN*, *Sym1* [, *Sym2* ... *Sym8*] [, *iDisplayMode*] [, *sSym9*] )**

*nAN*:

The AN where the animation will occur.

*Sym1*:

The name of the first symbol to animate in the format <[LibName.]SymName>. If you do not specify the library name, a symbol from the Global library will display (if it exists). Sym1 needs to be specified.

*Sym2..Sym8*:

The names of the symbols to animate in frames 2 to 8 in the format <[LibName.]SymName>. If you do not specify the library name, a symbol from the Global library will display (if it exists).

*iDisplayMode*:

Not used. Always set to -1, which means **Soft animation**. The background screen (a rectangular region beneath the symbol) is restored with the original image. Any objects that are within the rectangular region are destroyed when the background is restored. Use this mode when each animation symbol is a different size.

*Sym9*:

Not all symbols have to be specified. If for example, only two symbols are to display, specify Sym1 and Sym2.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DspSym](#)

## Example

```
DspSymAnm(25, "Pumps.Centrifuge", "Pumps.Floataion");
! Alternately displays the centrifuge symbol and the flotation symbol
(from the pumps library) at AN25.
```

### DspSymAnmEx

Animates a series of symbols at an AN. *Sym1* displays first, then *Sym2*, *Sym3* . . . *Sym9* and then *Sym1* displays again, etc. When the next symbol in the sequence is displayed, the current symbol is not erased, but is overwritten to provide a smoother animation. The symbols should all be the same size.

The frequency of changing the symbols is determined by the [Page]AnmDelay parameter.

You only need to call this function once to keep the animation going. To stop the animation call this function again with a different *Mode*.

**Note:** This function was designed to only be used on Cicode objects, or the animation point object from the version 3.xx/4.xx toolbox.

## Syntax

**DspSymAnmEx(*nAN*, *Mode*, *Sym1* [, *Sym2* ... *Sym9*] )**

*nAN*:

The AN where the animation will occur.

*Mode*:

Not used. Always set to -1, which means **Soft animation**. The background screen (a rectangular region beneath the symbol) is restored with the original image. Any objects that are within the rectangular region are destroyed when the background is restored. Use this mode when each animation symbol is a different size.

*Sym1*:

The name of the first symbol to animate in the format <[LibName.]SymName>. If you do not specify the library name, a symbol from the Global library will display (if it exists). Sym1 needs to be specified.

*Sym2..Sym9*:

The names of the symbols to animate in frames 2 to 9 in the format <[LibName.]SymName>. If you do not specify the library name, a symbol from the Global library will display (if it exists).

Not all symbols have to be specified. If for example, only two symbols are to display, specify Sym1 and Sym2.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DspSym](#)

## Example

```
DspSymAnmEx(25,-1,"Pumps.Centrifuge","Pumps.Floatation");
! Alternately displays the centrifuge symbol and the flotation symbol
(from the pumps library) at AN25.
```

## See Also

[Display Functions](#)

## DspSymAtSize

Displays a symbol or a genie at the specified scale and offset from the AN position.

By calling this function continuously, you can move symbols or genies around the screen and change their size and shape, to simulate trippers, elevators, and so on. You change the PositionX, PositionY values to change the position of the symbol/genie, the SizeX, SizeY values to change its size, or the symbol/Genie itself to change its shape.

You can only use this function at a blank AN, or an AN with a symbol defined without symbols configured. The AN needs to not be attached to any other animation object.

To display a Genie, the Genie should be configured to be used with this function. See "Create a New Genie" topic for more information.

## Syntax

**DspSymAtSize(*nAN, sSym, PositionX, PositionY, SizeX, SizeY, Mode [,Type]*)**

*nAN:*

The AN where the symbol will be animated.

*sSym:*

The name of the symbol to display, move, or size. If *sSym* is 0 (zero), any existing symbol at the AN is erased.

*PositionX:*

The horizontal offset position (from the AN) of the symbol (in pixels).

*PositionY:*

The vertical offset position (from the AN) of the symbol (in pixels).

*SizeX, SizeY:*

The horizontal and vertical scaling factors for the symbol (0 - 32000). For example, if *SizeX* and *SizeY* are both

32000, the symbol is displayed at its normal size. Please be aware that symbols can only be reduced in size.

*Mode:*

The mode of the display:

**-1 - Soft animation.** The background screen (a rectangular region beneath the symbol) is restored with the original image. Any objects that are within the rectangular region are destroyed when the background is restored. Use this mode when each animation symbol is a different size.

**0 - Overlap animation.** The background screen (beneath the symbol) is not erased - the next symbol is displayed on top. Transparent color is supported in this mode, allowing for symbol overlap. For this mode to display correctly, each symbol needs to be the same size.

**1 - Animate animation.** The background screen (beneath the symbol) is not erased - the next symbol is displayed on top. This mode provides the fastest animation. For this mode to display correctly, each symbol needs to be the same size. Transparent color is not supported in this mode.

**8 - Stops animation at last symbol displayed.** Use this mode where you want to freeze your animation at the end of the sequence.

**16 - Stops animation at current symbol displayed.** Use this mode where you want to freeze your animation instantly.

*Type:*

Symbol Type:

**0 - Symbol.** sSym parameter is interpreted as a symbol. If you do not specify the library name, a symbol from the Global library will display (if it exists).

**1 - Dynamic Genie.** sSym parameter is interpreted as a Genie.

**2 - Priority Genie.** sSym is interpreted as a priority which is a numeric key in the alarm priority table and the function selects "Library Name.Genie Name" from the table.

**3 - Priority Genie Thumbnail.** sSym is interpreted as a priority which is a numeric key in the alarm priority table and the function selects "Library Name.Thumbnail Name" from the table.

**4 - Mode Genie.** sSym is interpreted as a mode which is a display name in the alarm mode table. The function selects "Library Genie Name" from the table.

**5 - .Mode Genie Thumbnail.** sSym is interpreted as a mode which is a display name in the alarm mode table. The function selects "Library Genie Name" from the table.

---

**Note:**

- Type 0 symbols do not erase existing objects whilst type 1, 2, 3, 4, 5 symbols erase existing objects at the AN.
  - When using type 1, 2, 3, 4, 5, only mode 0 is supported
- 

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DspAnMove](#), [DspAnMoveRel](#), [DspSym](#)

## Example

```
! Display tripper moving in x axis at normal size.  
DspSymAtSize(21, "lib.tripper", x, 0, 32000, 32000, 0);  
! Display elevator going up and down.  
DspSymAtSize(22, "lib.elevator", 0, y, 32000, 32000, 0);  
! Display can getting bigger and smaller.  
DspSymAtSize(23, "lib.can", 0, 0, size, size, 0);  
!Display genie1 50% smaller than its original size  
DspSymAtSize(24, "lib.genie1", 0, 0, 16000, 16000, 0, 1);
```

## See Also

[Display Functions](#)

### DspText

Displays text at a specified AN location. This function does the same operation as DspStr(), however it uses a font number rather than a font name.

---

**Note:** This function was designed to only be used on Cicode objects, or the animation point object from the version 3.xx/4.xx toolbox.

---

## Syntax

**DspText(*hAN*, *iFont*, *sText* [, *iLength*] [, *iAlignMode*] [, *iLengthMode*] [, *bTooltip*])**

*hAN*:

The AN where the text will be displayed.

*iFont*:

The font number that is used to display the text. (To use the default font, set to -1.)

*sText*:

The text to display.

*iLength*:

Length of the Text to display, either in characters or pixels depending on Mode (default -1, no truncation).

*iAlignMode*:

The alignment of the text string:

0 - Left Justified (default).

1 - Right Justified.

2 - Center Justified.

*iLengthMode*:

The length mode of the text string:

0 - Length as pixels truncated (default).

1 - Length as pixels truncated with ellipsis.

2 - Length interpreted as characters.

*bTooltip:*

Determines if the original text is provided as tool tip when the displayed text becomes truncated.

0 - Tool tip is not available (default).

1 - Tool tip is available.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DspStr](#), [DspFont](#), [DspFontHnd](#)

## Example

```
/* Displays "Display this text" at AN25 using the font defined as
BigFont. */
hBigFont=DspFontHnd("BigFont");
DspText(25,hBigFont,"Display this text");
```

## DspTipMode

Switches the display of tool tips on or off. This function overrides the setting in the [\[Page\]TipHelp](#) parameter.

## Syntax

**DspTipMode(*nMode*)**

*nMode:*

The display mode:

0 - Off

1 - On

2 - Toggle the tool tip mode

3 - Do not change the mode, just return the current value

## Return Value

The old mode.

## Related Functions

[DspSetTip](#), [DspGetTip](#)

## Example

```
DspTipMode(1); //Switch on tool tips
```

## See Also

[Display Functions](#)

## DspTrend

Displays a trend at an AN. Values are plotted on the trend pens. You need to specify *Value1*, but *Value2* to *Value8* are optional. If more values (than configured pens) are specified, the additional values are ignored. If fewer values (than configured pens) are specified, the pens that have no values are not displayed.

`DspTrend()` is optimized so that it will not display the trend until a full set of samples has been collected. For example, if you have defined 100 samples for your trend, the trend will not display until value 100 is entered.

You should use this function only if you want to control the display of trends directly. If you use the standard Trends (defined in the Trends database) this function is called automatically.

---

**Note:** This function was designed to only be used on Cicode objects, or the animation point object from the version 3.xx/4.xx toolbox.

---

## Syntax

**DspTrend(*nAN*, *Trend*, *Value1* [,*Value2* ... *Value8*])**

*nAN*:

The AN where the trend will be displayed.

*Trend*:

The name of the trend to display in the format <[LibName.]TrnName>. If you do not specify the library name, a trend from the Global library will display (if it exists).

To display a Version 1.xx trend, specify the trend number (0 to 255). For example, if you specify trend 1, Plant SCADA displays the trend Global.Trn001.

*Value1*:

The value to display on Pen 1 of the trend.

*Value2...8*:

The values to display on Pen 2...Pen 8 of the trend (optional).

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DspDel](#)

## Example

```
/* Using the main_loop trend (from the trends library) at AN25,
display a value of 10 on Pen1, 20 on Pen2, 30 on Pen3 and 40 on
Pen4 of the trend. */
DspTrend(25,"Trends.Main_Loop",10,20,30,40);
/* Using trend definition 5 (Plant SCADA Version 1.xx)
at AN25, display a value of 10 on Pen1, 20 on Pen2, 30 on Pen3 and
40 on Pen4 of the trend. */
DspTrend(25,5,10,20,30,40);
/* Using the loops trend (from the global library) at AN26,
display a value of 100 on Pen1 and 500 on Pen2 of the trend. */
DspTrend(26,"Loops",100,500);
/* Display a trend configured with 100 samples immediately. The
data for the first 100 samples is stored in an array -
MyData[100]. On first display, grab all the data and call
DspTrend().*/
FOR i = 0 to 100 DO
    DspTrend(AN, "Loops", MyData[i]);
END
// display new samples every 300ms
WHILE TRUE DO
    // Shift MyData down and grab new sample
    TableShift(MyData, 100, 1);
    MyData[99] = MyFastData;
    DspTrend(AN, "Loops", MyData[99]);
    SleepMS(300);
END
/* Display a trend configured with 100 samples immediately. Dummy
data is pushed into the first 100 samples to fill the trend. Once
these values are entered, the trend will be updated each time a
new sample value is entered.*/
// fill up the trend.
FOR i = 0 to 100 DO
    DspTrend(AN, "Loops", 0);
END
// display new samples every 300ms
WHILE TRUE DO
    DspTrend(AN, "Loops", MyFastData);
    SleepMS(300);
END
```

## See Also

[Display Functions](#)

## DspTrendInfo

Get information on a trend definition.

## Syntax

**DspTrendInfo(*hTrend*, *Type*, *AN*)**

*hTrend*:

The name of the trend in the format <[LibName.]TrnName>. If you do not specify the library name, a trend from the Global library is assumed.

To get information on a Version 1.xx trend, specify the trend number (0 to 255). For example, if you specify trend 1, Plant SCADA obtains information from the trend Global.Trn001.

*nType*:

Type of trend info:

0 - Type of trend:

- 0 = line
- 1 = bar

1 - Number of samples in trend

2 - Height of trend (in pixels)

3 - Width of trend sample (in pixels)

4 - Number of trend pens

11 - Color of pen 1. If the pen uses flashing color, the initial color used. (Use type 19 to determine the secondary flashing color for pen 1.)

12 - Color of pen 2. If the pen uses flashing color, the initial color used. (Use type 20 to determine the secondary flashing color for pen 2.)

13 - Color of pen 3. If the pen uses flashing color, the initial color used. (Use type 21 to determine the secondary flashing color for pen 3.)

14 - Color of pen 4. If the pen uses flashing color, the initial color used. (Use type 22 to determine the secondary flashing color for pen 4.)

15 - Color of pen 5. If the pen uses flashing color, the initial color used. (Use type 23 to determine the secondary flashing color for pen 5.)

16 - Color of pen 6. If the pen uses flashing color, the initial color used. (Use type 24 to determine the secondary flashing color for pen 6.)

17 - Color of pen 7. If the pen uses flashing color, the initial color used. (Use type 25 to determine the secondary flashing color for pen 7.)

18 - Color of pen 8. If the pen uses flashing color, the initial color used. (Use type 26 to determine the secondary flashing color for pen 8.)

19 - The secondary color used for pen 1, if flashing color is used.

20 - The secondary color used for pen 2, if flashing color is used.

21 - The secondary color used for pen 3, if flashing color is used.

22 - The secondary color used for pen 4, if flashing color is used.

23 - The secondary color used for pen 5, if flashing color is used.

24 - The secondary color used for pen 6, if flashing color is used.

25 - The secondary color used for pen 7, if flashing color is used.

26 - The secondary color used for pen 8, if flashing color is used.

*nAN:*

The AN where the trend is displayed.

## Return Value

The trend information (as an integer). If Pen Color (*Types 11 - 18*) is requested from a bar trend, the return value is -1.

## Related Functions

[DspTrend](#)

## Example

```
! get the number of samples for the main_loop trend (from the
trends library).
nSamples = DspTrendInfo("Trends.Main_Loop", 1);
! get the number of samples for trend 3 (Plant SCADA
Version 1.xx).
nSamples = DspTrendInfo(3, 1);
```

## See Also

[Display Functions](#)

## DspWebContentGetURL

Gets the current URL for a Web Content control on a graphics page.

## Syntax

**DspWebContentGetURL(INT *nAN*)**

*nAN:*

The AN where the Web Content control is displayed.

## Return Value

The current URL of the specified Web Content control as a string.

The following hardware alarms will be generated if not successful:

- Cicode error message 303 will indicate that the AN is invalid or does not contain a Web Content object.

- Cicode error message 583 will indicate that the URL is longer than 255 characters.

In both cases, an empty string will be returned.

## Related Functions

[DspWebContentSetURL](#)

## See Also

[Display Functions](#)

### DspWebContentSetURL

Sets the URL for a Web Content control on a graphics page.

#### LOSS OF CONTROL

- Do not use the Plant SCADA Web Content control to display an untrusted or potentially unsafe web site, as this may leave your runtime system vulnerable to malicious activity.
- Do not enter a URL in the Web Content control that will allow users to navigate to an untrusted or potentially unsafe web site.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Before you implement the Web Content control as part of your runtime system, you should carefully consider the security implications of the content that will be accessible. If using an internet-based website or application, you will be externally exposing your SCADA system and network.

## Syntax

**DspWebContentSetURL(INT *nAN*, STRING *sURL*)**

*nAN*:

The AN where the Web Content control is displayed.

*sURL*:

A valid URL (maximum 255 characters).

## Return Value

0 (zero) if successful, otherwise an error is returned.

If the AN is invalid or does not contain a Web Content object, Cicode error message 303 will be returned (Invalid AN). This will also trigger a hardware alarm for error code 303.

## DLL Functions

Following are functions relating to DLLs:

<a href="#">DLLCall</a>	Calls a DLL function.
<a href="#">DLLCallEx</a>	Calls a DLL function, and passes the specified arguments to that function.
<a href="#">DLLClose</a>	Closes a link to a DLL function.
<a href="#">DLLOpen</a>	Opens a link to a DLL function.

## See Also

[Cicode Function Categories](#)

[Using Cicode Functions](#)

## DLLCall

Calls a DLL function, and passes a string of arguments to that function. Plant SCADA converts these arguments (where required) into the type specified in the DLLOpen call. If an argument cannot be converted, it is set to zero (0) or an empty string "".

You need to first open the DLL with the DLLOpen function.

Only one call to the DLLCall function can be made at a time, which means runtime will wait for the called function to return before doing anything else. If the called function takes too long to return, it won't let other tasks execute. Therefore, care needs to be taken so that one call returns before the next is made.

Good programming practice requires that functions which are not expected to complete in a short time are run as separate Windows threads and return a value immediately to Plant SCADA.

## Syntax

**DLLCall(*hFunction*, *sArgs*)**

*hFunction*:

The DLL function handle, returned from DLLOpen.

*sArgs*:

The string of arguments to pass to the DLL function. The argument string contains all the arguments for the function, separated by commas (,). Enclose string arguments in quote marks "", and use the string escape character (^) to put a string delimiter within a string. This syntax is the same as the syntax for the TaskNew() function

## Return Value

The result of the function, as a string.

## Related Functions

[DLLOpen](#), [DLLClose](#)

## Example

See [DLLOpen](#).

## See Also

[DLL Functions](#)

## DLLCallEx

Calls a DLL function, and passes the specified arguments to that function.

You need to first open the DLL with the [DLLOpen](#) function.

Only one call to the DLLCallEx() function can be made at a time, which means runtime will wait for the called function to return before doing anything else. If the called function takes too long to return, it won't let other tasks execute. Therefore, care needs to be taken so that one call returns before the next is made.

Good programming practice requires that functions which are not expected to complete in a short time are run as separate Windows threads and return a value immediately to Plant SCADA.

## Syntax

**DLLCallEx(*hFunction*, *vParameters*)**

*hFunction*:

The DLL function handle, returned from DLLOpen().

*vParameters*:

A variable length parameter list of method arguments. The parameters will be passed to the function in the order that you enter them.

Specifying too few or too many parameters will generate an Invalid Argument hardware error. An Invalid Argument hardware error will also be generated if you specify a parameter to the DLL function with the wrong type.

---

**Note:** This function does not support the passing of global variables into the *vParameters* argument.

## Return Value

The result of the function. If the DLL function returns a string then your Cicode return variable should be of type STRING. All other types will be INT.

## Related Functions

[DLLOpen](#), [DLLClose](#)

## Example

```
/* This function is called when Plant SCADA starts up,
to initialize all the DLLs that are called */
INT hAnsiUpper;
INT hGlobalAlloc;
FUNCTION InitMyDLLs()
    ! Open DLL to AnsiUpper
    hAnsiUpper = DLLOpen("USER.DLL", "AnsiUpper", "CC");
    hGlobalAlloc = DLLOpen("Kernel", "GlobalAlloc", "IIJ");
    END
/* This is the Cicode entry point into the DLL function call. This
function hides the DLL interface from the rest of Plant SCADA. */
STRING
FUNCTION AnsiUpper(STRING sString)
    STRING sResult;
    sResult = DLLCallEx(hAnsiUpper, sString);
    RETURN sResult;
END
/* Allocate memory and return memory handle */
INT
FUNCTION GlobalAlloc(INT Mode, INT Length)
    INT hMem;
    hMem = DLLCallEx(hGlobalAlloc, Mode, Length);
    RETURN hMem;
END
```

## See Also

[DLL Functions](#)

## DLLClose

Closes the link to a DLL function, and frees the memory allocated for that function link. When the link is closed, you cannot call the function. Plant SCADA automatically closes all function links at shutdown.

## Syntax

**DLLClose(*hFunction*)**

*hFunction*:

The DLL function handle, returned from DLLOpen().

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DLLOpen](#), [DLLCall](#)

## Example

See [DLLOpen](#).

## See Also

[DLL Functions](#)

## DLLOpen

Opens a link to a DLL function, by loading the specified DLL library into memory and attaching it to the named function. After you open the function link, you can call the function with the DLLCall function. You pass the function number returned from the DLLOpen function as an argument in the DLLCall function.

Plant SCADA only supports DLL functions that accept arguments via stack-based calling conventions. For example, in Win32 only cdecl and stdcall are supported.

---

**Note:** A DLL compiled for 32 bit cannot be called on an alarm server operating in Extended Memory mode. To allow this to work, you will need to recompile the DLL to target 64 bit.

One accepted method for interfacing with a DLL function is to write a Cicode function file. This file contains the DLLOpen() function to initialize the functions, and one Cicode function for each DLL function, as an interface. In this way, you can hide the DLL interface in this file. Any other Cicode function will call the Cicode interface, and the call to the DLL remains transparent.

Please be aware that DLLs need to be on the path. The file extension is not required.

---

**Note:** You need to specify the arguments to the function correctly. Plant SCADA has no way of checking the number and type of arguments to the function. If you specify the number of arguments incorrectly, your computer may display unexpected behavior. You should test your interface thoroughly before using it on a live system.

### **WARNING**

#### **UNINTENDED EQUIPMENT OPERATION**

Ensure that you specify the arguments to the DLLOpen() function correctly according to the following list.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

## Syntax

**DLLOpen(*sLib*, *sName*, *sArgs*)**

*sLib*:

The DLL library name.

*sName*:

The function name. An underscore (\_) is required in the function name for a 'C' function, but not for a Pascal function. When you call a DLL from a Cicode function, *sName* needs to be the same as the name defined in the .DEF file used to link the DLL. The file extension is not required.

*sArgs*:

The string specifying the function arguments. The first character in the string is the return value of the function.

*A* - Logical.

*B* - IEEE 8 byte floating point number.

*C* - Null terminated string. Maximum string length 255 characters.

*D* - Byte counted string. First byte contains the length of the string, maximum string length 255 characters.

*H* - Unsigned 2 byte integer.

*I* - Signed 2 byte integer.

*J* - Signed 4 byte integer.

## Return Value

The DLL function handle, or -1 if the library or function could not be found or loaded.

## Related Functions

[DLLCall](#), [DLLClose](#)

## Example

```
/* This function is called when Plant SCADA starts up,
to initialize the DLLs that are called */
INT hAnsiUpper;
INT hGlobalAlloc;
FUNCTION InitMyDLLs()
    ! Open DLL to AnsiUpper
    hAnsiUpper = DLLOpen("USER.DLL", "AnsiUpper", "CC");
    hGlobalAlloc = DLLOpen("Kernel", "GlobalAlloc", "IIJ");
END
/* This is the Cicode entry point into the DLL function call. This
function hides the DLL interface from the rest of Plant SCADA. */
STRING
FUNCTION AnsiUpper(STRING sString)
    STRING sResult;
    sResult = DLLCall(hAnsiUpper, "^" + sString + "^");
    RETURN sResult;
END
```

```
/* Allocate memory and return memory handle */
INT
FUNCTION GlobalAlloc(INT Mode, INT Length)
    STRING sResult;
    INT hMem;
    sResult = DLLCall(hGlobalAlloc, Mode : ##### + "," + Length : #####);
    hMem = StrToInt(sResult);
    RETURN hMem;
END
```

## Equipment Database Functions

The following are functions relate to the equipment database.

<a href="#">EquipBrowseClose</a>	Closes an equipment database browse session.
<a href="#">EquipBrowseFirst</a>	Gets the first equipment database entry in the browse session.
<a href="#">EquipBrowseGetField</a>	Gets the field indicated by the cursor position in the browse session.
<a href="#">EquipBrowseNext</a>	Gets the next equipment database entry in the browse session.
<a href="#">EquipBrowseNumRecords</a>	Returns the number of records in the current browse session.
<a href="#">EquipBrowseOpen</a>	Opens an equipment database browse session.
<a href="#">EquipBrowsePrev</a>	Gets the previous equipment database entry in the browse session.
<a href="#">EquipCheckUpdate</a>	Checks if the equipment database file has been updated, and provides the facility to reload it.
<a href="#">EquipGetParameter</a>	Reads a runtime parameter of an equipment database record from the EQPARAM.RDB database file.
<a href="#">EquipGetProperty</a>	Reads a property of an equipment database record from the EQUIP.DBF file.
<a href="#">EquipRefBrowseClose</a>	Closes an equipment database browse session.
<a href="#">EquipRefBrowseFirst</a>	Gets the first equipment database entry in the browse session.

<a href="#">EquipRefBrowseGetField</a>	Gets the field indicated by the cursor position in the browse session.
<a href="#">EquipRefBrowseNext</a>	Gets the next equipment database entry in the browse session.
<a href="#">EquipRefBrowseNumRecords</a>	Returns the number of records in the current browse session.
<a href="#">EquipRefBrowseOpen</a>	Opens an equipment database browse session.
<a href="#">EquipRefBrowsePrev</a>	Gets the previous equipment database entry in the browse session.
<a href="#">EquipSetProperty</a>	Sets the property of an item of equipment.
<a href="#">EquipStateBrowseClose</a>	Terminates a browsing session and cleans up the resources used by the session.
<a href="#">EquipStateBrowseFirst</a>	Places the data browse cursor at the first record.
<a href="#">EquipStateBrowseGetField</a>	Returns the value of the particular field in a record to which the data browse cursor is currently referencing.
<a href="#">EquipStateBrowseNext</a>	Places the data browse cursor at the next available record.
<a href="#">EquipStateBrowseNumRecords</a>	Returns the number of records that match the current filter criteria.
<a href="#">EquipStateBrowseOpen</a>	Initiates a new session for browsing the equipment states configured.
<a href="#">EquipStateBrowsePrev</a>	Places the data browse cursor at the previous record.

[Using Cicode Functions](#)

## EquipBrowseClose

The EquipBrowseClose function terminates an active data browse session and cleans up resources associated with the session.

This function is a non-blocking function. It does not block the calling Cicode task.

## Syntax

**INT EquipBrowseClose(LONG Session)**

### Session

The handle to a browse session previously returned by a EquipBrowseOpen call.

## Return Value

0 (zero) if the equipment database browse session exists, otherwise an error code is returned.

## Related Functions

[EquipBrowseFirst](#), [EquipBrowseGetField](#), [EquipBrowseNext](#), [EquipBrowseOpen](#), [EquipBrowsePrev](#),  
[EquipCheckUpdate](#), [EquipSetProperty](#)

## See Also

[Equipment Database Functions](#)

### EquipBrowseFirst

The EquipBrowseFirst function places the data browse cursor at the first record.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

INT **EquipBrowseFirst**(LONG Session)

*Session:*

The handle to a browse session previously returned by a EquipBrowseOpen call.

## Return Value

0 (zero) if the equipment database browse session exists, otherwise an error code is returned.

## Related Functions

[EquipBrowseClose](#), [EquipBrowseGetField](#), [EquipBrowseNext](#), [EquipBrowseNumRecords](#), [EquipBrowseOpen](#),  
[EquipBrowsePrev](#), [EquipCheckUpdate](#), [EquipGetProperty](#)

## See Also

[Equipment Database Functions](#)

### EquipBrowseGetField

The EquipBrowseGetField function retrieves the value of the specified field from the record the data browse cursor is currently referencing.

This function is a non-blocking function. It does not block the calling Cicode task.

## Syntax

STRING **EquipBrowseGetField**(LONG *Session*, STRING *FieldName*)

*Session*:

The handle to a browse session previously returned by a EquipBrowseOpen call.

*FieldName*:

The name of the field that references the value to be returned. Supported fields are:

Name, Cluster, Type, Area, Location, IODevice, Page, Help, Comment, Composite, Parent, Custom1, Custom2, Custom3, Custom4, Custom5, Custom6, Custom7, Custom8.

See [Browse Function Field Reference](#) for information about fields.

## Return Value

The value of the specified field as a string. An empty string may or may not be an indication that an error has been detected. The last error should be checked in this instance to determine if an error has actually occurred.

## Related Functions

[EquipBrowseClose](#), [EquipBrowseFirst](#), [EquipBrowseNext](#), [EquipBrowseNumRecords](#), [EquipBrowseOpen](#),  
[EquipBrowsePrev](#), [EquipCheckUpdate](#), [EquipGetProperty](#)

## Example

```
STRING fieldValue = "";
STRING fieldName = "TYPE";
INT errorCode = 0;
...
fieldValue = EquipBrowseGetField(iSession, sFieldName);
IF fieldValue <> "" THE
    // Successful case
ELSE
    // Function returned an error
END
...
```

## See Also

[Equipment Database Functions](#)

## EquipBrowseNext

The EquipBrowseNext function moves the data browse cursor forward one record. If you call this function after you have reached the end of the records, error 412 is returned (Databrowse session EOF).

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**INT EquipBrowseNext(LONG Session)**

*Session*

The handle to a browse session previously returned by a EquipBrowseOpen call.

## Return Value

0 (zero) if the equipment database browse session exists, otherwise an error is returned.

## Related Functions

[EquipBrowseClose](#), [EquipBrowseFirst](#), [EquipBrowseGetField](#), [EquipBrowseNumRecords](#), [EquipBrowseOpen](#),  
[EquipBrowsePrev](#), [EquipCheckUpdate](#), [EquipGetProperty](#)

## See Also

[Equipment Database Functions](#)

## EquipBrowseNumRecords

The EquipBrowseNumRecords function returns the number of records that match the filter criteria.

This function is a non-blocking function. It does not block the calling Cicode task.

## Syntax

**LONG EquipBrowseNumRecords(LONG Session)**

*Session:*

The handle to a browse session previously returned by a EquipBrowseOpen call.

## Return Value

The number of records that have matched the filter criteria. A value of 0 denotes that no records have matched. A value of -1 denotes that the browse session is unable to provide a fixed number. This may be the case if the data being browsed changed during the browse session.

## Related Functions

[EquipBrowseClose](#), [EquipBrowseFirst](#), [EquipBrowseGetField](#), [EquipBrowseNext](#), [EquipBrowseOpen](#),  
[EquipBrowsePrev](#), [EquipCheckUpdate](#), [EquipGetProperty](#)

## Example

```
INT numRecords = 0;
```

```
...
numRecords = EquipBrowseNumRecords(iSession);
IF numRecords <> 0 THEN
    // Have records
ELSE
    // No records
END
...
```

## See Also

[Equipment Database Functions](#)

### EquipBrowseOpen

The EquipBrowseOpen function initiates a new browse session and returns a handle to the new session that can be used in subsequent data browse function calls.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

LONG **EquipBrowseOpen**(STRING *Filter*, STRING *Fields* [, STRING *Clusters*] )

### *Filter:*

A filter expression specifying the records to return during the browse. An empty string indicates that all records will be returned. Where a fieldname is not specified in the filter, it is assumed to be equipment name. For example, the filter "AAA" is equivalent to "name=AAA".

The following regular expressions are supported: \*expr, expr\*, and \*expr\*. To specify an exclusion filtering condition, use the NOT keyword after the = operator.

### *Fields:*

Specifies via a comma delimited string the columns to be returned during the browse. An empty string indicates that the server will return all available columns. Supported fields are:

ALIAS, AREA, CLUSTER, COMMENT, CONTENT, CUSTOM1...8, DEFSTATE, DEVSCHEDE, HIDDEN, LOCATION, NAME, PAGE, PARENT, SCHEDID, SCHEDULED, TYPE.

See [Browse Function Field Reference](#) for information about fields.

### *Clusters:*

An optional parameter that specifies via a comma delimited string the subset of the clusters to browse. An empty string indicates that all connected clusters will be browsed.

## Return Value

Returns an integer handle to the browse session. Returns -1 when an error is detected.

The returned entries will be ordered alphabetically by name.

## Related Functions

[EquipBrowseClose](#), [EquipBrowseFirst](#), [EquipBrowseGetField](#), [EquipBrowseNext](#), [EquipBrowseNumRecords](#),  
[EquipBrowseOpen](#), [EquipCheckUpdate](#), [EquipGetProperty](#)

## Example

```
INT iSession;
...
iSession = EquipBrowseOpen("NAME=ABC*", "NAME,AREA",
"ClusterA,ClusterB");
IF iSession <> -1 THEN
    // Successful case
ELSE
    // Function returned an error
END
...
```

## See Also

[Equipment Database Functions](#)

## EquipBrowsePrev

The EquipBrowsePrev function moves the data browse cursor back one record. If you call this function after you have reached the beginning of the records, error 412 is returned (Databrowse session EOF).

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**INT EquipBrowsePrev(LONG Session)**

*Session:*

The handle to a browse session previously returned by a EquipBrowseOpen call.

## Return Value

0 (zero) if the equipment database browse session exists, otherwise an error is returned.

## Related Functions

[EquipBrowseClose](#), [EquipBrowseFirst](#), [EquipBrowseGetField](#), [EquipBrowseNext](#), [EquipBrowseNumRecords](#),  
[EquipBrowseOpen](#), [EquipCheckUpdate](#), [EquipGetProperty](#)

## See Also

[Equipment Database Functions](#)

## EquipCheckUpdate

The runtime environment will automatically check if the equipment database has been updated before each page open and before running an equipment browse open function ([EquipBrowseOpen](#)). It does this by checking the version of the database file. You may also update the database periodically in a background task to reload the database even if the page is not changed.

The EquipCheckUpdate function checks if the equipment database file has been updated, and provides the facility to reload it. The reload can only be performed if there are no open browse sessions.

## Syntax

```
INT EquipCheckUpdate(INT Reload[, STRING sCluster])
```

*Reload*:

1 (TRUE) if you want to reload the database.

0 (FALSE) checks the status of the database without reloading it.

*Cluster*:

The cluster name to check and/or reload the equipment database for. All clusters will be checked if omitted or an empty string is set.

## Return Value

0 (FALSE) if the equipment database has not changed, or 1 (TRUE) if it has been changed, otherwise an error is returned.

## Related Functions

[EquipBrowseClose](#), [EquipBrowseGetField](#), [EquipBrowseFirst](#), [EquipBrowseNext](#), [EquipBrowseNumRecords](#),  
[EquipBrowseOpen](#), [EquipBrowsePrev](#), [EquipGetProperty](#)

## See Also

[Equipment Database Functions](#)

## EquipGetParameter

Reads a runtime parameter of an equipment database record from the EQPARAM.RDB database file.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

```
EquipGetParameter(ClusterName, EquipmentName, ParameterName)
```

*ClusterName*

The name of the cluster (optional for a single cluster system)

*EquipmentName*

The name of the equipment from which to get information. The name of the equipment can be prefixed by the name of the cluster that is "ClusterName.Equipment".

*ParameterName*

The name of the parameter for which to retrieve a value.

**Return Value**

The value of the specified parameter as a string. If the parameter is a tag reference, the value of the tag shall be returned.

---

**Note:** The value field of the Equipment Runtime Parameters table can work like a tag reference when the Is Tag column is set to true or default. It can contain Variable tag, or equipment and item name reference of a variable tag (using equipment.item notation) that will result in the tag value being returned by this function.

---

An empty string may or may not be an indication that an error has been detected. The last error should be checked in this instance to determine if an error has actually occurred.

**Related Functions**

[EquipBrowseFirst](#), [EquipBrowseGetField](#), [EquipBrowseNext](#), [EquipBrowseNumRecords](#), [EquipBrowseOpen](#),  
[EquipBrowsePrev](#), [EquipCheckUpdate](#), [EquipGetProperty](#)

**See Also**

[Equipment Database Functions](#)

**EquipGetProperty**

This function reads a property of an equipment database record from the EQUIP.RDB database file.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

**Syntax**

STRING **EquipGetProperty**(STRING *Name*, STRING *Field*, INT *Mode*, STRING *Cluster*)

*Name:*

The name of the equipment from which to get information. The name of the equipment can be prefixed by the name of the cluster that is "ClusterName.Equipment".

*Field:*

The field to read. Supported fields are:

Name, Cluster, Type, Area, Location, IODevice, Page, Parent, Composite, Help, Comment, Alias, Content, Hidden, Custom1, Custom2, Custom3, Custom4, Custom5, Custom6, Custom7, Custom8, Defstate, Scheduled

- *Name* — The name of the equipment (254 characters).
- *Cluster* — The cluster to which the equipment belongs (16 characters).
- *Type* — The equipment-specific type of device (254 characters).

- *Area* — Area number (integer) (16 characters).
- *Location* — Equipment specific field (254 characters).
- *IODevice* — I/O Device name(s) (254 characters).
- *Page* — Page name (254 characters).
- *Parent* — The name of the parent equipment derived from the name of the equipment (maximum 254 characters).
- *Help* — Help context (254 characters).
- *Comment* — User comment (254 characters).
- *Custom1..8* — User definable fields (254 characters each).
- *Composite* — The equipment specific composite name (maximum 254 characters).
- *Defstate* — The default state.
- *Scheduled* — Specifies if the equipment participates in a schedule.
- *Alias* — Meaningful name of equipment (254 characters).
- *Content* — Workspace content associated with equipment instance.
- *Hidden* — Hide from equipment tree at runtime.

Runtime fields:

- *MODE* — the current mode of the equipment. 0 = automatic; 1= Manual Inherited; 2= Manual.
- *DRMODE* — the current DR mode level for the equipment. The value will be a positive integer to represent the current DR level or zero if inactive.
- *STATE* — the current state of the equipment. Although you can only set state for equipment in Override mode, it is still possible to get state for equipment in normal and inherited override mode.

*Mode:*

0 Block — values are retrieved from the report server, the value will also be stored in local memory cache.

1 Cache — values are first retrieved from local memory cache, if the property is missing from the memory cache, a request will be sent to the report server and the result will then be cached. If the property is missing from the memory cache or if a previous request is in progress, an empty string will be returned.

2 Local — values are retrieved from the local RDB. Error 348 (Property does not exist) will be returned if the property requested is not available. Requesting runtime fields will also return this error.

3 CacheThenLocal — values are first retrieved from local memory cache, if the property is missing from the memory cache, a request will be sent to the report server and the result will then be cached. If the property is missing from the memory cache or if a previous request is in progress, the local RDB will be accessed to retrieve the property value.

*Cluster*

The name of the cluster (optional for a single cluster system).

---

**Note:** Mode 1 and 3 will access the report server at least once, there will be a once off performance penalty on the report server, operating in this mode will always guarantee equipment properties being the latest. Mode 2 will be the fastest but cannot guarantee equipment will be up-to-date (see [Client Side Online Changes](#)). Mode 0 will be the slowest as each request is sent across the wire and the function will block until the report server responds.

---

## Return Value

The value of the specified field as a string. An empty string may or may not be an indication that an error has been detected. The last error should be checked in this instance to determine if an error has actually occurred.

[Equipment Database Functions](#)

## EquipRefBrowseGetField

The EquipRefBrowseGetField function retrieves the value of the specified field from the record the data browse cursor is currently referencing.

This function is a non-blocking function. It does not block the calling Cicode task.

## Syntax

```
STRING EquipRefBrowseGetField(LONG Session, STRING FieldName)
```

*Session:*

The handle to a browse session previously returned by a EquipRefBrowseOpen call.

*FieldName:*

The name of the field that references the value to be returned. Supported fields are:

ASSOC, CLUSTER, COMMENT, CUSTOM1...8, EQUIP, ORDER, REFCAT, REFCLUST, REFEQUIP, REFITEM.

See [Browse Function Field Reference](#) for information about fields.

## Return Value

The value of the specified field as a string. An empty string may or may not be an indication that an error has been detected. The last error should be checked in this instance to determine if an error has actually occurred.

## Related Functions

[EquipRefBrowseClose](#), [EquipRefBrowseFirst](#), [EquipRefBrowseNext](#), [EquipRefBrowseNumRecords](#),

[EquipRefBrowseOpen](#), [EquipRefBrowsePrev](#), [EquipGetProperty](#)

## Example

```
STRING fieldValue = "";
STRING fieldName = "TYPE";
INT errorCode = 0;
...
fieldValue = EquipRefBrowseGetField(iSession, sFieldName);
IF fieldValue <> "" THEN
    // Successful case
ELSE
    // Function returned an error
END
...
```

## See Also

[Equipment Database Functions](#)

## EquipRefBrowseNext

The EquipRefBrowseNext function moves the data browse cursor forward one record. If you call this function after you have reached the end of the records, error 412 is returned (Databrowse session EOF).

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

INT **EquipRefBrowseNext**(LONG *Session*)

*Session*

The handle to a browse session previously returned by a EquipRefBrowseNext call.

## Return Value

0 (zero) if the equipment reference database browse session exists, otherwise an error is returned.

## Related Functions

[EquipRefBrowseClose](#), [EquipRefBrowseFirst](#), [EquipRefBrowseGetField](#), [EquipRefBrowseNumRecords](#),  
[EquipRefBrowseOpen](#), [EquipRefBrowsePrev](#), [EquipCheckUpdate](#), [EquipGetProperty](#)

## See Also

[Equipment Database Functions](#)

## EquipRefBrowseNumRecords

The EquipRefBrowseNumRecords function returns the number of records that match the filter criteria.

This function is a non-blocking function. It does not block the calling Cicode task.

## Syntax

```
LONG EquipRefBrowseNumRecords(LONG Session)
```

*Session:*

The handle to a browse session previously returned by a EquipRefBrowseOpen call.

## Return Value

The number of records that have matched the filter criteria. A value of 0 denotes that no records have matched. A value of -1 denotes that the browse session is unable to provide a fixed number. This may be the case if the data being browsed changed during the browse session.

## Related Functions

[EquipRefBrowseClose](#), [EquipRefBrowseFirst](#), [EquipRefBrowseNext](#), [EquipRefBrowseOpen](#), [EquipRefBrowsePrev](#),  
[EquipCheckUpdate](#), [EquipGetProperty](#)

## Example

```
INT numRecords = 0;  
...  
numRecords = EquipRefBrowseNumRecords(iSession);  
IF numRecords <> 0 THEN  
    // Have records  
ELSE  
    // No records  
END  
...
```

[Equipment Database Functions](#)

## EquipRefBrowseOpen

The EquipRefBrowseOpen function initiates a new browse session and returns a handle to the new session that can be used in subsequent equipment reference browse function calls.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

LONG EquipRefBrowseOpen(STRING *Filter*, STRING *Fields* [, STRING *Sort*] )

*Filter:*

A filter expression specifying the records to return during the browse. An empty string indicates that all records will be returned. Where a fieldname is not specified in the filter, it is assumed to be equipment name. For example, the filter "AAA" is equivalent to "name=AAA".

All string fields can be filtered based on regular expressions. Using an operator other than = will cause strings to not match the filter criteria. The following regular expressions are supported \*expr, expr\*, and \*expr\*.

*Fields:*

Specifies via a comma delimited string the columns to be returned during the browse. An empty string indicates that the server will return all available columns. Supported fields are:

ASSOC, CLUSTER, COMMENT, CUSTOM1...8, EQUIP, ORDER, REFCAT, REFCLUST, REFEQUIP, REFITEM.

See [Browse Function Field Reference](#) for information about fields.

*Sort:*

Comma delimited list of record fields to be returned in order of sorting preferences. For example(GROUP:D, ORDER:A)

## Return Value

Returns an integer handle to the browse session. Returns -1 when an error is detected.

The returned entries will be ordered alphabetically by name.

## Related Functions

[EquipRefBrowseClose](#), [EquipRefBrowseFirst](#), [EquipRefBrowseGetField](#), [EquipRefBrowseNext](#),  
[EquipRefBrowseNumRecords](#), [EquipRefBrowsePrev](#), [EquipCheckUpdate](#), [EquipGetProperty](#)

## Example

```
INT iSession;
...
iSession = EquipRefBrowseOpen("NAME=ABC*", "NAME,AREA","GROUP");
IF iSession <> -1 THEN
    // Successful case
ELSE
    // Function returned an error
END
...
```

[Equipment Database Functions](#)

## EquipRefBrowsePrev

The EquipRefBrowsePrev function moves the data browse cursor back one record. If you call this function after you have reached the beginning of the records, error 412 is returned (Databrowse session EOF).

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**INT EquipRefBrowsePrev(LONG Session)**

*Session:*

The handle to a browse session previously returned by a EquipRefBrowseOpen call.

## Return Value

0 (zero) if the equipment database browse session exists, otherwise an error is returned.

## Related Functions

[EquipRefBrowseClose](#), [EquipRefBrowseFirst](#), [EquipRefBrowseGetField](#), [EquipRefBrowseNext](#),  
[EquipBrowseNumRecords](#), [EquipRefBrowseOpen](#), [EquipCheckUpdate](#), [EquipGetProperty](#)

## See Also

[Equipment Database Functions](#)

## EquipSetProperty

The EquipSetProperty function sets the property of an item of equipment.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**INT EquipSetProperty(STRING Name, STRING Field, STRING Value, STRING Cluster)**

*Name:*

The name of the equipment.

*Field:*

Only properties coming from the scheduler engine can be set:

- MODE: (the current mode of the equipment)
- STATE: (the current state of the equipment. The state only can be set for equipment in "Override" mode)
- DRMODE: (the DR mode of the equipment)

*Value:*

The value to be set:

- MODE: 0, automatic; 2 Manual
- STATE: Any state configured in the system for this equipment, also the mode set the mode to Manual otherwise an error will be sent.
- DRMODE: the current DR mode level for the equipment. The value will be a positive integer to represent the current DR level or zero if inactive.

*Cluster:*

The name of the cluster (optional)

## Return Value

Returns 0 if successful otherwise it returns an error.

## EquipStateBrowseClose

The EquipStateBrowseClose function terminates a browsing session and cleans up the resources used by the session. This function uses iSession as the argument which is previously returned by the EquipStateBrowseOpen function.

## Syntax

INT **EquipStateBrowseClose**(LONG Session )

*Session:*

The handle to a browse session previously returned by a EquipStateBrowseOpen call

## Return Value

Returns 0 if the equipment state database browse session has been closed successfully, otherwise an error is returned.

## Related Functions

[EquipStateBrowseOpen](#), [EquipStateBrowseFirst](#), [EquipStateBrowseGetField](#), [EquipStateBrowseNext](#),  
[EquipStateBrowseNumRecords](#), [EquipStateBrowsePrev](#), [EquipGetProperty](#)

## Example

```

[Equipment Database Functions](#)

### EquipStateBrowseFirst

The EquipStateBrowseFirst function places the data browse cursor at the first record.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

INT **EquipBrowseFirst**(LONG Session)

*Session:*

The handle to a browse session previously returned by a EquipStateBrowseOpen call.

## Return Value

0 (zero) if the equipment state database browse session exists, otherwise an error is returned.

## Related Functions

[Equipment Database Functions](#)

### EquipStateBrowseGetField

The EquipStateBrowseGetField function returns the value of the particular field in a record to which the data browse cursor is currently referencing. This function uses the field name whose value needs to be returned.

This function is a non-blocking function. It does not block the calling Cicode task.

## Syntax

STRING **EquipStateBrowseGetField**(LONG *Session*, STRING *Field*)

*Session*:

The handle to a browse session previously returned by a EquipStateBrowseOpen call.

*Field*:

The name of the field that references the value to be returned. Available fields are:

- Name – the state name
- Equipment – equipment name
- Delay – entry command delay
- Period – repeat command period
- Priority – the state priority
- Description – state description
- DRmode – demand-response mode of this state

## Return Value

The value of the specified field as a string. An empty string may or may not be an indication that an error has been detected. The last error should be checked in this instance to determine if an error has actually occurred.

## Related Functions

[EquipStateBrowseOpen](#), [EquipStateBrowseFirst](#), [EquipStateBrowseNext](#), [EquipStateBrowseNumRecords](#),  
[EquipStateBrowsePrev](#), [EquipGetProperty](#)

## Example

```
ErrSet(1);
    INT error;
    fieldValue = EquipStateBrowseGetField(iSession, sFieldName);
    error = IsError();

    IF(error <> 0) THEN
        //return error
    ELSE
        //successful
    ErrSet(0)
    end
```

## See Also

[Equipment Database Functions](#)

## EquipStateBrowseNext

The EquipStateBrowseNext function places the data browse cursor at the next available record. This function will return an error if called when the data cursor is at end of the records.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**INT EquipStateBrowseNext(LONG Session)**

*Session*

The handle to a browse session previously returned by a EquipStateBrowseOpen call.

## Return Value

0 (zero) if the equipment state database browse session exists, otherwise an error is returned.

### EquipStateBrowseOpen

The EquipStateBrowseOpen function initiates a new session for browsing the equipment states configured. It returns a handle for the browsing session which can be used for further browsing operations.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

LONG **EquipStateBrowseOpen**(STRING *Filter*, STRING *Fields* [, STRING *Clusters*] )

### *Filter*:

A filter expression specifying the records to return during the browse. An empty string indicates that every record will be returned. Where a field name is not specified in the filter, it is assumed to be tagname. For example, the filter "AAA" is equivalent to "name=AAA".

### *Fields*:

Specifies via a comma delimited string the columns to be returned during the browse. An empty string indicates that the server will return every available column. Available fields are:

CLUSTER, DELAY, DRMODE, EQUIPMENT, NAME, PERIOD, PRESTATE, PRIORITY.

See [Browse Function Field Reference](#) for information about fields.

### *Clusters*:

An optional parameter that specifies via a comma delimited string the subset of the clusters to browse. An empty string indicates that every connected cluster will be browsed.

## Return Value

Returns an integer handle to the browse session. Returns -1 when an error is detected.

## Related Functions

## Error Functions

The following functions relate to errors:

<a href="#">ErrCom</a>	Gets the communication status for the current Cicode task.
<a href="#">ErrDrv</a>	Gets a protocol-specific error message.
<a href="#">ErrGetHw</a>	Gets a hardware error code.
<a href="#">ErrHelp</a>	This function is obsolete.
<a href="#">ErrInfo</a>	Gets error information.
<a href="#">ErrLog</a>	Logs a system error.
<a href="#">ErrMsg</a>	Gets the error message associated with a hardware error.
<a href="#">ErrSet</a>	Sets the error mode.
<a href="#">ErrSetHw</a>	Sets a hardware error.
<a href="#">ErrSetLevel</a>	Sets the error level.
<a href="#">ErrTrap</a>	Generates an error trap.

IsError	Checks for an error.
---------	----------------------

## See Also

[Cicode Function Categories](#)

[Using Cicode Functions](#)

## ErrCom

Gets the communication status for the current Cicode task. You can call this function in reports, Cicode that is associated with an object, and in any Cicode task.

## Syntax

`ErrCom()`

## Return Value

0 (zero) if all I/O device data associated with the task is valid, otherwise an error is returned.

## Related Functions

[CodeSetMode](#)

## Example

```
IF ErrCom()<>0 THEN
    Prompt("I/O device data is bad");
END
```

In a report format:

```
{CICODE}
IF ErrCom()<>0 THEN
    PrintLn("This Report contains bad data");
END
{END}
```

## See Also

[Error Functions](#)

## ErrDrv

Gets a protocol-specific error message and native error code.

## Syntax

**ErrDrv(*sProtocol*, *sField*, *nError*)**

*sProtocol*:

The Plant SCADA protocol.

*sField*:

The field in the PROTERR.DBF database:

- PROTOCOL
- MASK
- ERROR
- MESSAGE
- REFERENCE
- ACTION
- COMMENT

*nError*:

The protocol specific error code. This field needs to be a variable as it also the place where the returned error code is stored.

Since the first 34 specific error codes are standard for all protocols, Plant SCADA may add 'masking' to make the error code unique. For example, if an I/O device returns errors 1 to 10 (which are already used), the driver may add 0x100000 to its error codes. When this function is called, the mask will be removed before the result is returned to this variable.

## Return Value

The error message (as a string), or an empty string ("") if the error is not found. The error code is returned into the *nError* variable.

## Related Functions

[ErrInfo](#), [ErrHelp](#)

## Example

```
// Get the error message and number associated with error 108
nError = 108;
sError = ErrDrv("TIWAY", "MESSAGE", nError);
```

## See Also

[Error Functions](#)

## ErrGetHw

Gets the current hardware error status for an I/O device.

I/O devices can be grouped into 2 distinct categories: Those that are created by the system engineer, and those that are created by Plant SCADA itself.

I/O devices that are created by the system engineer include any I/O device listed in the Plant SCADA I/O devices database, and any device visible as a record in the I/O Device form in the Project Editor.

I/O devices that are created by Plant SCADA include Generic, LAN, Cicode, Animation, Reports Server, Alarms Server, Trends Server, and I/O Server, and are those specifically not created by the system engineer.

The argument's values you supply in this function are used by Plant SCADA to determine which type of device hardware alarm you want to work with.

---

**Note:** Do not use this function if you have more than 511 I/O devices in your project and the flag [\[Code\]BackwardCompatibleErrHw](#) is set to 1. You may retrieve the hardware error status for the wrong I/O device.

---

## Syntax

**ErrGetHw(Device, DeviceType)**

*Device:*

For I/O devices that are created by the system engineer, select the IODevNo as the argument value.

To determine the **IODevNo** of a physical I/O device in your project, use the I/O device record number from the I/O Device form in the Plant SCADA Studio. When using an **IODevNo**, the **DeviceType** argument needs to be set to 2.

For I/O devices that are created by Plant SCADA itself, select one of the following options as the argument value:

- Generic
- LAN
- Cicode
- Animation
- Reports Server
- Alarms Server
- Trends Server
- I/O Server

*DeviceType:*

Select a value from the following options to indicate the 'Type of Device' used in the **Device** argument:

0 - for I/O devices that are created by Plant SCADA itself (Generic, LAN, Cicode, Animation, etc).

2 - for I/O devices that are created by the system engineer.

The **DeviceType** argument was added to this function in V5.40 and later. Earlier versions did not pass a value for the **DeviceType** argument (as it did not exist). Versions prior to V5.40 identified an I/O device by passing the IODevNo (masked with the value of 8192) to the function as the **Device** argument, in the structure:

IODevNo + 8192

This was for versions of Plant SCADA permitting a maximum limit of 4095 I/O devices.

Versions prior to V5.20 masked the IODevNo with a value of 512. The backward compatibility flag for using this mask needs to be set in the Citect.INI file (see [\[Code\]BackwardCompatibleErrHw](#)).

## Return Value

The detected error.

## Related Functions

[ErrHelp](#), [ErrInfo](#), [ErrMsg](#), [ErrSetHw](#)

## Example

```
Error=ErrGetHw(3,0);
! Sets Error to the current error status for the animation device.
IF Error=0 THEN
    DspText(4,0,"");
ELSE
    DspText(4,0,"Hardware error");
END
```

## See Also

[Error Functions](#)

## ErrInfo

Gets extended error information on the last error that was detected.

## Syntax

**ErrInfo(*nType*)**

*nType*:

The type of error information. If type is 0 (zero), function returns the animation number where the error occurred.

## Return Value

The error information.

## Example

```
! Get the animation number where the last error occurred
AN = ErrInfo(0);
```

## See Also

[Error Functions](#)

### ErrLog

Logs a message to the Plant SCADA system log file.

This function is useful for logging errors in user functions, and for debugging user functions. The Plant SCADA system log file 'SYSLOG.DAT' is created in the local Windows directory of the computer, %PROGRAMDATA%\AVEVA Plant SCADA <VersionNumber>\Logs.

## Syntax

**ErrLog(*Message*)**

*Message*:

The message to log. This field can also contain control (such as /n) and formatting characters.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DebugMsg](#), [DebugMsgSet](#), [CodeTrace](#), [TraceMsg](#), [Halt](#)

## Example

```
FUNCTION MyFunc(INT Arg)
    IF Arg<0 THEN
        ErrLog("Invalid arg in Myfunc");
        Halt();
    END
END
```

## See Also

[Error Functions](#)

### ErrMsg

Gets the error message associated with a detected hardware error.

## Syntax

**ErrMsg(*nError*)**

*nError:*

The hardware error number returned from the IsError() function.

## Return Value

The error message (as a string). A null value is returned if *nError* is not in the range of Cicode errors.

## Related Functions

[IsError](#), [ErrHelp](#), [ErrInfo](#), [ErrTrap](#)

## Example

```
//Get the message of the last hardware error
sMsg = ErrMsg(IsError());
```

## See Also

[Error Functions](#)

## ErrSet

Sets the error-checking mode. When *Mode* is set to 0 and an error occurs that causes a component to stop executing, Plant SCADA halts the execution of the Cicode task that caused the error, and generates a hardware error.

You can perform error checking by setting *Mode* to 1 and using the IsError() function to trap errors. When the type of error is determined, you can control what happens under particular error conditions. Errset(1) can be used for parts of Cicode when task termination is undesirable, working around the underlying issue in the Cicode. After executing ErrSet(1), Plant SCADA will not automatically check for errors, and the user can manually check for errors using the Cicode function [IsError\(\)](#) after a line of code is executed.

---

**Note:** ErrSet(1) is NOT global, and when used it will only affect all functions within the particular thread in which it has been called. It is recommended that you apply ErrSet() around specific small segments of Cicode that are problematic (i.e. single Cicode statements), and not around large sections of code.

The operation of the ErrSet function is unique to each Cicode task. If you enable user error checking for one task, it does not enable error checking for any other tasks.

---

**Note:** This has changed from previous versions of Plant SCADA where this feature used to affect all Cicode tasks.

It is important to note that ErrSet(1) and ErrSet(0) are intended to be used in pairs. When a thread starts, the error check level is 0 (Plant SCADA will halt your code on errors). Each time ErrSet(1) is called, the level is incremented by 1 (with a maximum of 1000). When ErrSet(0) is called the level is decremented by 1 (with a minimum of 0). Plant SCADA will only halt your code on errors if the error check level equals 0. It does not cause a problem to call ErrSet(1) when the level is already 1000, or to call ErrSet(0) when the level is already 0. The code will just continue to run at the current error check level.

If each function calls ErrSet(1) and ErrSet(0) in pairs, there won't be a problem. However, much user Cicode does not do this reliably. For example, if there are multiple RETURN statements in a function it would need to have an ErrSet(0) before each return to make sure the level was reset. It's also common practice to put ErrSet(1) at the

beginning of each function with no corresponding ErrSet(0). To avoid problems, you can use the [ErrSetLevel](#) function instead of ErrSet(). It allows you to set the level to any number (0 - 1000), but could be used to just set it to 0 or 1 to enable or disable Plant SCADA's automatic error checking instead of letting the error check level build up to higher numbers.

## Syntax

**ErrSet(*Mode*)**

*Mode*:

Error-checking mode:

0 - default - Plant SCADA will check for errors.

1 - The user needs to check for errors.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[IsError](#), [ErrSetHw](#), [ErrSetLevel](#)

## Example 1

```
ErrSet(1);
Test=Var/0;
DevWrite(hDevice, "data to write");
nError=IsError();
! Sets Error to 273 (divide by zero).
```

The nError variable will be set to 273 (Divide by 0 Error) if DevWrite is successful, as the internal error variable has not been reset. If DevWrite fails, the error code will correctly be set to a Cicode error such as 269 (bad handle specified).

## Example 2

If you wish to find code that does not correctly use ErrSet(), you can set the citect.ini parameter [Code]EnableErrorLogging=1 This parameter is available in Plant SCADA 7.50 Service Pack 1, Patch 7 and later. When enabled, it will log an error message and the Cicode function stack to the syslog file when the error check level reaches 100 or 1000:

```
ErrSet: Error check level has reached 100; usually this means there are mismatches between
ErrSet(1) and ErrSet(0). Call Stack:
ReadFile(10001 {Good});
hFile = 100 {Good, 2016-10-21T10:55:26}
nRow = 100 {Good, 2016-10-21T10:55:26}
ErrSet: Error check level has reached 1000; usually this means there are mismatches between
ErrSet(1) and ErrSet(0). It won't be increased any more. Call stack:
```

```
ReadFile(10001 {Good});  
hFile = 1000 {Good, 2016-10-21T10:55:26}  
nRow = 1000 {Good, 2016-10-21T10:55:26}
```

## Example 3

Since the ErrSet() state persists until the thread terminates, it is good to avoid leaving it in a different state than it was when your function started. For example, the following code checks if a page exists (which would cause a fatal error if it doesn't exist). This could be called from various other Cicode functions in the project. So, it uses ErrSetLevel() but saves the previous level number that is returned. At the end of the function it sets the previous error level again.

```
// Returns TRUE if the specified page exists, otherwise returns FALSE  
INT FUNCTION PageExists(STRING sPage)  
INT nErrLevelPrev = ErrSetLevel(1);  
IsError(); //Reset the last error number  
PageFileInfo(sPage, 0);  
ErrSetLevel(nErrLevelPrev);  
RETURN IsError() = 0; //Any error indicates PageFileInfo() failed  
END
```

## See Also

[Error Functions](#)

### ErrSetHw

Sets the hardware error status for a hardware device. Call this function to generate a hardware error.

I/O devices can be grouped into two distinct categories: those created by the system engineer, and those created by Plant SCADA itself.

I/O devices that are created by the system engineer, are any I/O device listed in the Plant SCADA I/O devices database, visible as records in the I/O Device form in the Project Editor.

I/O devices that are created by Plant SCADA, including Generic, LAN, Cicode, Animation, Reports Server, Alarms Server, Trends Server, and I/O Server (are those specifically not created by the system engineer).

The arguments values you supply in this function are used by Plant SCADA to determine the type of device hardware alarm you want to work with.

---

**Note:** To use this function, you need to set [\[Code\]BackwardCompatibleErrHw](#) to 1. You cannot use this function if you have more than 511 I/O devices in your project.

## Syntax

**ErrSetHw**(*Device*, *Error*, *DeviceType*)

*Device*:

For I/O devices that are created by the system engineer, select the IODevNo as the argument value.

To determine the **IODevNo** of a physical I/O device in your project, use the I/O device record number from the I/O Device form in the Plant SCADA Studio. When using an **IODevNo**, the *DeviceType* argument needs to be set

to 2.

For I/O devices that are created by Plant SCADA itself, select one of the following options as the argument value:

- 0 - Generic
- 1 - LAN
- 2 - Cicode
- 3 - Animation
- 4 - Reports Server
- 5 - Alarms Server
- 6 - Trends Server
- 7 - I/O Server

*Error:*

The error code.

*DeviceType:*

Select a value from the following options to indicate the 'Type of Device' used in the *Device* argument:

0 - For I/O devices that are created by Plant SCADA itself (Generic, LAN, Cicode, Animation, etc).

2 - For I/O devices that are created by the system engineer.

The *DeviceType* argument was added to this function in V5.40 and later. Earlier versions did not pass a value for the *DeviceType* argument (as it did not exist). Versions prior to V5.40 identified an I/O device by passing the IODevNo (masked with the value of 8192) to the function as the *Device* argument, in the structure:

IODevNo + 8192

This was for versions of Plant SCADA that permitted a maximum limit of 4095 I/O devices.

Versions prior to V5.20 masked the IODevNo with a value of 512. The backward compatibility flag for using this mask needs to be set in the Citect.INI file (see [\[Code\]BackwardCompatibleErrHw](#)).

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[ErrHelp](#) [ErrMsg](#) [ErrSet](#) [ErrSetHw](#)

## Example

```
ErrSetHw(4,273,0);
! Generates a divide by zero error (273) on the report device.
ErrSetHw(3,0,0)
! Resets any error on the animation device.
```

## See Also

[Error Functions](#)

## ErrSetLevel

Sets the nesting error level to enable Plant SCADA error checking inside a nested function (when Plant SCADA error checking has been disabled). This function returns the old error level and sets a new error level.

The nesting error level is incremented every time the ErrSet(1) function is called.

## Syntax

**ErrSetLevel(*Level*)**

*Level*:

The nesting error level.

## Return Value

Returns the old error level and sets a new error level.

## Related Functions

[ErrSet](#)

## Example

```
! ErrorLevel 0 defaults to ErrSet(0) - enables Plant SCADA error-checking.
FUNCTION MainFn()
    ErrSet(1);
    ! ErrorLevel 1 - disables Plant SCADA error checking.
    Fn1();
    ErrSet(0);
    ! Enables Plant SCADA error checking.
END
FUNCTION Fn1()
    ErrSet(1);
    ! ErrorLevel 2 - disables Plant SCADA error checking.
    Test=Var/0;
    Error=IsError();
    ! Sets Error to 273 (divide by zero).
    Fn2();
    ErrSet(0);
    ! Enables Plant SCADA error checking.
END
FUNCTION Fn2()
    OldErrorLevel=ErrSetLevel(0);
    ! Sets nesting error level to 0 to enable Plant SCADA error-checking.
    Test=Var/0;
    ! Cicode halts and a hardware alarm is generated.
    ErrSetLevel(OldErrorLevel)
    ! Resets nesting error level to disable Plant SCADA error-checking.
END
```

## See Also

[Error Functions](#)

### ErrTrap

Generates an error trap. If Plant SCADA error checking is enabled, this function will generate a hardware error and may halt Cicode execution (see *bHalt* argument). If user error checking is enabled, the user function specified in OnEvent(2,Fn) is called.

## Syntax

**ErrTrap(*Error*, *bHalt*)**

*Error*:

The error number to trap.

*bHalt*:

Determines whether the Cicode execution will be halted.

0 - Cicode execution is not halted

1 - Cicode execution is halted

## Return Value

0 (zero) if successful, otherwise an error is returned.

[ErrSetHw](#), [ErrSet](#), [ErrSetLevel](#), [OnEvent](#)

## Example

```
IF Tag=0 THEN
    ErrTrap(273); ! Traps a divide by zero error.
ELSE
    Value=10/Tag;
END
```

## See Also

[Error Functions](#)

### IsError

Gets the current error value. The error value is set when any error is detected, and is reset after this function is called. You can call this function if user error-checking is enabled or disabled.

You should call this function as soon as possible after the operation to be checked, because the error code could be changed by the next error.

## Syntax

```
IsError()
```

## Return Value

The current error value. The current error is reset to 0 after this function is called.

## Related Functions

[ErrSet](#)

## Example

```
! Enable user error-checking.  
ErrSet(1);  
! Invalid ArcSine.  
Ac=ArcSin(20.0);  
! Sets ErrorVariable to 274 (invalid argument passed).  
ErrorVariable=IsError()
```

## Event Functions

Following are functions used to trap and process asynchronous events:

<a href="#">CallEvent</a>	Calls the event function for an event type.
<a href="#">ChainEvent</a>	Calls an event function, by function number.
<a href="#">GetEvent</a>	Gets the function number of the current callback event.
<a href="#">OnEvent</a>	Sets an event callback function, by event type.
<a href="#">SetEvent</a>	Sets an event callback function, by function number.

## See Also

[Cicode Function Categories](#)

[Using Cicode Functions](#)

## CallEvent

Simulates an event, triggering any OnEvent() function that has the same Type argument specified.

Plant SCADA starts running the function immediately, without reading any data from the I/O devices. Any I/O device variable that you use will contain either 0 (zero) or the last value read.

## Syntax

**CallEvent(*Window*, *nType*)**

*Window*:

The number of the window, returned from the [WinNew\(\)](#), [WinNewAt\(\)](#), or [WinNumber\(\)](#) function.

*nType*:

The type of event:

- 0 - The mouse has moved. When the mouse moves the callback function is called. The return value must be 0.
- 1 - A key has been pressed. When the user presses a key, the callback function is called after Plant SCADA checks for hot keys. If the return value is 0, Plant SCADA checks for key sequences. If the return value is not 0, Plant SCADA assumes that you will process the key and does not check the key sequence. It is up to you to remove the key from the key command line. If you are using a right mouse button click as an event, you should read about the ButtonOnlyLeftClick parameter.
- 2 - Error event. This event is called if an error is detected in Cicode, so you can write a single error function to check for your errors. If the return value is 0, Plant SCADA continues to process the error and generates a hardware error - it may then halt the Cicode task. If the return value is not 0, Plant SCADA assumes that you will process the error, and continues the Cicode without generating a hardware error.
- 3 - Page user communication error. A communication error has been detected in the data required for this page. If the return value is 0 (zero), Plant SCADA still animates the page. If the return value is not zero, it does not update the page.
- 4 - Page user open. A new page is being opened. This event allows you to define a single function that is called when all pages are opened. The return value must be 0.
- 5 - Page user close. The current page is being closed. This event allows you to define a single function that is called when all pages are closed. The return value must be 0.
- 6 - Page user always. The page is active. This event allows you to define a single function that is called when all pages are active. The return value must be 0.
- 7 - Page communication error. A communication error has been detected in the data required for this page. Reserved for use by Plant SCADA.
- 8 - Page open. This event is called each time a page is opened. Reserved for use by Plant SCADA.
- 9 - Page close. This event is called each time a page is closed. Reserved for use by Plant SCADA.
- 10 - Page always. This event is called while a page is active. Reserved for use by Plant SCADA.
- 11..17 - Undefined.
- 18 - Report start. The report server is about to start a new report. This event is called on the report server. The return value must be 0.
- 19 - Device history. A device history has just completed. The return value must be 0.
- 20 - Login. A user has just logged in.
- 21 - Logout. A user has just logged out.

- 22 - Trend needs repainting. This event is called each time Plant SCADA re-animates a real-time trend or scrolls an historical trend. You should use this event to add additional animation to a trend, because Plant SCADA deletes all existing animation when a trend is re-drawn. (For example, if you want to display extra markers, you must use this event.)
- 23 - Hardware error has been detected.
- 24 - Keyboard cursor moved. This event is called each time the keyboard command cursor moves. The cursor can be moved by the cursor keys, the mouse, or the Cicode function KeySetCursor(). Note that you can find where the keyboard command cursor is located by calling the function KeyGetCursor().
- 25 - Network shutdown. A Shutdown network command has been issued.
- 26 - Runtime system shutdown and restart. (Required because of configuration changes.)
- 27 - Event. An event has occurred.
- 28 - Accumulator. An accumulator has logged a value.
- 29 - Slider. A slider has been selected.
- 30 - Slider. A slider has moved.
- 31 - Slider. A slider has been released (that is stopped moving).

While responding to slider events 29, 30, and 31, you can set any variables but you cannot call functions that cause immediate changes to animations on the page (for example, DspText() and DspSym()). Types 29, 30, & 31 relate only to V3.xx and V4.xx animations, and will be superseded in future releases.

- 32 - Shutdown. Plant SCADA is being shutdown.

- 33 - Reserved for Plant SCADA internal use.

34 - 41 - Plant SCADA Confirmation Events. Reserved for Plant SCADA internal use. For the confirmation events, two sets of event type code are defined. The runtime calls the Plant SCADA event handler first, and conditionally proceed to the user's event handler depending on the return value of the Plant SCADA event handler.

- 34 -Plant SCADA Event: Child Window Close Confirmation.
- 35 - Plant SCADA Event: Main Window Close Confirmation.
- 36 - Plant SCADA Event: Maximize Window Confirmation.
- 37 - Plant SCADA Event: Minimize Window Confirmation.
- 38 - Plant SCADA Event: Restore Window Confirmation.
- 39 - Plant SCADA Event: Move Window Confirmation.
- 40 - Plant SCADA Event: Size Window Confirmation.
- 41 - Plant SCADA Event: Shutdown Confirmation Confirmation.

42 to 49 - User Confirmation Events. These functions are called when a specific event (mainly from Window title bar) occur and before the runtime performs the intended action. This gives a chance for the user to decide what to do with the event. If the return value is 0, the event will be passed on to the default handler so the intended action will be performed. If the return value is not 0, the event will be ignored and no further action will be taken.

- 42 - Child Window Close Confirmation, when the close button of the windows' title bar is clicked or an equivalent Windows' message is received.
- 43 - Main Window Close Confirmation, when close button of the windows' title bar is clicked which will cause the process to shutdown.
- 44 - Maximize Window Confirmation, when the maximize button of the windows' title bar is clicked or an equivalent Windows' message is received.

- 45- Minimize Window Confirmation, when the minimize button of the windows' title bar is clicked or an equivalent Windows' message is received.
  - 46 - Restore Window Confirmation, when the restore button of the windows' title bar is clicked or an equivalent Windows' message is received.
  - 47 - Move Window Confirmation, when the window is being dragged or an equivalent Windows' message is received.
  - 48 - Size Window Confirmation, when the windows is being resized or an equivalent Windows' message is received.
  - 49 - Shutdown Confirmation, when shutdown() function is called.
- 50 - 127 - Reserved for future Plant SCADA use.
- 128 - 256 - User-defined events. These events are for your own use.

## Return Value

0 (zero) if successful, otherwise an error is set. To view the error, use the IsError() function.

## ChainEvent

Calls an event function using the function handle. This creates a chain of event handlers from a single event. Use the GetEvent() function to get the function number of the current event handler.

## Syntax

**ChainEvent(*hFn*)**

*hFn*:

The function handle, as returned from the GetEvent() function.

## Return Value

The return value of the called event function.

## Related Functions

[OnEvent](#), [GetEvent](#)

## Example

See [GetEvent](#).

## See Also

[Event Functions](#)

## GetEvent

Gets the function handle of the existing callback event handler. You can use this function handle in the ChainEvent() function to chain call the existing event function, or in the SetEvent() function to restore the event handler.

## Syntax

**GetEvent(*nType*)**

*nType*:

The type of event:

- 0 - The mouse has moved. When the mouse moves the callback function is called. The return value must be 0.
- 1 - A key has been pressed. When the user presses a key, the callback function is called after Plant SCADA checks for hot keys. If the return value is 0, Plant SCADA checks for key sequences. If the return value is not 0, Plant SCADA assumes that you will process the key and does not check the key sequence. It is up to you to remove the key from the key command line. If you are using a right mouse button click as an event, you should read about the ButtonOnlyLeftClick parameter.
- 2 - Error event. This event is called if an error is detected in Cicode, so you can write a single error function to check for your errors. If the return value is 0, Plant SCADA continues to process the error and generates a hardware error - it may then halt the Cicode task. If the return value is not 0, Plant SCADA assumes that you will process the error, and continues the Cicode without generating a hardware error.
- 3 - Page user communication error. A communication error has been detected in the data required for this page. If the return value is 0 (zero), Plant SCADA still animates the page. If the return value is not zero, it does not update the page.
- 4 - Page user open. A new page is being opened. This event allows you to define a single function that is called when all pages are opened. The return value must be 0.
- 5 - Page user close. The current page is being closed. This event allows you to define a single function that is called when all pages are closed. The return value must be 0.
- 6 - Page user always. The page is active. This event allows you to define a single function that is called when all pages are active. The return value must be 0.
- 7 - Page communication error. A communication error has been detected in the data required for this page.

Reserved for use by Plant SCADA.

- 8 - Page open. This event is called each time a page is opened. Reserved for use by Plant SCADA.
- 9 - Page close. This event is called each time a page is closed. Reserved for use by Plant SCADA.
- 10 - Page always. This event is called while a page is active. Reserved for use by Plant SCADA.
- 11..17 - Undefined.
- 18 - Report start. The report server is about to start a new report. This event is called on the report server. The return value must be 0.
- 19 - Device history. A device history has just completed. The return value must be 0.
- 20 - Login. A user has just logged in.
- 21 - Logout. A user has just logged out.
- 22 - Trend needs repainting. This event is called each time Plant SCADA re-animates a real-time trend or scrolls an historical trend. You should use this event to add additional animation to a trend, because Plant SCADA deletes all existing animation when a trend is re-drawn. (For example, if you want to display extra markers, you must use this event.)
- 23 - Hardware error has been detected.
- 24 - Keyboard cursor moved. This event is called each time the keyboard command cursor moves. The cursor can be moved by the cursor keys, the mouse, or the Cicode function KeySetCursor(). Note that you can find where the keyboard command cursor is located by calling the function KeyGetCursor().
- 25 - Network shutdown. A Shutdown network command has been issued.
- 26 - Runtime system shutdown and restart. (Required because of configuration changes.)
- 27 - Event. An event has occurred.
- 28 - Accumulator. An accumulator has logged a value.
- 29 - Slider. A slider has been selected.
- 30 - Slider. A slider has moved.
- 31 - Slider. A slider has been released (that is stopped moving).

While responding to slider events 29, 30, and 31, you can set any variables but you cannot call functions that cause immediate changes to animations on the page (for example, DspText() and DspSym()). Types 29, 30, & 31 relate only to V3.xx and V4.xx animations, and will be superseded in future releases.

- 32 - Shutdown. Plant SCADA is being shutdown.
- 33 - Reserved for Plant SCADA internal use.

34 - 41 - Plant SCADA Confirmation Events. Reserved for Plant SCADA internal use. For the confirmation events, two sets of event type code are defined. The runtime calls the Plant SCADA event handler first, and conditionally proceed to the user's event handler depending on the return value of the Plant SCADA event handler.

- 34 -Plant SCADA Event: Child Window Close Confirmation.
- 35 - Plant SCADA Event: Main Window Close Confirmation.
- 36 - Plant SCADA Event: Maximize Window Confirmation.
- 37 - Plant SCADA Event: Minimize Window Confirmation.
- 38 - Plant SCADA Event: Restore Window Confirmation.
- 39 - Plant SCADA Event: Move Window Confirmation.
- 40 - Plant SCADA Event: Size Window Confirmation.
- 41 - Plant SCADA Event: Shutdown Confirmation Confirmation.

42 to 49 - User Confirmation Events. These functions are called when a specific event (mainly from Window title

bar) occur and before the runtime performs the intended action. This gives a chance for the user to decide what to do with the event. If the return value is 0, the event will be passed on to the default handler so the intended action will be performed. If the return value is not 0, the event will be ignored and no further action will be taken.

- 42 - Child Window Close Confirmation, when the close button of the windows' title bar is clicked or an equivalent Windows' message is received.
  - 43 - Main Window Close Confirmation, when close button of the windows' title bar is clicked which will cause the process to shutdown.
  - 44 - Maximize Window Confirmation, when the maximize button of the windows' title bar is clicked or an equivalent Windows' message is received.
  - 45- Minimize Window Confirmation, when the minimize button of the windows' title bar is clicked or an equivalent Windows' message is received.
  - 46 - Restore Window Confirmation, when the restore button of the windows' title bar is clicked or an equivalent Windows' message is received.
  - 47 - Move Window Confirmation, when the window is being dragged or an equivalent Windows' message is received.
  - 48 - Size Window Confirmation, when the windows is being resized or an equivalent Windows' message is received.
  - 49 - Shutdown Confirmation, when shutdown() function is called.
- 50 - 127 - Reserved for future Plant SCADA use.
- 128 - 256 - User-defined events. These events are for your own use.

## Return Value

The function handle of the existing callback event handler, or -1 if there are no event handlers.

## Related Functions

[OnEvent](#), [CallEvent](#), [ChainEvent](#), [SetEvent](#)

## Example

```
! Get existing event handler.

! Trap mouse movements.  
OnEvent(0,MouseFn);  
..  
! Restore old event handler.  
SetEvent(0,hFn);  
INT  
FUNCTION MouseFn()  
..  
! Chain call old event handler.  
RETURN ChainEvent(hFn);  
END
```

## See Also

[Event Functions](#)

## OnEvent

Sets an event callback function for an event type. The callback function is called when the event occurs.

Using callback functions removes the need for polling or checking for events. Callback functions have no arguments and needs to return an integer. They also need to be non-blocking.

Plant SCADA starts running the function immediately, without reading any data from the I/O devices. Any I/O device variable that you use will contain either 0 (zero) or bad quality. Only local variables are supported.

The return value of the callback will depend on the type of the event. Set the Fn argument to 0 (zero) to disable the event.

### Note:

- For event type 42..49, a windows system event is received. When the user clicks any button of the Windows tile bar, or size/move the window, or shutting down a process, the callback function is called. If the return value is 0, the event will be processed by Plant SCADA in default mode which is the original behavior. If the return value is not 0, Plant SCADA assumes that you will process the event and discard the message internally.
- If the event handler is non-interactive with instant return value, it can be called directly.
- Since the event callback function cannot block, any blocking function calls or long loops should be moved to a separate function. The callback function can start with the TaskNew() command. For confirmation events, the event callback function should return a non-zero value to tell Plant SCADA not to continue processing the event. The new task can call the appropriate function to process the event, such as the Shutdown() function for a Shutdown Confirmation event.
- The "Shutdown Confirmation" event is raised in the following cases:
  - Calling shutdown() without setting the callEvent parameter to zero.
  - Closing the top level application window - after raising the event "Main Window Close Confirmation".
  - Receiving WM\_QUIT message what can come from any source both internal and external.
- The "Shutdown Confirmation" event is not raised in other cases including, but not limited to, the following known scenarios:
  - The RuntimeManager is doing stop, restart the program, or doing shutdown all.
  - The Windows Task Manager is doing End Task, End Process, or End Process Tree.

## Syntax

**OnEvent(*Type*, *Fn*)**

*nType*:

The type of event:

- 0 - The mouse has moved. When the mouse moves the callback function is called. The return value must be 0.
- 1 - A key has been pressed. When the user presses a key, the callback function is called after Plant SCADA checks for hot keys. If the return value is 0, Plant SCADA checks for key sequences. If the return value is not 0,

Plant SCADA assumes that you will process the key and does not check the key sequence. It is up to you to remove the key from the key command line. If you are using a right mouse button click as an event, you should read about the ButtonOnlyLeftClick parameter.

- 2 - Error event. This event is called if an error is detected in Cicode, so you can write a single error function to check for your errors. If the return value is 0, Plant SCADA continues to process the error and generates a hardware error - it may then halt the Cicode task. If the return value is not 0, Plant SCADA assumes that you will process the error, and continues the Cicode without generating a hardware error.
- 3 - Page user communication error. A communication error has been detected in the data required for this page. If the return value is 0 (zero), Plant SCADA still animates the page. If the return value is not zero, it does not update the page.
- 4 - Page user open. A new page is being opened. This event allows you to define a single function that is called when all pages are opened. The return value must be 0.
- 5 - Page user close. The current page is being closed. This event allows you to define a single function that is called when all pages are closed. The return value must be 0.
- 6 - Page user always. The page is active. This event allows you to define a single function that is called when all pages are active. The return value must be 0.
- 7 - Page communication error. A communication error has been detected in the data required for this page. Reserved for use by Plant SCADA.
- 8 - Page open. This event is called each time a page is opened. Reserved for use by Plant SCADA.
- 9 - Page close. This event is called each time a page is closed. Reserved for use by Plant SCADA.
- 10 - Page always. This event is called while a page is active. Reserved for use by Plant SCADA.
- 11..17 - Undefined.
- 18 - Report start. The report server is about to start a new report. This event is called on the report server. The return value must be 0.
- 19 - Device history. A device history has just completed. The return value must be 0.
- 20 - Login. A user has just logged in.
- 21 - Logout. A user has just logged out.
- 22 - Trend needs repainting. This event is called each time Plant SCADA re-animates a real-time trend or scrolls an historical trend. You should use this event to add additional animation to a trend, because Plant SCADA deletes all existing animation when a trend is re-drawn. (For example, if you want to display extra markers, you must use this event.)
- 23 - Hardware error has been detected.
- 24 - Keyboard cursor moved. This event is called each time the keyboard command cursor moves. The cursor can be moved by the cursor keys, the mouse, or the Cicode function KeySetCursor(). Note that you can find where the keyboard command cursor is located by calling the function KeyGetCursor().
- 25 - Network shutdown. A Shutdown network command has been issued.
- 26 - Runtime system shutdown and restart. (Required because of configuration changes.)
- 27 - Event. An event has occurred.
- 28 - Accumulator. An accumulator has logged a value.
- 29 - Slider. A slider has been selected.
- 30 - Slider. A slider has moved.
- 31 - Slider. A slider has been released (that is stopped moving).

While responding to slider events 29, 30, and 31, you can set any variables but you cannot call functions that cause immediate changes to animations on the page (for example, DspText() and DspSym()). Types 29, 30, & 31 relate only to V3.xx and V4.xx animations, and will be superseded in future releases.

- 32 - Shutdown. Plant SCADA is being shutdown.
- 33 - Reserved for Plant SCADA internal use.

34 - 41 - Plant SCADA Confirmation Events. Reserved for Plant SCADA internal use. For the confirmation events, two sets of event type code are defined. The runtime calls the Plant SCADA event handler first, and conditionally proceed to the user's event handler depending on the return value of the Plant SCADA event handler.

- 34 -Plant SCADA Event: Child Window Close Confirmation.
- 35 - Plant SCADA Event: Main Window Close Confirmation.
- 36 - Plant SCADA Event: Maximize Window Confirmation.
- 37 - Plant SCADA Event: Minimize Window Confirmation.
- 38 - Plant SCADA Event: Restore Window Confirmation.
- 39 - Plant SCADA Event: Move Window Confirmation.
- 40 - Plant SCADA Event: Size Window Confirmation.
- 41 - Plant SCADA Event: Shutdown Confirmation Confirmation.

42 to 49 - User Confirmation Events. These functions are called when a specific event (mainly from Window title bar) occur and before the runtime performs the intended action. This gives a chance for the user to decide what to do with the event. If the return value is 0, the event will be passed on to the default handler so the intended action will be performed. If the return value is not 0, the event will be ignored and no further action will be taken.

- 42 - Child Window Close Confirmation, when the close button of the windows' title bar is clicked or an equivalent Windows' message is received.
- 43 - Main Window Close Confirmation, when close button of the windows' title bar is clicked which will cause the process to shutdown.
- 44 - Maximize Window Confirmation, when the maximize button of the windows' title bar is clicked or an equivalent Windows' message is received.
- 45- Minimize Window Confirmation, when the minimize button of the windows' title bar is clicked or an equivalent Windows' message is received.
- 46 - Restore Window Confirmation, when the restore button of the windows' title bar is clicked or an equivalent Windows' message is received.
- 47 - Move Window Confirmation, when the window is being dragged or an equivalent Windows' message is received.
- 48 - Size Window Confirmation, when the windows is being resized or an equivalent Windows' message is received.
- 49 - Shutdown Confirmation, when shutdown() function is called.

50 - 127 - Reserved for future Plant SCADA use.

128 - 256 - *User-defined events. These events are for your own use.*

*Fn:*

The function to call when the event occurs. This callback function needs to have no arguments, so you specify the function with no parentheses (). The callback function needs to return INT as its return data type. You cannot specify a Plant SCADA built-in function as a callback function.

Set *Fn* to 0 to disable the event.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[GetEvent](#), [CallEvent](#), [ChainEvent](#)

## Examples

**Example 1** - Calls a function called KeyFn to determine if the ESC key has been pressed on a key press event.

```
OnEvent(1,KeyFn);
INT
FUNCTION KeyFn()
    INT Key;
    Key=KeyPeek(0);
    IF Key=27 THEN
        Prompt("ESC pressed");
        RETURN 1;
    ELSE
        RETURN 0;
    END
END
```

**Example 2** - Calls a function called MouseFn to display the position of the mouse whenever it is moved.

```
OnEvent(0,MouseFn);
INT
FUNCTION MouseFn()
    INT X,Y;
    DspGetMouse(X,Y);
    RETURN 0;
END
```

**Example 3** - Presents a user with a confirmation dialog box when the main window close button is pressed.

```
sFUNCTION XYZStartup()
    OnEvent(43, ConfirmShutdown);
END

INT FUNCTION ConfirmShutdown()
    TaskNew("_ShutdownDlg", "", 2+8);
    RETURN 1;
END

FUNCTION _ShutdownDlg()
    STRING sMsg = "Are you sure ?";
    INT nRC;

    nRC = Message("Close this window and shutdown", sMsg, 1+32);
```

```
IF nRC = 0 THEN
    Shutdown("", "", 1, "", 0);
END
END
```

## See Also

[Event Functions](#)

## SetEvent

Sets an event callback function by specifying a function handle. You can use this function with the GetEvent function to restore an old event handler.

## Syntax

**SetEvent(*nType*, *hFn*)**

*nType*:

The type of event:

- 0 - The mouse has moved. When the mouse moves the callback function is called. The return value must be 0.
- 1 - A key has been pressed. When the user presses a key, the callback function is called after Plant SCADA checks for hot keys. If the return value is 0, Plant SCADA checks for key sequences. If the return value is not 0, Plant SCADA assumes that you will process the key and does not check the key sequence. It is up to you to remove the key from the key command line. If you are using a right mouse button click as an event, you should read about the ButtonOnlyLeftClick parameter.
- 2 - Error event. This event is called if an error is detected in Cicode, so you can write a single error function to check for your errors. If the return value is 0, Plant SCADA continues to process the error and generates a hardware error - it may then halt the Cicode task. If the return value is not 0, Plant SCADA assumes that you will process the error, and continues the Cicode without generating a hardware error.
- 3 - Page user communication error. A communication error has been detected in the data required for this page. If the return value is 0 (zero), Plant SCADA still animates the page. If the return value is not zero, it does not update the page.
- 4 - Page user open. A new page is being opened. This event allows you to define a single function that is called when all pages are opened. The return value must be 0.
- 5 - Page user close. The current page is being closed. This event allows you to define a single function that is called when all pages are closed. The return value must be 0.
- 6 - Page user always. The page is active. This event allows you to define a single function that is called when all pages are active. The return value must be 0.
- 7 - Page communication error. A communication error has been detected in the data required for this page. Reserved for use by Plant SCADA.
- 8 - Page open. This event is called each time a page is opened. Reserved for use by Plant SCADA.
- 9 - Page close. This event is called each time a page is closed. Reserved for use by Plant SCADA.
- 10 - Page always. This event is called while a page is active. Reserved for use by Plant SCADA.
- 11..17 - Undefined.

- 18 - Report start. The report server is about to start a new report. This event is called on the report server. The return value must be 0.
- 19 - Device history. A device history has just completed. The return value must be 0.
- 20 - Login. A user has just logged in.
- 21 - Logout. A user has just logged out.
- 22 - Trend needs repainting. This event is called each time Plant SCADA re-animates a real-time trend or scrolls an historical trend. You should use this event to add additional animation to a trend, because Plant SCADA deletes all existing animation when a trend is re-drawn. (For example, if you want to display extra markers, you must use this event.)
- 23 - Hardware error has been detected.
- 24 - Keyboard cursor moved. This event is called each time the keyboard command cursor moves. The cursor can be moved by the cursor keys, the mouse, or the Cicode function KeySetCursor(). Note that you can find where the keyboard command cursor is located by calling the function KeyGetCursor().
- 25 - Network shutdown. A Shutdown network command has been issued.
- 26 - Runtime system shutdown and restart. (Required because of configuration changes.)
- 27 - Event. An event has occurred.
- 28 - Accumulator. An accumulator has logged a value.
- 29 - Slider. A slider has been selected.
- 30 - Slider. A slider has moved.
- 31 - Slider. A slider has been released (that is stopped moving).

While responding to slider events 29, 30, and 31, you can set any variables but you cannot call functions that cause immediate changes to animations on the page (for example, DspText() and DspSym()). Types 29, 30, & 31 relate only to V3.xx and V4.xx animations, and will be superseded in future releases.

- 32 - Shutdown. Plant SCADA is being shutdown.

- 33 - Reserved for Plant SCADA internal use.

34 - 41 - Plant SCADA Confirmation Events. Reserved for Plant SCADA internal use. For the confirmation events, two sets of event type code are defined. The runtime calls the Plant SCADA event handler first, and conditionally proceed to the user's event handler depending on the return value of the Plant SCADA event handler.

- 34 -Plant SCADA Event: Child Window Close Confirmation.
- 35 - Plant SCADA Event: Main Window Close Confirmation.
- 36 - Plant SCADA Event: Maximize Window Confirmation.
- 37 - Plant SCADA Event: Minimize Window Confirmation.
- 38 - Plant SCADA Event: Restore Window Confirmation.
- 39 - Plant SCADA Event: Move Window Confirmation.
- 40 - Plant SCADA Event: Size Window Confirmation.
- 41 - Plant SCADA Event: Shutdown Confirmation Confirmation.

42 to 49 - User Confirmation Events. These functions are called when a specific event (mainly from Window title bar) occur and before the runtime performs the intended action. This gives a chance for the user to decide what to do with the event. If the return value is 0, the event will be passed on to the default handler so the intended action will be performed. If the return value is not 0, the event will be ignored and no further action will be taken.

- 42 - Child Window Close Confirmation, when the close button of the windows' title bar is clicked or an

equivalent Windows' message is received.

- 43 - Main Window Close Confirmation, when close button of the windows' title bar is clicked which will cause the process to shutdown.
- 44 - Maximize Window Confirmation, when the maximize button of the windows' title bar is clicked or an equivalent Windows' message is received.
- 45 - Minimize Window Confirmation, when the minimize button of the windows' title bar is clicked or an equivalent Windows' message is received.
- 46 - Restore Window Confirmation, when the restore button of the windows' title bar is clicked or an equivalent Windows' message is received.
- 47 - Move Window Confirmation, when the window is being dragged or an equivalent Windows' message is received.
- 48 - Size Window Confirmation, when the windows is being resized or an equivalent Windows' message is received.
- 49 - Shutdown Confirmation, when shutdown() function is called.

50 - 127 - Reserved for future Plant SCADA use.

128 - 256 - *User-defined events. These events are for your own use.*

*hFn*

The function handle, as returned from the GetEvent function.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[GetEvent](#)

## Example

See [GetEvent](#).

## File Functions

The following functions relate to file operations:

<a href="#">FileClose</a>	Closes a file.
<a href="#">FileCopy</a>	Copies a file or group of files.
<a href="#">FileDelete</a>	Deletes a file.

<a href="#">FileEOF</a>	Checks for the end of a file.
<a href="#">FileExist</a>	Checks if a file exists.
<a href="#">FileFind</a>	Finds a file that matches a specified search criteria.
<a href="#">FileFindClose</a>	Closes a find (started with FileFind) that did not run to completion.
<a href="#">FileGetTime</a>	Gets the time on a file.
<a href="#">FileMakePath</a>	Creates a file path string from individual components.
<a href="#">FileOpen</a>	Opens or creates an ASCII file.
<a href="#">FilePrint</a>	Prints a file on a device.
<a href="#">FileRead</a>	Reads characters from a file.
<a href="#">FileReadBlock</a>	Reads a block of characters from a file.
<a href="#">FileReadLn</a>	Reads a line from a file.
<a href="#">FileRename</a>	Renames a file.
<a href="#">FileRichTextPrint</a>	Prints a rich text file.
<a href="#">FileSeek</a>	Seeks a position in a file.
<a href="#">FileSetTime</a>	Sets the time on a file.
<a href="#">FileSize</a>	Gets the size of a file.
<a href="#">FileSplitPath</a>	Splits a file path into individual string components.
<a href="#">FileWrite</a>	Writes characters to a file.
<a href="#">FileWriteBlock</a>	Writes a block of characters to a file.
<a href="#">FileWriteLn</a>	Writes a line to a file.

## See Also

[Cicode Function Categories](#)  
[Using Cicode Functions](#)

## FileClose

Closes a file. All data written to the file is flushed to disk when the file is closed, and the file number becomes invalid.

## Syntax

**FileClose(*File*)**

*File*:

The file number.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[FileOpen](#)

## Example

```
File=FileOpen("C:\Data\Report.Txt","r");
..
! Do file operations.
..
! Close the file.
FileClose(File);
```

## See Also

[File Functions](#)

## FileCopy

Copies a file. You can use the DOS wild card characters (\*) and (?) to copy groups of files. In asynchronous mode, this function will return immediately and the copy will continue in the background. Copying files does not interfere with the operation of other Plant SCADA tasks, because this function is time-sliced.

If synchronous mode is selected, this function becomes a blocking function.

## Syntax

**FileCopy(*sSource*, *sDest*, *nMode*)**

*sSource*:

The name of the source file to copy.

*sDest*:

The name of destination file to copy to. To copy a file to the printer, specify the name as "LPT1.DOS".

*nMode*:

The copy mode:

0 - Normal

1 - Copy only if the file time is different.

2 - Copy in asynchronous mode.

Multiple modes can be selected by adding them together (for example, set *Mode* to 3 to copy in asynchronous mode if the file time is different).

## Return Value

0 (zero) if successful, otherwise an error is returned. However, if you copy in asynchronous mode, the return value does not reflect whether the copy operation was successful or not, because the function returns before the actual copy is complete.

## Related Functions

[FileDelete](#)

## Example

```
! Copy Report.Txt to Report.Bak.  
FileCopy ("C:\Data\Report.Txt", "C:\Data\Report.Bak",0);  
/* Copy AlarmLog.Txt to AlarmLog.Bak only if the file time is  
different. Copy in the background. */  
FileCopy ("AlarmLog.Txt", "AlarmLog.Bak",1+2);
```

## See Also

[File Functions](#)

## FileDelete

Deletes a file.

## Syntax

**FileDelete(*sName*)**

*Name:*

The name of the file to delete.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[FileCopy](#)

## Example

```
! Delete old report file.  
FileDelete("C:\Data\Report.Txt");
```

## See Also

[File Functions](#)

### FileEOF

Determines if the end of the file has been reached.

## Syntax

**FileEOF(*File*)**

*File*:

The file number.

## Return Value

1 if the end of file has been reached, otherwise 0 (zero).

## Related Functions

[FileSeek](#)

## Example

```
WHILE NOT FileEOF(File) DO  
    Str=FileReadLn(File);  
END
```

## See Also

[File Functions](#)

### FileExist

Checks if a file exists. If the return value is 1, the file exists.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**FileExist(*sName*)**

**Name:**

The name of the file to check.

## Return Value

TRUE (1) if the file exists, otherwise FALSE (0).

## Related Functions

[FileOpen](#)

## Example

```
! Check if the file exists
IF FileExist("C:\Data\Report.Txt") THEN
    ! The file exists
END
```

## See Also

[File Functions](#)

## FileFind

Finds a file that matches a specified search criteria. To find a list of files, you need to first call this function with the required path and mode (to find the first file), then call the function again with an empty path and a mode of 0 (to find the remaining files). After the last file is found, an empty string is returned.

If the search is for multiple files, FileFindClose needs to be called if the search does not run to completion (for example, you do not run until an empty string is returned).

## Syntax

**FileFind(*sPath*, *nMode*)**

***sPath:***

The name of the file to check. To search for multiple files, the wildcards \* and ? can be used to match multiple entries.

***nMode:***

The type of file to check:

0 - Normal files (includes files with read-only and archived attributes)

1 - Read-only files only

2 - Hidden files only

4 - System files only

16 - Subdirectories only

32 - Archived files only

128 - Files with no attributes only

These numbers can be added together to search for multiple types of files during one search.

## Return Value

The full path and filename. If no files are found, an empty string is returned.

## Related Functions

[FileOpen](#), [FileSplitPath](#), [FileMakePath](#)

## Example

```
! Search for all dBase files in the run directory and make a backup
sPath = FileFind("[run]:\*.dbf", 0);
WHILE StrLength(sPath) > 0 DO
    FileSplitPath(sPath, sDrive, sDir, sFile, sExt);
    sBak = FileMakePath(sDrive, sDir, sFile, "BAK");
    FileCopy(sPath, sBak, 0);
    ! Find the next file
    sPath = FileFind("", 0);
END
```

## See Also

[File Functions](#)

## FileFindClose

Closes a find (started with [FileFind](#)) that did not run to completion.

## Syntax

**FileFindClose()**

## Return Value

0 if no error is detected, or a Cicode error code if an error occurred.

## Related Functions

[FileFind](#)

## Example

```
//Find the first dbf file starting with fred
```

```
sPath = FileFind("[run]:\fred*.dbf", 0);
IF (StrLength(sPath) > 0) THEN
    //Do work here
    FileFindClose();
END
```

## See Also

[File Functions](#)

### FileGetTime

Gets the time on a file.

## Syntax

**FileGetTime(*File*)**

*File*:

The file number.

## Return Value

The file time of the file (in the Plant SCADA time/date variable format).

## Related Functions

[FileOpen](#), [FileClose](#), [FileSetTime](#)

## Example

```
File = FileOpen("[data]:report.txt", "r");
! Get the time of the file
iTime = FileGetTime(File);
FileClose(File);
```

## See Also

[File Functions](#)

### FileMakePath

Creates a file path string from individual components.

## Syntax

**FileMakePath(*sDrive*, *sDir*, *sFile*, *sExt*)**

*sDrive:*

The disk drive.

*sDir:*

The directory string.

*sFile:*

The file name (without the extension).

*sExt:*

The file extension.

## Return Value

The full path as a string.

## Related Functions

[FileSeek](#), [FileFind](#), [FileSplitPath](#)

## Example

See [FileFind](#).

## See Also

[File Functions](#)

## FileOpen

Opens a file and returns a file number that can be used by other file functions. The maximum file size supported is 1 Megabyte for displaying text files.

You can also use this function to check if a file exists, by opening the file in read-only mode. A return value of -1 indicates that the file cannot be opened.

[ErrSet\(1\)](#) needs to be in the previous line of your code, else the execution stops and a hardware error is generated. If [ErrSet\(1\)](#) is used then it does not halt, and -1 is returned.

## Syntax

**FileOpen(*sName*, *nMode*)**

*sName:*

The name of the file to open.

*nMode:*

The mode of the opened file:

- "a" - Append mode. Allows you to append to the file without removing the end of file marker. The file cannot be read. If the file does not exist, it will be created.

- "a+" - Append and read modes. Allows you to append to the file and read from it. The end of file marker will be removed before writing and restored when writing is complete. If the file does not exist, it will be created.
- "r" - Read-only mode. Allows you to (only) read from the file. If the file does not exist or cannot be found, the function call will return the value -1.
- "r+" - Read/write mode. Allows you to read from, and write to, the file. If the file already exists (before the function is called), its contents will be deleted. If the file does not exist or cannot be found, the function call will return the value -1.
- "w" - Write mode. Opens an empty file for writing. If the file already exists (before the function is called), its contents will be deleted. If the file does not exist or cannot be found, the file will be created.
- "w+" - Read/write mode. Opens an empty file for both reading and writing. If the file already exists (before the function is called), its contents will be deleted. If the file does not exist or cannot be found, the file will be created.

## Return Value

The file number. If the file cannot be opened, -1 is returned and the code is halted.

## Related Functions

[FileClose](#), [FileRead](#), [FileReadLn](#), [FileWrite](#), [FileWriteLn](#)

## Example

```
! Open a file in read-only mode.  
ErrSet(1);  
File=FileOpen("C:\Data\Report.Txt","r");  
ErrSet(0);
```

## See Also

[File Functions](#)

## FilePrint

Prints a file on a device.

## Syntax

**FilePrint(*Devicename*, *Filename*)**

*Devicename*:

The name of the target device.

*Filenname*:

The name of the file to print on the device.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[FileOpen](#), [FileWrite](#), [FileWriteLn](#)

## Example

```
! Print a data file on the system printer.  
FilePrint("Printer_Device","Data.txt");
```

## See Also

[File Functions](#)

## FileRead

Reads a number of characters from a file. The string can contain less characters than requested if the end of file is reached. A maximum of 255 characters can be read in each call.

## Syntax

**FileRead**(*File*, *Length*)

*File*:

The file number.

*Length*:

The number of characters to read.

## Return Value

The text from the file (as a string).

## Related Functions

[FileOpen](#), [FileClose](#), [FileReadLn](#)

## Example

```
WHILE NOT FileEOF(File) DO  
    Str=FileRead(File,20);  
END
```

## See Also

[File Functions](#)

### FileReadBlock

Reads a number of characters from a file. The buffer can contain less characters than requested if the end of file is reached. A maximum of 255 characters can be read in each call. The data should be treated as a binary data and should not be passed to string functions. You may use StrGetChar() function to extract each character from the buffer, or pass the buffer to another function which will accept binary data.

## Syntax

**FileReadBlock(*File*, *Buffer*, *Length*)**

*File*:

The file number.

*Buffer*:

The buffer to return the binary data. This may be a string or a string packed with binary data. The string terminator is ignored and the length argument specifies the number of characters to write. Must be a string variable.

*Length*:

The number of characters to read.

## Return Value

The number of characters read from the file. When the end of the file is found 0 will be returned. If an error occurs -1 will be returned and IsError() will return the error code.

## Related Functions

[FileOpen](#), [FileClose](#), [FileRead](#), [FileWriteBlock](#), [StrGetChar](#)

## Example

```
// read binary file and copy to COM port
length = FileReadBlock(File, buf, 128);
WHILE length > 0 DO
    ComWrite(hPort, buf, length, 0);
    length = FileReadBlock(File, buf, 128);
END
```

## See Also

[File Functions](#)

## FileReadLn

Reads a line from a file. Up to 255 characters can be returned. The carriage return and newline characters are not returned. If the line is longer than 255 characters, the error overflow (code 275) is returned - you should call this function again to read the rest of the line.

## Syntax

**FileReadLn(*File*)**

*File*:

The file number.

## Return Value

The text, as a string.

## Related Functions

[FileOpen](#), [FileClose](#), [FileRead](#)

## Example

```
sLine = FileReadLn(hFile);
! do stuff with the string
WHILE IsError() = 275 DO
    ! read the rest of the line
    sLine = FileReadLn(hFile);
    ! do stuff with the rest of the line
END
```

## See Also

[File Functions](#)

## FileRename

Renames a file.

## Syntax

**FileRename(*Oldname*, *Newname*)**

*Oldname*:

The original name of the file.

*Newname*:

The new name of the file.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[FileCopy](#), [FileDelete](#)

## Example

```
! Rename REPORT.TXT as REPORT.OLD.  
FileRename("C:\Data\Report.Txt", "C:\Data\Report.Old");
```

## See Also

[File Functions](#)

## FileRichTextPrint

Prints the rich text file *sFilename* to the printer given by *sPortname*.

## Syntax

**FileRichTextPrint(*sFilename*, *sPortName*)**

*sFilename*:

The filename of the rich text format file. The filename needs to be entered in quotation marks "".

Remember that the filename for a saved report comes from the File Name field in the Devices form. The location of the saved file needs to also be included as part of the filename. For example, if the filename in the Devices form listed [Data];RepDev.rtf, then you would need to enter "[Data]\repdev.rtf" as your argument. Alternatively, you can manually enter the path, for example, "c:\MyApplication\data\repdev.rtf".

If you are keeping a number of history files for the report, instead of using the extension rtf, you need to change it to reflect the number of the desired history file, for example, 001.

*PortName*:

The name of the printer port to which the rich text file will be printed. This name needs to be enclosed within quotation marks "". For example "LPT1", to print to the local printer, or "\\\Pserver\canon1" using UNC to print to a network printer.

## Return Values

0 if successful, otherwise an error is returned.

## Related Functions

[PageRichTextFile](#), [DspRichTextPrint](#)

## Example

```
// This would print the file [Data]\richtext.rtf to LPT1. Remember
// that the [Data] path is specified in the Citect.ini file. The file
// richtext.rtf is the name of the output file for the report, as
// specified in the Devices form. //
iResult = FileRichTextPrint("[Data]\richtext.rtf","LPT1:");
// This would print the file f:\Plant SCADA\data\richtext.rtf to LPT1.
// The file richtext.rtf is the name of the output file for the
// report, as specified in the Devices form. //
iResult =
FileRichTextPrint("f:\Plant SCADA\data\richtext.rtf","LPT1:");
```

## See Also

[File Functions](#)

## FileSeek

Moves the file pointer to a specified position in a file.

## Syntax

**FileSeek(File, Offset)**

*File:*

The file number.

*Offset:*

The offset in bytes, from 0 to (maximum file size -1). This value needs to be  $\geq 0$ .

## Return Value

The new file position, or -1 if an error is detected.

## Related Functions

[FileSize](#)

## Example

```
! Seek to the start of the file.
FileSeek(File,0);
```

## See Also

[File Functions](#)

## FileSetTime

Sets the time on a file.

**Note:** In order for this function to work, the file needs to first be opened in write or read/write mode.

---

## Syntax

**FileSetTime(*File*, *iTime*)**

*File*:

The file number.

*iTime*:

The new file time, in the Plant SCADA time/date variable format.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[FileOpen](#), [FileClose](#), [FileGetTime](#)

## Example

```
File = FileOpen("[data]:report.txt", "r+");
! set the file to the current time
FileSetTime(File, TimeCurrent());
FileClose(File);
```

## See Also

[File Functions](#)

## FileSize

Gets the size of a file.

## Syntax

**FileSize(*File*)**

*File*:

The file number.

## Return Value

The size of the file in bytes.

## Related Functions

[FileSeek](#)

## Example

```
! Get the size of the file.  
Size=FileSize(File);
```

## See Also

[File Functions](#)

## FileSplitPath

Splits a file path into individual string components. You enter the full path string as *sPath*. The individual components of the path name are returned in the arguments *sDrive*, *sDir*, *sFile*, and *sExt*. Arguments must be declared as Cicode variables. If declared as local variables or tags, an "Incompatible Types" error will be returned.

## Syntax

**FileSplitPath(*sPath*, *sDrive*, *sDir*, *sFile*, *sExt*)**

*sPath*:

The full path string.

*sDrive*:

The disk drive. Must be a String type variable.

*sDir*:

The directory string. Must be a String type variable.

*sFile*:

The file name (without the extension). Must be a String type variable.

*sExt*:

The file extension. Must be a String type variable.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[FileSeek](#), [FileFind](#), [FileMakePath](#)

## Example

See [FileFind](#).

## See Also

[File Functions](#)

## FileWrite

Writes a string to a file. The string is written at the current file position. The maximum number of characters allowed is 255.

## Syntax

**FileWrite**(*File*, *String*)

*File*:

The file number.

*String*:

The string to write.

## Return Value

The number of characters written.

## Related Functions

[FileOpen](#), [FileClose](#), [FileWriteLn](#)

## Example

```
! Write to the file.  
FileWrite(File,"Data");
```

## See Also

[File Functions](#)

## FileWriteBlock

Writes a string or buffer to a file. The data is written at the current file position. You may create the binary data by using the StrSetChar function or by reading the data from some other function. This function is similar to the FileWrite() function however you specify the length of data to write to the file. The FileWrite() function will send the data to the file until the sting terminator is found. FileWriteBlock() will ignore any string terminator and copy the length of bytes to the file. This allows this function to be used for binary data transfer.

## Syntax

**FileWriteBlock(*File*, *Buffer*, *Length*)**

*File*:

The file number.

*Buffer*:

The data to write to the file. This may be a string or a string packed with binary data. The string terminator is ignored and the length argument specifies the number of characters to write. Must be a string variable.

*Length*:

The number of characters to write. The maximum number of characters you may write in one call is 255. (If you use a string without a terminator in a function that expects a string, or in a Cicode expression, you could get invalid results.) To use the string to build up a buffer, you do not need the terminating 0 (zero).

## Return Value

The number of characters written to the file. If an error is detected -1 will be returned and IsError() will return the error code.

## Related Functions

[FileOpen](#), [FileClose](#), [FileWrite](#), [FileReadBlock](#), [StrSetChar](#)

## Example

```
STRING buf;
FOR I = 0 TO 20 DO
    StrSetChar(buf, I, I); // put binary data into string
END
! Write binary data to the file.
FileWrite(File, buf, 20);
```

## See Also

[File Functions](#)

## FileWriteLn

Writes a string to a file, followed by a newline character. The string is written at the current file position. The maximum number of characters allowed is 255.

## Syntax

**FileWriteLn(*File*, *String*)**

*File*:

The file number.

*String*:

The string to write.

## Return Value

The number of characters written (including the carriage return and newline characters).

## Related Functions

[FileOpen](#), [FileClose](#), [FileWrite](#)

## Example

```
! Write a line to the file.  
FileWriteLn(File,"Line of file data");
```

## See Also

## Form Functions

Following are functions relating to forms:

<a href="#">FormActive</a>	Checks if a form is currently active.
<a href="#">FormAddList</a>	Adds a text string to a list box or combo box.
<a href="#">FormButton</a>	Adds a button to a form.
<a href="#">FormCheckBox</a>	Adds a check box to the current form.
<a href="#">FormComboBox</a>	Adds a combo box to the current form.
<a href="#">FormCurr</a>	Gets the current form and field handles.

FormDestroy	Removes a form from the screen.
FormEdit	Adds edit fields to a form.
FormField	Adds general fields to a form.
FormGetCurrlInst	Gets data associated with a field.
FormGetData	Gets the data associated with a form.
FormGetInst	Gets data associated with a field on a form.
FormGetText	Gets field text on an active form.
FormGoto	Go to a specified form.
FormGroupBox	Adds a group box to the current form.
FormInput	Adds an input field to a form.
FormListAddText	Adds a new text entry to a combo box or a list box.
FormListBox	Adds a list box to the current form.
FormListDeleteText	Deletes existing text from combo box or list box.
FormListSelectText	Selects (highlights) a text entry in a combo box or a list box.
FormNew	Creates a new form.
FormNumPad	Provides a keypad form for the operator to add numeric values.
FormOpenFile	Displays a File Open dialog box.
FormPassword	Adds a password (no echo) input field.
FormSecurePassword	Adds a secure password (no echo) input field.
FormPosition	Sets the position of a form on the screen, before it is displayed.
FormPrompt	Adds a prompt to a form.
FormRadioButton	Adds a radio button to the current form.
FormRead	Displays a form and reads user input.
FormSaveAsFile	Displays a File Save As dialog box.
FormSelectPrinter	Displays the Select Printer dialog box.

FormSetData	Sets data in a form.
FormSetInst	Associates data to a field on a form.
FormSetText	Sets field text on an active form.
FormWndHnd	Gets the window handle for the given form.

[Cicode Function Categories](#)

[Using Cicode Functions](#)

## FormActive

Checks if a form is currently active (displayed on the screen). This function is useful when forms are being displayed in asynchronous mode and another Cicode task is trying to access the form.

## Syntax

**FormActive(*hForm*)**

*hForm*:

The form handle, returned from the FormNew() function. The form handle identifies the table where all data on the associated form is stored.

## Return Value

TRUE (1) if the form is active or FALSE (0) if it is not.

## Related Functions

[FormDestroy](#), [FormNew](#)

## Example

See [FormDestroy](#).

## See Also

[Form Functions](#)

## FormAddList

Adds a text string to a list box or combo box. You should call this function only after the FormNew() function, and

immediately after either the FormComboBox() or the FormListBox(), and before the FormRead() function otherwise an error is returned. The text is added at the end of the list box or combo box.

To add text to a form that is already displayed, use the FormListAddText() function, and use the FormListSelectText() function to highlight text on the list.

## Syntax

**FormAddList(*sText*)**

*sText*:

The text string to add to the list box or combo box.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[FormNew](#), [FormRead](#), [FormListBox](#), [FormComboBox](#), [FormListAddText](#), [FormListDeleteText](#), [FormListSelectText](#)

## Example

See [FormComboBox](#) and [FormListBox](#).

## See Also

[Form Functions](#)

## FormButton

Adds a button to the current form. You can add buttons that run callback functions (specified in *Fn*) to perform any actions you need, as well as the standard buttons - an [OK] button to save the operator's entries and close the form, and a [Cancel] button to close the form but discard the changes.

You should call this function only after the FormNew() function and before the FormRead() function. The button is added to the form at the specified column and row position. The width of the button is automatically sized to suit the text.

## Syntax

**FormButton(*Col*, *Row*, *sText*, *Fn*, *Mode*)**

*Col*:

The number of the column in which the button will be placed. Enter a number from 0 (column 1) to the form width - 1. For example, to place the button in column 8, enter 7.

*Row*:

The number of the row in which the button will be placed. Enter a number from 0 (row 1) to the form height - 1.

For example, to place the button in row 6, enter 5.

*sText:*

The text to display on the button.

*Fn:*

The callback function to call when the button is selected. Set to 0 to call no function. Please be aware that the Fn parameter needs to be of type INT and the callback function cannot contain a blocking function.

*Mode:*

Button mode:

0 - **Normal** button. When this button is selected the callback function is called.

1 - **OK** button. When this button is selected, the form is closed, and all operator-entered data is copied to buffers (specified by the other form functions). FormRead() returns 0 (zero) to indicate a successful read. The callback function specified in Fn is called. Be aware that this mode destroys the form.

2 - **Cancel** button. When this button is selected, the form is closed and operator-entered data is discarded. FormRead() returns with an error 299. The callback function specified in Fn is called. Be aware that this mode destroys the form.

3 - **Disabled** button. When this button is drawn, it will be shaded and not available for use.

## Return Value

The field handle if the button is successfully added, otherwise -1 is returned.

## Related Functions

[FormNew](#), [FormRead](#)

## Example

```
! Create a form, add buttons and then display the form on the
current page
FUNCTION FnMenu()
    FormNew("MENU",20,6,1);
    FormButton(0 ,4 , " FIND ", FindMenu, 0);
    FormButton(10,4 , " TAG ", ShowTag, 0);
    FormButton(0 ,5 , " CANCEL ", KillForm, 0);
    FormButton(10,5 , " GOTO ", GotoPg, 0);
    FormRead(0);
END
```

## See Also

[Form Functions](#)

## FormCheckBox

Adds a check box to the current form. The check box is a form control that allows the operator to make individual

selections. Each check box can be either checked (true) or cleared (false).

You should call this function only after the FormNew() function and before the FormRead() function. The check box is added to the form at the specified column and row position. The width of the button is automatically sized to suit the text.

## Syntax

**FormCheckBox(*Col*, *Row*, *sText*, *sBuf*)**

*Col*:

The number of the column in which the check box will be placed. Enter a number from 0 (column 1) to the form width - 1. For example, to place the check box in column 8, enter 7.

*Row*:

The number of the row in which the check box will be placed. Enter a number from 0 (row 1) to the form height - 1. For example, to place the check box in row 6, enter 5.

*sText*:

The text associated with the check box.

*sBuf*:

The string buffer in which to put the state of the check box. You should initialize this buffer to the state of the check box. When the form returns, this buffer will contain either '1' or '0' if the box is checked.

## Return Value

The field handle if the check box is successfully added, otherwise -1 is returned.

## Related Functions

[FormNew](#), [FormRead](#)

## Example

```
! Create a form, add check boxes, and display the form.  
! The operator may select none or all of the check boxes.  
FUNCTION FnMenu()  
    STRING sNuts, sCherrys, sChocolate;  
    sNuts = "1";  
    sCherrys = "0";  
    sChocolate = "1";  
    FormNew("IceCream",20,6,1); ]  
    FormCheckBox(2 ,2,"Nuts", sNuts);  
    FormCheckBox(2 ,3,"Cherrys", sCherrys);  
    FormCheckBox(2 ,4,"Chocolate", sChocolate);  
    FormRead(0);  
    If sNuts = "1" THEN  
        ! add the nuts  
    END  
    IF sCherrys = "1" THEN  
        ! add the cherrys
```

```
END
IF sChocolate = "1" THEN
    ! add the chocolate
END
END
```

## See Also

[Form Functions](#)

### FormComboBox

Adds a combo box to the current form. A combo box is a form control that allows the operator to type a selection or make a single selection from a text list.

You should call this function only after the FormNew() function and before the FormRead() function. The combo box is added to the form at the specified column and row position with the specified width and height. If more items are placed in the list than the list can display, a scroll bar displays (to scroll to the hidden items).

Use the FormAddList() function to add items for display in the list box. If the form is already displayed, you can use the FormListAddText() and FormListSelectText() functions to add (and highlight) text in the list box.

## Syntax

**FormComboBox(*Col*, *Row*, *Width*, *Height*, *sBuf* [, *Mode*] )**

*Col*:

The number of the column in which the combo box will be placed. Enter a number from 0 (column 1) to the form width - 1. For example, to place the combo box in column 8, enter 7.

*Row*:

The number of the row in which the combo box will be placed. Enter a number from 0 (row 1) to the form height - 1. For example, to place the combo box in row 6, enter 5.

*Width*:

The width of the list box, which should be wide enough to display your widest item. Items wider than the list box are clipped.

*Height*:

The height of the list box (the number of items that can be seen in the list box without scrolling).

*sBuf*:

The string buffer in which to store the selected item. The *sBuf* parameter can also hold the starting selection for the Combo box. For example if you set the *sBuf* string to "HELLO" before calling FormComboBox, HELLO will be displayed in the box upon opening the form. Must be a String type variable.

*Mode*:

The mode in which to create the combo box:

0 - Sort the combo box elements alphabetically.

1 - Place elements in combo box in the order they were added.

Default mode is 0.

## Return Value

The field handle if the combo box is successfully added, otherwise -1 is returned.

## Related Functions

[FormNew](#), [FormRead](#), [FormAddList](#), [FormListAddText](#), [FormListSelectText](#), [FormListBox](#)

## Example

```
! Create a form, add combo box and then display the form
! the operator may type in or select one of the items from the list
FUNCTION FnMenu()
    STRING sBuf;
    FormNew("Select Item",20,6,1);
    FormComboBox(2 ,2, 15, 5, sBuf, 1);
    FormAddList("Item One");
    FormAddList("Item two");
    FormAddList("Item three");
    FormRead(0);
    ! sBuf should contain the selected item or entered text
END
```

## See Also

[Form Functions](#)

## FormCurr

Gets the form and field handles for the current form and field. You should call this function only from within a callback function. You can then use the same callback function for all forms and fields, regardless of how the boxes, buttons, etc. on the forms are used. You should use this function with the FormGetInst() function.

## Syntax

**FormCurr(*hForm*, *hField*)**

*hForm*:

Variable containing the form handle, returned from the [FormNew\(\)](#) function. The form handle identifies the table where all data on the associated form is stored.

*hField*:

Variable containing the field handle of the field currently selected.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[FormGetInst](#)

## Example

See [FormGetInst](#).

## See Also

[Form Functions](#)

## FormDestroy

Destroys a form that is removes it from the screen. Use this function (from an event) to close a form.

## Syntax

**FormDestroy(*hForm*)**

*hForm*:

The form handle, returned from the [FormNew\(\)](#) function. The form handle identifies the table where all data on the associated form is stored.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[FormNew](#)

## Example

```
/* Display message to the operator. If after 10 seconds the
operator has not selected OK, then destroy the form. */
hForm=FormNew("Hello",4,20,0);
FormPrompt(1,1,"Something bad has happened");
FormButton(5,2,"OK",0,1);
FormRead(1);
! Wait 10 seconds.
Sleep(10);
IF FormActive(hForm) THEN
    ! Destroy form.
    FormDestroy(hForm);
END
```

## See Also

[Form Functions](#)

## FormEdit

Adds an edit field to the current form. You should call this function only after the FormNew() function and before the FormRead() function. A user input/edit box is added to the form at the specified column and row position. The operator can enter or edit the text in the edit box. This text is then passed to this function as *Text*.

## Syntax

**FormEdit**(*Col*, *Row*, *Text*, *Width*, *Height*, *bReadOnly* [, *maxTextLength*] )

*Col*:

The number of the column in which the edit field will be placed. Enter a number from 0 (column 1) to the form width - 1. For example, to place the edit field in column 8, enter 7.

*Row*:

The number of the row in which the edit field will be placed. Enter a number from 0 (row 1) to the form height - 1. For example, to place the edit field in row 6, enter 5.

*Text*:

Variable containing the text in the edit field. Text initially contains the default text (if any) for the operator to edit. When the function closes, this argument is passed back with the operator's input.

*Width*:

The width of the edit field.

*Height*:

The height of the edit field as measured using average character height. When value specified is less than 1 or not specified, it is default to 1 (single line). When multiple lines are specified, the content of the edit box will be word wrapped.

*bReadOnly*:

Flag to indicate whether the edit box is read only. Default is FALSE if not specified.

*maxTextLength*:

This optional parameter specifies the maximum length of input text. The default value is 0 meaning the string can have the maximum length allowed in the system (Cicode allows strings of 255 characters).

## Return Value

The field handle if the string is successfully added, otherwise -1 is returned.

## Related Functions

[FormNew](#), [FormRead](#)

## Example

```
STRING Recipe;
FormNew("Recipe",5,30,0);
! Add edit field, default Recipe to "Jam".
Recipe="Jam";
FormEdit(1,2,Recipe,20);
! Read the form.
FormRead(0);
! Recipe will now contain the operator-entered data.
```

## See Also

[Form Functions](#)

### FormField

Adds a field control device (such as a button , check box, or edit field) to the current form. You should call this function only after the FormNew() function and before the FormRead() function. This function allows you to specify a control device with more detail than the other field functions.

## Syntax

**FormField**(*Col*, *Row*, *Width*, *Height*, *Type*, *Buffer*, *Label*, *Fn* [, *maxTextLength*] )

*Col*:

The number of the column in which the control will be placed. Enter a number from 0 (column 1) to the form width - 1. For example, to place the control in column 8, enter 7.

*Row*:

The number of the row in which the control will be placed. Enter a number from 0 (row 1) to the form height - 1. For example, to place the control in row 6, enter 5.

*Width*:

The width of the control device.

*Height*:

The height of the control device.

*nType*:

The type of control device:

0 - None

1 - Edit

2 - Edit Password

3 - Text

4 - Button

5 - OK button

6 - Cancel button

7 - Group box

8 - Radio button

9 - Check box

*Buffer:*

The output buffer for the field string. The default value of the control device is initialized to the value of the buffer. If you specify a Radio button or Check box, you should initialize the buffer to "0" or "1". The result of the field will also be set to "0" or "1".

*Label:*

The display label for a button, or the default label for an edit field

*Fn:*

The callback function to call when the button is selected. Set to 0 to call no function. Please be aware that the Fn parameter needs to be of type INT, and the callback function cannot contain a blocking function. For types other than 4,5, and 6, set this argument to 0.

*maxTextLength:*

This optional parameter specifies the maximum length of input text for edit fields (this parameter is ignored for other controls). The default value is 0 meaning the string can have the maximum length allowed in the system (Cicode allows strings of 255 characters).

## Return Value

The field handle if the field is successfully added, otherwise it will return -1.

## Related Functions

[FormNew](#), [FormRead](#)

## Example

```
! Display a form with check boxes to start
!! specific motors.
FUNCTION SelectMotor()
    INT hform;
    STRING check1 = "0";
    STRING check2 = "0";
    STRING check3 = "0";
    hform = FormNew("Selection Menu", 26, 22, 6);
    FormField(16, 1, 12, 1, 9, check1, "Primary ", 0);
    FormField(16, 2, 12, 1, 9, check2, "Secondary", 0);
    FormField(16, 3, 12, 1, 9, check3, "backup ", 0);
    FormButton( 9, 20, " &Cancel ", 0, 2);
    IF FormRead(0) = 0 THEN
        IF check1 = "1" THEN
            StartMotor(MOTOR_1);
        END
        IF check2 = "1" THEN
            StartMotor(MOTOR_2);
        END
        IF check3 = "1" THEN
```

```
    StartMotor(MOTOR_3);
END
END
END
```

## See Also

[Form Functions](#)

### FormGetCurrInst

Extracts data associated with a field (set by the FormSetInst() function). You should call this function only from within a field callback function. This function is the same as calling the FormCurr() function and then the FormGetInst() function.

## Syntax

**FormGetCurrInst(*iData*, *sData*)**

*iData*:

Variable containing integer data.

*sData*:

Variable containing string data.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[FormCurr](#), [FormGetInst](#), [FormSetInst](#)

## Example

```
INT
FUNCTION GetNextRec()
    INT hDev;
    STRING Str;
    FormGetCurrInst(hDev,Str);
    DevNext(hDev);
    RETURN 0;
END
```

## See Also

[Form Functions](#)

## FormGetData

Gets all data associated with a form and puts it into the output string buffers. Normally the field data is copied to the output string buffers only when the user selects the [OK] button. If you want to use the data while the form is displayed, call this function to get the data. You should call this function only while the form is displayed otherwise an error is returned, for example, from a field callback function.

## Syntax

**FormGetData(*hForm*)**

*hForm*:

The form handle, returned from the FormNew() function. The form handle identifies the table where all data on the associated form is stored.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[FormCurr](#), [FormNew](#)

## Example

```
! Field callback to save data.  
FUNCTION Save()  
    INT hForm,hField;  
    FormCurr(hForm,hField);  
    FormGetData(hForm);  
    ! Access all data.  
    ..  
END
```

## See Also

[Form Functions](#)

## FormGetInst

Extracts the data associated with a field (set by the FormSetInst() function). You would normally use this function in a field callback function. It allows single callback functions to know that the form and field are associated.

## Syntax

**FormGetInst(*hForm*, *hField*, *iData*, *sData*)**

*hForm*:

The form handle, returned from the FormNew() function. The form handle identifies the table where all data on the associated form is stored.

*hField*:

The field handle of the field currently selected.

*iData*:

Integer data.

*sData*:

Variable containing string data.

## Return Value

The data (as a string).

## Related Functions

[FormSetInst](#), [FormCurr](#), [FormGetCurrInst](#), [FormNew](#)

## Example

```
INT
FUNCTION GetNextRec()
    INT hDev,hForm,hField;
    STRING Str;
    ! Get field data, for example, the hDev value.
    ..
    FormCurr(hForm,hField);
    FormGetInst(hForm,hField,hDev,Str);
    DevNext(hDev);
    ! Display new record in form.
    ..
    RETURN 0;
END
```

## See Also

[Form Functions](#)

## FormGetText

Gets the current text from a form field. You should call this function only while the form is displayed; for example,, from a field callback function.

## Syntax

**FormGetText(*hForm*, *hField*)**

*hForm*:

The form handle, returned from the FormNew() function. The form handle identifies the table where all data on the associated form is stored.

*hField:*

The field handle of the field currently selected.

## Return Value

The field text (as a string).

## Related Functions

[FormSetText](#), [FormNew](#)

## Example

```
FUNCTION Search()
    INT hForm,hField;
    STRING Recipe;
    FormCurr(hForm,hField);
    Recipe=FormGetText(hForm,hField);
    ! Go and find recipe.
    ..
END
```

## See Also

[Form Functions](#)

## FormGoto

Goes to a specified form. The form is displayed on top of all windows and the keyboard focus is set to this form.

## Syntax

**FormGoto(*hForm*)**

*hForm:*

The form handle, returned from the FormNew() function. The form handle identifies the table where all data on the associated form is stored.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[FormNew](#)

## Example

```
FormGoto(hForm);
```

## See Also

[Form Functions](#)

## FormGroupBox

Adds a group box to the current form. A group box is a form control box drawn to the specified size. If the box contains radio buttons, they are grouped together. You should call this function only after the FormNew() function and before the FormRead() function.

The group box is added to the form at the specified column and row position with the specified width and height. Use the FormRadioButton() function to add the radio buttons to the box, and call this function between each group of radio buttons.

## Syntax

**FormGroupBox(*Col*, *Row*, *Width*, *Height* [, *Text*] )**

*Col*:

The number of the column in which the group box will be placed. Enter a number from 0 (column 1) to the form width - 1. For example, to place the group box in column 8, enter 7.

*Row*:

The number of the row in which the group box will be placed. Enter a number from 0 (row 1) to the form height - 1. For example, to place the group box in row 6, enter 5.

*Width*:

The width of the group box, which should be wide enough to display your widest item.

*Height*:

The height of the group box.

*Text*:

The text to display as the group box label.

## Return Value

The field handle if the group box is successfully added, otherwise -1 is returned.

## Related Functions

[FormNew](#), [FormRead](#), [FormRadioButton](#)

## Example

```
! Create a form, add to radio buttons groups and then display the
form
! The operator may select one of the radio buttons from each group
FUNCTION FnMenu()
    STRING sFast, sSlow, sMedium;
    STRING sNorth, sSouth, sEast, sWest;
    FormNew("Select Item",40,7,1);
    FormGroupBox(1 ,1, 15, 5, "Speed");
    FormRadioButton(2 ,2,"Fast", sFast);
    FormRadioButton(2 ,3,"Medium", sMedium);
    FormRadioButton(2 ,4,"Slow", sSlow);
    FormGroupBox(19 ,2, 15, 6, "Direction");
    FormRadioButton(20 ,2,"North", sNorth);
    FormRadioButton(20 ,3,"South", sSouth);
    FormRadioButton(20 ,4,"East", sEast);
    FormRadioButton(20 ,5,"West", sWest);
    FormRead(0);
END
```

## See Also

[Form Functions](#)

## FormInput

Adds a prompt and edit field to the current form. You should call this function only after the FormNew() function and before the FormRead() function. When FormRead() is called, the form will display with the prompt and edit box. The operator's input is passed back as a string (*Text*).

## Syntax

**FormInput(*Col*,*Row*,*Prompt*,*Text*,*Width* [, *maxTextLength*] )**

*Col*:

The number of the column in which the prompt will be placed. Enter a number from 0 (column 1) to the form width - 1. For example, to place the prompt in column 8, enter 7.

*Row*:

The number of the row in which the prompt will be placed. Enter a number from 0 (row 1) to the form height - 1. For example, to place the prompt in row 6, enter 5.

*Prompt*:

The prompt string.

*Text*: - Output Parameter

Variable containing the output text string containing the operator's input.

---

**Note:** Only Cicode variables can be used in output parameters, variable or local tags cannot be used and will result in a compiler error if attempted.

*Width*:

The width of the edit field.

*maxTextLength:*

This optional parameter specifies the maximum length of input text. The default value is 0 meaning the string can have the maximum length allowed in the system (Cicode allows strings of 255 characters).

## Return Value

The field handle if it is added successfully, otherwise -1 is returned.

## Related Functions

[FormNew](#), [FormRead](#)

## Example

```
FormInput(1,2,"Recipe",Recipe,20);
```

## See Also

[Form Functions](#)

## FormListAddText

Adds a new text entry to a combo box or a list box while the form is displayed. It only adds the text to the list - it does not select it. Use the [FormListSelectText\(\)](#) function to select (highlight) an entry. Call this function only when the form is displayed, for example, from a field callback function.

## Syntax

**FormListAddText(*hForm*, *hField*, *Text*)**

*hForm:*

The form handle, returned from the [FormNew\(\)](#) function. The form handle identifies the table where all data on the associated form is stored.

*hField:*

The field handle of the field currently selected.

*Text:*

The output text string containing the operator's input.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[FormListSelectText](#), [FormListDeleteText](#), [FormSetText](#), [FormNew](#)

## Example

```
/* create a form with a list */
hForm = FormNew("Ingredients", 40, 10, 1);
hField = FormListBox(2,2,20,5,sBuf);
FormAddList("Flour");
FormAddList("Water");
FormAddList("Salt");
FormAddList("Sugar");
/* Display the form */
FormRead(1);
..
/*Add Milk to list */
FormListAddText(hForm, hField, "Milk");
..
```

## See Also

[Form Functions](#)

## FormListBox

Adds a list box to the current form. The list box is a form control that allows the operator to select from a list of items. You should call this function only after the FormNew() function and before the FormRead() function.

The list box is added to the form at the specified column and row position with the specified width and height. If more items are placed in the list than the list can display, a scroll bar displays for scrolling to the hidden items.

Use the FormAddList() function to add items for display in the list box. If the form is already displayed, you can use the FormListAddText() and FormListSelectText() functions to add (and highlight) text in the list box.

## Syntax

**FormListBox(*Col*, *Row*, *Width*, *Height*, *sBuf* [, *Mode*] )**

*Col*:

The number of the column in which the list box will be placed. Enter a number from 0 (column 1) to the form width - 1. For example, to place the list box in column 8, enter 7.

*Row*:

The number of the row in which the list box will be placed. Enter a number from 0 (row 1) to the form height - 1. For example, to place the list box in row 6, enter 5.

*Width*:

The width of the list box, in characters. Width should be wide enough to display your widest item. Items wider than the list box are clipped.

*Height*:

The height of the list box, as the number of items that can be seen in the list box without scrolling.

*sBuf:*

The string buffer in which to store the selected item. Must be a String type variable.

*Mode:*

The mode in which to create the list box:

0 - Sort the list box elements alphabetically.

1 - Place elements in list box in the order they were added.

Mode 0 is the default.

## Return Value

The field handle if the list box is successfully added, otherwise -1 is returned.

## Related Functions

, [FormRead](#), [FormAddList](#), [FormListAddText](#), [FormListSelectText](#), [FormComboBox](#)

## Example

```
! Create a form, add list box and then display the form.  
! The operator may select one of the items from the list.  
STRING sBuf;  
FUNCTION FnMenu()  
    FormNew("Select Item",20,6,1);  
    FormListBox(2,2,15,5,sBuf,1);  
    FormAddList("Item One");  
    FormAddList("Item two");  
    FormAddList("Item three");  
    FormButton(0,0,"OK",0,1);  
    FormButton(5,0,"CANCEL",0,2);  
    FormRead(0);  
    SELECTION= sBuf;  
END
```

## See Also

[Form Functions](#)

## FormListDeleteText

Deletes an existing text entry from a combo box or a list box while the form is displayed. It only deletes the text from the list - it does not change the selection. Call this function only when the form is displayed, for example, from a field callback function.

## Syntax

**FormListDeleteText(*hForm*, *hField*, *Text*)**

*hForm*:

The form handle, returned from the FormNew() function. The form handle identifies the table where all data on the associated form is stored.

*hField*:

The field handle of the field currently selected.

*Text*:

The text to delete.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[FormListSelectText](#), [FormListAddText](#), [FormNew](#)

## Example

```
/* create a form with a list */  
hForm = FormNew("Ingredients", 40, 10, 1);  
hField = FormListBox(2,2,20,5,sBuf);  
FormAddList("Flour");  
FormAddList("Water");  
FormAddList("Salt");  
FormAddList("Sugar");  
/* Display the form */  
FormRead(1);  
..  
/*Remove Sugar from the list */  
FormListDeleteText(hForm, hField, "Sugar");  
..
```

## See Also

[Form Functions](#)

## FormListSelectText

Selects (highlights) a text entry in a Combo box or a List box while the form is displayed. The text to be selected needs to exist in the list. (Use the FormListAddText() function to add a text entry to a list.) Call this function only when the form is displayed, for example, from a field callback function.

## Syntax

**FormListSelectText(*hForm*, *hField*, *Text*)**

*hForm*:

The form handle, returned from the FormNew() function. The form handle identifies the table where all data on the associated form is stored.

*hField*:

The field handle of the field currently selected.

*Text*:

The text to be selected. If this text is not present in the list, then no item will be selected (and this text will not be added).

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[FormListAddText](#), [FormSetText](#), [FormNew](#)

## Example

```
/* Create a form with a list */  
hForm = FormNew("Ingredients", 40, 10, 1);  
hField = FormListBox(2,2,20,5,sBuf);  
FormAddList("Flour");  
FormAddList("Water");  
FormAddList("Salt");  
FormAddList("Sugar");  
/* Display the form */  
FormRead(1);  
..  
/*Select Flour */  
FormListSelectText(hForm, hField, "Flour");
```

## See Also

[Form Functions](#)

## FormNew

Creates a new data entry form and defines its size and mode. After the form is created, you can add fields, and then display the form.

Before you can display a form on the screen, you need to call this function to set the size and mode of the form, and then call the various form field functions, FormInput(), FormButton(), FormEdit() etc to add user input fields to the form. To display the form on the screen (to allow the user to enter data) call the FormRead() function.

## Syntax

**FormNew(*Title*, *Width*, *Height*, *Mode*)**

*Title*:

The title of the form.

*Width*:

The character width of the form (1 to 131).

*Height*:

The character height of the form (1 to 131).

*Mode*:

The mode of the form:

0 - Default font and text spacing

1 - Small font

2 - Fixed pitch font

4 - Static text compression where the vertical spacing is reduced. This can cause formatting errors if buttons are too close, because the vertical spacing will be less than the height of a button.

8 - Keep the form on top of the Plant SCADA window.

16 - The current window cannot be changed or closed until the form is finished or cancelled.

32 - Makes a form with no caption.

128 - The form will not close if the **ESC** or **ENTER** key is pressed, unless you specifically define at least one button on the form which acts as an **OK** or **Cancel** button. For a form with no buttons, the **ENTER** key normally closes the form; this mode disables that behavior.

256 – Makes a from with no system-menu (mostly appears as a single close button X) .

Multiple modes can be selected by adding them (for example, to use Modes 4 and 2, specify Mode 6).

## Return Value

The form handle if the form is created successfully, otherwise -1 is returned. The form handle identifies the table where all data on the associated form is stored.

## Related Functions

[FormDestroy](#), [FormInput](#), [FormButton](#), [FormEdit](#), [FormRead](#)

## Example

```
FormNew("Recipe",30,5,0);
FormInput(1,1,"Recipe No",Recipe,20);
FormInput(1,2,"Amount",Amount,10);
FormRead(0);
```

## See Also

[Form Functions](#)

### FormNumPad

Provides a keypad form for the operator to add numeric values. You can customize the standard form as a mathematical keypad, with the +, -, and / operators and the decimal point. For a time keypad, use the AM, PM, and : (hour/minute divider) buttons. You can also include a password edit field.

## Syntax

**FormNumPad(*Title*, *Input*, *Mode*)**

*Title*:

The title to display on the number pad form.

*Input*:

The existing or default value. This value is returned if the form is cancelled or accepted without changes.

*Mode*:

The buttons to include on the keypad form. The Mode can be a combination of the following:

0 - Standard keypad

1 - Password edit field

2 - not used

4 - With +/- button

8 - With / button

16 - With . button

32 - With : button

64 - With AM, PM buttons

128 - with Now button

512 - with 1hr, 2hr and 8hr buttons

Multiple modes can be selected by adding them. For example, to include +/- buttons and a . button, specify Mode 20 (16+4).

**Note:** Modes 128 and 512 can not be used together on one FormNumPad.

## Return Value

The string value entered by the operator. The IsError() function returns 0 (zero). If the form was cancelled, the value of *Input* is returned, and the IsError() function returns error number 299.

## Example

```
/* Set defaults first, then four keypad forms to adjust recipe. */  
Qty_Flour=FormNumPad("Add Flour", Qty_Flour, 17);
```

```
Qty_Water=FormNumPad("Add Water", Qty_Water, 17);
Qty_Salt=FormNumPad("Add Salt", Qty_Salt, 17);
Qty_Sugar=FormNumPad("Add Sugar", Qty_Sugar, 17);
```

## See Also

[Form Functions](#)

### FormOpenFile

Displays a File Open dialog box.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**FormOpenFile(*sTitle*, *sFileName*, *sFilter*, [*bResetToDefault*])**

*sFileName*:

The name of the default file to display in the "File Name" field.

*sTitle*:

A title to display at the top of the form.

*sFilter*:

A file filter list to display in the "List Files of Type" field. The file filter list has the following format:

<File Type>|<Filter>|

Where:

File Type is the text that displays in the drop-down box, for example All Files (\*.\*). Filter is the file type, for example \*.Cl

*bResetToDefault*

Boolean parameter. When set forces the path to reset to the default path specified.

True = default path specified

False = last file specified

For example, FormOpenFile(*sTitle*, *sFileName*, *sFilter* [, *bResetToDefault* = FALSE])

## Return Value

The name and full path of the selected file (as a string) or an empty string ("") if the Cancel button is selected.

## Related Functions

[FormSaveAsFile](#), [FormSelectPrinter](#)

## Example

```
// Display the Open File dialog with the following filter list:
```

```
// All Files (*.*)  
// Exe Files (*.EXE)  
// Cicode Files (*.CI)  
sFilename = FormOpenFile("Open", "*.CI", "All Files (*.*)|*.|Exe  
Files (*.EXE)|*.EXE|Cicode Files (*.CI)|*.CI|");
```

## See Also

[Form Functions](#)

### FormPassword

Adds both a password prompt and edit field to the current form. You should call this function only after the FormNew() function and before the FormRead() function. When FormRead() is called, the form will also display the password prompt and edit field.

The operator's input is not echoed in the field; a single asterisk (\*) is displayed for each character.

## Syntax

**FormPassword**(*Col*, *Row*, *Prompt*, *Password*, *Width*)

*Col*:

The number of the column in which the prompt will be placed. Enter a number from 0 (column 1) to the form width - 1. For example, to place the prompt in column 8, enter 7.

*Row*:

The number of the row in which the prompt will be placed. Enter a number from 0 (row 1) to the form height - 1. For example, to place the prompt in row 6, enter 5.

*Prompt*:

The prompt string.

*Password*:

Variable containing the password entered by the operator.

*Width*:

The width of the edit field.

## Return Value

The field handle if it is added successfully, otherwise -1 is returned.

## Related Functions

[FormEdit](#), [FormNew](#), [FormRead](#)

## Example

```
! Add Password input.
```

```
FormPassword(1,2,"Enter Password",Password,10);
```

## See Also

[Form Functions](#)

## FormPosition

Sets the position of a form on the screen, before it is displayed. You should call this function only after the FormNew() function and before the FormRead() function.

## Syntax

**FormPosition(*X, Y, Mode*)**

*X, Y:*

The x and y pixel coordinates of the form.

*Mode:*

Not used, set it to 0.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[FormNew](#), [FormRead](#)

## Example

```
hForm = FormNew("title", 20, 5, 0);
! display form at x=100, y=50
FormPosition(100, 50, 0);
```

## See Also

[Form Functions](#)

## FormPrompt

Adds a prompt field to the current form. You should call this function only after the FormNew() function and before the FormRead() function.

## Syntax

**FormPrompt(*Col, Row, Prompt [,Width] [,Height]*)**

*Col:*

The number of the column in which the prompt will be placed. Enter a number from 0 (column 1) to the form width - 1. For example, to place the prompt in column 8, enter 7.

*Row:*

The number of the row in which the prompt will be placed. Enter a number from 0 (row 1) to the form height - 1. For example, to place the prompt in row 6, enter 5.

*Prompt:*

The prompt string.

*Width:*

The width of the area that the prompt string will wrap within (measured using average character width). For this setting to be applied, you also need to specify a value for Height.

*Height:*

The height of the area that the prompt string will display within (measured using average character height). For this setting to be applied, you also need to specify a value for Width.

## Return Value

The field handle if it is added successfully, otherwise -1 is returned.

## Related Functions

[FormNew](#), [FormRead](#)

## Example

```
FormPrompt(1,2,"Enter Recipe");
```

## See Also

[Form Functions](#)

## FormRadioButton

Adds a radio button to the current form, allowing the operator to make a selection from a multiple choice list. You should call this function only after the FormNew() function and before the FormRead() function.

The radio button is added to the form at the specified column and row position. The width of the button will be sized to suit the text.

By default, all radio buttons are placed into the one group. If you require separate groups, use this function in conjunction with the FormGroupBox() function.

## Syntax

**FormRadioButton(*Col*, *Row*, *sText*, *sBuf*)**

*Col:*

The number of the column in which the button will be placed. Enter a number from 0 (column 1) to the form width - 1. For example, to place the button in column 8, enter 7.

*Row:*

The number of the row in which the button will be placed. Enter a number from 0 (row 1) to the form height - 1. For example, to place the button in row 6, enter 5.

*sText:*

The text associated with the radio button.

*sBuf:*

The string buffer in which to put the state of the radio button. You should initialize this buffer to the state of the button. When the form returns, this buffer will contain either '1' or '0' if the radio button is checked.

## Return Value

The field handle if the radio button is successfully added, otherwise -1 is returned.

## Related Functions

[FormNew](#), [FormRead](#), [FormGroupBox](#), [FormCheckBox](#)

## Example

```
! Create a form, add radio buttons and then display the form.  
! The operator may only select one radio button , either Fast,  
Medium or Slow  
FUNCTION FnMenu()  
    STRING sFast, sSlow, sMedium;  
    sFast = "1";  
    sMedium = "0";  
    sSlow = "0";  
    FormNew("Speed",20,6,1);  
    FormRadioButton(2 ,2,"Fast", sFast);  
    FormRadioButton(2, 3,"Medium", sMedium);  
    FormRadioButton(2 ,4,"Slow", sSlow);  
    FormRead(0);  
    If sFast = "1" THEN  
        ! do fast stuff  
    ELSE  
        IF sMedium = "1" THEN  
            ! do Medium stuff  
        ELSE  
            IF sSlow = "1" THEN  
                ! do slow stuff  
            END  
    END  
END
```

## See Also

[Form Functions](#)

### FormRead

Displays the current form (created with the `FormNew()` function), with all the fields that were added (with the form field functions).

You can display the form and wait for the user to finish entering data by setting the `Mode` to 0. This mode is the most commonly used, with [OK] and [Cancel] buttons to either save or discard operator entries and to close the form.

To display the form and return before the user has finished, use Mode 1. This mode is used to animate the data on the form or to perform more complex operations.

This function is a blocking function. It will block the calling Cicode task until the operation is complete.

## Syntax

`FormRead(Mode)`

*Mode*:

Mode of the form:

0 - Wait for the user.

1 - Do not wait for the user.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[FormNew](#)

## Example

```
! Display the form and wait for the user.  
FormRead(0);  
! Display the form and do not wait for the user.  
FormRead(1);  
! While the form is displayed, update the time every second.  
WHILE FormActive(hForm) DO  
    FormSetText(hForm,hField,Time());  
    Sleep(1);  
END
```

## See Also

[Form Functions](#)

### FormSaveAsFile

Displays a File Save As dialog box.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**FormSaveAsFile(*sTitle*, *sFileName*, *sFilter* [, *sDefExt*] )**

*sTitle*:

A title to display at the top of the form.

*sFileName*:

The name of the default file to display in the "File Name" field.

*sFilter*:

A file filter list to display in the "List Files of Type" field. The file filter list has the following format:

<File Type>|<Filter>|

where:

File Type is the text that displays in the drop-down box, for example All Files (\*.\*). Filter is the file type, for example \*.CI

*sDefExt*:

The file extension that will be used as a default when you use the FormSaveAsFile() function. If you do not specify a default extension, files will be saved without an extension.

## Return Value

The name and full path of the selected file (as a string) or an empty string ("") if the Cancel button is selected.

## Related Functions

[FormOpenFile](#), [FormSelectPrinter](#), [FormSaveAsFile](#)

## Example

```
// Display the SaveAs dialog with the following filter list:  
// All Files (*.*)  
// Exe Files (*.EXE)  
// Cicode Files (*.CI)  
sFilename = FormSaveAsFile("Save As", "Alarms", "All Files  
(*.*)|*.EXE|Cicode Files (*.CI)|*.CI|",  
"ci");
```

[Form Functions](#)

### FormSecurePassword

Adds both a password prompt and edit field to the current form. You should call this function only after the FormNew() function and before the FormRead() function. When FormRead() is called, the form will also display the password prompt and edit field.

The operator's input is not echoed in the field; a single asterisk (\*) is displayed for each character. The function does not return the password as a plain text, it returns an encrypted password string. The user can send this string to the UserLogin or UserVerify functions.

## Syntax

**FormSecurePassword(*Col*, *Row*, *Prompt*, *Password*, *Width*)**

*Col*:

The number of the column in which the prompt will be placed. Enter a number from 0 (column 1) to the form width - 1. For example, to place the prompt in column 8, enter 7.

*Row*:

The number of the row in which the prompt will be placed. Enter a number from 0 (row 1) to the form height - 1. For example, to place the prompt in row 6, enter 5.

*Prompt*:

The prompt string. Must be a String type variable.

*Password*:

The encrypted password entered by the operator.

*Width*:

The width of the edit field.

## Return Value

The field handle if it is added successfully, otherwise -1 is returned.

## Related Functions

[FormEdit](#), [FormRead](#), [UserLogin](#), [UserVerify](#)

## Example

```
! Add Password input.  
FormSecurePassword(1,2,"Enter Password",Password,10);
```

### FormSelectPrinter

Displays the Select Printer dialog box.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**FormSelectPrinter()**

## Return Value

The name of the selected printer (as a string) or an empty string ("") if the Cancel button is selected.

## Related Functions

[FormOpenFile](#), [FormSaveAsFile](#)

## Example

```
// Display the Select Printer dialog
sPrinter = FormSelectPrinter();
```

## See Also

[Form Functions](#)

### FormSetData

Sets all the edit data from the string buffers into the form. You should call this function only while the form is active.

## Syntax

**FormSetData(*hForm*)**

*hForm*:

The form handle, returned from the FormNew() function. The form handle identifies the table where all data on the associated form is stored.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[FormGetData](#), [FormNew](#)

## Example

```
INT
FUNCTION MyNextRec(
    INT hForm,hField;
    FormCurr(hForm,hField);
    FormSetData(hForm);
    RETURN 0;
END
```

## See Also

[Form Functions](#)

## FormSetInst

Associates an integer and string value with each field on a form. This data could then be used by a callback function. You can use a single callback function for all fields, and use the data to perform different operations for each field.

## Syntax

**FormSetInst(*hForm*, *hField*, *iData*, *sData*)**

*hForm*:

The form handle, returned from the `FormNew()` function. The form handle identifies the table where all data on the associated form is stored.

*hField*:

The field handle of the field currently selected.

*iData*:

Integer data.

*sData*:

String data.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[FormGetInst](#), [FormNew](#)

## Example

```
! Open recipe database.  
hDev=DevOpen("Recipe", 0);  
hForm=FormNew("Recipe",20,5,0);  
hField=FormButton(5,2,"Next",GetNextRec,0);  
FormSetInst(hForm,hField,hDev,"");  
/* The device handle hDev is put into the next button , so when the  
button is selected it can get hDev and get the next record. */
```

## See Also

[Form Functions](#)

## FormSetText

Sets new field text on a field. This function allows you to change field text while the form is displayed. Call this function only when the form is displayed, for example, from a field callback function.

If you are using this function on a Combo box or a List box, it will select the text from the Combo box or List box list. If no text exists in the Combo box or List box list, the function will add it.

## Syntax

**FormSetText(*hForm*, *hField*, *Text*)**

*hForm*:

The form handle, returned from the FormNew() function. The form handle identifies the table where all data on the associated form is stored.

*hField*:

The field handle of the field currently selected. If the *hField* is a handle to the secure edit field created with FormSecurePassword, the text in the secure edit field will not be changed. However, when an empty string is passed to FormSetText(), the contents of the secure edit field will be cleared.

*Text*:

New field text.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[FormCurr](#), [FormListSelectText](#), [FormListAddText](#), [FormNew](#), [FormSecurePassword](#), [FormSetText](#)

## Example

```
/* Create a form with a field */
hForm = FormNew("Ingredients", 40, 10, 1);
hField = FormPrompt(2,2,"Motor1:");
/* Display the form*/
FormRead(1);
..
/* Change the text in the field */
FormSetText(hForm, hField, "Pump1:");
..
```

## See Also

[Form Functions](#)

### FormWndHnd

Gets the window handle for the given form. The window handle may be used by 'C' programs and Plant SCADA *Wn...* functions. You should call this function only after the *FormRead()* function.

The window handle is not the same as the Plant SCADA window number and cannot be used with functions that expect the Plant SCADA window number (the *Win...* functions).

## Syntax

**FormWndHnd(*hForm*)**

*hForm*:

The form handle, returned from the *FormNew()* function. The form handle identifies the table where data on the associated form is stored.

## Return Value

The window handle if successful, otherwise a 0 is returned.

## Related Functions

[FormNew](#), [FormRead](#), [WndFind](#)

## Example

```
/* Create a form with a field */
hForm = FormNew("Ingredients", 40, 10, 1);
hField = FormPrompt(2,2,"Motor1:");
/* Display the form*/
FormRead(1);
/* Get the form's window number for future reference */
hWnd = FormWndHnd(hForm);
```

## Format Functions

Following are functions used for formatting data:

<a href="#">FmtClose</a>	Closes a format template.
<a href="#">FmtFieldHnd</a>	Gets the handle of a field in a format template.
<a href="#">FmtGetField</a>	Gets field data from a format template.
<a href="#">FmtGetFieldCount</a>	Retrieves the number of fields in a format object.
<a href="#">FmtGetFieldHnd</a>	Gets field data from a format template using a field handle.
<a href="#">FmtGetFieldName</a>	Retrieves the name of a particular field in a format object.
<a href="#">FmtGetWidth</a>	Retrieves the width of a particular field in a format object.
<a href="#">FmtOpen</a>	Creates a new format template.
<a href="#">FmtSetField</a>	Sets data in a field of a format template.
<a href="#">FmtSetFieldHnd</a>	Sets data in a field of a format template using a field handle.
<a href="#">FmtToStr</a>	Converts format template data to a string

## See Also

[Cicode Function Categories](#)

[Using Cicode Functions](#)

## FmtClose

Closes a format template. After it is closed, the template cannot be used. Closing the template releases system memory.

## Syntax

**FmtClose(*hFmt*)**

*hFmt*:

The format template handle, returned from the FmtOpen() function. The handle identifies the table where all data on the associated format template is stored.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[FmtOpen](#)

## Example

```
FmtClose(hFmt);
```

## See Also

[Format Functions](#)

## FmtFieldHnd

Gets the handle of a field in a format template. You can then use the field handle in the FmtGetFieldHnd() and FmtSetFieldHnd() functions. By using a handle, you only need to resolve the field name once and then call other functions as required (resulting in improved performance.)

## Syntax

**FmtFieldHnd(*hFmt, Name*)**

*hFmt:*

The format template handle, returned from the FmtOpen() function. The handle identifies the table where all data on the associated format template is stored.

*sName:*

The field name.

## Return Value

The handle of the format template field, or -1 if the field cannot be found.

## Related Functions

[FmtGetFieldHnd](#), [FmtSetFieldHnd](#), [FmtOpen](#)

## Example

```
!Resolve names at startup.  
hName=FmtFieldHnd(hFmt,"Name");  
hDesc=FmtFieldHnd(hFmt,"Desc");  
!Set field data.  
FmtSetFieldHnd(hFmt,hName,"CV101");
```

## See Also

[Format Functions](#)

### FmtGetField

Gets field data from a format template. Use this function to extract data after a call to StrToFmt().

## Syntax

**FmtGetField(*hFmt, sName*)**

*hFmt*:

The format template handle, returned from the FmtOpen() function. The handle identifies the table where data on the associated format template is stored.

*sName*:

The field name.

## Return Value

The data (as a string). If the field does not contain any data, an empty string will be returned.

## Related Functions

[StrToFmt](#), [FmtOpen](#), [FmtSetField](#), [FmtToStr](#)

## Example

```
StrToFmt(hFmt,"CV101 Raw Coal Conveyor");  
Str=FmtGetField(hFmt,"Name");  
! Str will contain "CV101".
```

## See Also

[Format Functions](#)

## FmtGetFieldCount

Retrieves the number of fields in a format object.

## Syntax

**FmtGetFieldCount(*hFmt*)**

*hFmt*:

The format template handle, returned from the FmtOpen() function. The handle identifies the table where data on the associated format template is stored.

## Return Value

Number of fields in the specified format.

## Related Functions

[FmtGetField](#), [FmtOpen](#)

## See Also

[Format Functions](#)

## FmtGetFieldHnd

Gets field data from a format template. Use this function to extract data after a call to StrToFmt(). This function has the same effect as FmtGetField(), except that you use a field handle instead of the field name.

## Syntax

**FmtGetFieldHnd(*hFmt*, *hField*)**

*hFmt*:

The format template handle, returned from the FmtOpen() function. The handle identifies the table where all data on the associated format template is stored.

*hField*:

The field handle.

## Return Value

The data (as a string). If the field does not contain any data, an empty string will be returned.

## Related Functions

[FmtGetField](#), [StrToFmt](#), [FmtOpen](#), [FmtFieldHnd](#)

## Example

```
StrToFmt(hFmt,"CV101 Raw Coal Conveyor");
hField=FmtFieldHnd(hFmt,"Name");
Str=FmtGetField(hFmt,hField);
! Str will contain "CV101".
```

## See Also

[Format Functions](#)

### FmtGetFieldName

Retrieves the name of a particular field in a format object.

## Syntax

**FmtGetFieldName(*hFmt*, *hField*)**

*hFmt*:

The format template handle, returned from the FmtOpen() function. The handle identifies the table where data on the associated format template is stored.

*hField*:

The field handle.

## Return Value

Name of requested field

## Related Functions

[FmtGetField](#), [FmtOpen](#)

## See Also

[Format Functions](#)

### FmtGetWidth

Retrieves the width of a particular field in a format object.

## Syntax

**FmtGetWidth(*hFmt*, *hField*)**

*hFmt*:

The handle to a format object. The handle identifies the table where data on the associated format template is stored.

*hField*:

The field handle.

## Return Value

Width of the requested field.

## Related Functions

[FmtGetField](#), [FmtGetFieldName](#), [FmtOpen](#)

## See Also

[Format Functions](#)

## FmtOpen

Creates a format template. After you create a template, you can use it for formatting data into strings or extracting data from a string. To format a template, use the same syntax as a device format, that is {<name>[,width[,justification]]}. The maximum number of formats that can be created in a project is 512. If you attempt to create formats in excess of this number, an error code (code 258: CT\_ERROR\_BUFFER\_OVERRUN) will be generated.

**Note:** This function should be concluded with the FmtClose function, otherwise the same error code (code 258: CT\_ERROR\_BUFFER\_OVERRUN) will be generated.

## Syntax

INT **FmtOpen**(STRING *Name*, STRING *Format*, INT *Mode*)

*Name*:

The name of the format template or Alarm Category.

*Format*:

The format of the template, as {<name>[,width[,justification]]}. Not used for alarm format. See [Format Templates](#) for more information.

*Mode*:

The mode of the open:

0 - Open the existing format.

1 - Open a new format.

2 - Open Summary Format from Alarm Category specified by Name.

3 - Open Display Format from Alarm Category specified by Name.

4 – Open SOE format from Alarm Category specified by Name.

5 – Reopen a format. If the format name already exists, it will reopen with the specified format template.

Otherwise, a new format will open.

## Return Value

The format template handle, or -1 if the format cannot be created.

## Related Functions

[FmtClose](#)

## Examples

```
hFmt=FmtOpen("MyFormat", "{Name}{Desc,20}",0);
FmtSetField(hFmt, "Name", "CV101");
FmtSetField(hFmt, "Desc", "Raw Coal Conveyor");
Str =FmtToStr(hFmt);
! Str will contain "CV101 Raw Coal Conveyor".
FmtOpen("0", "", 2);
! Display Format from Alarm Category 0
FmtOpen("0", "", 3);
! Summary Format from Alarm Category 0.
```

## See Also

[Format Functions](#)

## FmtSetField

Sets data in a field of a format template. After you have set all the fields, you can build the formatted string with the FmtToStr() function.

## Syntax

**FmtSetField(*hFmt*, *Name*, *Data*)**

*hFmt*:

The format template handle, returned from the FmtOpen() function. The handle identifies the table where all data on the associated format template is stored.

*sName*:

The name of the format template.

*Data*:

Field data.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[FmtGetField](#), [FmtToStr](#), [FmtOpen](#)

## Example

```
hFmt=FmtOpen("MyFormat","{Name}{Desc, 20}",0);
FmtSetField(hFmt,"Name", "CV101");
FmtSetField(hFmt,"Desc", "Raw Coal Conveyor");
Str =FmtToStr(hFmt);
! Str will contain "CV101 Raw Coal Conveyor".
```

## See Also

[Format Functions](#)

## FmtSetFieldHnd

The fields you can build the formatted string with the FmtToStr() function. This function has the same effect as FmtSetField() except that you use a field handle instead of the field name.

## Syntax

**FmtSetFieldHnd(*hFmt*, *hField*, *Data*)**

*hFmt*:

The format template handle, returned from the FmtOpen() function. The handle identifies the table where all data on the associated format template is stored.

*hField*:

The field handle.

*Data*:

Field data.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[FmtFieldHnd](#), [FmtToStr](#), [FmtSetField](#), [FmtOpen](#)

## Example

```
hField=FmtFieldHnd(hFmt, "Name");
FmtSetFieldHnd(hFmt,hField, "CV101");
```

## See Also

[Format Functions](#)

### FmtToStr

Builds a formatted string from the current field data (in a format template).

## Syntax

**FmtToStr(*hFmt*)**

*hFmt*:

The format template handle, returned from the FmtOpen() function. The handle identifies the table where all data on the associated format template is stored.

## Return Value

The formatted string as defined in the format description.

## Related Functions

[StrToFmt](#), [FmtOpen](#)

## Example

```
! Get the formatted string.  
Str=FmtToStr(hFmt);
```

## Fuzzy Logic Functions

The following functions relate to fuzzy logic control.

<a href="#">FuzzyClose</a>	Closes specified fuzzy instance.
<a href="#">FuzzyGetCodeValue</a>	Gets a specified Code variable from the specified instance.
<a href="#">FuzzyGetShellValue</a>	Gets a specified Shell variable from the specified instance.
<a href="#">FuzzyOpen</a>	Creates a new fuzzy instance.

<a href="#">FuzzySetCodeValue</a>	Sets a specified Code variable in the specified instance.
<a href="#">FuzzySetShellValue</a>	Sets a specified Shell variable in the specified instance.
<a href="#">FuzzyTrace</a>	Controls the tracing.

## See Also

[Cicode Function Categories](#)

[Using Cicode Functions](#)

## FuzzyClose

Frees all memory and information for the specified instance. After the fuzzy instance is closed, the handle given in the *hFuzzy* parameter is no longer valid.

## Syntax

**FuzzyClose(*hFuzzy*)**

*hFuzzy*:

The fuzzy instance handle (and integer greater than 0).

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[FuzzyOpen](#)

## Example

See [FuzzyOpen](#).

## See Also

[Fuzzy Logic Functions](#)

## FuzzyGetCodeValue

Gets a value for the specified input of the specified instance.

## Syntax

**FuzzyGetCodeValue(*hFuzzy*, *iIOIndex*, *NoHitFlag*)**

*hFuzzy*:

The fuzzy instance handle (and integer greater than 0).

*iIOIndex*:

Specifies the variable to receive the value. The I/O-Indices start with 0 and increment by 1 for each variable. To find the correct index for a specific variable, the variables need to be sorted in alpha-numerical order, first the inputs and then the outputs.

*NoHitFlag*:

Variable to receive the new value of the No-hit-flag. The No- hit-flag is TRUE if no rule was active for the variable specified by *iIOIndex*, otherwise it is FALSE. Must be an Integer type variable - it cannot be a constant or PLC variable tag.

## Return Value

The code value if the function was successful, otherwise -1. Use *IsError()* to find the error number if the function does not succeed.

## Related Functions

[FuzzyOpen](#), [FuzzySetCodeValue](#)

## Example

See [FuzzyOpen](#).

## See Also

[Fuzzy Logic Functions](#)

## FuzzyGetShellValue

Gets a value for the specified input of the specified instance. The variables in the instance needs to have the data type REAL (floating point values).

## Syntax

**FuzzyGetShellValue(*hFuzzy*, *iIOIndex*, *NoHitFlag*)**

*hFuzzy*:

The fuzzy instance handle (and integer greater than 0).

*iIOIndex*:

Specifies the variable to receive the value. The I/O-Indices start with 0 and increment by 1 for each variable. To

find the correct index for a specific variable, the variables need to be sorted in alpha-numerical order, first the inputs and then the outputs.

*NoHitFlag*:

Variable to receive the new value of the No-hit-flag. The No- hit-flag is TRUE if no rule was active for the variable specified by *iIOIndex*, otherwise it is FALSE. Must be an Integer type variable - it cannot be a constant or PLC variable tag.

## Return Value

The shell value if the function was successful. Use [IsError](#) to find the error number if the function does not succeed.

## Related Functions

[FuzzyOpen](#), [FuzzySetShellValue](#)

## Example

See [FuzzyOpen](#).

## See Also

[Fuzzy Logic Functions](#)

## FuzzyOpen

This function loads a \*.FTR file, allocates memory and creates a handle for this fuzzy instance. To use the FuzzyTech functions you need to be a registered user of one or more of the following fuzzyTech products: *fuzzyTECH Online Edition*, *fuzzyTECH Precompiler Edition*, or *fuzzyTECH for Business PlusC*. And you need to only use *fuzzyTECH* to generate the \*.FTR file for FTRUN.

The application needs to call the FuzzyClose function to delete each fuzzy instance handle returned by the FuzzyOpen function.

## Syntax

**FuzzyOpen(*sFile*)**

*sFile*:

Specifies the filename of the .FTR file to load.

## Return Value

The handle to the fuzzy instance, or -1 if the function cannot complete the operation. Use [IsError](#) to find the error number.

## Related Functions

[FuzzyClose](#), [FuzzyGetShellValue](#), [FuzzySetShellValue](#), [FuzzyGetCodeValue](#), [FuzzySetCodeValue](#), [FuzzyTrace](#).

## Example

```
INT hFuzzy;
INT NoHitFlag;
INT Status;
REAL MemOutput;
// open the Fuzzy Tech runtime instance
hFuzzy = FuzzyOpen
("%PROGRAMFILES(X86)%\AVEVA Plant SCADA\Bin\traffic.ftr");
Status = IsError();
IF hFuzzy <> -1 THEN
    MemOutput = PLCOutput;
    WHILE Status = 0 DO
        FuzzySetShellValue(hFuzzy, 0, 42.0);
        FuzzySetShellValue(hFuzzy, 1, 3.14150);
        MemOutput = FuzzyGetShellValue(hFuzzy, 2, NoHitFlag);
        Status = IsError();
        // Only write to PLC if output changes.
        // This reduces load on PLC communication.
        IF MemOutput <> PLCOutput THEN
            PLCOutput = MemOutput;
        END
        SleepMS(500);
    END
    FuzzyClose(hFuzzy);
END
```

## See Also

[Fuzzy Logic Functions](#)

### FuzzySetCodeValue

Sets a value for the specified input of the specified instance.

## Syntax

**FuzzySetCodeValue(*hFuzzy*, *iIOIndex*, *iCodeValue*)**

*hFuzzy*:

The fuzzy instance handle (and integer greater than 0).

*iIOIndex*:

Specifies the variable to receive the value. The I/O-Indices start with 0 and increment by 1 for each variable. To find the correct index for a specific variable, the variables need to be sorted in alpha-numerical order, first the inputs and then the outputs.

*iCodeValue*:

The value to be copied to the variable specified by *iIOIndex*.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[FuzzyOpen](#), [FuzzyGetCodeValue](#)

## Example

See [FuzzyOpen](#).

## See Also

[Fuzzy Logic Functions](#)

## FuzzySetShellValue

Sets a value for the specified input of the specified instance.

## Syntax

**FuzzySetShellValue**(*hFuzzy*, *iIOIndex*, *rShellValue*)

*hFuzzy*:

The fuzzy instance handle (and integer greater than 0).

*iIOIndex*:

Specifies the variable to receive the value. The I/O-Indices start with 0 and increment by 1 for each variable. To find the correct index for a specific variable, the variables need to be sorted in alpha-numerical order, first the inputs and then the outputs.

*rShellValue*:

The value to be copied to the variable specified by *iIOIndex*.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[FuzzyOpen](#), [FuzzyGetShellValue](#)

## Example

See [FuzzyOpen](#).

## See Also

[Fuzzy Logic Functions](#)

## FuzzyTrace

Controls the trace process (starting and stopping) of the specified instance.

## Syntax

**FuzzyTrace(*hFuzzy*, *TraceOn*)**

*hFuzzy*:

The fuzzy instance handle (and integer greater than 0).

*TraceOn*:

Specifies whether to start or to stop a trace process for the Fuzzy instance specified by *hFuzzy*. If this parameter is TRUE (1), the trace process is started. If this parameter is FALSE (0), the trace process is stopped.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[FuzzyOpen](#)

## Example

See [FuzzyOpen](#).

## Group Functions

Following are functions relating to groups of objects:

<a href="#">GrpClose</a>	Closes a group.
<a href="#">GrpDelete</a>	Deletes items from a group.

<a href="#">GrpFirst</a>	Gets the first item in a group.
<a href="#">GrpIn</a>	Tests if an item is in a group.
<a href="#">GrpInsert</a>	Inserts items into a group.
<a href="#">GrpMath</a>	Performs mathematical operations on groups.
<a href="#">GrpName</a>	Gets the name of a group from a group handle.
<a href="#">GrpNext</a>	Gets the next item in a group.
<a href="#">GrpOpen</a>	Opens a group.
<a href="#">GrpToStr</a>	Converts a group into a string

## See Also

[Cicode Function Categories](#)

[Using Cicode Functions](#)

## GrpClose

Closes a group. The group is destroyed and the group handle becomes invalid. You should close a group when it is not in use, to release the associated memory. Plant SCADA closes all groups on shutdown.

## Syntax

**GrpClose(*hGrp*)**

*hGrp*:

The group handle, returned from the GrpOpen() function. The group handle identifies the table where all data on the associated group is stored.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[GrpOpen](#)

## Example

```
hGrp=GrpOpen( "MyGrp",1 );
..
GrpClose(hGrp);
```

## See Also

[Group Functions](#)

### GrpDelete

Deletes a single element or all elements from a group. You can also delete another group from within the group.

## Syntax

**GrpDelete(*hGrp*, *Value*)**

*hGrp*:

The group handle, returned from the GrpOpen() function. The group handle identifies the table where all data on the associated group is stored.

*Value*:

The element to delete from the group, from 0 to 16375.

- Set *Value* to -1 to delete all elements from the group.
- Set *Value* to a group handle to delete another group from this group.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[GrpInsert](#), [GrpOpen](#)

## Example

```
! Delete 10 and 14 from a group.  
GrpDelete(hGrp,10);  
GrpDelete(hGrp,14);
```

## See Also

[Group Functions](#)

### GrpFirst

Gets the value of the first element in a group. The first element in the group is the element with the lowest value. You can follow this function with a GrpNext() call, to get the value of all the elements in a group.

## Syntax

**GrpFirst(*hGrp*)**

*hGrp*:

The group handle, returned from the GrpOpen() function. The group handle identifies the table where all data on the associated group is stored.

## Return Value

The value of the first element in a group or -1 if the group is empty.

## Related Functions

[GrpOpen](#), [GrpNext](#)

## Example

```
Value=GrpFirst(hGrp);
IF Value<>-1 THEN
  Prompt("First value is "+Value:###);
END
```

## See Also

[Group Functions](#)

## GrpIn

Determines if an element is in a group.

## Syntax

**GrpIn(*hGrp, Value*)**

*hGrp*:

The group handle, returned from the GrpOpen() function. The group handle identifies the table where all data on the associated group is stored.

*Value*:

The element to locate, from 0 to 16375.

Set *Value* to a group handle to check if another group exists in the group.

## Return Value

1 if the element is in the group, otherwise 0 is returned.

## Related Functions

[GrpOpen](#), [GrpInsert](#), [GrpDelete](#)

## Example

```
IF GrpIn(hGrp,10) THEN
    Prompt("Area 10 in this group");
END
```

## See Also

[Group Functions](#)

## GrpInsert

Adds an element (or another group) to a group.

## Syntax

**GrpInsert(*hGrp*, *Value*)**

*hGrp*:

The group handle, returned from the GrpOpen() function. The group handle identifies the table where all data on the associated group is stored.

*Value*:

The element to add to the group, from 0 to 16375.

- Set *Value* to -1 to add all elements (0 to 16375) to the group.
- Set *Value* to a group handle to insert another group into the group.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[GrpOpen](#), [GrpDelete](#), [GrpIn](#)

## Example

```
! Add 10 and 14 to a group.
GrpInsert(hGrp,10);
GrpInsert(hGrp,14);
```

## See Also

[Group Functions](#)

## GrpMath

Performs mathematical operations on two groups, and stores the result in another group. You can add the two groups, subtract one from the other, or perform Boolean AND, NOT, and XOR operations on the two groups.

## Syntax

**GrpMath(*hResult*, *hOne*, *hTwo*, *Type*)**

*hResult*:

The group number where the result is placed.

*hOne*:

Number of first group used in the mathematical operation.

*hTwo*:

Number of the second group used in the mathematical operation.

*nType*:

Type of mathematical operation:

0 - Add groups one and two.

1 - Subtract group two from group one.

2 - AND groups one and two.

3 - NOT groups one and two.

4 - XOR groups one and two.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[GrpOpen](#)

## Example

```
hOne=GrpOpen("Plantwide",0);
hTwo=GrpOpen("Section1",0);
hResult=GrpOpen("Result",0);
! Subtract Section1 from Plantwide and place in Result.
GrpMath(hResult,hOne,hTwo,1);
```

## See Also

[Group Functions](#)

### GrpName

Gets the name of a group from a group handle.

## Syntax

**GrpName(*hGrp*)**

*hGrp*:

The group handle, returned from the GrpOpen() function. The group handle identifies the table where all data on the associated group is stored.

## Return Value

The name of the group (as a string).

## Related Functions

[GrpOpen](#)

## Example

```
! Get the current group name.  
sName=GrpName(hGrp);
```

## See Also

[Group Functions](#)

### GrpNext

Gets the value of the next element in a group. You can get the value of all the elements in a group. Call the GrpFirst() function to get the value of the first element, and then call this function in a loop.

## Syntax

**GrpNext(*hGrp, Value*)**

*hGrp*:

The group handle, returned from the GrpOpen() function. The group handle identifies the table where all data on the associated group is stored.

*Value:*

The value returned from GrpFirst() or the latest GrpNext() call.

## Return Value

The value of the next element in a group, or -1 if the end of the group has been found.

## Related Functions

[GrpFirst](#)

## Example

```
! Count all values in a group.  
Count=0;  
Value=GrpFirst(hGrp);  
WHILE Value<>-1 DO  
    Count=Count+1;  
    Value=GrpNext(hGrp,Value);  
END  
Prompt("Number of values in group is "+Count:###);
```

## See Also

[Group Functions](#)

## GrpOpen

Creates a group and returns a group handle, or gets the group handle of an existing group. After you open a group, you can use the group number in functions that use groups, for example, SetArea() and AlarmSetInfo(). You can open a group that is specified in the Groups database. You can also create groups at runtime.

When you open a group that is defined in the database, a copy of the group is made - the original group is not used. You can therefore change the values in the group without affecting other facilities that use this group.

## Syntax

**GrpOpen(sName, nMode)**

*sName*

The name of the group to open.

*Mode*

The mode of the open:

0 - Open an existing group

1 - Create a new group

2 - Attempts to open an existing group. If the group does not exist, it will create it.

## Return Value

The group handle , or -1 if the group cannot be created or opened. The group handle identifies the table where data on the associated group is stored.

## Related Functions

[GrpClose](#)

## Example

```
! Open Plantwide group defined in the database.  
hGrp=GrpOpen("Plantwide",0);  
! Set current user area to Plantwide.  
SetArea(hGrp);  
GrpClose(hGrp);  
! Set area to 1...10, 20 and 25 by creating a new group.  
hGrp=GrpOpen("MyGrp",1);  
StrToGrp(hGrp,"1..10,20,25");  
SetArea(hGrp);  
GrpClose(hGrp);
```

## See Also

[Group Functions](#)

## GrpToStr

Converts a group into a string of values separated by ", " and " .. ". You can then display the group on the screen or in a report.

## Syntax

**GrpToStr(*hGrp*)**

*hGrp*:

The group handle, returned from the GrpOpen() function. The group handle identifies the table where all data on the associated group is stored.

## Return Value

The group (as a string).

## Related Functions

[GrpOpen](#), [StrToGrp](#)

## Example

```
! Display current areas.  
hGrp=GetArea();  
Str=GrpToStr(hGrp);  
DspStr(21,"WhiteFont",Str);
```

## See Also

[Group Functions](#)

## I/O Device Functions

Following are functions relating to I/O devices:

<a href="#">DriverInfo</a>	Provides information about the driver for a particular I/O device.
<a href="#">IODeviceControl</a>	Provides control of individual I/O devices.
<a href="#">IODeviceInfo</a>	Gets information on an I/O device.
<a href="#">IODeviceStats</a>	Gets statistical information for I/O devices.

## See Also

[Cicode Function Categories](#)

[Using Cicode Functions](#)

## DriverInfo

Provides information about the driver for a specified I/O device. Select the device using the *IODevice* argument, and the information to be returned using the *Type* argument.

This function can only be used if the I/O Server is on the current machine. When the I/O Server is not in the calling process, this function will become blocking and cannot be called from a foreground task. In this case, the return value will be undefined and a Cicode hardware alarm will be raised.

## Syntax

**DriverInfo**(*IODevice*, *nType* [, *sClusterName*] [, *ServerName*] )

*IODevice*:

The name of the I/O device.

*nType*:

The type of information returned about the driver. Specify one of the following:

0 - Driver Name

- 1 - Driver Title
- 2 - Block constant
- 3 - Max Retrys
- 4 - Transmit Delay
- 5 - Receive Timeout
- 6 - Polltime
- 7 - Watchtime (milliseconds)

---

**Note:** The DISKDRV driver name is returned as "Disk" instead of "DISKDRV". If the Polltime is set as "Interrupt", the function returns "0".

---

*sClusterName:*

Specifies the name of the cluster in which the I/O Server resides. This is optional if you have one cluster or are resolving the I/O server via the current cluster context. The argument is enclosed in quotation marks "".

*ServerName:*

Specifies the name of the the I/O Server. This parameter is only required if you are running more than one I/O server process from the same cluster on the same computer and need to instruct the system which process to redirect to. The argument is enclosed in quotation marks "".

## Return Value

The driver information as a string. In the case of an error the return value is an empty string.

## Example

```
// Using the IODevice Number
sName = DriverInfo(20, 0); ! Get the name of the driver used with I/O device 20
sName = DriverInfo(2, 1); ! Get the title of the driver used with I/O device 2
// Using the IODevice Name
sName = DriverInfo("IODev",3);
! Get the Max Retrys value of the driver used with IODev
sName = DriverInfo("IODev1",5);
! Get the Receive Timeout value of the driver used with IODev1
```

## See Also

[I/O Device Functions](#)

## IODeviceControl

Provides control of individual I/O devices. You might need to call this function several times. If you use incompatible values for the various options of this function, you might get unpredictable results.

This function can only be used if the I/O Server is on the current machine. When the I/O Server is not in the calling process, this function will become blocking and cannot be called from a foreground task. In this case, the return value will be undefined and a Cicode hardware alarm will be raised.

## Syntax

**IODeviceControl(*IODevice*, *nType*, *Data* [, *sClusterName*] [, *ServerName*] )**

*IODevice*:

The number or name of the I/O device. If you call this function from an I/O server, you can use the I/O device name. If you call this function from a client, you may use either the I/O device number or name. To specify all I/O devices, use "\*" (asterisk) or -1.

*nType*:

The type of control action:

0 - No longer supported.

1 - Enable/Disable the I/O device on the I/O server. If disabled, attempts to read and write from the I/O device are ignored. (If another I/O device is configured as a standby I/O server, Plant SCADA switches communications to that I/O device.) The I/O server does not attempt to communicate with the I/O device until it is re-enabled. When the I/O device is re-enabled, the I/O server attempts to re-establish communication immediately. Mode 1 can only be called by the I/O Server which is associated with this device.

2 - No longer supported. An invalid argument error is returned if this option is specified.

3 - No longer supported. An invalid argument error is returned if this option is specified.

4 - The data in the associated I/O device cache is flushed. This allows flushing of the data from the I/O device without waiting for the aging time. This is useful when you have long cache time and you want to force a read from the I/O device. The Data value is ignored with this mode.

5 - (For scheduled and remote I/O devices). The I/O device is added to the bottom of the list of I/O devices to be contacted. I/O devices already in the list (already waiting to be contacted) are given priority over this I/O device.

6 - (For scheduled and remote I/O devices). The I/O device is added to the top of the list of I/O devices to be contacted; it is given high priority. If there are already I/O devices at the top of the list with high priority, then this I/O device will be added to the list after them (that is it will be contacted after them). For dial-up remote I/O devices, if the modem is already in use - connected to another I/O device - this I/O device will not be dialled until that connection has been terminated.

7 - (For scheduled and remote I/O devices). The I/O device is added to the top of the list of I/O devices to be contacted, and it is given top priority. For dial-up remote I/O devices, if the modem is currently connected to another I/O device, the connection will be cancelled, and the top priority I/O device will be dialled. It will also stay connected until manually disconnected with another call to `IODeviceControl()`.

---

**Note:** This mode will not attempt to disconnect any other persistent connections. Persistent connections can only be disconnected using mode 8.

---

8 - (For scheduled and remote I/O devices). Disconnect an I/O device. Current requests will be completed before the I/O device is disconnected.

9 - (For scheduled I/O devices). The communication schedule for the I/O device is disabled. This is to minimize the likelihood that the I/O device will be contacted when its scheduled dial-time occurs.

10 - (For scheduled I/O devices). Puts the I/O device into Write On Request mode. That is, as soon as a write request is made, the I/O device will be added to the list of I/O devices to be contacted. It is given priority over existing read requests, but not over existing write requests. In this situation, there will be a delay while the I/O device is contacted. Do not mistake this pause for inactivity (for example, do not continually execute a command during this delay).

11 - Change the I/O device cache timeout. If the I/O Server is restarted, the cache timeout will return to its original value. (For scheduled I/O devices, this value can be checked using the Kernel Page Unit command. For all

other I/O devices, this value is configured in the Cache Time field at the I/O Devices Properties form.)

12 - The time of day at which to add the I/O device to the list of I/O devices to be contacted. Set the time in Data in seconds from midnight (for example, specify 6 p.m. as 18 \* 60 \* 60). Use Type 12 to specify a one-time communication.

13 - The communication period (the time between successive communication attempts). The value you specify represents different periods, depending on what type of schedule you are using (that is daily, weekly, monthly, or yearly. This is set using Type 15.). You can choose to specify the communication period either in seconds from midnight, day of week (0 to 6, Sunday = 0), month (1 to 12), or year. Enter the value in Data. For example, if your schedule is weekly, and you set Data = 3, you are specifying each Wednesday. If your schedule is monthly, Data = 3 indicates March. For daily communication, set the period in Data in seconds from midnight; for example, set Data to 6 \* 60 \* 60 to contact the I/O device every 6 hours.

14 - The time at which the I/O Server will first attempt to communicate with the I/O device. Set the time in Data in seconds from midnight, for example, to synchronize at 10a.m., set Data to 10 \* 60 \* 60.

15 - Type of schedule. Set Data to one of the following:

- 1 - Daily
- 2 - Weekly
- 3 - Monthly
- 4 - Yearly

16 - (For remote I/O devices) Read all tags from the I/O device. Data is unused - set it to 0 (zero).

18 - Set Control Inhibit (Control Mode) for all tags of the I/O device.

*Data:*

Data for the control operation\*:

1:

- Disable the I/O device (Disable Write On Request mode for Type 10)
- Set Control Inhibit to ON (mode for type 18)

0:

- Enable the I/O device (Enable Write On Request mode for Type 10) or the I/O device name (for Type 2 or 3).
- Set Control Inhibit to OFF (mode for type 18)

\* For Type 5-8, Data is ignored; enter 0 (zero).

*sClusterName:*

Specifies the name of the cluster in which the I/O Server resides. This is optional if you have one cluster or are resolving the I/O server via the current cluster context. The argument is enclosed in quotation marks "".

*ServerName:*

Specifies the name of the the I/O Server. This parameter is only required if you are running more than one I/O server process from the same cluster on the same computer and need to instruct the system which process to redirect to. The argument is enclosed in quotation marks "".

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[IODeviceInfo](#), [IODeviceStats](#), [TagReadEx](#), [TagWrite](#)

## Example

```
IODeviceControl(4, 1, 1); ! Disable I/O device 4
```

## See Also

[I/O Device Functions](#)

### IODeviceInfo

Gets information about a specified I/O device.

Apart from when *Type* is set to 3 or 17, this function can only be used if the I/O Server is on the current machine, otherwise the function will not succeed and will return empty string. When the I/O Server is not in the calling process, this function will become blocking and cannot be called from a foreground task. In this case, the return value will be undefined and a Cicode hardware alarm will be raised.

If both the primary and standby I/O devices are on the same server and they have the same I/O device name, you can get information about them individually by specifying the following:

```
IODeviceInfo("PLC1,P",1); // for the Primary  
IODeviceInfo("PLC1,S",1); // for the Standby
```

Where:

- P represents the primary I/O device
- S the standby I/O device.

If you have more than one standby device on the same server, there is currently no way of using this function for other than the first standby device.

---

**Note:** When the I/O server is not in the calling process, this function could become a blocking function if the information required by this function is on an I/O server (except types 3 and 17, which are normally non-blocking). If this is the case, this function cannot be called from a foreground task (such as a graphics page) or an expression. Otherwise the return value will be undefined and a Cicode hardware alarm raised.

---

## Syntax

**IODeviceInfo(*IODevice*, *Type* [, *sClusterName*] [, *ServerName*])**

*IODevice*:

The I/O device number, or the I/O device name enclosed in double quotes.

*nType*:

The type of information:

0 - Name of I/O device

1 - Protocol of I/O device

2 - Protocol address

3 - Client I/O device state

- 1 = Running - Client is either talking to an online I/O device or talking to a scheduled device that is not currently connected but has a valid cache

- 2 = Standby - Client is talking to an online standby I/O device

- 4 = Starting - Client is talking to an I/O device that is attempting to come online

- 8 = Stopping - Client is talking to an I/O device that is in the process of stopping

- 16 = Offline - Client is pointing to an I/O device that is currently offline

- 32 = Disabled - Client is pointing to a device that is disabled

- 66 = Standby write - client is talking to an I/O device configured as a standby write device

4 - Current generic error number (decimal)

5 - Current driver error number (decimal)

6 - Disabled flag

7 - Statistics, minimum read time

8 - Statistics, maximum read time

9 - Statistics, average read time

10 - I/O server I/O device state

- 1 = Running - I/O device for this I/O server is online or a scheduled device that is not currently connected but has a valid cache

- 2 = Standby - I/O device for this I/O server is online and a standby unit

- 4 = Starting - I/O device for this I/O server is attempting to come online. Starting may be combined with either Offline or Remote such as: 20 = Starting(4) + Offline(16) or 132 = Starting(4) + Remote(128).

- 8 = Stopping - I/O device for this I/O server is currently in the process of stopping

- 16 = Offline (only valid on an I/O server) - I/O device for this I/O server is currently offline

- 32 = Disabled - I/O device for this I/O server is disabled

- 66 = Standby write - I/O device for this I/O server is configured as a standby write device

- 128 = Remote (returned in combination with another value specified above - see Starting) - I/O device for this I/O server is a scheduled device but not currently connected

11 - Unit number

12 - Configured I/O server name

13 - Configured Port name

14 - Configured startup mode

15 - Configured comment

16 - The primary I/O server name the client uses to communicate to this device

17 - The I/O Server the client is using to communicate to this device. Will be Standby if the Primary is down.

18 - State of the remote unit:

- 0 = Remote unit is disconnected and OK

- 1 = Remote unit is connected and online

- 2 = Remote unit is in the dial queue

If you are trying to determine the state of a remote device that is configured for scheduled communications, you should use this type in conjunction with type 10. Firstly, use type 10 to determine if the device is in running state. If it is, use type 18 to determine its connection state.

This mode causes redirection to the I/O server if running in separate processes.

19 - Number of successful attempts to communicate with the scheduled I/O device.

20 - Number of unsuccessful attempts to communicate with the scheduled I/O device.

21 - Write mode: Write On Request, and normal (as per schedule defined in the Express Communications Wizard).

22 - Number of queued read requests for the scheduled I/O device. (This mode causes redirection to the I/O server if running in separate processes.)

23 - Number of queued write requests for the scheduled I/O device. (This mode causes redirection to the I/O server if running in separate processes.)

24 - The cache timeout (in milliseconds).

26 - The name of the line device (for example, modem) you are using to connect to the I/O device. (This mode causes redirection to the I/O server if running in separate processes.)

27 - The call\_status of a currently connected remote I/O device.

- DIALCALLSTATE\_UNAVAIL — 1
- DIALCALLSTATE\_IDLE — 2
- DIALCALLSTATE\_OFFERING — 3
- DIALCALLSTATE\_ACCEPTED — 4
- DIALCALLSTATE\_DIALTONE — 5
- DIALCALLSTATE\_DIALING — 6
- DIALCALLSTATE\_RINGBACK — 7
- DIALCALLSTATE\_BUSY — 8
- DIALCALLSTATE\_SPECIALINFO — 9
- DIALCALLSTATE\_CONNECTED — 10
- DIALCALLSTATE\_PROCEEDING — 11
- DIALCALLSTATE\_ONHOLD — 12
- DIALCALLSTATE\_CONFERENCE — 13
- DIALCALLSTATE\_ONHOLDPENDCONF — 14
- DIALCALLSTATE\_ONHOLDPENDTRANSFER — 15
- DIALCALLSTATE\_DISCONNECTED\_NORMAL — 16
- DIALCALLSTATE\_DISCONNECTED\_LINELOST — 17
- DIALCALLSTATE\_DISCONNECTED\_UNKNOWN — 18
- DIALCALLSTATE\_DISCONNECTED\_REJECT — 19
- DIALCALLSTATE\_DISCONNECTED\_PICKUP — 20
- DIALCALLSTATE\_DISCONNECTED\_FORWARDED — 21
- DIALCALLSTATE\_DISCONNECTED\_BUSY — 22
- DIALCALLSTATE\_DISCONNECTED\_NOANSWER — 23
- DIALCALLSTATE\_DISCONNECTED\_BADADDRESS — 24

- DIALCALLSTATE\_DISCONNECTED\_UNREACHABLE — 25
- DIALCALLSTATE\_DISCONNECTED\_CONGESTION — 26
- DIALCALLSTATE\_DISCONNECTED\_INCOMPATIBLE — 27
- DIALCALLSTATE\_DISCONNECTED\_UNAVAIL — 28
- DIALCALLSTATE\_DISCONNECTED\_NODIALTONE — 29
- DIALCALLSTATE\_DISCONNECTED\_NUMBERCHANGED — 30
- DIALCALLSTATE\_DISCONNECTED\_OUTOFORDER — 31
- DIALCALLSTATE\_DISCONNECTED\_TEMPFAILURE — 32
- DIALCALLSTATE\_DISCONNECTED\_QOSUNAVAIL — 33
- DIALCALLSTATE\_DISCONNECTED\_BLOCKED — 34
- DIALCALLSTATE\_DISCONNECTED\_DONOTDISTURB — 35
- DIALCALLSTATE\_DISCONNECTED\_CANCELLED — 36
- DIALCALLSTATE\_UNKNOWN — 48

(This mode causes redirection to the I/O server if running in separate processes.)

28 - The call rate (in bits per second) which may be the DTE or DCE connection speed depending on the server modem settings. (This mode causes redirection to the I/O server if running in separate processes.)

30 - The last time an I/O device from the remote I/O device redundant group was connected (primary or any standbys).

31 -The state of the remote I/O device redundant group:

- 0 = not connected (none of the redundant I/O devices connected)
- 1 =connected (one of the redundant I/O devices is connected)

32 - The next time the specified I/O device is scheduled to connect (unless a higher priority I/O device comes online).

#### *sClusterName:*

Specifies the name of the cluster in which the I/O Server resides. This is optional if you have one cluster or are resolving the I/O server via the current cluster context. The argument is enclosed in quotation marks "".

#### *ServerName:*

Specifies the name of the I/O Server. This parameter is only required if you are running more than one I/O server process from the same cluster on the same computer and need to instruct the system which process to redirect to. The argument is enclosed in quotation marks "".

## Return Value

The type of information (as a string).

## Related Functions

[IODeviceControl](#), [IODeviceStats](#), [TagReadEx](#), [TagWrite](#)

## Example

```
//Using the IODDevice Number
```

```
sName = IODeviceInfo(20, 0); ! Get the name of I/O device 20
sName = IODeviceInfo(2, 1); ! Get the protocol of I/O device 2
//Using the IODevice Name
sName = IODeviceInfo("IODev",10); ! Get the I/O Server State
sName = IODeviceInfo("IODev1",3); ! Get the State of IODev1
```

## See Also

[I/O Device Functions](#)

### IODeviceStats

Gets statistical information for all I/O devices, and displays the information in a dialog box.

**Note:** In a multi-process environment this function needs to be called from the I/O server process or redirected there using [MsgRPC](#). If this isn't done, some of the information on the IODeviceStats form will not be displayed correctly.

## Syntax

**IODeviceStats()**

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[IODeviceInfo](#)

## Example

```
IODeviceStats(); ! display all I/O device information
```

## Keyboard Functions

Following are functions relating to the keyboard:

<a href="#">KeyAllowCursor</a>	Allows the command cursor to move to any AN or only to ANs that have commands defined.
<a href="#">KeyBs</a>	Deletes the last character from the key command line.

<a href="#">KeyDown</a>	Moves the command cursor down.
<a href="#">KeyGet</a>	Gets the raw key code from the key command line.
<a href="#">KeyGetCursor</a>	Gets the AN where the cursor is positioned.
<a href="#">KeyLeft</a>	Moves the command cursor left.
<a href="#">KeyMove</a>	Moves the command cursor in the requested direction.
<a href="#">KeyPeek</a>	Gets a key from the key command line without removing the key.
<a href="#">KeyPut</a>	Puts a raw key code into the key command line.
<a href="#">KeyPutStr</a>	Puts a string into the key command line.
<a href="#">KeyReplay</a>	Replays the last key sequence.
<a href="#">KeyReplayAll</a>	Replays and executes the last key sequence.
<a href="#">KeyRight</a>	Moves the command cursor right.
<a href="#">KeySetCursor</a>	Moves the command cursor to a specified AN.
<a href="#">KeySetSeq</a>	Adds a keyboard sequence at runtime.
<a href="#">KeyUp</a>	Moves the command cursor up.
<a href="#">SendKeys</a>	Sends a keystroke (or string of keystrokes) to a window.

## See Also

[Cicode Function Categories](#)

[Using Cicode Functions](#)

## KeyAllowCursor

Allows (or disallows) the command cursor to move to the specified AN or to all ANs. The command cursor normally moves only to ANs that have commands defined.

## Syntax

**KeyAllowCursor(*nAN*, *State*)**

*nAN*:

The AN where the command cursor can move. If 0, all ANs are implied.

*State:*

Allow state:

0 - Do not allow the cursor to move to this AN.

1 - Allow the cursor to move to this AN.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[KeyGetCursor](#)

## Example

```
KeyAllowCursor(20,1);
! Allows the command cursor to move to AN20.
KeyAllowCursor(0,1);
! Allows the command cursor to move to any AN.
```

## See Also

[Keyboard Functions](#)

## KeyBs

Removes the last key from the key command line. If the key command line is empty, this function will not perform any action.

You should call this function using a "Hot Key" command (as shown in the example below), otherwise the backspace character is placed into the key command line and the command does not execute. A "Hot Key" command is a command that executes as soon as it is placed into the key command line.

## Syntax

`KeyBs()`

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[KeyGet](#)

## Example

### System Keyboard

Key Sequence	*Bs
Command	KeyBs()
Comment	Define a backspace Hot Key

(\*) represents a HotKey command)

```
/* If "START A B C" is in the key command line and "START" is
the Key Name for the "F1" key: */
KeyBs();
! Removes ASCII "C".
KeyBs();
! Removes ASCII "B".
KeyBs();
! Removes ASCII "A".
KeyBs();
! Removes Key_F1.
KeyBs();
! Performs no action.
```

## See Also

[Keyboard Functions](#)

## KeyDown

Moves the command cursor down the page to the closest AN. If an AN-Down cursor override is specified (in the Page Keyboard database) for the graphics page, the command cursor moves to that AN instead.

## Syntax

`KeyDown()`

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[KeyUp](#), [KeyLeft](#), [KeyRight](#), [KeyMove](#)

## Example

See [KeyDown](#).

## See Also

[Keyboard Functions](#)

### KeyGet

Gets the last key code from the key command line. The key is removed from the command line. Use this function to process the operator key commands directly. You should call this function from the keyboard event function.

## Syntax

`KeyGet()`

## Return Value

The last key code from the key command line. If the key command line is empty, 0 (zero) is returned.

## Related Functions

[KeyPeek](#), [KeyPut](#)

## Example

```
/* If "START A B C" is in the key command line and "START" is
the Key Name for the "F1" key: */
Variable=KeyGet();
! Sets Variable to 67 (ASCII "C").
Variable=KeyGet();
! Sets Variable to 66 (ASCII "B").
Variable=KeyGet();
! Sets Variable to 65 (ASCII "A").
Variable=KeyGet();
! Sets Variable to 170 (the ASCII value of the F1 key (Key_F1)).
Variable=KeyGet();
! Sets Variable to 0.
```

## See Also

[Keyboard Functions](#)

### KeyGetCursor

Gets the AN at the position of the command cursor.

If this function is called from within a larger piece of code, the cursor may have moved away from where it was originally positioned when the larger piece of code was started.

If you are using groups, and there are currently two command cursors, the AN for the innermost will be returned. For example, if there is a cursor for a group as well as a cursor for one of its objects, the AN for the

object will be returned.

## Syntax

`KeyGetCursor()`

## Return Value

The AN at the position of the command cursor. If no cursor is visible, -1 is returned.

## Related Functions

[KeySetCursor](#)

## Example

```
! If the command cursor is on AN25:  
AN=KeyGetCursor();  
! Sets AN to 25.
```

## See Also

[Keyboard Functions](#)

## KeyLeft

Moves the command cursor left (across the page) to the closest AN. If an AN-Left cursor override is specified (in the Page Keyboard database) for the graphics page, the command cursor moves to that AN instead.

## Syntax

`KeyLeft()`

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[KeyRight](#), [KeyUp](#), [KeyDown](#), [KeyMove](#)

## Example

See [KeyRight](#).

## See Also

[Keyboard Functions](#)

## KeyMove

Moves the command cursor in a specified direction to the closest AN. If an AN cursor override is specified, the command cursor moves to that AN directly. This function is equivalent to the KeyUp(), KeyDown(), KeyLeft(), and KeyRight() functions.

## Syntax

**KeyMove(*Direction*)**

*Direction*:

Direction to move the cursor:

0 - Do not move

1 - Left

2 - Right

3 - Up

4 - Down

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[KeyUp](#), [KeyDown](#), [KeyLeft](#), [KeyRight](#)

## Example

```
KeyMove(1);
! Moves the cursor left.
```

## See Also

[Keyboard Functions](#)

## KeyPeek

Gets the ascii key code from the key command line (at a specified offset), without removing the key from the key command line. An offset of 0 returns the key code from the last position in the key command line.

## Syntax

**KeyPeek(*Offset*)**

*Offset*:

The offset from the end of the key command line

## Return Value

The ASCII key code.

## Related Functions

[KeyGet](#)

## Example

```
! If "A B C" is in the key command line:  
Variable=KeyPeek(0);  
! Sets Variable to 67 (ASCII "C")  
Variable=KeyPeek(2);  
! Sets Variable to 65 (ASCII "A")
```

## See Also

[Keyboard Functions](#)

## KeyPut

Puts an ASCII key code or Keyboard key code into the last position of the key command line. If this key completes any command, that command will execute.

## Syntax

**KeyPut(*KeyCode*)**

*KeyCode*:

The key code to put into the key command line.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[KeyGet](#)

## Example

```
KeyPut(Key_F1);
/* Puts "Key_F1" (the Key Code for the "F1" key) into the last
position of the key command line. If "START" is the Key Name for
the "F1" key, this would be equivalent to
KeyPutStr("START"). In either case, "START" will display on the
key command line. */
KeyPut(StrToChar("A"));
/* Puts the Key Code for the "A" key into the last position of the
key command line. */
```

## See Also

[Keyboard Functions](#)

### KeyPutStr

Puts a string at the end of the key command line. The string can contain either key names or data characters. If this string completes any command, that command will execute.

## Syntax

**KeyPutStr(*String*)**

*String*:

The string to put into the key command line.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[KeyPut](#)

## Example

```
KeyPutStr("START ABC");
! Places "START ABC" at the end of the key command line.
KeyPutStr("TURN PUMP 1 ON");
! Places "TURN PUMP 1 ON" at the end of the key command line.
```

## See Also

[Keyboard Functions](#)

## KeyReplay

Replays the last key sequence (except for the last key, which would execute the command). This function is useful when a command is to be repeated. To call this function from the keyboard, use a Hot Key "\*" (asterisk) command, otherwise the KeyReplay() function itself is replayed.

## Syntax

**KeyReplay(*Sub*)**

*Sub*:

Number of characters to subtract before replay. Default value is 1.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[KeyReplayAll](#)

## Example

If the previous contents of the key command line were:

```
"START ABC ENTER"  
KeyReplay();  
! Replays "START ABC".
```

## See Also

[Keyboard Functions](#)

## KeyReplayAll

Replays the last key sequence and executes the command. To call this function from the keyboard, use a Hot Key " \* " (asterisk) command, otherwise the KeyReplayAll() function itself is replayed.

## Syntax

**KeyReplayAll()**

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[KeyReplay](#)

## Example

If the previous contents of the key command line were:

```
"START ABC ENTER"  
KeyReplayAll();  
! Replays "START ABC ENTER" and executes the command.
```

## See Also

[Keyboard Functions](#)

## KeyRight

Moves the command cursor right (across the page) to the closest AN. If an AN-Right cursor override is specified (in the Page Keyboard database) for the graphics page, the command cursor moves to that AN instead.

## Syntax

**KeyRight()**

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[KeyUp](#), [KeyDown](#), [KeyLeft](#), [KeyMove](#)

## Example

See [KeyLeft](#).

## See Also

[Keyboard Functions](#)

## KeySetCursor

Displays the command cursor at a specified AN. A keyboard command needs to exist, or you need to first call the KeyAllowCursor() function (at the AN) to allow the cursor to move to the AN. If the AN does not exist, or if a command does not exist at that AN, or if KeyAllowCursor() has not been called, the command cursor does not

move.

## Syntax

**KeySetCursor(*nAN*)**

*nAN*:

The AN where the command cursor will be displayed.

## Return Value

If the AN does not exist, or if a command does not exist at that AN, or if KeyAllowCursor() has not been called, the return value is 1. Otherwise, the function will return 0.

## Related Functions

[KeyGetCursor](#), [KeyAllowCursor](#)

## Example

```
! Move the command cursor to AN20.  
KeySetCursor(20);
```

## See Also

[Keyboard Functions](#)

## KeySetSeq

Adds a keyboard sequence to the current page at runtime. The key sequence is only added to the current window. When the page is closed, the keyboard sequence is deleted.

## Syntax

**KeySetSeq(*sKeySeq*, *AN*, *Fn*)**

*sKeySeq*:

The keyboard sequence.

*nAN*:

The AN where the keyboard sequence will apply. If you set AN to 0 (zero), the keyboard sequence will apply to all ANs on the page.

*Fn*:

The function to call when the keyboard sequence matches. This function needs to be a callback function.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DspButton](#), [DspButtonFn](#)

## Example

```
/* Set the key sequence and call the "Callback" function when the
sequence is found. */
KeySetSeq("F2 ### Enter", 0, Callback);
! This function is called when the key sequence is found.
INT
FUNCTION CallBack()
    INT Value;
    ! Get user data.
    Value=Arg1;
    ..
    RETURN 0;
END
```

## See Also

[Keyboard Functions](#)

## KeyUp

Moves the command cursor up the page to the closest AN. If an AN-Up cursor override is specified (in the Page Keyboard database) for the graphics page, the command cursor moves to that AN.

## Syntax

`KeyUp()`

## Return Value

0 (zero) if successful, otherwise an error is returned.

[KeyDown](#), [KeyLeft](#), [KeyRight](#), [KeyMove](#)

## See Also

[Keyboard Functions](#)

## SendKeys

Sends a keystroke (or string of keystrokes) to a window as if they were typed on the keyboard. The window receives input focus and is brought to the foreground.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**SendKeys(*sTitle*, *sKeys*)**

*sTitle*:

The title (caption) of the destination window.

*sKeys*:

The key (or keys) to send to *sTitle*.

- To send a single keyboard character, use the character itself. For example, to send the letter a, set *sKeys* to a. To send more than one character, append each additional character to the string. For example, to send the letters a, b, and c, set *sKeys* to abc.
- The plus (+), caret (^), and percent sign (%) have special meanings. To send one of these special characters, enclose the character with braces. For example, to send the plus sign, use {+}. To send a { character or a } character, use {{}} and {{}}, respectively.
- To specify characters that are not displayed when you press a key (such as **Enter** or **Tab**) and other keys that represent actions rather than characters, use the codes shown below:

Key	Code
Backspace	{backspace} or {bs} or{bksp}
Break	{break}
Caps Lock	{capslock}
Clear	{clear}
Del	{delete} or {del}
End	{end}
Enter	{enter} or ~
Esc	{escape} or {esc}
Help	{help}
Home	{home}
Insert	{insert}
Num Lock	{numlock}

Page Down	{pgdn}
Page Up	{pgup}
Print Screen	{prtsc}
Scroll Lock	{scrolllock}
Tab	{tab}
Up Arrow	{up}
Down Arrow	{down}
Right Arrow	{right}
Left Arrow	{left}
F1	{f1}
F2	{f2}
F3	{f3}
F4	{f4}
F5	{f5}
F6	{f6}
F7	{f7}
F8	{f8}
F9	{f9}
F10	{f10}
F11	{f11}
F12	{f12}

To specify keys combined with any combination of **Shift**, **Ctrl**, and **Alt**, precede the regular key code with one or more of these codes:

Key	Code
Shift	+
Ctrl	^
Alt	%

To specify that **Shift**, **Ctrl**, and/or **Alt** are held down while several keys are pressed, enclose the keys in

parentheses. For example, to hold down the **Shift** key while sending E then C, use +(EC). To hold down **Shift** while sending E, followed by C without the **Shift** key, use +EC. To specify repeating keys, use the form {key number}. For example, {left 42} means send the left arrow key 42 times. Be aware that you need to leave a space between the key and number.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[WndFind](#)

## Example

```
SendKeys("Untitled - Notepad", "abc");
// Send the key sequence "abc" to the Notepad application
```

## See Also

[Keyboard Functions](#)

## Mail Functions

Following are functions relating to sending or receiving mail:

<a href="#">MailError</a>	Gets the last mail error code
<a href="#">MailLogoff</a>	Logoff from the mail system
<a href="#">MailLogon</a>	Logon to the mail system
<a href="#">MailRead</a>	Reads a standard mail message
<a href="#">MailSend</a>	Sends a standard mail message

## MailError

Gets the last mail error code. The error code is extracted from the MAPI mail system and explains what caused the MAPI error.

## Syntax

**MailError()**

## Return Value

0 (zero) if successful, otherwise an error is returned. Refer also to MAPI errors.

## Related Functions

[MailLogon](#), [MailLogoff](#), [MailSend](#), [MailRead](#)

## Example

```
! Logon to the mail system
IF MailLogon("RodgerG", "password", 0) THEN
    error = MailError();
    !do what is required
END
```

## See Also

[Mail Functions](#)

## MailLogoff

Logs off from the mail system. You should log off the mail system when all mail operations are complete. Plant SCADA automatically logs off the mail system on shutdown.

## Syntax

**MailLogoff()**

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[MailLogon](#), [MailLogoff](#), [MailRead](#)

## Example

```
! Send the report to Rodger
MailLogon("Andrew", "password", 0);
MailSend("Rodger Gaff", "Report", "This is the weekly report",
```

```
"[data]:weekly.txt", 0);  
MailLogoff();
```

## See Also

[Mail Functions](#)

## MailLogon

Logs on to the mail system. You need to call this function before any other mail function.

The mail system uses the MAPI standard interface, so you can use any mail system that supports this standard.

You should log on to the mail system when Plant SCADA starts, and log off only at shutdown. (The logon procedure can take a few seconds to complete.) You can only log on as one user at a time for each computer, so you can only read mail for this user name.

## Syntax

**MailLogon(*sName*, *sPassword*, *iMode*)**

*sName*:

The name of the mail user. This name is the user's mail box name (the unique shorthand name, not the full user's name).

*sPassword*:

The password of the mail user.

*iMode*:

The mode of the logon:

0 - Normal logon.

2 - Get unique logon, do not share existing mail client logon.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[MailLogoff](#), [MailSend](#), [MailRead](#), [MailError](#)

## Example

```
! Send the report to James  
MailLogon("RodgerG", "password", 0);  
MailSend("James Glover", "Report", "This is the weekly report",  
"[data]:weekly.txt", 0);  
MailLogoff();
```

## See Also

[Mail Functions](#)

### MailRead

Reads a standard mail message. The mail message can contain text, an attached file, or both.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

Before you can use this function, you need to use the MailLogon() function to log on to the mail system. You can only read mail sent to the user name specified in the MailLogon() function.

## Syntax

**MailRead(*sName*, *sSubject*, *sNote*, *sFileName*, *iMode*)**

*sName*:

The name of the mail user who sent the message. Must be a String type variable.

*sSubject*:

The subject text of the mail message. Must be a String type variable.

*sNote*:

The note section of the message. If the message is longer than 255 characters, Plant SCADA will save the message in a file and return the file name in *sNote*. Use the file functions to read the message. The name of the file will be in the form CTxxxxx where x is a unique number. You need to delete the file after you have finished with the mail message. Must be a String type variable.

*sFileName*:

The name of any attached file. If there is no attached file in the message, specify *sFileName* as an empty string "". Must be a String type variable.

*iMode*:

The mode of the read:

0 - Read a message. If no message is available, wait for a message.

1 - Read a message. If no message is available, return with an error code.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[MailLogon](#), [MailLogoff](#), [MailSend](#), [MailError](#)

## Example

```
! Logon to the mail system
MailLogon("RodgerG", "password", 0);
```

```
! Read a message. Don't wait if no message
IF MailRead(sName, sSubject, sNote, sFileName, 1) = 0 THEN
    ! got message now do something with it
END
WHILE TRUE DO
    ! wait for a mail message
    MailRead(sName, sSubject, sNote, sFileName, 0);
END;
MailLogoff();
```

## See Also

[Mail Functions](#)

## MailSend

Sends a standard mail message. The mail message can contain text, an attached file, or both.

Before you can use this function, you need to use the MailLogon() function to log on to the mail system. You can only send mail from the user name specified in the MailLogon() function. You can send mail to any mail user or to another Plant SCADA client.

## Syntax

**MailSend(*sName*, *sSubject*, *sNote*, *sFileName*, *iMode*)**

*sName*:

The name of the mail user who will receive the message. This name is the user's full name (not their mailbox name).

*sSubject*:

The subject text of the mail message (a short description of what the message is about).

*sNote*:

The note section of the message (the main section of the message text). You can enter up to 255 characters, or a file name for longer messages. If you enter a file name, set *iMode* to 1.

*sFileName*:

The name of any attached file. If there is no attached file in the message, set *sFileName* to an empty string "".

*iMode*:

The mode of the send:

0 - Normal mail message.

1 - The *sNote* argument is the name of a text file to send as the note.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[MailLogon](#), [MailLogoff](#), [MailRead](#), [MailError](#)

## Example

```
! Logon to the mail system
MailLogon("Wombat", "password", 0);
! send the report to Andrew
MailSend("Andrew Bennet", "Report", "Attached is the weekly report",
"[data]:weekly.txt", 0);
! send hello message to JR
MailSend("Jack Russell", "Hello", "You've only got yourself to blame!", "", 0);
! send a big note to Nigel
MailSend("Nigel Colless", "Big Message", "[data]:message.txt", "", 1);
MailLogoff();
```

## Map Functions

Map functions allow for values to be associated with keys within the map.

As the handle to a map (or map name) is a string, it can be stored either as a key or as a value in another map, therefore maps can be used to create arbitrarily complex data structures.

By treating a map as being equivalent to an "instance" of an "object" in an "object-oriented" language, it is possible to achieve a simplified object oriented programming style. This can be done by passing the map name as a parameter to the "object's" functions.

The keys in the map are case sensitive and are ordered alphabetically as can be observed by sequentially discovering each key in the map (using MapKeyFirst and MapKeyNext). The alphabetic ordering is not lexicographic ordering and only determines a repeatable order for a given set of keys.

Following are map functions:

<a href="#">MapOpen</a>	Create a new or open an existing map.
<a href="#">MapClear</a>	Clear all entries in a map.
<a href="#">MapClose</a>	Deletes a previously created map.
<a href="#">MapExists</a>	Check if the map exists using a returned error code.
<a href="#">MapKeyCount</a>	Retrieves the number of keys in a map.
<a href="#">MapKeyDelete</a>	Delete a key and its value from a map.
<a href="#">MapKeyExists</a>	Check if a key exists in a map.
<a href="#">MapKeyFirst</a>	Retrieves the first key in a maps so that all the keys in

	a map can be discovered.
MapKeyNext	Retrieves the next key after the supplied key in a map so that all the keys in a map can be discovered.
MapValueGet	Retrieves the value from a key in a map.
MapValueSet	Sets the value of a key in a map.
MapValueSetQuality	Sets the quality of a value in a map.

## See Also

[Cicode Function Categories](#)

[Using Cicode Functions](#)

## MapClear

Clears all entries in a map and returns the error status.

## Syntax

**INT MapClear(STRING sMapName)**

*sMapName:*

Name of the map to be cleared.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

If the map name is empty an “Invalid argument” error (274) will be raised and returned.

If the map does not exist a “Record not found” error (536) will be returned.

## Example

```
! Demonstrate MapClear.
STRING sMapName = MapOpen();
! sMapName is a randomly generated text that uniquely identifies the map
INT iMapValueSetResult = MapValueSet(sMapName, "SomeKey", "SomeValue");
! iMapValueSetResult will be set to 0 (NO ERROR)
INT iMapKeyCountResultExpectOne = MapKeyCount(sMapName);
! iMapKeyCountResultExpectOne will be set to 1
INT iMapClearResult = MapClear(sMapName);
! iMapClearResult will be set to 0 (NO ERROR)
INT iMapKeyCountResultExpectZero = MapKeyCount(sMapName);
! iMapKeyCountResultExpectZero will be set to 0
INT iMapCloseResult = MapClose(sMapName);
! iMapCloseResult will be set to 0 (NO ERROR)
```

```
! The map that is identified by sMapName is now closed and unavailable
```

[Map Functions](#)

### MapClose

Closes a map and returns the error status.

---

**Note:** There is no limit on the number of maps or map items you can create. However, a large number of maps may require a lot of memory. It is recommended that maps created in custom Cicode are destroyed using MapClose when they are no longer needed.

---

**Note:** If the map was created with a close callback, that callback is run before the map is internally closed, so that the map name can be used in the closed callback.

---

## Syntax

```
INT MapClose(STRING sMapName)
```

*sMapName*:

Name of the map to be closed.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

If the map name is empty an "Invalid argument" error (274) will be raised and returned.

If the map does not exist a "Record not found" error (536) will be returned.

## Example

```
! Demonstrate MapClose.  
STRING sMapName = MapOpen();  
! sMapName is a randomly generated text that uniquely identifies the map  
INT iMapCloseResult = MapClose(sMapName);  
! iMapCloseResult will be set to 0 (NO ERROR)  
! The map that is identified by sMapName is now closed and unavailable
```

## Related Functions

### MapExists

Checks for the existence of the map.

## Syntax

**INT MapExists(STRING sMapName)**

*sMapName:*

Name of the map.

## Return Value

TRUE if the map exists, or FALSE if not.

If the map or key name is empty an "Invalid argument" error (274) will be raised.

## Example

```
! Demonstrate MapExists.  
STRING sMapName = MapOpen();  
! sMapName is a randomly generated text that uniquely identifies the map  
INT iMapExistsResultExpectTrue = MapExists(sMapName);  
! iMapExistsResultExpectTrue will be set to TRUE (non-zero)  
INT iMapCloseResult = MapClose(sMapName);  
! The map that is identified by sMapName is now closed and unavailable  
INT iMapExistsResultExpectFalse = MapExists(sMapName);  
! iMapExistsResultExpectFalse will be set to FALSE (zero)
```

## Related Functions

### MapKeyCount

Use this function to retrieve the number of keys in a map.

## Syntax

```
INT MapKeyCount(STRING sMapName)
```

*sMapName*:

Name of the map.

## Return Value

The number of keys in the map, or a value less than 0 if an error is encountered.

If the map name is empty an "Invalid argument" error (274) will be raised.

## Example

```
! Demonstrate MapKeyCount.  
STRING sMapName = MapOpen();  
! sMapName is a randomly generated text that uniquely identifies the map  
INT iMapKeyCountResultExpectZero = MapKeyCount(sMapName);  
! iMapKeyCountResultExpectZero will be set to 0  
INT iMapValueSetResult = MapValueSet(sMapName, "SomeKey", "SomeValue");  
INT iMapKeyCountResultExpectOne = MapKeyCount(sMapName);  
! iMapKeyCountResultExpectOne will be set to 1  
INT iMapCloseResult = MapClose(sMapName);  
! The map that is identified by sMapName is now closed and unavailable
```

## Related Functions

## See Also

[Map Functions](#)

## MapKeyDelete

Use this function to delete a key and value from a map.

## Syntax

```
INT MapKeyDelete(STRING sMapName, STRING sKeyName)
```

*sMapName*:

Name of map.

*sKeyName*:

Name of key and value to be deleted.

## Return Value

0 (zero) if successful, otherwise an error code is returned.  
If the map name is empty an "Invalid argument" error (274) will be raised and returned.  
If the map or the key does not exist a "Record not found" error (536) will be returned.

## Example

```
! Demonstrate MapKeyDelete.
STRING sMapName = MapOpen();
! sMapName is a randomly generated text that uniquely identifies the map
INT iMapValueSetResult = MapValueSet(sMapName, "SomeKey", "SomeValue");
INT iMapKeyCountResultExpectOne = MapKeyCount(sMapName);
! iMapKeyCountResultExpectOne will be set to 1
INT iMapKeyDeleteResult = MapKeyDelete(sMapName, "SomeKey");
INT iMapKeyCountResultExpectZero = MapKeyCount(sMapName);
! iMapKeyCountResultExpectZero will be set to 0
INT iMapCloseResult = MapClose(sMapName);
! The map that is identified by sMapName is now closed and unavailable
```

## Related Functions

## See Also

[Map Functions](#)

## MapKeyExists

Use this function to check if a key exists in a map.

## Syntax

INT **MapKeyExists**(STRING *sMapName*, STRING *sKeyName*)

*sMapName*:

Name of map to get the value from.

*sKeyName*:

Name of the key to get the value from.

## Example

```
! Demonstrate MapKeyExists.
STRING sMapName = MapOpen();
! sMapName is a randomly generated text that uniquely identifies the map
```

```
INT iMapKeyExistsResultExpectFalse = MapKeyExists(sMapName, "SomeKey");
! iMapKeyExistsResultExpectFalse will be set to FALSE (zero)
INT iMapViewSetResult = MapValueSet(sMapName, "SomeKey", "SomeValue");
INT iMapKeyExistsResultExpectTrue = MapKeyExists(sMapName, "SomeKey");
! iMapKeyExistsResultExpectTrue will be set to TRUE (non-zero)
INT iMapCloseResult = MapClose(sMapName);
! The map that is identified by sMapName is now closed and unavailable
```

## Return Value

TRUE if the map exists, or FALSE if not.

If the map name is empty an "Invalid argument" error (274) will be raised.

## Related Functions

[MapClear](#), [MapClose](#), [MapOpen](#), [MapKeyCount](#), [MapKeyDelete](#), [MapKeyFirst](#), [MapViewGet](#), [MapKeyNext](#), [MapViewSet](#), [MapViewSet](#)

## See Also

[Map Functions](#)

## MapKeyFirst

Use this function to retrieve the first key in a map so that all the keys in a map can be discovered.

## Syntax

STRING **MapKeyFirst**(STRING *sMapName*)

*sMapName*:

Name of map to get the value from.

## Return Value

The first key in the map, if there are no keys in the map an empty string is returned.

If the map name is empty an "Invalid argument" error (274) will be raised.

**Note:** This key can then be used in [MapKeyNext](#) to discover all the property keys in the map.

## Example

```
! Demonstrate MapKeyFirst.
STRING sMapName = MapOpen();
! sMapName is a randomly generated text that uniquely identifies the map
INT iMapSetValueResult1 = MapSetValue(sMapName, "somekey", "somevalue");
INT iMapSetValueResult2 = MapSetValue(sMapName, "SomeKey", "SomeValue");
STRING sMapKeyFirstResult = MapKeyFirst(sMapName);
```

```
! sMapKeyFirstResult will be set to "SomeKey"
! This shows that the keys are visited in alphabetical order, and that
! the keys are case sensitive
INT iMapCloseResult = MapClose(sMapName);
! The map that is identified by sMapName is now closed and unavailable
```

## Related Functions

### MapKeyNext

Use this function to retrieve the next key after the supplied key in a map so that all the keys in a map can be discovered

## Syntax

```
STRING MapKeyNext(STRING sMapName, STRING sKeyName)
```

*sMapName*:

Name of map to retrieve the value from.

*sKeyName*:

Name of the key to retrieve the value for.

## Return Value

The next key if successful or, an empty string if no next key exists.

If the map name is empty an "Invalid argument" error (274) will be raised.

## Example

```
! Demonstrate MapKeyNext.
STRING sMapName = MapOpen();
! sMapName is a randomly generated text that uniquely identifies the map
INT iMapSetValueResult1 = MapSetValue(sMapName, "somekey", "somevalue");
INT iMapSetValueResult2 = MapSetValue(sMapName, "SomeKey", "SomeValue");
STRING sMapKeyFirstResult = MapKeyFirst(sMapName);
! sMapKeyFirstResult will be set to "SomeKey"
STRING sMapKeyNextResult = MapKeyNext(sMapName, sMapKeyFirstResult);
! sMapKeyNextResult will be set to "somekey"
! This shows that the keys are visited in ordinal order, and that
! the keys are case sensitive
INT iMapCloseResult = MapClose(sMapName);
```

! The map that is identified by sMapName is now closed and unavailable

## Related Functions

[MapClear](#), [MapClose](#), [MapOpen](#), [MapKeyCount](#), [MapKeyDelete](#), [MapKeyExists](#), [MapKeyFirst](#), [MapViewGet](#), [MapViewSet](#), [MapViewSet](#)

[Map Functions](#)

### MapOpen

Use this function to create a new map or to open an existing map.

**Note:** There is no limit on the number of maps or map items you can create. However, a large number of maps may require a lot of memory. It is recommended that maps created in custom Cicode are destroyed using MapClose when they are no longer needed.

## Syntax

STRING **MapOpen**(STRING *sMapName*, INT *nOpenMode*, STRING *sCloseCallback*)

*sMapName*:

Name of the map to create or open. The default name is an empty string. If name is empty, it will generate an available random name.

*nOpenMode*:

Indicates the open or create mode of the map. Modes include:

- Mode 0 - Create a new map. If a map with the same name exists an "Out of handles" error (271) will be raised.
- Mode 1 - Opens an existing map. if there is no map with that name a "Record not found" error (536) will be raised.
- Mode 2 – Open an existing map , or creates a new map if the map name does not exist. The error codes from modes 0 and 1 can occur.

*sCloseCallback*:

The function to call when this instance is closed.

## Return Value

Name of map if successful, otherwise an empty string will be returned.

If the map name is empty an "Invalid argument" error (274) will be raised.

If the open mode is less than 0 or greater than 2, an "Invalid argument" error (274) will be raised.

If an empty map name is supplied along with open mode 1, an "Invalid argument" error (274) will be raised.

## Example

```
! Demonstrate MapOpen.
STRING sMapName = MapOpen();
! sMapName is a randomly generated text that uniquely identifies the map
INT iMapCloseResult = MapClose(sMapName);
! The map that is identified by sMapName is now closed and unavailable

! Demonstrate MapOpen with a close callback
STRING sMapName = MapOpen("", 0, "MyCloseCallback");
! sMapName is a randomly generated text that uniquely identifies the map
INT iMapCloseResult = MapClose(sMapName);
! The map that is identified by sMapName is now closed and unavailable
! The function MyCloseCallback is called, but it may or may not be
! completed before the MapClose function returns.

! This is a MapClose callback function
! The callback must take one string argument which is the name of the
! map that is being closed.
FUNCTION MyCloseCallback(STRING sMapName)
! sMapName is a valid map for the duration of the callback, at the
! exit of the callback the memory is released and any subsequent
! use of the map will result in an error.
END
```

## Related Functions

### MapViewGet

Use this function to retrieve the value from a key in a map.

## Syntax

VARIANT **MapViewGet**(STRING *sMapName*, STRING *sKeyName*)

*sMapName*:

Name of map.

*sKeyName*:

Name of the key to retrieve the value from.

## Return Value

Value returned is a VARIANT that also contains QUALITY and TIMESTAMP components, otherwise an error code is returned.

If the map or key does not exist an "Invalid argument" error (274) is raised.

## Example

```
! Demonstrate MapValueGet.  
STRING sMapName = MapOpen();  
! sMapName is a randomly generated text that uniquely identifies the map  
INT iMapValueSetResult = MapValueSet(sMapName, "SomeKey", "SomeValue");  
STRING sMapViewGetResult = MapValueGet(sMapName, "SomeKey");  
! sMapViewGetResult will be set to "SomeValue"  
INT iMapCloseResult = MapClose(sMapName);  
! The map that is identified by sMapName is now closed and unavailable
```

## Related Functions

## See Also

[Map Functions](#)

## MapViewSet

Use this function to set a value of a map key.

## Syntax

INT **MapViewSet**(STRING *sMapName*, STRING *sKeyName*, VARIANT *Value* INT *nSetMode*)

*sMapName*:

Name of the map to create or open.

*sKeyName*:

Name of the key to set.

*Value*:

Name of the value to be set

*nSetMode*:

0 - Create a new property

1- Override an existing property

2 - Assign the value whether the key already exists or not. This is the default mode.

## Return Value

If the value is set correctly, the result is "No Error" (0), otherwise an error code is returned.  
If the map name or key name is empty, an "Invalid argument" error (274) will be raised and returned.  
If the map does not exist a "Record not found" error (536) will be returned.  
If the key does not exist and set mode is 1, a "Record not found" error (536) will be returned.  
If the key exists and set mode is 0, an "Out of handles" error (271) will be returned.

## Example

```
! Demonstrate MapValueSet.
STRING sMapName = MapOpen();
! sMapName is a randomly generated text that uniquely identifies the map
INT iMapValueSetResult = MapValueSet(sMapName, "SomeKey", "SomeValue");
STRING sMapValueGetResult = MapValueGet(sMapName, "SomeKey");
! sMapValueGetResult will be set to "SomeValue"
INT iMapCloseResult = MapClose(sMapName);
! The map that is identified by sMapName is now closed and unavailable
```

## Related Functions

## MapViewSetQuality

Use this function to set the quality of a property in a map.

## Syntax

**INT MapValueSetQuality(STRING *sMapName*, STRING *sKeyName*, QUALITY *Quality*)**

*sMapName*:

Name of the map.

*sKeyName*:

Name of the key to override the quality for

*Quality*:

Quality to override in an existing value. There is no default value. The QUALITY type is created using the QualityCreate function.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

If the map name or key name is empty, an "Invalid argument" error (274) will be raised and returned.

If the map does not exist or the key does not exist within the map a "Record not found" error (536) will be returned

## Example

```
! Demonstrate MapValueSetQuality.  
STRING sMapName = MapOpen();  
! sMapName is a randomly generated text that uniquely identifies the map  
INT iMapViewSetResult = MapValueSet(sMapName, "SomeKey", "SomeValue");  
QUALITY qVariableQualityResultExpectGood =  
VariableQuality(MapValueGet(sMapName, "SomeKey"));  
! qVariableQualityResultExpectGood is set to GOOD QUALITY (checked below)  
INT iQualityIsGoodResultExpectTrue =  
QualityIsGood(qVariableQualityResultExpectGood);  
! iQualityIsGoodResultExpectTrue is set to TRUE (non-zero)  
INT iMapViewSetQualityResult =  
MapViewSetQuality(sMapName, "SomeKey", QualityCreate(QUAL_BAD));  
! iMapViewSetQualityResult will be set to 0 (NO ERROR)  
QUALITY qVariableQualityResultExpectBad =  
VariableQuality(MapValueGet(sMapName, "SomeKey"));  
! qVariableQualityResultExpectBad is set to BAD QUALITY (checked below)  
INT iQualityIsGoodResultExpectFalse =  
QualityIsGood(qVariableQualityResultExpectBad);  
! iQualityIsGoodResultExpectFalse is set to FALSE (zero)  
INT iMapCloseResult = MapClose(sMapName);  
! The map that is identified by sMapName is now closed and unavailable
```

## Math and Trigonometry Functions

Following are mathematical or trigonometrical functions:

Abs	Gets the absolute value of a number.
ArcCos	Gets the arccosine of an angle.
ArcSin	Gets the arcsine of an angle.

ArcTan	Gets the arctangent of an angle.
Cos	Gets the cosine of an angle.
DegToRad	Converts an angle from degrees to radians.
Exp	Raises e to the power of a number.
Fact	Gets the factorial of a number.
HighByte	Gets the high-order byte of a two-byte integer.
HighWord	Gets the high-order word of a four-byte integer.
Ln	Gets the natural logarithm of a number.
Log	Gets the base 10 logarithm of a number.
LowByte	Gets the low-order byte of a two-byte integer.
LowWord	Gets the low-order word of a four-byte integer.
Max	Gets the higher of two numbers.
Min	Gets the lower of two numbers.
Pi	Gets the value of pi.
Pow	Raises a number to the power of another number.
RadToDeg	Converts an angle from radians to degrees.
Rand	Gets a random number.
Round	Rounds a number.
Sign	Gets the sign of a number.
Sin	Gets the sine of an angle.
Sqrt	Gets the square root of a number.
Tan	Gets the tangent of an angle.

## Abs

Calculates the absolute (positive) value of a number. The absolute value of a number is the number without its sign.

## Syntax

**Abs(*Number*)**

*Number*:

Any number.

## Return Value

The absolute (positive) value of *Number*.

## Related Functions

[Sign](#)

## Example

```
Variable=Abs(-67);
! Sets Variable to 67.
Variable=Abs(67);
! Sets Variable to 67.
```

## See Also

[Math and Trigonometry Functions](#)

## ArcCos

Calculates the arccosine of an angle.

## Syntax

**ArcCos(*Number*)**

*Number*

The cosine of the angle.

## Return Value

The arccosine (the angle, in radians) of *Number*.

## Related Functions

[Cos](#)

## Example

```
Variable=ArcCos(0.4);  
! Sets Variable to 1.1592...
```

## See Also

[Math and Trigonometry Functions](#)

## ArcSin

Calculates the arcsine of an angle.

## Syntax

**ArcSin(*Number*)**

*Number:*

The sine of the angle.

## Return Value

The arcsine (the angle, in radians) of *Number*.

## Related Functions

[Sin](#)

## Example

```
Variable=ArcSin(1);  
! Sets Variable to 1.5707...
```

## See Also

[Math and Trigonometry Functions](#)

## ArcTan

Calculates the arctangent of an angle.

## Syntax

**ArcTan(*Number*)**

*Number*:

The tangent of the angle.

## Return Value

The arctangent (the angle, in radians) of *Number*.

## Related Functions

[Tan](#)

## Example

```
Variable=ArcTan(0.4);  
! Sets Variable to 0.3805...
```

## See Also

[Math and Trigonometry Functions](#)

## Cos

Calculates the trigonometric cosine of an angle.

## Syntax

**Cos(*Angle*)**

*Angle*:

Any angle (in radians).

## Return Value

The cosine of *Angle*.

## Related Functions

[ArcCos](#)

## Example

```
Variable=Cos(0.7854);
```

```
! Sets Variable to 0.7071...
```

## See Also

[Math and Trigonometry Functions](#)

### DegToRad

Converts an angle from degrees to radians.

## Syntax

**DegToRad(*Angle*)**

*Angle*:

Any angle (in degrees).

## Return Value

The angle in radians.

## Related Functions

[RadToDeg](#)

## Example

```
Variable=DegToRad(180);  
! Sets Variable to 3.1415... (pi).
```

## See Also

[Math and Trigonometry Functions](#)

### Exp

Calculates the exponential of a number (natural logarithm base e).

## Syntax

**Exp(*Number*)**

*Number*:

Any number.

## Return Value

The exponential of *Number* (to the base e).

## Related Functions

[Log](#)

## Example

```
Variable=Exp(1);  
! Sets Variable to 2.7182...
```

## See Also

[Math and Trigonometry Functions](#)

## Fact

Calculates the factorial of a number.

## Syntax

**Fact(*Number*)**

*Number*:

Any number.

## Return Value

The factorial of *Number*.

## Example

```
Variable=Fact(6);  
! Sets Variable to 720 (that is 720=1x2x3x4x5x6).
```

## See Also

[Math and Trigonometry Functions](#)

## HighByte

Gets the high-order byte of a two-byte integer.

## Syntax

**HighByte**(*TwoByteInteger*)

*TwoByteInteger*:

A two-byte integer.

## Return Value

The high-order byte (that is | X | - | )

## Related Functions

[LowByte](#), [HighWord](#), [LowWord](#)

## Example

```
Variable=HighByte(0x5678);  
! Sets Variable to 0x56.
```

## See Also

[Math and Trigonometry Functions](#)

## HighWord

Gets the high-order word of a four-byte integer.

## Syntax

**HighWord**(*FourByteInteger*)

*FourByteInteger*:

A four-byte integer.

## Return Value

The high-order word (that is | X | X | - | - | )

## Related Functions

[LowWord](#), [HighByte](#), [LowByte](#)

## Example

```
Variable=HighWord(0x12345678);
```

```
! Sets Variable to 0x1234.
```

## See Also

[Math and Trigonometry Functions](#)

### Ln

Calculates the natural (base e) logarithm of a number.

## Syntax

**Ln(Number)**

*Number:*

Any number.

## Return Value

The natural (base e) logarithm of *Number*.

## Related Functions

[Log](#)

## Example

```
Variable=Ln(2);  
! Sets Variable to 0.6931...
```

## See Also

[Math and Trigonometry Functions](#)

### Log

Calculates the base 10 logarithm of a number.

## Syntax

**Log(Number)**

*Number:*

Any number.

## Return Value

The base 10 logarithm of *Number*.

## Related Functions

[Ln](#)

## Example

```
Variable=Log(100);  
! Sets Variable to 2 (that is 100=10 to the power of 2).
```

## See Also

[Math and Trigonometry Functions](#)

## LowByte

Gets the low-order byte of a two-byte integer.

## Syntax

**LowByte**(*TwoByteInteger*)

*TwoByteInteger*:

A two-byte integer.

## Return Value

The low-order byte (that is | - | X |)

## Related Functions

[HighByte](#), [LowWord](#), [HighWord](#)

## Example

```
Variable=LowByte(0x5678);  
! Sets Variable to 0x78.
```

## See Also

[Math and Trigonometry Functions](#)

## LowWord

Gets the low-order word of a four-byte integer.

## Syntax

**LowWord(*FourByteInteger*)**

*FourByteInteger*:

A four-byte integer.

## Return Value

The low-order word (that is | - | - | X | X |)

## Related Functions

[HighByte](#), [LowByte](#), [HighWord](#)

## Example

```
Variable=LowWord(0x12345678);  
! Sets Variable to 0x5678
```

## See Also

[Math and Trigonometry Functions](#)

## Max

Gets the higher of two numbers.

## Syntax

**Max(*Number1*, *Number2*)**

*Number1*:

The first number.

*Number2*:

The second number.

## Return Value

The higher of numbers *Number1* and *Number2*.

## Related Functions

[Min](#)

## Example

```
Variable=Max(24,12);  
! Sets Variable to 24.
```

## See Also

[Math and Trigonometry Functions](#)

## Min

Returns the lower of two numbers.

## Syntax

**Min**(*Number1*, *Number2*)

*Number1*:

The first number.

*Number2*:

The second number.

## Return Value

The lower of numbers *Number1* and *Number2*.

## Related Functions

[Max](#)

## Example

```
Variable=Min(24,12);  
! Sets Variable to 12.
```

## See Also

[Math and Trigonometry Functions](#)

## Pi

Gets the value of pi (the ratio of the circumference of a circle to its diameter).

## Syntax

**Pi()**

## Return Value

The value of pi.

## Example

```
Variable=Pi();
! Sets Variable to 3.1415...
```

## See Also

[Math and Trigonometry Functions](#)

## Pow

Calculates  $x$  to the power of  $y$ .

## Syntax

**Pow( $X, Y$ )**

$X$ :

The base number.

$Y$ :

The exponent.

## Return Value

$X$  to the power of  $Y$ .

## Related Functions

[Exp](#)

## Example

```
Variable=Pow(5,3);
```

```
! Sets Variable to 125.
```

## See Also

[Math and Trigonometry Functions](#)

### RadToDeg

Converts an angle from radians to degrees.

## Syntax

**RadToDeg(*Angle*)**

*Angle*:

Any angle (in degrees).

## Return Value

The angle in degrees.

## Related Functions

[DegToRad](#)

## Example

```
Variable=RadToDeg(Pi());  
! Sets Variable to 180.
```

## See Also

[Math and Trigonometry Functions](#)

### Rand

Generates a random number between 0 and a specified maximum number less one.

The **Rand** function is zero-based, so the resultant number generated will range from zero to one less than the number provided in the *Maximum* argument.

## Syntax

**Rand(*Maximum*)**

*Maximum*:

The maximum number. This number needs to be between 2 and 32767 (inclusive).

## Return Value

A random number of integer type.

## Example

```
Variable=Rand(101);
! Sets Variable to a random number from 0 to 100.
// To create a random number between 0 and 1 with 2 decimal places,
divide the above variable by 100, as shown here: //
Variable = Variable/100;
```

## See Also

[Math and Trigonometry Functions](#)

## Round

Rounds a number to a specified number of decimal places.

## Syntax

**Round**(*Number*, *Places*)

*Number*:

The floating-point number to round.

*Places*:

The number of decimal places.

## Return Value

The number rounded to *Places* decimal places.

## Example

```
IF round(rTag,2) = 15.60 THEN
    tag2 = 5
END
```

## See Also

[Math and Trigonometry Functions](#)

## Sign

Gets the sign of a number.

## Syntax

**Sign(Number)**

*Number:*

Any number.

## Return Value

The sign of *Number*.

## Related Functions

[Abs](#)

## Example

```
Variable=Sign(100);
! Sets Variable to 1.
Variable=Sign(-300);
! Sets Variable to -1.
Variable=Sign(0);
! Sets Variable to 0.
```

## See Also

[Math and Trigonometry Functions](#)

## Sin

Calculates the trigonometric sine of an angle.

## Syntax

**Sin(Angle)**

*Angle:*

Any angle (in radians).

## Return Value

The sine of *Angle*.

## Related Functions

[ArcSin](#)

## Example

```
Variable=Sin(0.7854);  
! Sets Variable to 0.7071...
```

## See Also

[Math and Trigonometry Functions](#)

## Sqrt

Gets the square root of a number.

## Syntax

**Sqrt(*Number*)**

*Number*:

Any positive number.

## Return Value

The square root of *Number*.

## Related Functions

[Pow](#)

## Example

```
Variable=Sqrt(4);  
! Sets Variable to 2.
```

## See Also

[Math and Trigonometry Functions](#)

## Tan

Calculates the trigonometric tangent of an angle.

## Syntax

**Tan(*Angle*)**

*Angle*:

Any angle (in degrees).

## Return Value

The tan of *Angle*.

## Related Functions

[ArcTan](#)

## Example

```
Variable=Tan(1);  
! Sets Variable to 1.5574
```

## See Also

## Menu Functions

The following functions allow you to access the contents of the menu configuration database in a tree-like format, and change the contents of the tree. Be reminded that changes made to the menu tree will not be persisted back to the menu configuration database.

<a href="#">MenuGetChild</a>	Returns the handle to the child node with the specified name.
<a href="#">MenuGetFirstChild</a>	Returns the handle to the first child of a menu node.
<a href="#">MenuGetGenericNode</a>	Returns the handle to the base node of the menu tree for the generic pages.
<a href="#">MenuGetNextChild</a>	Returns the next node that shares the same parent.
<a href="#">MenuGetNodeByPath</a>	Returns a menu handle corresponding to a menu item.
<a href="#">MenuGetPageNode</a>	Returns the handle to the base node of the menu tree of a specified page.
<a href="#">MenuGetParent</a>	Returns the parent node of the menu item.
<a href="#">MenuGetPrevChild</a>	Returns the previous node that shares the same parent.
<a href="#">MenuGetWindowNode</a>	Returns the handle to the root node for a given window.

<a href="#">MenuNodeAddChild</a>	Dynamically adds a new item to the menu at runtime.
<a href="#">MenuNodeGetCurr</a>	Gets the handle of a menu node when an associated command is called.
<a href="#">MenuNodeGetDepth</a>	Returns the depth of a specified menu node within a menu hierarchy.
<a href="#">MenuNodeGetProperty</a>	Return the item value of the specified menu node.
<a href="#">MenuNodeGetTargetPage</a>	Returns the target page for a specified menu node.
<a href="#">MenuNodeHasCommand</a>	Checks whether the menu node has a valid Cicode command associated with it.
<a href="#">MenuNodeIsDisabled</a>	Checks whether the menu node is disabled by evaluating its DisabledWhen Cicode expression.
<a href="#">MenuNodeGetExpanded</a>	Returns the expansion state value of the specified menu node.
<a href="#">MenuNodeIsHidden</a>	Checks whether the menu node is hidden by evaluating its HiddenWhen Cicode expression.
<a href="#">MenuNodeRemove</a>	Remove the menu node from the menu tree.
<a href="#">MenuNodeRunCommand</a>	Run the associated command for a menu node.
<a href="#">MenuNodeSetDisabledWhen</a>	Set the DisabledWhen expression for a newly added node.
<a href="#">MenuNodeSetExpanded</a>	Sets the expansion state value of the specified menu node.
<a href="#">MenuNodeSetHiddenWhen</a>	Set the HiddenWhen expression for a newly added node.
<a href="#">MenuNodeSetProperty</a>	Set the item value of the specified menu node.
<a href="#">MenuReload</a>	Reload base Menu Configuration from the compiled database.

## See Also

### MenuGetChild

Returns the handle to the child node with the specified name.

## Syntax

**MenuGetChild(*hParent*, *sName*)**

*hParent*:

Handle to the parent node in the menu tree.

*sName*:

The name of the child Menu node requested.

## Return Value

The handle of the child node with the requested name, or -1 if unsuccessful.

## Related Functions

[MenuGetFirstChild](#), [MenuGetGenericNode](#), [MenuGetNextChild](#), [MenuGetPageNode](#), [MenuGetParent](#),

## See Also

[Menu Functions](#)

## MenuGetFirstChild

Returns the handle to the first child of a menu node.

## Syntax

**MenuGetFirstChild(*hNode*)**

*hNode*:

The handle to the parent node in the menu tree.

## Return Value

The handle to the first child node of a menu node, or -1 if unsuccessful.

## Related Functions

[MenuGetChild](#), [MenuGetGenericNode](#), [MenuGetNextChild](#), [MenuGetPageNode](#), [MenuGetParent](#),  
[MenuGetPrevChild](#), [MenuGetWindowNode](#), [MenuNodeAddChild](#), [MenuNodeGetCurr](#), [MenuNodeGetDepth](#),

## See Also

[Menu Functions](#)

### MenuGetGenericNode

Returns the handle to the base node of the menu tree for the generic pages. Its child nodes represent the menu items that do not have a page specified in the menu configuration database.

## Syntax

**MenuGetGenericNode([*bCreate*])**

*bCreate*:

Determines if the node should be created if it does not exist. Defaults to 0, do not create.

## Return Value

The handle to the base node of the menu tree, or -1 if it cannot find the node.

## Related Functions

[MenuGetChild](#), [MenuGetFirstChild](#), [MenuGetNextChild](#), [MenuGetPageNode](#), [MenuGetParent](#),  
[MenuGetPrevChild](#), [MenuGetWindowNode](#), [MenuNodeAddChild](#), [MenuNodeGetCurr](#), [MenuNodeGetDepth](#),  
[MenuNodeGetExpanded](#), [MenuNodeGetProperty](#), [MenuNodeGetTargetPage](#), [MenuNodeHasCommand](#),  
[MenuNodeIsDisabled](#), [MenuNodeIsHidden](#), [MenuNodeRemove](#), [MenuNodeRunCommand](#),  
[MenuNodeSetDisabledWhen](#), [MenuNodeSetHiddenWhen](#), [MenuNodeSetProperty](#), [MenuReload](#)

## See Also

[Menu Functions](#)

### MenuGetNextChild

Returns the next node that shares the same parent.

## Syntax

**MenuGetNextChild(*hChild*)**

*hChild*:

Handle to the current node in the menu tree

## Return Value

The handle to next node that shares the same parent, or -1 if unsuccessful.

## Related Functions

[MenuGetChild](#), [MenuGetFirstChild](#), [MenuGetGenericNode](#), [MenuGetPageNode](#), [MenuGetParent](#),  
[MenuGetPrevChild](#), [MenuGetWindowNode](#), [MenuNodeAddChild](#), [MenuNodeGetCurr](#), [MenuNodeGetDepth](#),

[MenuNodeIsDisabled](#), [MenuNodeIsHidden](#), [MenuNodeRemove](#), [MenuNodeRunCommand](#),  
[MenuNodeSetDisabledWhen](#), [MenuNodeSetHiddenWhen](#), [MenuNodeSetProperty](#), [MenuReload](#)

## See Also

[Menu Functions](#)

## MenugetNodeByPath

Returns a menu handle corresponding to a menu item expressed as a string path in the format  
<level>.<level>.<level>.<level>.

## Syntax

MenugetNodeByPath(INT *hMenuNode*, STRING *sMenuPath*)

*hMenuNode*

The menu to which the specified menu path belongs. Root menu node returned from [MenuGetPageNode\(\)](#).

*sMenuPath*

The menu path for which to get the handle.

## Return Value

Returns a menu handle for use with other Plant SCADA menu functions.

## Example

```
MenugetNodeByPath(hNavigationMenu, "MyPlant.MyArea.Page1")
```

## Related Functions

[MenuGetChild](#), [MenuGetFirstChild](#), [MenuGetGenericNode](#), [MenuGetNextChild](#), [MenuGetPageNode](#),  
[MenuGetParent](#), [MenuGetPrevChild](#), [MenuGetWindowNode](#), [MenuNodeAddChild](#), [MenuNodeGetCurr](#),  
[MenuNodeGetDepth](#), [MenuNodeGetExpanded](#), [MenuNodeGetProperty](#), [MenuNodeGetTargetPage](#),  
[MenuNodeHasCommand](#), [MenuNodeIsDisabled](#), [MenuNodeIsHidden](#), [MenuNodeRemove](#),  
[MenuNodeRunCommand](#), [MenuNodeSetDisabledWhen](#), [MenuNodeSetHiddenWhen](#), [MenuNodeSetProperty](#),  
[MenuReload](#)

## See Also

[Menu Functions](#)

### MenuGetPageNode

Returns the handle to the menu tree for a specified page. Its child nodes represent the menu items that have the particular page specified in the menu configuration database.

## Syntax

**MenuGetPageNode(*sPage* [, *nMode*])**

*sPage*:

The name of the page for which to return the menu tree handle.

*nMode*:

The mode to use for generating the menu handle for the page:

0 - Return the base node for the menu tree for the specified page if it exists, otherwise return -1 (do not create). Default value.

1 - Return the base node for the menu tree for the specified page. Create the menu tree if it does not already exist.

2 - Return a new duplicate of the menu tree for the specified page if it exists, otherwise return -1. Automatically dispose of the menu tree on page close.

3 - Return a new duplicate of the menu tree for the specified page if it exists, otherwise return -1. Do not automatically dispose of the menu tree. Call [MenuNodeRemove\(\)](#) to remove menu tree.

## Return Value

The handle of the menu tree, or -1 if no menu tree exists for a specified page.

## Related Functions

[MenuGetChild](#), [MenuGetFirstChild](#), [MenuGetGenericNode](#), [MenuGetNextChild](#), [MenuGetParent](#), [MenuGetPrevChild](#), [MenuGetWindowNode](#), [MenuNodeAddChild](#), [MenuNodeGetCurr](#), [MenuNodeGetDepth](#), [MenuNodeGetExpanded](#), [MenuNodeGetProperty](#), [MenuNodeGetTargetPage](#), [MenuNodeHasCommand](#), [MenuNodeIsDisabled](#), [MenuNodeIsHidden](#), [MenuNodeRemove](#), [MenuNodeRunCommand](#), [MenuNodeSetDisabledWhen](#), [MenuNodeSetHiddenWhen](#), [MenuNodeSetProperty](#), [MenuReload](#)

## See Also

[Menu Functions](#)

### MenuGetParent

Returns the parent node of the menu item.

## Syntax

**MenuGetParent(*hNode*)**

*hNode*:

Handle to the current node in the menu tree.

## Return Value

The handle to parent menu node of the given menu item, or -1 if unsuccessful.

## Related Functions

[MenuGetChild](#), [MenuGetFirstChild](#), [MenuGetGenericNode](#), [MenuGetNextChild](#), [MenuGetPageNode](#),  
[MenuGetPrevChild](#), [MenuGetWindowNode](#), [MenuNodeAddChild](#), [MenuNodeGetCurr](#), [MenuNodeGetDepth](#),  
[MenuNodeGetExpanded](#), [MenuNodeGetProperty](#), [MenuNodeGetTargetPage](#), [MenuNodeHasCommand](#),  
[MenuNodeIsDisabled](#), [MenuNodeIsHidden](#), [MenuNodeRemove](#), [MenuNodeRunCommand](#),  
[MenuNodeSetDisabledWhen](#), [MenuNodeSetHiddenWhen](#), [MenuNodeSetProperty](#), [MenuReload](#)

## See Also

[Menu Functions](#)

## MenuGetPrevChild

Returns the previous node that shares the same parent.

## Syntax

**MenuGetPrevChild(*hChild*)**

*hChild*:

Handle to the current node in the menu tree.

## Return Value

The handle to previous node that shares the same parent, or -1 if unsuccessful.

## Related Functions

[MenuGetChild](#), [MenuGetFirstChild](#), [MenuGetGenericNode](#), [MenuGetNextChild](#), [MenuGetPageNode](#),  
[MenuGetParent](#), [MenuGetWindowNode](#), [MenuNodeAddChild](#), [MenuNodeGetCurr](#), [MenuNodeGetDepth](#),  
[MenuNodeGetExpanded](#), [MenuNodeGetProperty](#), [MenuNodeGetTargetPage](#), [MenuNodeHasCommand](#),  
[MenuNodeIsDisabled](#), [MenuNodeIsHidden](#), [MenuNodeRemove](#), [MenuNodeRunCommand](#),  
[MenuNodeSetDisabledWhen](#), [MenuNodeSetHiddenWhen](#), [MenuNodeSetProperty](#), [MenuReload](#)

## See Also

[Menu Functions](#)

### MenuGetWindowNode

Returns the handle to the root node for a given window. This menu node is dynamically created for each page instance. Its child nodes represent the menu items for the generic pages merged with the ones specific to this page.

## Syntax

**MenuGetWindowNode(*hWin*)**

*hWin*:

The window number of the desired window. You can call WinNumber() to get the window number of the page that calls this Cicode function.

## Return Value

The handle to the root node of a given window, or -1 if unsuccessful.

## Related Functions

[MenuGetChild](#), [MenuGetFirstChild](#), [MenuGetGenericNode](#), [MenuGetNextChild](#), [MenuGetPageNode](#), [MenuGetParent](#), [MenuGetPrevChild](#), [MenuNodeAddChild](#), [MenuNodeGetCurr](#), [MenuNodeGetDepth](#), [MenuNodeGetExpanded](#), [MenuNodeGetProperty](#), [MenuNodeGetTargetPage](#), [MenuNodeHasCommand](#), [MenuNodeIsDisabled](#), [MenuNodeIsHidden](#), [MenuNodeRemove](#), [MenuNodeRunCommand](#), [MenuNodeSetDisabledWhen](#), [MenuNodeSetHiddenWhen](#), [MenuNodeSetProperty](#), [MenuReload](#)

## See Also

[Menu Functions](#)

### MenuNodeAddChild

Dynamically add a new item to the menu at runtime. Be reminded that the changes are for the current session only and will not be persisted to the \_Pagemen.RDB file.

Be reminded that changes made to the menu tree will not be persisted back to the menu configuration database.

## Syntax

**MenuNodeAddChild(*hParent*, *sName*, *sCommandName* [, *sCommandArgs*] [, *sSymbol*] [, *iOrder*])**

*hParent*:

Handle of the parent node to add the new menu item under.

*sName*:

The string label of the new menu item.

*sCommandName*:

Specifies the name of the Cicode function to run.

*sCommandArgs*:

Specifies the parameters of the Cicode function to run.

*sSymbol*:

The symbol to be associated with the menu item.

*iOrder*:

The relative position in the menu for new item.

## Return Value

The handle of the new node, or -1 if unsuccessful.

## Related Functions

[MenuGetChild](#), [MenuGetFirstChild](#), [MenuGetGenericNode](#), [MenuGetNextChild](#), [MenuGetPageNode](#), [MenuGetParent](#), [MenuGetPrevChild](#), [MenuGetWindowNode](#), [MenuNodeGetCurr](#), [MenuNodeGetDepth](#), [MenuNodeGetExpanded](#), [MenuNodeGetProperty](#), [MenuNodeGetTargetPage](#), [MenuNodeHasCommand](#), [MenuNodeIsDisabled](#), [MenuNodeIsHidden](#), [MenuNodeRemove](#), [MenuNodeRunCommand](#), [MenuNodeSetDisabledWhen](#), [MenuNodeSetHiddenWhen](#), [MenuNodeSetProperty](#), [MenuReload](#)

## See Also

[Menu Functions](#)

## MenuNodeGetCurr

Each menu node can have a Command associated with it when a menu is configured. This function allows you to get the handle of the menu node when this associated command is called.

**Note:** This function should only be used with expressions or Cicode functions invoked from the Command field of a menu configuration record.

## Syntax

**MenuNodeGetCurr( )**

## Return Value

The handle of the menu node.

## Related Functions

[MenuGetChild](#), [MenuGetFirstChild](#), [MenuGetGenericNode](#), [MenuGetNextChild](#), [MenuGetPageNode](#), [MenuGetParent](#), [MenuGetPrevChild](#), [MenuGetWindowNode](#), [MenuNodeAddChild](#), [MenuNodeGetDepth](#), [MenuNodeGetExpanded](#), [MenuNodeGetProperty](#), [MenuNodeGetTargetPage](#), [MenuNodeHasCommand](#), [MenuNodeIsDisabled](#), [MenuNodeIsHidden](#), [MenuNodeRemove](#), [MenuNodeRunCommand](#), [MenuNodeSetDisabledWhen](#), [MenuNodeSetHiddenWhen](#), [MenuNodeSetProperty](#), [MenuReload](#)

## Example

```
// Assume the following Cicode function is set to the Command field of a menu configuration record
FUNCTION MyMenuCommand()
    INT hNode = MenuNodeGetCurr(); // Get the current menu node that runs this command
    // Get more information from the menu record
    STRING sTargetPage = MenuNodeGetProperty(hNode, 13);
    // Display the page
    PageDisplay(sTargetPage);
END
```

## See Also

[Menu Functions](#)

## MenuNodeGetDepth

Returns the depth of a specified menu node within a menu hierarchy.

## Syntax

**MenuNodeGetDepth(*hNode*)**

*hNode*:

Handle of the menu node.

## Return Value

The depth of the specified node within the menu hierarchy. For example, 0 indicates it is on the root node of the menu, 1 indicates one level below the root node, and so on.

## Related Functions

[MenuGetChild](#), [MenuGetFirstChild](#), [MenuGetGenericNode](#), [MenuGetNextChild](#), [MenuGetPageNode](#), [MenuGetParent](#), [MenuGetPrevChild](#), [MenuGetWindowNode](#), [MenuNodeAddChild](#), [MenuNodeGetCurr](#), [MenuNodeGetExpanded](#), [MenuNodeGetProperty](#), [MenuNodeGetTargetPage](#), [MenuNodeHasCommand](#), [MenuNodeIsDisabled](#), [MenuNodeIsHidden](#), [MenuNodeRemove](#), [MenuNodeRunCommand](#), [MenuNodeSetDisabledWhen](#), [MenuNodeSetHiddenWhen](#), [MenuNodeSetProperty](#), [MenuReload](#)

## See Also

[Menu Functions](#)

### MenuNodeGetProperty

Return the item value of the specified menu node.

## Syntax

**MenuNodeGetProperty(*hNode*, *iField*)**

*hNode*:

Handle to the current node in the menu tree.

*iField*:

Field for which you want the value:

0 - Name of menu item.

1 - Icon symbol to be associated with the menu item.

2 - Privilege level required to run the command, otherwise the menu item is disabled.

3 - Area level required to run the command, otherwise the menu item is disabled.

4 - Disabled Style. Allows different display style for a disabled menu item.

5 - Checked setting. Whether the menu item will display a check box next to the label.

6 - Width. Specifies the menu item width in pixels.

7 - Comment.

8 - Cluster.

9 - Equipment.

10 - Expansion state value stored by .

11 - Order.

12 - Page.

13 - Target page of the menu item.

101-108 - Custom 1 to Custom 8.

## Return Value

The value for the specified menu node field.

### MenuNodeGetTargetPage

Returns the target page for a specified menu node.

## Syntax

**MenuNodeGetTargetPage(*hNode*)**

*hNode*:

Handle of the menu node. If not specified, the handle of the menu node will be determined through its association with the command that is currently being called. Each menu node can have a Command associated with it when a menu is configured.

## Return Value

The name of the target page for the specified node.

### MenuNodeHasCommand

Checks whether the menu node has a valid Cicode command associated with it.

## Syntax

**MenuNodeHasCommand(*hNode*)**

*hNode*:

Handle of node to check.

## Return Value

1 if the menu node has a valid Cicode command, 0 if the menu node has no Cicode command.

## Related Functions

[MenuGetChild](#), [MenuGetFirstChild](#), [MenuGetGenericNode](#), [MenuGetNextChild](#), [MenuGetPageNode](#),

[Menu Functions](#)

## MenuNodeIsDisabled

Checks whether the menu node is disabled by evaluating its DisabledWhen Cicode expression.

## Syntax

**MenuNodeIsDisabled(*hNode*)**

*hNode*:

Handle of node to check.

## Return Value

1 if menu node DisabledWhen expression evaluates to true, 0 if menu node DisabledWhen expression evaluates to false.

## Related Functions

[MenuGetChild](#), [MenuGetFirstChild](#), [MenuGetGenericNode](#), [MenuGetNextChild](#), [MenuGetPageNode](#),  
[MenuGetParent](#), [MenuGetPrevChild](#), [MenuGetWindowNode](#), [MenuNodeAddChild](#), [MenuNodeGetCurr](#),

[MenuNodeHasCommand](#), [MenuNodeIsHidden](#), [MenuNodeRemove](#), [MenuNodeRunCommand](#),  
[MenuNodeSetDisabledWhen](#), [MenuNodeSetHiddenWhen](#), [MenuNodeSetProperty](#), [MenuReload](#)

## Example

```
INT hNode = MenuNodeFirstChild(hParent);
IF (MenuNodeIsDisabled(hNode)) THEN
    ! set the menu item graphic state to disabled
END
```

## See Also

[Menu Functions](#)

### MenuNodeGetExpanded

Gets the expansion state value of the specified menu node in number. The expansion state value is user defined can be any integer value. The value is set by [MenuNodeSetExpanded](#) function and the initial value is zero(0).

## Syntax

**MenuNodeGetExpanded(*hNode*)**

*hNode*:

Handle to the current node in the menu tree.

## Return Value

The expansion state value to set for the Menu node or -1 if unsuccessful.

## Related Functions

[MenuGetChild](#), [MenuGetFirstChild](#), [MenuGetGenericNode](#), [MenuGetNextChild](#), [MenuGetPageNode](#), [MenuGetParent](#), [MenuGetPrevChild](#), [MenuGetWindowNode](#), [MenuNodeAddChild](#), [MenuNodeGetCurr](#), [MenuNodeGetDepth](#), [MenuNodeGetProperty](#), [MenuNodeGetTargetPage](#), [MenuNodeHasCommand](#), [MenuNodeIsDisabled](#), [MenuNodeIsHidden](#), [MenuNodeRemove](#), [MenuNodeRunCommand](#), [MenuNodeSetDisabledWhen](#), [MenuNodeSetHiddenWhen](#), [MenuNodeSetProperty](#), [MenuReload](#)

## Example

```
MenuNodeSetExpanded(100, 99)
//Put 99 as an expansion state of the menu node handle 100
MenuNodeGetExpanded(100)
//This will return 99 that is stored by the previous call
```

## See Also

[Menu Functions](#)

### MenuNodeIsHidden

Checks whether the menu node is hidden by evaluating its HiddenWhen Cicode expression.

## Syntax

**MenuNodeIsHidden(*hNode*)**

*hNode:*

Handle of node to check.

## Return Value

1 if menu node HiddenWhen expression evaluates to true, 0 if menu node HiddenWhen expression evaluates to false.

## Related Functions

[MenuGetChild](#), [MenuGetFirstChild](#), [MenuGetGenericNode](#), [MenuGetNextChild](#), [MenuGetPageNode](#), [MenuGetParent](#), [MenuGetPrevChild](#), [MenuGetWindowNode](#), [MenuNodeAddChild](#), [MenuNodeGetCurr](#), [MenuNodeGetDepth](#), [MenuNodeGetExpanded](#), [MenuNodeGetProperty](#), [MenuNodeGetTargetPage](#), [MenuNodeHasCommand](#), [MenuNodesDisabled](#), [MenuNodeRemove](#), [MenuNodeRunCommand](#), [MenuNodeSetDisabledWhen](#), [MenuNodeSetHiddenWhen](#), [MenuNodeSetProperty](#), [MenuReload](#)

## Example

```
INT hNode = MenuNodeFirstChild(hParent);
IF (MenuNodeIsHidden(hNode)) THEN
    ! set the menu item graphic state to hidden
END
```

## See Also

[Menu Functions](#)

## MenuNodeRemove

Remove the menu node from the menu tree.

Be reminded that changes made to the menu tree will not be persisted back to the menu configuration database.

## Syntax

**MenuNodeRemove(*hNode*)**

*hNode:*

Handle of node to remove.

## Return Value

Zero (0) if node successfully removed. -1 if *hNode* is an invalid menu handle.

## Related Functions

[MenuGetChild](#), [MenuGetFirstChild](#), [MenuGetGenericNode](#), [MenuGetNextChild](#), [MenuGetPageNode](#), [MenuGetParent](#), [MenuGetPrevChild](#), [MenuGetWindowNode](#), [MenuNodeAddChild](#), [MenuNodeGetCurr](#), [MenuNodeGetDepth](#), [MenuNodeGetExpanded](#), [MenuNodeGetProperty](#), [MenuNodeGetTargetPage](#), [MenuNodeHasCommand](#), [MenuNodesDisabled](#), [MenuNodesHidden](#), [MenuNodeRunCommand](#), [MenuNodeSetDisabledWhen](#), [MenuNodeSetHiddenWhen](#), [MenuNodeSetProperty](#), [MenuReload](#)

## See Also

[Menu Functions](#)

### MenuNodeRunCommand

Run the associated command for a menu node.

## Syntax

**MenuNodeRunCommand(*hNode*)**

*hNode*:

Handle of node to run command.

## Return Value

No error(0) on success. Bad handle specified (269) if *hNode* does not refer to a valid node.

## Related Functions

[MenuGetChild](#), [MenuGetFirstChild](#), [MenuGetGenericNode](#), [MenuGetNextChild](#), [MenuGetPageNode](#), [MenuGetParent](#), [MenuGetPrevChild](#), [MenuGetWindowNode](#), [MenuNodeAddChild](#), [MenuNodeGetCurr](#), [MenuNodeGetDepth](#), [MenuNodeGetExpanded](#), [MenuNodeGetProperty](#), [MenuNodeGetTargetPage](#), [MenuNodeHasCommand](#), [MenuNodesDisabled](#), [MenuNodesHidden](#), [MenuNodeRemove](#), [MenuNodeSetDisabledWhen](#), [MenuNodeSetHiddenWhen](#), [MenuNodeSetProperty](#), [MenuReload](#)

[Menu Functions](#)

### MenuNodeSetDisabledWhen

Set the DisabledWhen expression for a newly added node. Be aware this function only works for menu nodes added with [MenuNodeAddChild\(\)](#). The DisabledWhen expression may only be set once for a node.

Be reminded that changes made to the menu tree will not be persisted back to the menu configuration database.

## Syntax

**MenuNodeSetDisabledWhen(*hNode*, *sDisabledWhenName* [, *sDisabledWhenArgs*] [, *iDisabledStyle*])**

*hNode*:

Handle of node to run command

*sDisabledWhenName*:

Cicode function for DisabledWhen expression. The function needs to return an INT.

*sDisabledWhenArgs*:

Cicode parameters for DisabledWhen expression. Only supports static arguments.

*iDisabledStyle*:

Disabled Style. Allows different display styles for a disabled menu item.

## Return Value

No Error(0) on success, Bad handle specified (269) if hNode does not refer to a valid node, Invalid argument passed (274) if DisabledWhen Cicode has already been set or is not a valid expression.

## Related Functions

[MenuGetChild](#), [MenuGetFirstChild](#), [MenuGetGenericNode](#), [MenuGetNextChild](#), [MenuGetPageNode](#),

[MenuNodeGetDepth](#), [MenuNodeGetExpanded](#), [MenuNodeGetProperty](#), [MenuNodeGetTargetPage](#),  
[MenuNodeHasCommand](#), [MenuNodesDisabled](#), [MenuNodesHidden](#), [MenuNodeRemove](#),  
[MenuNodeRunCommand](#), [MenuNodeSetHiddenWhen](#), [MenuNodeSetProperty](#), [MenuReload](#)

## Example

```
INT hNode = MenuNodeAddChild((hParent, "LogIn", "LogIn");
INT Error = MenuNodeSetDisabledWhen(hNode, "UserInfo", "0", 1);
```

## See Also

[Menu Functions](#)

## MenuNodeSetExpanded

Set the expansion state value of the specified menu node in number. The expansion state value is defined by project designer and can be any integer value. The initial value is zero(0). It is not recommended to use -1 for the expansion state value though because this number indicates an error for [MenuNodeGetExpanded](#) function.

**Note:** Changes made to the menu tree will not be persisted back to the menu configuration database.

## Syntax

**MenuNodeSetExpanded(*hNode*, *iValue*)**

*hNode:*

Handle to the current node in the menu tree.

*iValue:*

The expansion state value to set for the Menu node.

## Return Value

Zero (0) if successful. -1 if hNode is invalid or an error code for any other error.

## Related Functions

[MenuGetChild](#), [MenuGetFirstChild](#), [MenuGetGenericNode](#), [MenuGetNextChild](#), [MenuGetPageNode](#), [MenuGetParent](#), [MenuGetPrevChild](#), [MenuGetWindowNode](#), [MenuNodeAddChild](#), [MenuNodeGetCurr](#), [MenuNodeGetDepth](#), [MenuNodeGetExpanded](#), [MenuNodeGetProperty](#), [MenuNodeGetTargetPage](#), [MenuNodeHasCommand](#), [MenuNodesDisabled](#), [MenuNodesHidden](#), [MenuNodeRemove](#), [MenuNodeRunCommand](#), [MenuNodeSetDisabledWhen](#), [MenuNodeSetHiddenWhen](#), [MenuNodeSetProperty](#), [MenuReload](#)

## Example

```
MenuNodeSetExpanded(100, 99)
//Put 99 as an expansion state of the menu node handle 100
MenuNodeGetExpanded(100)
//This will return 99 that is stored by the previous call
```

## See Also

[Menu Functions](#)

## MenuNodeSetHiddenWhen

Set the HiddenWhen expression for a newly added node. Be aware this function only works for menu nodes added with [MenuNodeAddChild\(\)](#). The HiddenWhen expression may only be set once for a node.

Be reminded that changes made to the menu tree will not be persisted back to the menu configuration database.

## Syntax

**MenuNodeSetHiddenWhen**(*hNode*, *sHiddenWhenName* [, *sHiddenWhenArgs*])

*hNode:*

Handle of node to run command.

*sHiddenWhenName:*

Cicode function for HiddenWhen expression. The function needs to return an INT.

*sHiddenWhenArgs:*

Cicode parameters for HiddenWhen expression. Only supports static arguments.

## Return Value

No Error (0) on success, Bad handle specified (269) if hNode does not refer to a valid node, or Invalid argument passed (274) if HiddenWhen Cicode has already been set or is not a valid expression.

## Related Functions

[MenuGetChild](#), [MenuGetFirstChild](#), [MenuGetGenericNode](#), [MenuGetNextChild](#), [MenuGetPageNode](#),

[MenuNodeHasCommand](#), [MenuNodesDisabled](#), [MenuNodesHidden](#), [MenuNodeRemove](#),  
[MenuNodeRunCommand](#), [MenuNodeSetDisabledWhen](#), [MenuNodeSetProperty](#), [MenuReload](#)

## Example

```
INT hNode = MenuNodeAddChild(hParent, "LogIn", "LogIn");
INT Error = MenuNodeSetHiddenWhen(hNode, "UserInfo", "0");
```

## See Also

[Menu Functions](#)

## MenuNodeSetProperty

Set the item value of the specified menu node.

Be reminded that changes made to the menu tree will not be persisted back to the menu configuration database.

## Syntax

**MenuNodeSetProperty**(*hNode*, *iField*, *sValue*)

*hNode*:

Handle to the current node in the menu tree.

*iField*:

Field for which you want to set the value:

0 - Name of menu item.

1 - Icon symbol to be associated with the menu item.

2 - Privilege level required to run the command, otherwise the menu item is disabled.

3 - Area level required to run the command, otherwise the menu item is disabled.

4 - Disabled Style. Allows different display style for a disabled menu item.

5 - Checked setting. Whether the menu item will display a check box next to the label.

6 - Width. Specifies the menu item width in pixels.

7 - Comment.

8 - Cluster.

9 - Equipment.

10 - Expansion state value.

13 - Target page for the menu item.

101 to108 - Custom 1 to Custom 8.

*sValue*:

The item value to set for the Menu node.

---

**Note:** The Cluster and Equipment fields are not validated at runtime.

---

## Return Value

Zero (0) if successful. -1 if *hNode* or *iField* is invalid. An error code for others.

[Menu Functions](#)

## MenuReload

Reload base Menu Configuration from the compiled database.

Be reminded that the menu configuration loaded on the currently displayed page will not change until the page is refreshed. By default, menu configuration is automatically reloaded whenever a page is displayed.

## Syntax

**MenuReload()**

## Return Value

None.

## Miscellaneous Functions

Following are miscellaneous functions.

<a href="#">AreaCheck</a>	Determines whether the current user has access to a specified area.
<a href="#">Assert</a>	Verifies a particular condition is true, or halts the task.
<a href="#">Beep</a>	Beeps the speaker or sound card in the computer.
<a href="#">CitectInfo</a>	Gets information about a Plant SCADA variable.
<a href="#">CodeTrace</a>	Traces Cicode into the Kernel and the SYSLOG.DAT file.
<a href="#">DebugBreak</a>	Causes a breakpoint error to start the Cicode Debugger.
<a href="#">DebugMsg</a>	In-line debug messages of user Cicode.
<a href="#">DebugMsgSet</a>	Enables/disables the DebugMsg function.
<a href="#">DelayShutdown</a>	Causes Plant SCADA to shut down after a specified period
<a href="#">DisplayRuntimeManager</a>	Starts and displays Plant SCADA Runtime Manager.
<a href="#">DumpKernel</a>	Dumps Kernel data to the Kernel.dat file.
<a href="#">EngToGeneric</a>	Converts a variable into generic scale format.
<a href="#">Exec</a>	Executes an application or PIF file.
<a href="#">GetArea</a>	Gets the current viewable areas.
<a href="#">GetEnv</a>	Gets an environment variable.
<a href="#">GetLogging</a>	Gets the current value for one or more logging

	parameters.
InfoForm	Displays graphics object help information for the AN closest to the cursor.
InfoFormAn	Displays graphics object help information for an AN.
Input	Gets text input from the operator.
IntToReal	Converts an integer variable into a real (floating point) number.
KerCmd	Executes a command in a kernel window.
KernelQueueLength	Obtains the number of rows in a queue.
KernelTableInfo	Provides a consistent method of accessing items within a Kernel Table.
KernelTableItemCount	Obtains the number of rows in a Kernel Table.
LanguageFileTranslate	Translates an ASCII file into the local language.
Message	Displays a message box on the screen.
ParameterGet	Gets the value of a system parameter.
ParameterPut	Updates a system parameter.
ProcessIsClient	Determines if the currently executing process contains a Client component.
ProcessIsServer	Determines if the currently executing process contains a particular server component.
ProcessRestart	Restarts the current process in which Cicode is running.
ProductInfo	Returns information about the Plant SCADA product.
ProjectInfo	Returns information about a particular project, which is identified by a project enumerated number.
ProjectRestartGet	Gets the path to the project to be run the next time Plant SCADA is restarted.
ProjectRestartSet	Sets the path to the project to be run the next time Plant SCADA is restarted.
ProjectSet	Sets the name or path of the current project.
Prompt	Displays a message in the prompt line.

<a href="#">Pulse</a>	Pulses (jogs) a variable tag every two seconds.
<a href="#">ServerDumpKernel</a>	Dumps Kernel data to the KERNEL.DAT file either on a local server or on a remote server.
<a href="#">ServiceGetList</a>	Gets information about services running in the component calling this function.
<a href="#">SetArea</a>	Sets the current viewable areas.
<a href="#">SetLanguage</a>	This function is now obsolete.
<a href="#">SetLogging</a>	Adjusts logging parameters while online.
<a href="#">Shutdown</a>	Ends Plant SCADA's operation.
<a href="#">ShutdownForm</a>	Displays a form that allows an operator to shut down the Plant SCADA system.
<a href="#">ShutdownMode</a>	Gets the mode of the shutdown/restart.
<a href="#">SwitchConfig</a>	Switches focus to the Plant SCADA configuration application.
<a href="#">TestRandomWave</a>	Generates a random wave.
<a href="#">TestSawWave</a>	Generates a saw wave.
<a href="#">TestSinWave</a>	Generates a sine wave.
<a href="#">TestSquareWave</a>	Generates a square wave.
<a href="#">TestTriangWave</a>	Generates a triangular wave.
<a href="#">Toggle</a>	Toggles a digital tag on or off.
<a href="#">TraceMsg</a>	Displays a message in the Kernel and Debugger debug windows.
<a href="#">Version</a>	Gets the version number of the Plant SCADA software.

## See Also

[Cicode Function Categories](#)

[Using Cicode Functions](#)

## AreaCheck

Determines whether the current user has access to a specified area.

## Syntax

**AreaCheck(*Area*)**

*Area*:

The area number (0 - 255)

## Return Value

TRUE (1) if the user has access to the *Area* or FALSE (0) if not.

## Related Functions

[GetArea](#), [GetPriv](#)

## Example

```
IsArea = AreaCheck(5);
```

## See Also

[Miscellaneous Functions](#)

## Assert

Verifies that the specified expression is TRUE. If then expression is FALSE, the current task will be halted. This is useful to help prevent the execution of code you do not want to run in the event an error has been detected.

This function can be used in a debug mode, where the FALSE assertion will be logged to the Kernel and SysLog.DAT, with the time, date, Cicode file name, and line number. Additionally the operator will be prompted with a dialog. The debug mode can be set by using the [\[Code\]DebugMessage](#) parameter or DebugMsgSet() function.

---

**Note:** If you have the "Plant SCADA Runtime will start debugger on hardware errors" option set in the Cicode Editor, the Debugger will start with the position before the Halt() instruction. You need to 'step over' this command if you want to continue debugging the function that called the Assert().

---

## Syntax

**Assert(*bCondition*)**

*bCondition*:

The boolean expression. This expression needs to evaluate to TRUE (1) or FALSE (0).

## Return Value

None. However, if the assertion tests as FALSE, error 347 is generated.

## Related Functions

[Halt](#), [DebugMsg](#), [DebugMsgSet](#), [CodeTrace](#), [TraceMsg](#), [ErrLog](#)

## Example

```
INT
FUNCTION FileDisplayEx(STRING sFileName);
    INT hFile;
    hFile = FileOpen(sFileName, "r");
    Assert(hFile <> -1);
    ...
    FileClose(hFile);
    RETURN 0;
END
```

## See Also

[Miscellaneous Functions](#)

## Beep

Beeps the internal speaker or sound card (installed in the computer). If you use the internal speaker on your computer, the function does not return until the sound has completed. If you use a sound card, the function returns immediately and the sound plays in the background.

Use the Windows Control Panel to set up waveforms.

## Syntax

**Beep(*nSound*)**

*nSound*:

The type of sound:

-1 - Standard beep

0 - Default beep waveform

1 - Critical stop waveform

2 - Question waveform

3 - Exclamation waveform

4 - Asterisk waveform

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[DspPlaySound](#)

## Example

```
/* Beeps the speaker with the default waveform. */  
Beep(0);
```

## See Also

[Miscellaneous Functions](#)

## CitectInfo

Gets information about a Plant SCADA variable. This function returns internal statistics and other information about the Plant SCADA runtime system.

**Note:** This function is a non-blocking function and can only access data contained within the calling process; consequently it cannot return data contained in a different server process. This function is not redirected automatically by Plant SCADA runtime. If you want to make a call from one process to return data in another, use `MsgRPC()` to make a remote procedure call on the other process. Alternatively, include the server process that has the information that `CitectInfo` requires in the calling process.

## Syntax

`CitectInfo(sGroup, sName, sType)`

### **sGroup:**

The name of the group to which the variable belongs. Valid group names are: "General", "Port", "IODevice", "Network", "Stats", "Memory", "Disk", "Queue" or "Security".

### **sName:**

The name of the variable. This name depends on `sGroup`:

"General" - the name is ignored.

"Port" - the name of the I/O port configured in the database (with the Ports database). The port information is only valid for an I/O server. If the port name is "total", the total statistics for the I/O server are returned.

"IODevice" - the name of the I/O device configured in the I/O devices database.

"Network" - the name is ignored.

"Stats" - The name of the statistics buffer or Statistical Information Record (SIR):

- "Alarm Proc" - Alarm Processing (includes Digital, Analog, Advanced and High Resolution alarms).
- "Citect n" - The Plant SCADA window where n is the window number (returned from the `WinNumber()` function)
- "Code n" - The user Cicode task (thread) where n is the task handle (returned from the `TaskHnd()` function)
- "Reset" - Reset the Plant SCADA statistics.
- "Elapsed Time MS" - The elapsed time since statistics have been reset. Returns -1 if more than 20 days has

elapsed.

"Memory" - the measurement used

- 0 = bytes
- KB = kilobytes
- MB = megabytes
- GB = gigabytes

"Disk" - The disk drive to access:

- 0 = The current drive
- 3 = C:
- 4 = D: and so on.

"Queue" - The name of the queue.

**sType:**

The type of information to get, depending on *sGroup*:

"General" - General statistics:

- 0 - CPU usage
- 1 - Plant SCADA Kernel cycles per second
- 2 - Plant SCADA Kernel tasks per second
- 3 - Plant SCADA Kernel boot time
- 4 - Plant SCADA Kernel running time (in seconds)
- 5 - Plant SCADA startup time
- 6 - Plant SCADA running time in seconds
- 7 - Not supported in v7.10 or later
- 8 - Total read requests
- 9 - Total read requests per second
- 10 - Total write requests
- 11 - Total write requests per second
- 12 - Total Physical read requests
- 13 - Total Physical read requests per second
- 14 - Total Physical write requests
- 15 - Total Physical write requests per second
- 16 - Total Blocked read requests
- 17 - Total Blocked write requests
- 18 - Total Digital read requests
- 19 - Total Register read requests
- 20 - Total Digital read requests per second
- 21 - Total Register read requests per second
- 22 - Total Cache reads count
- 23 - Total Cache reads %

24 - Overall Average response time (ms)  
25 - Overall Minimum response time (ms)  
26 - Overall Maximum response time (ms)  
27 - Request sample for response times  
28 - Static point count is no longer supported. Calling the function with parameter 28 returns a value of 0 and a hardware alarm is raised.  
29 - Dynamic point count currently in use

30 - Number of pending read requests from the device  
31 - Number of pending write requests to the device  
32 - Determines if Plant SCADA Kernel window is open  
33 - Percentage of the CPU used by the current Plant SCADA process  
34 - Total CPU time spent by the current Plant SCADA process in milliseconds  
35 - Total number of handles opened by the current Plant SCADA process  
36 - Total number of threads owned by the current Plant SCADA process

"Port" - Port information for the I/O Server:

0 - Read requests  
1 - Write requests  
2 - Physical read requests  
3 - Physical write requests  
4 - Cached read requests  
5 - Cached write requests  
6 - Blocked read requests  
7 - Blocked write requests  
8 - Read requests per second  
9 - Write requests per second  
10 - Error count  
11 - Read bytes counter  
12 - Channel usage %  
13 - Read bytes per second  
14 - Statistics, minimum read time  
15 - Statistics, maximum read time  
16 - Statistics, average read time  
17 - Statistics, time of samples  
18 - Statistics, number of sample

100 - 119 - Driver specific counter values. Plant SCADA drivers can maintain up to 20 unique counters that can be accessed via this function. They are zero based, indexed from 100 to 119. If a value is not defined or maintained by the driver, 0 is returned for the value of the counter.

"IODevice" - I/O device information for the I/O device:

0 - Client side status:

- 1 = Running - Client is either talking to an online IO device or talking to a scheduled device that is not currently connected but has a valid cache
- 2 = Standby - Client is talking to an online standby IO device
- 4 = Starting - Client is talking to an IO device that is attempting to come online
- 8 = Stopping - Client is talking to an IO device that is in the process of stopping
- 16 = Offline - Client is pointing to an IO device that is currently offline
- 32 = Disabled - Client is pointing to a device that is disabled
- 66 = Standby write - Client is talking to an I/O device configured as a standby write device

1 - I/O Server status:

- 1 = Running - I/O Server is either talking to an online IO device or talking to a scheduled device that is not currently connected but has a valid cache
- 2 = Standby - I/O Server is talking to an online standby IO device
- 4 = Starting - I/O Server is talking to an IO device that is attempting to come online
- 8 = Stopping - I/O Server is talking to an IO device that is in the process of stopping
- 16 = Offline - I/O Server is pointing to an IO device that is currently offline
- 32 = Disabled - I/O Server is pointing to a device that is disabled
- 66 = Standby write - I/O Server is talking to an I/O device configured as a standby write device

2 - If this I/O device is a standby device

3 - Last generic error

4 - Last driver error

5 - Error count

6 - Initialization count

7 - Statistics, minimum read time

8 - Statistics, maximum read time

9 - Statistics, average read time

10 - Statistics, number of samples

"Network" - Network statistical information:

0 - Read Network Control Blocks (NCBs)

1 - Maximum pending read NCBs

2 - Minimum pending read NCBs

3 - Current pending read NCBs

4 - Number of short read NCBs

5 - Write NCBs

6 - Maximum pending write NCBs

7 - Minimum pending write NCBs

8 - Current pending write NCBs

9 - Number of short write NCBs

10 - Total NCBs

11 - Maximum pending total NCBs

12 - Minimum pending total NCBs

13 - Current pending total NCBs

14 - Number of short total NCBs

15 - Minimum send response time in milliseconds

16 - Maximum send response time in milliseconds

17 - Average send response time in milliseconds

18 - Send packet count

"Stats" - Statistical information:

0 - Minimum time between code executions (cycles)

1 - Maximum time between code executions (cycles)

2 - Average time between code executions (cycles)

3 - Total cycle time in milliseconds

4 - Minimum time to execute the code in milliseconds

5 - Maximum time to execute the code in milliseconds

6 - Average time to execute the code in milliseconds

7 - Total execute time in milliseconds

"Memory" - Memory information:

0 - Free virtual memory

1 - Free windows system resources as %

2 - Free Physical Memory

3 - Memory Paging File Size

4 - Total Physical Memory

5 - Total % of Physical Memory Used

6 - Total working set size counter for current Plant SCADA process

7 - Private bytes counter of current Plant SCADA process

"Disk" - Disk information:

0 - Free disk space in bytes

1 - Total disk space in bytes

2 - Free disk space in kilobytes

3 - Total disk space in kilobytes

4 - Free disk space in megabytes

5 - Total disk space in megabytes

"Queue" - Queue information:

0 - Returns the length of the queue from the process that this is being called on.

"Security" - Encryption information:

0 - Returns the encryption status:

- 0 = Insecure

- 1 = Mixed

- 2 = Encrypted.

## Return Value

The type of information (as an integer).

## Related Functions

[IODeviceInfo](#), [WinNumber](#), [TaskHnd](#)

## Example

```
! Get free memory
FreeMemory = CitectInfo("Memory", "", 0);
! Get free disk space on C:
FreeDisk = CitectInfo("Disk", 3, 0);
! Get max cycle time for digital alarms
MaxCycleTime = CitectInfo("Stats","Digital Alm","1");
```

## See Also

[Miscellaneous Functions](#)

## CodeTrace

Traces Cicode into the Kernel and the SYSLOG.DAT file. Use this function for finding bugs in your Cicode. It will trace the functions called, the arguments to those functions, and their return values. It will also trace any errors, writes to the I/O devices, and task state changes.

**Note:** Use this function only during system development; it can cause excessive loading on the CPU.

### UNINTENDED EQUIPMENT OPERATION

Only use the CodeTrace() function during system development and testing. This function is not intended for use in an operational system.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

## Syntax

**CodeTrace(*hTask*, *nMode*)**

*hTask*:

The Cicode task handle as returned from TaskHnd() function or any of the following special values:

0 - Foreground Cicode.

-2 - The next created task.

-3 - New created tasks.

-4 - All tasks.

*nMode:*

The mode of the trace:

0 - Tracing off

1 - Trace user Cicode functions calls

2 - Trace built-in function calls

4 - Trace errors

8 - Trace writes to the I/O devices

16 - Trace task state changes

-1 - All modes (except 0)

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[Assert](#), [TaskHnd](#), [DebugMsg](#), [DebugMsgSet](#), [TraceMsg](#), [ErrLog](#)

## Example

```
// Start tracing errors
CodeTrace(TaskHnd(), 4);
...
// Stop tracing
CodeTrace(TaskHnd(), 0);
// trace functions in new task
CodeTrace(-2, 1 + 2);
TaskNew("MyFunc", "data", 0);
```

## See Also

[Miscellaneous Functions](#)

## DebugBreak

Causes a breakpoint exception error to occur (error number 342). This allows programmers to trap invalid states in their Cicode. If the Cicode Editor is not running, and the **Plant SCADA Runtime will start debugger on hardware errors** option is set (**Debug** menu - **Options**), the Debugger will be started. When the debugger starts, the correct Cicode file, function, and line will be displayed.

## Syntax

**DebugBreak()**

## Return Value

None.

## Related Functions

[DspKernel](#), [KerCmd](#), [DumpKernel](#), [TraceMsg](#)

## Example

```
!Check to see that rSpan is greater than zero else cause a break.  
If rSpan equals 0 it would cause a Divide by Zero hardware error  
anyway.  
IF rSpan > 0 THEN  
    rCalcRate = iAmount/rSpan;  
ELSE  
    DebugBreak();  
END
```

## See Also

[Miscellaneous Functions](#)

## DebugMsg

Provides in-line debug messages of user Cicode, to the Kernel, Debugger Debug window, and the SysLog.DAT file. This function can be enabled or disabled with the [\[Code\]DebugMessage](#) parameter or [DebugMsgSet\(\)](#) function at runtime.

## Syntax

**DebugMsg(*sMessage*)**

*sMessage*:

The debugging message to log. Be sure to enclose this message in double quotes ("").

## Return Value

None.

## Related Functions

[Assert](#), [DebugMsgSet](#), [CodeTrace](#), [TraceMsg](#), [ErrLog](#)

## Example

INT

```
FUNCTION
FileDisplayEx(STRING sFileName);
    INT hFile;
    hFile = FileOpen(sFileName, "r");
    DebugMsg("When opening file " + sFileName + ", the handle was:
    " + IntToStr(hFile));
    ...
    FileClose(hFile);
    RETURN 0;
END
```

## See Also

[Miscellaneous Functions](#)

## DebugMsgSet

Enables/disables the DebugMsg() logging functionality. It also controls whether logging is enabled for the Assert() function. This function also sets the [\[Code\]DebugMessage](#) parameter appropriately.

## Syntax

**DebugMsgSet(*nMode*)**

*nMode*:

The logging mode:

0 - Disable logging.

1 - Enable logging.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[Assert](#), [DebugMsg](#)

## Example

Buttons

Text	Debug Enable
Command	DebugMsgSet(1)
Comment	Enable debug logging

## See Also

[Miscellaneous Functions](#)

### DelayShutdown

Terminates Plant SCADA's operation after the specified delay period (in milliseconds). This function is suitable to be called by the CTAPI. The delay period enables the user to close the connection between the CTAPI and third-party applications before Plant SCADA shuts down.

## Syntax

**DelayShutdown(*Delay*)**

*Delay*:

The period (in milliseconds) after which Plant SCADA will shut down.

## Return Value

No return value.

## Example

```
DelayShutdown(10 000)
!Terminates Plant SCADA's operation after 10 seconds
```

## See Also

[Miscellaneous Functions](#)

### DisplayRuntimeManager

This function will start the Plant SCADA Runtime Manager if it is not already running, otherwise it will just bring the Plant SCADA Runtime Manager to the foreground.

## Syntax

**DisplayRuntimeManager()**

## Return Value

0 (zero) if successful, otherwise an error is returned.

## See Also

[Miscellaneous Functions](#)

## DumpKernel

Dumps Kernel data to the KERNEL.DAT file. Instead of creating a new file subsequent calls to this function will append Kernel data to the KERNEL.DAT file.

## Syntax

**DumpKernel(*iMode*, *sName*)**

*iMode*:

The Kernel data to dump:

0x0001	Dump general statistics.
0x0002	Dump the task.
0x0004	Dump the I/O device.
0x0008	Dump the driver.
0x0010	Dump netstat. (This mode is deprecated and no longer active in version 7.10 or later.)
0x0020	Dump the table.
0x0040	Dump the queue.
0x0100	Dump list of current SCADA parameter settings
0x4000	Dump in verbose mode.
0x8000	Dump kernel data in non-verbose mode. To dump data in verbose mode, set <i>iMode</i> to 0xc000 (0x8000 + 0x4000).

You can select any one of the above modes or may add them together to get more than one type of information. For example, to dump driver and I/O device data in verbose mode, set *iMode* to 0x400c (0x0004 + 0x0008 + 0x4000). Using 0x4000 on its own will dump no data, it needs to be combined with another mode.

*sName*:

The queue or table name (if "", returns data for all queues or tables). Only valid if *iMode* is 0x0020 and 0x0040.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DspKernel](#), [KerCmd](#), [TraceMsg](#)

## Example

```
DumpKernel(0x8000, "");  
!Dump the Kernel data
```

## See Also

[Miscellaneous Functions](#)

## EngToGeneric

Gets a variable in the Plant SCADA generic scale format. Plant SCADA uses this scale to display trends. It calls this function automatically for trends defined in the project. If you want to display a trend using Cicode you need to call this function.

## Syntax

**EngToGeneric**(*Value*, *EngLow*, *EngHigh*)

*Value*:

The value to convert to the Plant SCADA generic scale format.

*EngLow*:

The engineering units zero scale.

*EngHigh*:

The engineering units full scale.

## Return Value

The variable (in the range 0 - 32000).

## Related Functions

[DspBar](#), [DspTrend](#)

## Example

```
/* Using trend definition 5 at AN20, display the value of Tag1 on  
Pen1 of the trend. Tag1 has an engineering scale of 0 to 100. */  
DspBar(20,5,EngToGeneric(Tag1,0,100));
```

## See Also

[Miscellaneous Functions](#)

## Exec

Executes an application, LNK file or PIF file (32 bit system only). The application or command starts up and continues to run in parallel with Plant SCADA.

This function can return while the application is still starting up, so you should use the Sleep() function to allow the application enough time to start.

**Note:** Users can run this function only if their Allow Exec role is set to TRUE in the Security | Roles view **and** the [Security]BlockExec parameter is set to 0. For more information about the Allow Exec role, refer to [\[Security\]BlockExec](#).

## Syntax

**Exec**(*Command* [, *Mode*] )

*Command*:

The operating system command to execute (maximum of 255 characters).

*Mode*:

The mode of the window:

1 - Normal

3 - Maximized

6 - Minimized

If you do not enter a mode, the default mode is 1.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

Sleep

## Example

```
Exec("c:\winnt\system32\mspaint.exe");
! Starts up the Paint application with a normal window.
Exec("cmd /c mkdir c:\test");
! Uses the DOS shell to create a new directory
```

You need to quote paths and applications passed to the exec function (using ^" to embed quotes) so that the function can be executed correctly when long file names are used. For example:

```
Exec(PathToStr("^^" + "[BIN] :\Ctcicode") + "^" ^" +
PathToStr("[RUN] :\cicode.ci") + "^")
```

## See Also

[Miscellaneous Functions](#)

## GetArea

Gets the current logged-in areas.

## Syntax

**GetArea()**

## Return Value

The login area groups as an integer that represents a group handle. If this group is modified, the actual login areas do not change.

## Related Functions

[SetArea](#)

## Example

```
! If the current areas are 1, 5 and 20:  
hGrp=GetArea();  
Str=GrpToStr(hGrp);  
! sets Str to "1,5,20".
```

## See Also

[Miscellaneous Functions](#)

## GetEnv

Gets a DOS environment variable.

## Syntax

**GetEnv(*sName*)**

*sName*:

The name of the environment variable. The length of the name should not exceed 255 characters.

## Return Value

The DOS environment variable (as a string).The return value returns up to 255 characters and is truncated if exceeds.

## Example

```
/* Get the current DOS path. */
sPath = GetEnv("Path");
```

## See Also

[Miscellaneous Functions](#)

### GetLogging

Gets the current value for logging parameters.

The parameters you can query include the following:

- [Debug]DriverTrace
- [Debug]SysLogSize
- [Debug]Priority
- [Debug]CategoryFilterMode
- [Debug]CategoryFilter
- [Debug]SeverityFilterMode
- [Debug]SeverityFilter
- [Debug]LogShutDown
- [Debug]DebugAllTrans
- [Debug]EnableLogging
- [IOServer]RedundancyDebug
- [General]Verbose
- [General]VerboseToSysLog
- [CtAPI]Debug

## Syntax

**GetLogging(Section, Name)**

*Section*:

The INI section name.

*sName*:

The system parameter name.

## Return Value

If the function succeeds, the value is returned as a string. An empty string is returned if an error occurs. To get extended error information, call [IsError\(\)](#).

## Related Functions

[SetLogging](#)

## See Also

[Miscellaneous Functions](#)

## InfoForm

Displays graphics object information for the object under the mouse pointer. If there is no object directly under the mouse pointer, it displays information for the nearest object. Each tag associated with the object is displayed, along with its raw and engineering values and a button that displays the details from the Variable Tags settings. The function also displays the Cicode expression, with any result that the expression has generated.

This function only supports the display of simple Cicode expressions.

---

**Note:** [DsplInfoNew](#), [InfoForm](#) and [InfoFormAn](#) will not work if the parameter [General]SymbolicInfo = 0.

---

## Syntax

**InfoForm(*Mode*)**

*Mode*:

For security purposes, the Write button on the information form displayed by this function can be disabled.

0 - The **Write** button on the displayed information form will be available and will function normally.

1 - The **Write** button will not be shown.

If you omit the mode, the default mode is 0.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[InfoFormAn](#)

## Example

System Keyboard

Key Sequence	AnHelp
Command	InfoForm();
Comment	Display graphics object help for the AN closest to the cursor

## See Also

[Miscellaneous Functions](#)

### InfoFormAn

Displays graphics object information for a specified AN. This function displays each tag associated with the object, along with its raw and engineering values and a button that displays the details from the Variable Tags form. The function also displays the Cicode expression, with any result that the expression has generated.

**Note:** [DsplInfoNew](#), [InfoForm](#) and [InfoFormAn](#) will not work if the parameter [\[General\]SymbolicInfo = 0](#).

## Syntax

**InfoFormAn(***nAN* [, *Mode*] **)**

*nAN*:

The AN of the graphics object for which information is displayed.

*Mode*:

For security purposes, the Write button on the information form displayed by this function can be disabled.

0 - The **Write** button on the displayed information form will be available and will function normally.

1 - The **Write** button will not be shown.

If you omit the mode, the default mode is 0.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[InfoForm](#)

## Example

System Keyboard

Key Sequence	### AnHelp
Command	InfoFormAn(Arg1);
Comment	Display graphics object help for a specified AN

## See Also

[Miscellaneous Functions](#)

## Input

Displays a dialog box in which an operator can input a single value. The dialog box has a title, a prompt, and a single edit field. For multiple inputs, use the [Form Functions](#).

This function is a blocking function. It will block the calling Cicode task until the operation is complete.

## Syntax

**Input**(*Title*, *Prompt*, *Default*)

*Title*:

The title of the input box.

*Prompt*:

The prompt text.

*Default*:

The default text that the operator can edit or replace.

## Return Value

The edit field entry (as a string). If the user presses the **Cancel** button, an empty string is returned and the [IsError\(\)](#) function returns the error code 299.

## Related Functions

[Message](#), [FormNew](#)

## Example

```
/* Shut down Plant SCADA if the user inputs "Yes". */
STRING sStr;
sStr=Input("Shutdown","Do you wish to shutdown?","Yes");
IF sStr="Yes" THEN
Shutdown();
END
```

## See Also

[Miscellaneous Functions](#)

## IntToReal

Converts an integer into a real (floating point) number.

When calling statements such as comparison or arithmetic operations that involve a mixture of variables of REAL and INT data types, there is no need to explicitly convert the variable of INT data type to REAL data type using the IntToReal function. Plant SCADA will automatically convert variables of INT data type to REAL data type before the operation is carried out.

However, if the expression only consists of variables of INT data type, the result of the expression will remain as INT data type and be subjected to its limitations such as integer overflow and wraparound. This does not change even if the expression is to be assigned to a variable of REAL data type.

If you want to increase the range of the expression, you will need to convert at least one of its operands to REAL data type using the IntToReal function (see Example 2 below).

## Syntax

**IntToReal(Number)**

*Number:*

The integer to convert.

## Return Value

The real number.

## Related Functions

[RealToStr](#), [StrToInt](#)

## Example 1

```
! Sets Variable to 45.0
Variable=IntToReal(45);
! Sets Variable to -45.0
Variable=IntToReal(-45);
```

## Example 2

```
INT nVar1 = 1000000001;
INT nVar2 = 2000000002;
REAL rVar1 = 1.00001;
REAL rVar2 = 0.0;

// rVar2 = 1000000002.00001, IntToReal is not needed when operands are mixture of INT and
REAL data types
rVar2 = nVar1 + rVar1;

// rVar2 = -1294967293.0, result is wrapped around due to range overflow of integer data
type
rVar2 = nVar1 + nVar2;

// rVar2 = 3000000003.0, result is promoted to REAL data type when one of the INT operands
is converted
rVar2 = nVar1 + IntToReal(nVar2);
```

## See Also

[Converting and Formatting Cicode Variables](#)

## KerCmd

Executes a command in a Kernel window.

## Syntax

**KerCmd(*Window*, *sCommand*)**

*Window*:

The name of the Kernel window.

*sCommand*:

The command to execute in the Kernel window.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DspKernel](#), [TraceMsg](#), [DumpKernel](#)

## See Also

[Miscellaneous Functions](#)

## KernelQueueLength

Obtains the number of records in a queue.

## Syntax

**KernelQueueLength(*sName*)**

*sName*:

The name of the queue, which can be enumerated by the page queue kernel command.

## Return Value

This function returns the Length value of the page queue command.

## Related Functions

None

## See Also

[Miscellaneous Functions](#)

## KernelTableInfo

Provides a consistent method of accessing items within Kernel Table.

## Syntax

**KernelTableInfo(*sTable*, *sRecord*, *sField*)**

*sTable*:

The name of the table. The following tables are supported:

<b>sTable</b>	<b>sRecord</b>	<b>sField</b>	<b>Notes</b>
Bufferpool	The value of the 'Name' field	Mode, Size, Total, Free, InUse, Max, Peak, Short, Gets, TotErr, Grow, Shrink	These names are unique when each Bufferpool is created
CiCode	The value of the 'Name' field or the 'HND' field. If the user specifies a number as the sRecord we will assume it is a handle, otherwise we will look it up as a string name	Name, HND, State, CPU_Time, Poll_Time, Slice	The CiCode function TaskNew exposes the handle. That is why record access by handle is acceptable for this table. The name field may or may not be unique (if you run the same CiCode task twice with different parameters). Accessing by 'Name' will not succeed if there are duplicates
Task	The value of the 'Name' field	Mode, Hnd, State, Prty, Cpu, Min, Max, Avg, Count	None
Tran	The value of the TRAN 'Name' field	Name, Node, Type, Mode, Hnd, Cnt, Send, Rec, Wait, Stack, Service, State, Login, ReconnectCount, UpTime, TotalTxRxBytes	The counters ReconnectCount, UpTime and TotalTxRxBytes can be viewed in verbose mode on Table Tran page of the Kernel

sTable	sRecord	sField	Notes
Trendqueues	The value of the 'DriverName' field	FlushQueueLength, FlushQueuesMax , TotalFlushes, FileWrites	None

*sRecord:*

The key to a column in the table depending on the *sTable* parameter.

*sField:*

The key to a column in the table depending on the *sTable* parameter.

## Return Value

Returns the content of a field of the given table in the format of a Cicode STRING.

## Related Functions

[DspKernel](#), [DumpKernel](#)

## See Also

[Miscellaneous Functions](#)

## KernelTableItemCount

Obtains the number of rows in a Kernel Table.

## Syntax

**KernelTableItemCount(sName)**

*sName:*

The name of the table that can be enumerated by the page table kernel command.

## Return Value

Returns the number of active records in the table (not the length value displayed by the page table kernel command).

The following tables row counts are not returned by this command (it returns 0)

- IODevices.Tags
- IODevices.Subs
- IODevices.Blocks
- CSAToPSI.Subs

[KernelTableInfo](#), [DumpKernel](#)

### LanguageFileTranslate

Translates an ASCII file into a local language. Use this function to translate RTF reports for viewing on client screens.

The local language used by this function is specified by the [\[Language\]LocalLanguage](#) parameter. You need to set this parameter accordingly.

## Syntax

**LanguageFileTranslate(*sSourceFile*, *sDestFile*)**

*sSourceFile*:

The name of the ASCII file containing multi-language text, which will be copied and translated. You should specify the full path or use path substitution. The path and name should be contained within quotation marks.

*sDestFile*:

The name of the destination file which will be created/ replaced with the local/translated version of the source file. You should specify the full path or use path substitution. The path and name should be contained within quotation marks.

## Return Value

1 if successful, otherwise 0.

## Related Functions

[StrToLocalText](#)

## Example

```
/* Translates the text in Shift.RTF and saves it in LShift.RTF. */
LanguageFileTranslate("c:\MyApplication\data\Shift.RTF", "c:\MyApplication\data\
LShift.RTF");
/* Translates the text in [Data]:Shift.RTF and saves it in
[LocalData]:LShift.RTF. */
LanguageFileTranslate("[Data]:Shift.RTF", "[LocalData]:LShift.RTF"
);
```

## See Also

[Miscellaneous Functions](#)

## Message

Displays a message box on the screen and waits for the user to select the **OK** or **Cancel** button.

This function is a blocking function. It will block the calling Cicode task until the operation is complete.

This function will be blocked if called from a non-client process, as well as from kernel window of a client process if [\[Client\]DisableDisplay](#) is set to TRUE.

## Syntax

**Message**(*Title*, *Prompt*, *Mode*)

*Title*:

The title of the message box. The maximum length is 254 chars.

*Prompt*:

The prompt displayed in the message box.

*Mode*:

The mode of the message box:

0 - **OK** button

1 - **OK** and **Cancel** button

16 - Stop Icon

32 - Question Icon

48 - Exclamation Icon

64 - Information Icon

Select more than one mode by adding the modes. For example, set Mode to 33 to display the **OK** and **Cancel** buttons and the Question icon. You can only display one icon for the message box.

## Return Value

0 (zero) if successful, otherwise an error is returned. If the user presses the Cancel button the function returns an error code of 299.

## Related Functions

[Input](#)

## Example

```
/* Display an error message in a message box. */  
IF Total<>100 THEN  
    Message("Error","Total not 100%",48);  
END
```

## See Also

[Miscellaneous Functions](#)

### ParameterGet

Gets the value of a parameter. The parameter can exist in a local Citect.ini file, a profile INI file, or the parameters database.

- If a project is using a profile INI file, the value of the specified parameter will be retrieved from the profile INI.
- If the specified parameter exists in both Citect.ini and the parameters database, the value of the parameter is retrieved from the Citect.ini.
- If the parameter does not exist in any of these locations, the default value is returned.

## Syntax

**ParameterGet(Section, Name, Default)**

*Section:*

The section name.

*sName:*

The parameter name.

*Default:*

The default value of the parameter.

---

**Note:** If in your Cicode you perform a ParameterGet("alarm", "saveperiod", 1000) for the [Alarm]SavePeriod parameter, and no entry exists in the profile INI file, the Citect.ini or the parameters records, the returned value will be 1000. However Plant SCADA will internally be using the default value of 600.

---

## Return Value

The parameter (as a string).

## Related Functions

[ParameterPut](#), [WndGetFileProfile](#), [WndPutFileProfile](#)

## Example

```
Variable=ParameterGet("Page","Windows","4");
```

## See Also

[Miscellaneous Functions](#)

## ParameterPut

Updates a system parameter in the CITECT.INI file. If the system parameter does not exist, it is added to the CITECT.INI file.

## Syntax

**ParameterPut**(*Section*, *Name*, *Value*)

*Section*:

The section name.

*sName*:

The system parameter name.

*Value*:

The value to put in the system parameter.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[ParameterGet](#), [WndGetFileProfile](#), [WndPutFileProfile](#)

## Example

```
/* Changes the [Page] Windows system parameter in CITECT.INI to "4". */
ParameterPut("Page","Windows","4");
```

## See Also

[Miscellaneous Functions](#)

## ProcessIsClient

Determines if the currently executing process contains a Client component.

## Syntax

**ProcessIsClient()**

## Return Value

TRUE (1) if the process contains a Client component, otherwise FALSE (0).

## Related Functions

[ProcessIsServer](#), [ServerInfo](#), [ServerInfoEx](#), [ServiceGetList](#)

## Example

To execute local variable simulation code on the client only:

```
IF (ProcessIsClient()) THEN
    SimulateLocalVariables();
END
```

## See Also

[Miscellaneous Functions](#)

## ProcessIsServer

Determines if the currently executing process contains a particular server component.

## Syntax

**ProcessIsServer(*sServerType* [, *sClusterName*] [, *sServerName*])**

*sServerType*:

Case insensitive string specifying the type of server to check for. Supported values are "IOServer", "Trend", "Alarm" and "Report".

*sClusterName*:

Optional case insensitive string specifying the cluster name to combine with the server type specified in the first argument and the server name (if specified).

*sServerName*:

Optional case insensitive string specifying a server name to combine with the server type specified in the first argument and the cluster name (if specified).

## Return Value

TRUE (1) if the process contains the specified component, otherwise FALSE (0).

## Related Functions

[ProcessIsClient](#), [ServerInfo](#), [ServerInfoEx](#), [ServiceGetList](#)

## Example

To execute disk PLC tag simulation code only on the I/O server in Cluster1 with the name IOServer3:

```
IF (ProcessIsServer("IOServer", "Cluster1", "IOServer3")) THEN
```

```
SimulateDiskTags();  
END
```

## See Also

[Miscellaneous Functions](#)

## ProcessRestart

Restarts the current process in which Cicode is running.

## Syntax

```
INT error = ProcessRestart()
```

## Return Value

0 (zero) if successful, otherwise the following error is returned:

256 - General software error

See [Cicode and General Errors](#).

## Related Functions

[ServerRestart](#)

## Example

```
ProcessRestart()
```

## See Also

[Miscellaneous Functions](#)

## ProductInfo

Returns information about the Plant SCADA product.

## Syntax

**ProductInfo(*iType*)**

*iType*:

Type of information required:

0 - product name, default

1 - product company

- 2 - product major version
- 3 - product minor version
- 4 - product version string

## Return Value

The product information. An empty string will be returned if the type is invalid.

## Related Functions

[ProjectInfo](#)

## See Also

[Miscellaneous Functions](#)

## ProjectInfo

Returns information about a particular project, which is identified by a project enumerated number.

## Syntax

**ProjectInfo(*iProject*, *iType*)**

*iProject*:

Project number. This is a sequential number generated by the Compiler starting from 0,1,2,3,4,5... to 1026, so the maximum include projects are limited to 1027.

*iType*:

Type of information to return:

- 0 - Project name
- 1 - Project description
- 2 - Project major revision number
- 3 - Project minor revision number
- 4 - Project date
- 5 - Project time

## Return Value

The specified project information. An empty string will be returned if the project number or type is invalid

## Example

```
INT hFile;  
INT iProjectNumber = 0;
```

```
INT iMaxProjects = 1028;
STRING sProjectName;
//Iterate over all projects and write the version numbers to a file
hFile = FileOpen("[Data]:ProjectInfo.txt","a+");
//Iterate of the project numbers and retrieve the project name
WHILE iProjectNumber < iMaxProjects DO
    sProjectName = ProjectInfo(iProjectNumber,0);
    FileWriteLn(hFile,sProjectName);
    iProjectNumber = iProjectNumber + 1;
END
fileClose(hFile);
```

## ProjectRestartGet

Gets the path to the project to be run the next time Plant SCADA is restarted. You need to have a project already set using either [ProjectSet](#) or [ProjectRestartSet](#). Use this function with the [Shutdown\(\)](#) function to shut down and then restart the project that is currently running.

## Syntax

[ProjectRestartGet\(\)](#)

## Return Value

The path to the project to be run the next time Plant SCADA is restarted.

## Related Functions

[Shutdown](#), [ShutdownMode](#), [ProjectSet](#), [ProjectRestartSet](#)

## Example

See [Shutdown](#).

## See Also

[Miscellaneous Functions](#)

## ProjectRestartSet

Sets the path to the project to be run the next time Plant SCADA is restarted.

### Syntax

**ProjectRestartSet(*sPath*)**

*sPath*:

The path to the project. You need to use the full path.

### Return Value

0 (zero) if successful, otherwise an error code is returned.

### Related Functions

[Shutdown](#), [ShutdownMode](#), [ProjectSet](#), [ProjectRestartGet](#)

### See Also

[Miscellaneous Functions](#)

## ProjectSet

Sets either the name or the path of the project to be run next time Plant SCADA is restarted. The project path is written to the [\[CtEdit\]Run](#) parameter.

### Syntax

**ProjectSet(*sProject*)**

*sProject*:

The name of the project (for example "DEMO"), or the path to the project. If you specify the path to the project, you need to use the full path. If you do not specify a project, the current project will be used.

### Return Value

0 (zero) if successful, otherwise an error code is returned.

### Related Functions

[Shutdown](#), [ShutdownMode](#), [ProjectRestartGet](#)

## Example

```
/* Set the next project to "Demo". */
ProjectSet("Demo");
/* Set the next project to "MyPath". */
ProjectSet("I:\Plant SCADA\PROJECT1\MYPATH");
```

## See Also

[Miscellaneous Functions](#)

## Prompt

Displays a message in the prompt line (AN=2) on the operator's computer.

## Syntax

**Prompt(*String*)**

*String*:

The message to be displayed.

---

**Note:** This Cicode function only works on a Plant SCADA process with a display, such as a display client or a server running in single process mode and not as a service.

---

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[Message](#), [DspError](#)

## Example

```
/* Display "This is a prompt!" at the prompt AN. */
Prompt("This is a prompt!");
```

## See Also

[Miscellaneous Functions](#)

## Pulse

Pulses (jogs) a variable tag on, then off. The variable tag is switched ON (1) and two seconds later it is switched OFF (0). The exact period of the pulse is determined by the communication channel to the I/O device. If the

communication channel is busy, the pulse time may be longer than two seconds. The code in the I/O device should not be dependant on a pulse time of exactly 2 seconds. Use the pulse as a trigger only.

**Note:** The Pulse function cannot be used with Super Genie associations.

## Syntax

**Pulse(*sTag*)**

*sTag*:

The digital tag to pulse.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[Toggle](#)

## Example

Button

Text	Jog 145
Command	Pulse(M145)
Comment	Pulse the variable tag M145 every two seconds

[Miscellaneous Functions](#)

## ServerDumpKernel

Dumps Kernel data to the KERNEL.DAT file (written to the Logs folder) either on a local server or on a remote server. The server is specified with the server and cluster parameters. Instead of creating a new file subsequent calls to this function will append Kernel data to the KERNEL.DAT file. This is a blocking function.

## Syntax

**ServerDumpKernel(*iMode*, *sName*, *sServer* [, *sCluster*])**

*iMode*:

The Kernel data to dump:

0x0001 - Dump general statistics.

0x0002 - Dump the task.  
0x0004 - Dump the I/O device.  
0x0008 - Dump the driver.  
0x0010 - Dump netstat. (This mode is deprecated and no longer active in version 7.10 or later.)  
0x0020 - Dump the table.  
0x0040 - Dump the queue.  
0x0100 - Dump list of current SCADA parameter settings  
0x4000 - Dump in verbose mode.  
0x8000 - Dump kernel data in non-verbose mode. To dump data in verbose mode, set *iMode* to 0xc000 (0x8000 + 0x4000).

You can select any one of the above modes or may add them together to get more than one type of information. For example, to dump netstat and I/O device data in verbose mode, set *iMode* to 0x4014 (0x0004 + 0x0010 + 0x4000). Using 0x4000 on its own will dump no data, it needs to be combined with another mode.

*sName*:

The queue or table name (empty for all queues or tables). Only valid if *iMode* is 0x0020 and 0x0040.

*sServer*:

Specifies the name of the server, as defined in the project, on which kernel data will be dumped.

*sCluster*:

Specifies the cluster of the server on which kernel data will be dumped. This parameter is optional in a single cluster environment.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[DumpKernel](#), [DspKernel](#), [KerCmd](#), [TraceMsg](#)

## Example

```
ServerDumpKernel(0x8000, "");  
!Dump the Kernel data
```

## See Also

[Miscellaneous Functions](#)

## ServiceGetList

Determines the service type(s), cluster name(s), and service name(s) of all services currently running in the component that called this function. It also determines if the client component is running.

If you call this function from a component that is running purely as a Control Client or View-only Client, the

function will return "Client".

If you call this function from a single-process component that includes:

- I/O server called IOServ1 on ClustA
- Trend server called Trend1 on ClustB
- Alarm server called Alarm1 on ClustA
- Report server called Report1 on ClustB
- Client

The function will return a string similar to:

"IOServer.ClustA.IOServ1,Trend.ClustB.Trend1,Alarm.ClustA.Alarm1,Report.ClustB.Report1,Client"

The order of components in the string is not fixed so the exact string may vary from the above. You should parse the returned string or alternatively use [ProcessIsClient](#) or [ProcessIsServer](#) to find the information you need.

## Syntax

**ServiceGetList()**

## Return Value

String in the form:

*serviceType1.clusterName1.serviceName1,serviceType2.clusterName2.serviceName2, ... ,Client*

## Related Functions

[ProcessIsClient](#), [ProcessIsServer](#), [ServerInfo](#), [ServerInfoEx](#)

## See Also

[Miscellaneous Functions](#)

## SetArea

Sets the current viewable areas. You can pass a single area number, or a group of areas to set multiple areas. You can only set areas that are flagged for the current user.

## Syntax

**SetArea(*Area*)**

*Area*:

The area to set (1 to 255).

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[GrpOpen](#)

## Example

```
/* Set current viewable area to Area 1. */  
SetArea(1);
```

## See Also

[Miscellaneous Functions](#)

## SetLogging

Adjusts logging parameters while online. The parameters you can modify include the following:

- [\[Debug\]DriverTrace](#)
- [\[Debug\]SysLogSize](#)
- [\[Debug\]Priority](#)
- [\[Debug\]CategoryFilterMode](#)
- [\[Debug\]CategoryFilter](#)
- [\[Debug\]SeverityFilterMode](#)
- [\[Debug\]SeverityFilter](#)
- [\[Debug\]LogShutDown](#)
- [\[Debug\]DebugAllTrans](#)
- [\[Debug\]EnableLogging](#)
- [\[IOServer\]RedundancyDebug](#)
- [\[General\]Verbose](#)
- [\[General\]VerboseToSysLog](#)
- [\[CtAPI\]Debug](#)

## Syntax

**SetLogging**(*Section*, *Name*, *Value*, *Persist*)

*Section*:

The INI section name.

*sName*:

The system parameter name.

*Value:*

The value you would like to set the parameter to.

*Persist:*

Makes the value persistent across restarts by writing the value to the INI file.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[GetLogging](#)

## See Also

[Miscellaneous Functions](#)

## Shutdown

Terminates Plant SCADA's operation. Use this function to shut down the Plant SCADA system, otherwise buffered data could be lost. This function impacts the operation of the computer as a whole, it is not process-based. If a computer is the target for shutdown, all Plant SCADA processes on the computer will be shutdown.

---

**Note:** With one exception, the Shutdown command will succeed only if there is an Alarm Server in your system. The exception to this is if you specify an empty string for the *sDest* parameter (shutdown this computer only). In this case the shutdown will succeed even if there is no Alarm Server.

---

The shutdown can affect only the computer that calls it, or all or part of a Plant SCADA network. If you are shutting down a network, specify the computers (Control Clients and servers) to be shut down in *sDest*, and the extent of the shutdown in *Mode*.

---

**Note:** If [\[Shutdown\]NetworkIgnore](#) parameter is set to 0 (zero) and a client receives a shutdown request message from a server, phase 2 clients only receive a shutdown request when the first phase 1 client has reconnected to the server. Set this parameter to 0 for all the computers that will send or accept a shutdown command.

---

You can allow selected computers to override the shutdown with the [\[Shutdown\]NetworkIgnore](#) parameter. (You might set this parameter for key servers, for example, I/O servers.)

---

Use the [ShutdownForm\(\)](#) function to prompt the user for verification before shutting Plant SCADA down.

---

**Note:** If the [\[Shutdown\]NetworkStart](#) parameter is set to 0 (zero), the [Shutdown\(\)](#) function will ignore the *sDest* argument. This will result in the shutting down and restarting of the machine the function is run on regardless of the machine specified.

## Syntax

**Shutdown( [*sDest*] [, *sProject*] [, *Mode*] [, *sClusterName*] [, *CallEvent*])**

*sDest:*

The destination computer(s) on which Plant SCADA will be shut down, as a string:

- "" (blank string) - this computer only (default value).
- ["Computer\_Name"] - a specified Plant SCADA computer. Use the name defined in the computer's CITECT.INI file. If this is not configured, you can use the Windows computer name.
- ["Server\_Name"] - a specified Plant SCADA server computer. Shutdown will only work if the specified server is the only one configured on the computer.
- "All Clients" - All Plant SCADA client computers on the network.
- "All Servers" - All Plant SCADA server computers on the network.
- "Everybody" - All Plant SCADA computers on the network.

*sProject:*

The full path of the project to run on restart as a string. The path is written to the configuration files and is used when the system restarts. The default value is "", which means that no changes are made to the configuration and the current project is restarted.

*Mode:*

The type of shutdown:

- 1 - Shutdown Plant SCADA only - Default value.
- 2 - Shutdown and restart Plant SCADA (without logging off Windows).
- 3 - Shutdown and restart Plant SCADA and log off Windows (an auto login to the Operating System and Plant SCADA needs to be configured to run on start up or log in).
- 4 - Shutdown Plant SCADA and re-boot the computer.
- 5 - Shutdown Plant SCADA only.
- 6 - Shutdown and restart Plant SCADA on remote computers, but not this computer.
- 7 - Shutdown Plant SCADA and shutdown the computer. If the computer supports power off feature the power will be turned off.

*sClusterName:*

The name of the cluster to which the machine(s) named in *Dest* belong. This is not required if:

- the function is called with *Dest* empty (the default); OR
- the client is connected to only one cluster containing an Alarm Server.

*CallEvent:*

Flag for initiating a user-specified shutdown event prior to shutting down. Refer to [OnEvent\(\)](#) type code for the value of shutdown event.

0 - no event

1 - raise event. The user defined shutdown event handler will be called before the shutdown occurs - Default value

---

**Note:** If the event handler is non-interactive with an instant return value, it can be called directly.

---

**Note:** If the event handler is interactive or with a long delay in processing the event, it needs to be called indirectly using the `NewTask("EventHandler")` function, and the actual handler, `EventHandler()`, needs to call `Shutdown()` with the `CallEvent` flag set to 0 from the handler if it decides the shutdown is permitted.

---

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[ProjectRestartGet](#), [ProjectRestartSet](#), [ProjectSet](#), [ShutdownMode](#), [ShutdownForm](#), [OnEvent](#)

## Example

```
/* Shut down Plant SCADA on this computer. */  
Shutdown();  
/* Shut down and restart Plant SCADA clients, but not this computer. */  
Shutdown("All Clients", ProjectRestartGet(), 6, "ClusterXYZ");
```

## See Also

[Miscellaneous Functions](#)

## ShutdownForm

Displays a dialog box to verify that the user really wants to shut down the Plant SCADA system. If the user selects [Yes], Plant SCADA is shut down.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**ShutdownForm()**

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[Shutdown](#)

## Example

System Keyboard

Key Sequence	Shutdown
Command	ShutdownForm();
Comment	Display the shutdown form

## Buttons

Text	Shutdown
Command	ShutdownForm();
Comment	Display the shutdown form

## See Also

[Miscellaneous Functions](#)

## ShutdownMode

Gets the mode of the last Shutdown function call. The mode is useful to identify the type of Shutdown that was performed.

## Syntax

**ShutdownMode()**

## Return Value

The shutdown mode set when shutdown was called.

## Related Functions

[Shutdown](#)

## Example

```
nMode = ShutdownMode()
If nMode = 4 Then
    Prompt ("Plant SCADA closed down and computer was rebooted")
END
```

## See Also

[Miscellaneous Functions](#)

## SwitchConfig

Switches focus to a specific Plant SCADA configuration application. If the specified application is not running, it will be started.

## Syntax

**SwitchConfig(*nApp*)**

*nApp*:

The configuration application:

- 1 - Graphics Builder (CTDRAW32.EXE)
- 2 - Not in Use
- 3 - Plant SCADA Studio (CITECTIDE.EXE)
- 4 - Cicode Editor (CTCICODE.EXE)

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Example

```
! Switch to the Graphics Builder.  
SwitchConfig(1);
```

## See Also

[Miscellaneous Functions](#)

## TestRandomWave

Generates a random wave. The height of the wave is restricted by minimum and maximum values. You can offset the starting point of the wave, for example, to display multiple waves at the same AN. You can use this function to generate test input.

## Syntax

**TestRandomWave( [*Period*] [, *Low*] [, *High*] [, *Offset*] )**

*Period*:

The number of seconds required to generate one cycle of the wave. If no period is entered, the period has a default of 60.

*Low*:

The lowest value of the wave. If no low value is entered, this value has a default of 0.

*High*:

The highest value of the wave. If no high value is entered, this value has a default of 100.

*Offset*:

The offset in seconds, to generate the wave. If no offset is entered, the offset has a default of 0.

## Return Value

The value of the random wave.

## Related Functions

[TestSawWave](#), [TestSinWave](#), [TestSquareWave](#), [TestTriangWave](#)

## Example

```
/* Specify a random wave of 60 seconds duration, with a minimum
value of 0 units and a maximum value of 100 units, with no offset.
*/
TestRandomWave(60,0,100,0);
```

## See Also

[Miscellaneous Functions](#)

## TestSawWave

Generates a saw wave. The height of the wave is restricted by minimum and maximum values. You can offset the starting point of the wave, for example, to display multiple waves at the same AN. You can use this function to generate test input.

## Syntax

**TestSawWave( [Period] [, Low] [, High] [, Offset] )**

*Period:*

The number of seconds required to generate one cycle of the wave. If no period is entered, the period has a default of 60.

*Low:*

The lowest value of the wave. If no low value is entered, this value has a default of 0.

*High:*

The highest value of the wave. If no high value is entered, this value has a default of 100.

*Offset:*

The offset in seconds, to generate the wave. If no offset is entered, the offset has a default of 0.

## Return Value

The value of the saw wave.

## Related Functions

[TestRandomWave](#), [TestSinWave](#), [TestSquareWave](#), [TestTriangWave](#)

## Example

```
/* Specifies a saw wave of 60 seconds duration, with a minimum
value of 0 units and a maximum value of 100 units, with no offset.
*/
TestSawWave();
```

## See Also

[Miscellaneous Functions](#)

## TestSinWave

Generates a sine wave. The height of the wave is restricted by minimum and maximum values. You can offset the starting point of the wave, for example, to display multiple waves at the same AN. You can use this function to generate test input.

## Syntax

**TestSinWave( [Period] [, Low] [, High] [, Offset] )**

*Period:*

The number of seconds required to generate one cycle of the wave. If no period is entered, the period has a default of 60.

*Low:*

The lowest value of the wave. If no low value is entered, this value has a default of 0.

*High:*

The highest value of the wave. If no high value is entered, this value has a default of 100.

*Offset:*

The offset in seconds, to generate the wave. If no offset is entered, the offset has a default of 0.

## Return Value

The value of the sine wave.

## Related Functions

[TestRandomWave](#), [TestSawWave](#), [TestSquareWave](#), [TestTriangWave](#)

## Example

```
/* Specifies a sine wave of 30 seconds duration, with a minimum
value of 0 units and a maximum value of 100 units, with no offset.
*/
TestSinWave(30);
```

## See Also

[Miscellaneous Functions](#)

### TestSquareWave

Generates a square wave. The height of the wave is restricted by minimum and maximum values. You can offset the starting point of the wave, for example, to display multiple waves at the same AN. You can use this function to generate test input.

## Syntax

**TestSquareWave( [Period] [, Low] [, High] [, Offset] )**

*Period:*

The number of seconds required to generate one cycle of the wave. If no period is entered, the period has a default of 60.

*Low:*

The lowest value of the wave. If no low value is entered, this value has a default of 0.

*High:*

The highest value of the wave. If no high value is entered, this value has a default of 100.

*Offset:*

The offset in seconds, to generate the wave. If no offset is entered, the offset has a default of 0.

## Return Value

The value of the square wave.

## Related Functions

[TestRandomWave](#), [TestSawWave](#), [TestSinWave](#), [TestTriangWave](#)

## Example

```
/* Specifies a square wave of 30 seconds duration, with a minimum
value of -1000 units and a maximum value of 1000 units, with an
offset of 10 seconds. */
TestSquareWave(30, -1000, 1000, 10);
```

## See Also

[Miscellaneous Functions](#)

### TestTriangWave

Generates a triangular wave. The height of the wave is restricted by minimum and maximum values. You can offset the starting point of the wave, for example, to display multiple waves at the same AN. You can use this function to generate test input.

## Syntax

**TestTriangWave( [Period] [, Low] [, High] [, Offset] )**

*Period:*

The number of seconds required to generate one cycle of the wave. If no period is entered, the period has a default of 60.

*Low:*

The lowest value of the wave. If no low value is entered, this value has a default of 0.

*High:*

The highest value of the wave. If no high value is entered, this value has a default of 100.

*Offset:*

The offset in seconds, to generate the wave. If no offset is entered, the offset has a default of 0.

## Return Value

The value of the triangular wave.

## Related Functions

[TestRandomWave](#), [TestSawWave](#), [TestSinWave](#), [TestSquareWave](#)

## Example

```
/* Specifies a triangular wave of 60 seconds duration, with a
minimum value of 0 units and a maximum value of 100 units, with no
offset. */
TestTriangWave();
```

## Toggle

Toggles a digital tag on or off. If the variable tag is ON (1), this function will turn it OFF. If the variable tag is OFF (0), this function will turn it ON.

## Syntax

**Toggle(*sTag*)**

*sTag*:

The digital tag to toggle.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[Pulse](#)

## Example

Buttons

Text	Motor 145
Command	Toggle(M145)
Comment	Toggle the variable tag M145 (Motor 145) on or off

To toggle the Paging Alarm property:

```
Toggle(MyCluster.Alarm_1.Paging);
```

## See Also

[Miscellaneous Functions](#)

## TraceMsg

Displays a message in the Kernel and Debugger debug windows.

## Syntax

**TraceMsg(*String*)**

*String*:

The message to display.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[DspKernel](#), [KerCmd](#), [DumpKernel](#), [DebugBreak](#), [Assert](#), [DebugMsg](#), [DebugMsgSet](#), [ErrLog](#)

## Example

```
TraceMsg("Error Found");
// Displays "Error Found" in the debug window
```

## Version

Gets the version number of the Plant SCADA software in use.

## Syntax

**Version(*nType*)**

*nType*:

The type of version:

- 0 - Major version number
- 1 - Minor version number
- 2 - Revision number
- 3 - Version text

## Return Value

The version number as a string.

## Example

```
! If the Plant SCADA version number is 1.2:
Version(0);
! Returns 1.
Version(1);
! Returns 2.
Version(3);
! Returns "1.2".
```

## .Net Functions

### CAUTION

#### CAUTION

.Net Functions do not support events and static methods. Do not use these functions to manipulate objects on graphics pages.

The following functions allow you to access web services via .net objects.

<a href="#">DIIClassDispose</a>	Use this function to clean up resources used by the .Net object and any other .Net objects created via the use of the object.
<a href="#">DIIClassCreate</a>	Use this function to instantiate a new .Net object by specifying the path, class and arguments required for the matching constructor of the class.
<a href="#">DIIClassGetProperty</a>	Use this function to get a property of the .Net object.
<a href="#">DIIClassIsValid</a>	Use this function to validate class. Uses the handle of the class returned from DIIClassCreate.
<a href="#">DIIClassCallMethod</a>	Use this function to call a method of a .Net object, passing in the method name and any arguments required for the matching prototype of the method.
<a href="#">DIIClass SetProperty</a>	Use this function to set a property of the .Net object. The property may be of any type or an object itself.

When returning data from a .net assembly to Cicode, use the [Conversion Table](#).

## See Also

[Cicode Function Categories](#)

[Using Cicode Functions](#)

### **DIIClassDispose**

Use this function to clean up resources used by the .Net object and any other objects created via the use of the object.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**INT DllClassDispose(OBJECT Object)**

*Object:*

.Net object.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[DllClassCreate](#), [DllClassIsValid](#), [DllClassCallMethod](#), [DllClassSetProperty](#), [DllClassGetProperty](#)

## Example

See [DllClassCreate](#)

## See Also

[.Net Functions](#)

## DllClassCreate

Use this function to instantiate a new .Net object by specifying the path, class and arguments required for the matching constructor of the class.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

---

**Note:** If your .Net assembly was compiled for 32 bit, it will not be supported on an alarm server operating in Extended Memory mode. To allow this to work, you will need to recompile the assembly to target "Any CPU" or "x64".

---

## Syntax

**OBJECT DllClassCreate(STRING sPath, STRING sClass [, vParameters Args])**

*sPath:*

The full path string.

*sClass:*

The class of the object.

*Args:*

Args for the constructor.

## Return Value

.Net object if successful, otherwise an error code is returned.

## Related Functions

[DIIClassDispose](#), [DIIClassIsValid](#), [DIIClassCallMethod](#), [DIIClassSetProperty](#), [DIIClassGetProperty](#)

## Example

```
FUNCTION RunDllProxyTest()
    STRING sPath = "C:\Program Files (x86)\Reference Assemblies\Microsoft\
Framework\.NETFramework\v4.0\Profile\Client\System.dll";
    OBJECT hMailMessageProxy;
    OBJECT hSmtpClientProxy;
    OBJECT hEmailAddressProxy;
    INT result;
    OBJECT hEmailAddressCollection;
    hMailMessageProxy = DllClassCreate(sPath, "MailMessage");
    result = DllClassIsValid(hMailMessageProxy);
    hSmtpClientProxy = DllClassCreate(sPath, "SmtpClient", "mysmtpserver.mycompany.com");
    result = DllClassIsValid(hSmtpClientProxy);
    hEmailAddressProxy = DllClassCreate(sPath, "MailAddress", "myemail@hotmail.com");
    result = DllClassIsValid(hEmailAddressProxy);
    result = DllClassSetProperty(hMailMessageProxy, "From", hEmailAddressProxy);
    hEmailAddressCollection = DllClassGetProperty(hMailMessageProxy, "To");
    DllClassCallMethod(hEmailAddressCollection, "Add", "myemail@mycompany.com");
    result = DllClassSetProperty(hMailMessageProxy, "Subject", "Test");
    result = DllClassSetProperty(hMailMessageProxy, "Body", "Hello!");
    DllClassCallMethod(hSmtpClientProxy, "Send", hMailMessageProxy);

    result = DllClassDispose(hEmailAddressProxy);
    result = DllClassDispose(hSmtpClientProxy);
    result = DllClassDispose(hMailMessageProxy);
END
```

## See Also

[.Net Functions](#)

### DIIClassIsValid

Use this function to validate the handle for the class returned from [DIIClassCreate](#).

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**INT DIIClassIsValid(*OBJECT*)**

## Return Value

1 if handle is valid or 0

## Related Functions

[DIIClassCreate](#), [DIIClassDispose](#), [DIIClassCallMethod](#), [DIIClassSetProperty](#), [DIIClassGetProperty](#)

## Example

See [DIIClassCreate](#)

## See Also

[.Net Functions](#)

## DIIClassSetProperty

Use this function to set a property of the .Net object. The property may be of any type or an object itself. This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

INT DIIClassSetProperty(OBJECT *object*, STRING *sProperty*, VARIANT *Value*)

*object*:

.Net object.

*sProperty*

The name of the property of the .Net object.

*Value*

The value to which the property of the .Net object will be set to.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[DIIClassDispose](#), [DIIClassIsValid](#), [DIIClassCallMethod](#), [DIIClassCreate](#), [DIIClassGetProperty](#)

## Example

See [DIIClassCreate](#).

## See Also

[.Net Functions](#)

### DllClassGetProperty

Use this function to get a property of the .Net object.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

VAR DllClassGetProperty(OBJECT *object*, STRING *sProperty*)

*object*:

.Net object.

*sProperty*:

The property to read.

## Return Value

Var if successful, otherwise an error code is returned.

## Related Functions

[DllClassDispose](#), [DllClassIsValid](#), [DllClassCallMethod](#), [DllClassCreate](#), [DllClassSetProperty](#)

## Example

See [DllClassCreate](#).

## See Also

[.Net Functions](#)

### DllClassCallMethod

Use this function to call a method of a .Net object, passing in the method name and any arguments required for the matching prototype of the method.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

**Note:** This function is unable to call a static method as it requires an instance of the class to be created before a method can be called from it.

## Syntax

**VAR DllClassCallMethod(OBJECT *object*, STRING *sMethod*, VARARGS *args*)**

*object*:

.Net object.

*sMethod*:

The name of the method

*args*

Args for functions.

## Return Value

Var if successful, otherwise an error code is returned.

## Related Functions

[DllClassDispose](#), [DllClassIsValid](#), [DllClass SetProperty](#), [DllClassCreate](#), [DllClassGetProperty](#)

## Example

See [DllClassCreate](#)

## Conversion Table

 CAUTION	
<b>CAUTION</b>	
When returning data from a .net assembly to Cicode, use the following conversion table so that there is no loss of data. Failure to do so will result in a hardware error and the Cicode will stop execution.	
.Net Data Type	Cicode Data Type
Object	OBJECT
DateTime	OBJECT
Boolean	INT
Byte	INT

.Net Data Type	Cicode Data Type
SByte	INT
Int16	INT
UInt16	INT
Int32	INT
UInt32	REAL
Int64	REAL
UInt64	REAL
Single	REAL
Double	REAL
Decimal	REAL
Char	STRING
String	STRING

## Page Functions

Following are functions relating to graphics pages:

<a href="#">PageAlarm</a>	Displays a category of active alarms on the predefined alarms page.
<a href="#">PageBack</a>	Displays the previously displayed page in the Window.
<a href="#">PageDisabled</a>	Displays a category of disabled alarms on the predefined alarms page.
<a href="#">PageDisplay</a>	Displays a graphics page.
<a href="#">PageExists</a>	Checks if a particular page exists in your project.
<a href="#">PageFile</a>	Displays a file on the predefined file to screen page.
<a href="#">PageFileInfo</a>	Returns the width or height of an unopened page in pixels.

<a href="#">PageFileInfoEx</a>	Returns the width, height or content type of an unopened page.
<a href="#">PageForward</a>	PageForward() restores the previously displayed page in the window following a PageBack command.
<a href="#">PageGetInt</a>	Gets a local page-based integer.
<a href="#">PageGetStr</a>	Gets a local page-based string.
<a href="#">PageGoto</a>	Displays a graphics page without pushing the last page onto the page navigation history.
<a href="#">PageHardware</a>	Displays the active hardware alarms on the predefined alarms page.
<a href="#">PageHistoryDspMenu</a>	Displays a pop-up menu which lists the page history of current window.
<a href="#">PageHistoryEmpty</a>	Used to determine if the page history of the current window is empty.
<a href="#">PageHome</a>	Displays the predefined home page in the window.
<a href="#">PageInfo</a>	Gets page information.
<a href="#">PageLast</a>	Displays the last ten graphics pages.
<a href="#">PageListCount</a>	Gets number of pages in the page list of the current window.
<a href="#">PageListCurrent</a>	Gets index of the current page in the page list of the current window.
<a href="#">PageListInfo</a>	Gets information of a page at the specific index in the page list of current window.
<a href="#">PageListDisplay</a>	Recalls (displays) a page at the specific index in the page list of the current window, and moves the current index to the page. When a page is recalled, the original parameters (such as cluster context, super genie associations, PageTask arguments if applicable) used to display the page will be restored.
<a href="#">PageListDelete</a>	Removes a page at the specific index from the page list of the current window.
<a href="#">PageMenu</a>	Displays a menu page with page selection buttons.
<a href="#">PageNext</a>	Displays the next graphics page.
<a href="#">PagePeekCurrent</a>	Return the index in the page navigation history for the

	current page..
<a href="#">PagePeekLast</a>	Gets information about a Page at an offset in the page navigation history.
<a href="#">PagePopLast</a>	Gets the last page in the page navigation history.
<a href="#">PagePopUp</a>	Displays the pop up window at the mouse position.
<a href="#">PagePrev</a>	Displays the previous graphics page.
<a href="#">PageProcessAnalyst</a>	Displays a Process Analyst page (in the same window) preloaded with the pre-defined Process Analyst View (PAV) file.
<a href="#">PageProcessAnalystPens</a>	Display a page and add the specified pens to the first pane of the specified PA object on the page.
<a href="#">PagePushLast</a>	Puts a page on the end of the page navigation history.
<a href="#">PageRecall</a>	Displays the page at a specified depth in the page navigation history.
<a href="#">PageRichTextFile</a>	Used as a page entry function - creates a rich text object, and loads a rich text file into that object.
<a href="#">PageSelect</a>	Displays a dialog box with a list of graphics pages defined in the project.
<a href="#">PageSetInt</a>	Stores a local page-based integer.
<a href="#">PageSetStr</a>	Stores a local page-based string.
<a href="#">PageSOE</a>	Displays a category of sequence of events (SOE) entries on the SOE page.
<a href="#">PageSummary</a>	Displays a category of alarm summary entries on the predefined alarm page.
<a href="#">PageTask</a>	Used for running preliminary Cicode before displaying a page in a window.
<a href="#">PageTransformCoords</a>	Converts Page coordinates to absolute screen coordinates.
<a href="#">PageTrend</a>	Displays a standard trend page in a single cluster system.
<a href="#">PageTrendEx</a>	Displays a standard trend page in a multi-cluster system.

## See Also

[Cicode Function Categories](#)

[Using Cicode Functions](#)

## PageAlarm

Displays a category of active alarms on the alarm page.

To use this function, you need to have a page in your project that was created using the Alarm template. By default, the name of the page is expected to be "Alarm". However, you can use an alarm page with a different name by adjusting the setting for the INI parameter [\[Page\]AlarmPage](#).

---

**Note:**

- The operation of this function has changed. In Version 2.xx this function displayed the built-in alarm page from the Include project.
  - This function is not supported in the server process in a multiprocessor environment. Calling this function from the server process results in a hardware alarm being raised.
- 

## Syntax

**PageAlarm( [Category] )**

*Category:*

The alarm category to display. Set to 0 (the default) to display all alarm categories.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[PageDisabled](#), [PageHardware](#)

## Example

System Keyboard

Key Sequence	AlarmPage
Command	PageAlarm(0)
Comment	Display active alarms on the alarm page

System Keyboard

Key Sequence	Alarm ### Enter
Command	PageAlarm(Arg1)

Comment	Display a specified category of active alarms on the alarm page
---------	---

## See Also

[Page Functions](#)

### PageBack

Displays the previously displayed page in the Window.

## Syntax

**PageBack([iCount])**

*iCount*:

Optional parameter to specify the number of pages to move back. Default value is 1.

## Return Value

No Error (0) on success. Bad handle specified (269) if current window handle does not correspond to a valid window. Invalid argument passed (274) if count is outside of allowable bounds.

## Related Functions

[PageForward](#), [PageHistoryDspMenu](#), [PageHistoryEmpty](#)

## See Also

[Page Functions](#)

### PageDisabled

Displays a category of disabled alarms on the disabled alarms page.

To use this function, you need to have a page in your project that was created using the Disabled template. By default, the name of the page is expected to be "Disabled". However, you can use a page with a different name by adjusting the setting for the INI parameter [\[Page\]DisabledPage](#).

---

#### Note:

- The operation of this function has changed. In Version 2.xx this function displayed the built-in alarm page from the Include project.
  - This function is not supported in the server process in a multiprocessor environment. Calling this function from the server process results in a hardware alarm being raised.
-

## Syntax

**PageDisabled( [Category] )**

*Category:*

The alarm category to display. Set to 0 (the default) to display all alarm categories.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[PageAlarm](#)

## Example

System Keyboard

Key Sequence	DisabledPage
Command	PageDisabled(0)
Comment	Display disabled alarms on the alarm page

System Keyboard

Key Sequence	Disabled ### Enter
Command	PageDisabled(Arg1)
Comment	Display a specified category of disabled alarms on the alarm page

## See Also

[Page Functions](#)

## PageDisplay

Displays a graphics page in the active window. The page needs to be in one of the operator's current areas. The page to be displayed is identified by its Page Name or the Page Number.

---

**Note:** If you just need to update the associations on a Super Genie window (rather than reloading the entire page), you can use the function [AssWinReplace](#).

You can specify if the page operates within the context of a particular cluster in a multiple cluster project. When the page launches during runtime, the ClusterName argument is used to resolve any tags that have a cluster omitted.

Plant SCADA stores the current page before it displays the required page. You can call PageLast() to re-display the pages in the page navigation history.

You cannot call this function from the Exit command field (see [Edit the Properties for a Page](#)) or a Cicode object.

**Note:** This function is not supported in the server process in a multiprocessor environment. Calling this function from the server process results in a hardware alarm being raised.

## Syntax

**PageDisplay(*Page*,[*ClusterName*])**

*Page*:

The name or page number of the page to display (in quotation marks ""). Can be prefixed by the name of a host cluster, that is "ClusterName.Page". This will take precedence over the use of the ClusterName parameter if the two differ.

*ClusterName*:

The name of the cluster that will accommodate the page at runtime (in quotation marks ""). The specified cluster is used to resolve any tags that have a cluster omitted. If the Page parameter is prefixed with the name of a cluster, this parameter will not be used.

This parameter is optional, however if you omit a cluster context in the Page properties, then any tags which omit an explicit Cluster. TagName will be ambiguous and become unresolved if you have multiple clusters defined in the project. Note that this ambiguity and resulting unresolved state will only occur if the parameter [\[General\]TagDB](#) is set to "0" which disables variable tag database loading.

## Return Value

0 (zero) if the page is successfully displayed, otherwise an error is returned.

## Related Functions

[PageGoto](#), [PageLast](#)

## Example

Buttons

Text	Mimic Page
Command	PageDisplay("Mimic")
Comment	Display the "Mimic" page

System Keyboard

Key Sequence	Page ##### Enter
Command	PageDisplay(Arg1)
Comment	Display a specified page

```
PageDisplay("MIMIC1");
! Displays page "MIMIC1".
PageDisplay("MIMIC2");
/* Displays page "MIMIC2" and places page "MIMIC1" onto the
page navigation history. */
PageDisplay("10");
/* Displays page "10" and places page "MIMIC2" onto the page navigation history. */
PageLast();
/* Displays the last page, that is page "MIMIC2" and
removes it from the page navigation history. */
```

**Note:** Before Plant SCADA version 5.0, page records could be edited in the Project Editor. One of the fields available for configuration was "Page Number". The value entered for a page could then be used in runtime with the Page Cicode functions such as PageDisplay(), PageGoto(), and PageInfo(1). For example, PageDisplay("1") can be used to display the page that has "1" (without the quotes) set in the **Page Number** field. PageInfo(1) returns the Page Number of the current page. From version 5.0 on, this feature is only backwards-supported. The "Alias" field in the project Pages.DBF file still contains the Page Numbers from upgraded projects; however, the Pages database records are no longer available for direct editing in Plant SCADA.

## See Also

[Page Functions](#)

## PageExists

Use this function to check if a particular page exists in your project.

## Syntax

**INT PageExists(STRING[sPageName])**

*sPageName*:

The name of the page to check for.

## Return Value

1 if the page does exist, 0 if the page does not.

## See Also

[Page Functions](#)

## PageFile

Displays a file on the page. After the file is displayed, you can scroll up and down through the file. To use this function, you need to use the Graphics Builder to create a page called "File" (using the file template).

**Note:**

- The operation of this function has changed. In Version 2.xx this function displayed the built-in alarm page from

---

the Include project.

- This function is not supported in the server process in a multiprocessor environment. Calling this function from the server process results in a hardware alarm being raised.
- 

## Syntax

**PageFile(*sName*)**

*sName*:

The name of the file to display.

## Return Value

0 (zero) if the file is successfully displayed, otherwise an error is returned.

## Related Functions

[DspFile](#)

## Example

System Keyboard

Key Sequence	File ##### Enter
Command	PageFile(Arg1)
Comment	Display the specified file on the page

## See Also

[Page Functions](#)

## PageFileInfo

Returns the width or height of an unopened page.

## Syntax

**PageFileInfo(*sPageName*, *nMode*)**

*sPageName*:

The name of the page you would like to retrieve size information for.

*nMode*:

Retrieves either the width or the height of the specified page in pixels.

0 - returns the page width

1 - returns the page height

## Return Value

The height or width of the specified page in pixels, depending on the value set for *nMode*.

## See Also

[Page Functions](#)

### PageFileInfoEx

Returns the width, height, content type, parent or title of an unopened page.

## Syntax

**PageFileInfoEx(*sPage*, *nMode*)**

*sPageName*:

The name of the page for which you would like to retrieve information.

*nMode*:

Determines if the width, height, content type, parent or title is returned for the specified page.

0 - returns the page width.

1 - returns the page height.

2 - returns the content type of the page.

3 - returns the parent page of the page.

4 - returns the configured page title of the page.

## Return Value

The height, width, content type, parent or title of the specified page, depending on the value set for *nMode*.

## See Also

[Page Functions](#)

### PageForward

If PageBack() is called, PageForward() will restore the previously displayed page in the window. PageForward requires PageBack to have been called and no other page display functions to have been called in between. Calling the display functions PageDisplay or PageGoto will remove the forward pages from the Page Navigation History.

## Syntax

**PageForward([*iCount*])**

*iCount*:

Optional parameter to specify the number of pages to move forward. Default value is 1.

## Return Value

No Error (0) on success. Bad handle specified (269) if current window handle does not correspond to a valid window. Invalid argument passed (274) if count is outside of allowable bounds.

## Related Functions

[PageBack](#), [PageHistoryDspMenu](#), [PageHistoryEmpty](#), [PageDisplay](#), [PageGoto](#)

## See Also

[Page Functions](#)

## PageGetInt

Returns the integer value associated with a variable name on a particular page. If two or more windows are displayed, each window has a unique copy of the variable. You can use these variables in Cicode to keep track of variables unique to each window.

---

**Note:**

- You can find out the current setting for [Page]ScanTime parameter, by calling this function as follows: PageGetInt(-2).
  - This function is not supported in the server process in a multiprocessor environment. Calling this function from the server process results in a hardware alarm being raised.
- 

## Syntax

**PageGetInt(*sLabel* [, *iWinNum*])**

*sLabel*:

String name of the variable to return

*iWinNum*:

Window number of the page. Default is current window.

## Return Value

Integer stored in variable *sLabel*.

## Related Functions

[PageSetInt](#), [PageGetStr](#), [PageSetStr](#)

## See Also

[Page Functions](#)

### PageGetStr

Gets the string associated with a variable name on a particular page. Page-based variables are local to each display page. If two or more windows are displayed, each window has a unique copy of the variable. You can use these variables in Cicode to keep track of variables unique to each window.

**Note:** This function is not supported in the server process in a multiprocessor environment. Calling this function from the server process results in a hardware alarm being raised.

## Syntax

**PageGetStr(*sLabel* [, *iWinNum*])**

*sLabel*:

String name of the variable to return

*iWinNum*:

Window number of the page. Default is current window.

## Return Value

Value stored in variable *sLabel*.

## Related Functions

[PageSetInt](#), [PageGetInt](#), [PageSetStr](#)

## See Also

[Page Functions](#)

### PageGoto

Displays a graphics page in the active window. The page needs to be in one of the operator's current areas. You can specify either the Page Name or the Page Number of the graphics page.

You can also specify if the page operates within the context of a particular cluster in a multiple cluster project. When the page launches during runtime, the ClusterName argument is used to resolve any tags that have the cluster name omitted.

This function is similar to PageDisplay(), however PageGoto() does not put the current page into the page

navigation history.

You cannot call this function from the Exit command field (see [Edit the Properties for a Page](#)) or a Cicode Object.

**Note:** This function is not supported in the server process in a multiprocessor environment. Calling this function from the server process results in a hardware alarm being raised.

## Syntax

**PageGoto(*Page*, *ClusterName*)**

*Page*:

The name or page number of the page to display (in quotation marks ""). Can be prefixed by the name of a host cluster, that is "ClusterName.Page". This will take precedence over the use of the ClusterName parameter if the two differ.

*sClusterName*:

The name of the cluster that will accommodate the page at runtime (in quotation marks ""). The specified cluster is used to resolve any tags that have the cluster name omitted. If the Page parameter is prefixed with the name of a cluster, this parameter will not be used.

## Return Value

0 (zero) if the page is successfully displayed, otherwise an error is returned.

## Related Functions

[PageDisplay](#)

## Example

```
PageDisplay("MIMIC1");
! Displays page "MIMIC1".
PageDisplay("MIMIC2");
/* Displays page "MIMIC2" and places page "MIMIC1" onto the
page navigation history. */
PageGoto("10");
/* Displays page "10". Page "MIMIC2" is not placed onto the
page navigation history. */
```

**Note:** Before Plant SCADA version 5.0, page records could be edited in the Project Editor. One of the fields available for configuration was "Page Number". The value entered for a page could then be used in runtime with the Page Cicode functions such as PageDisplay(), PageGoto(), and PageInfo(1).

For example, PageDisplay("1") can be used to display the page that has "1" (without the quotes) set in the **Page Number** field. PageInfo(1) returns the Page Number of the current page.

From version 5.0 on, this feature is only backwards-supported. The "Alias" field in the project Pages.DBF file still contains the Page Numbers from upgraded projects; however, the Pages database records are no longer available for direct editing in Plant SCADA.

## See Also

[Page Functions](#)

### PageHardware

Displays the active hardware alarms on the hardware alarms page.

To use this function, you need to have a page in your project that was created using the Hardware template. By default, the name of the page is expected to be "Hardware". However, you can use a page with a different name by adjusting the setting for the INI parameter [\[Page\]HardwarePage](#).

---

**Note:**

- This function is not supported in the server process in a multiprocessor environment. Calling this function from the server process results in a hardware alarm being raised.
  - When similar hardware alarms are triggered, for example "Tag not found" alarms, the hardware alarm page and hardware alarm queue show the last invalid entry. The previous entry of the same description is overwritten.
- 

## Syntax

`PageHardware()`

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[PageAlarm](#)

## Example

System Keyboard

Key Sequence	Hardware
Command	<code>PageHardware()</code>
Comment	Display active hardware alarms on the hardware alarms page

## See Also

[Page Functions](#)

## PageHistoryDspMenu

Displays a pop-up menu which lists the page history of current window. The user can select any page in the history to recall the page. When full page history is specified, the currently displayed page will also be listed and marked in the menu.

## Syntax

**PageHistoryDspMenu([*iType*])**

*iType*:

The type of page history to be listed:

0 - full history (default)

1 - back history

2 - forward history

## Return Value

Zero (0) if the function is executed successfully. Otherwise an error is returned.

## Related Functions

[PageBack](#), [PageForward](#), [PageHistoryEmpty](#)

## See Also

[Page Functions](#)

## PageHistoryEmpty

Used to determine if the page history of the current window is empty. The currently displayed page is not counted as history.

## Syntax

**PageHistoryEmpty([*iType*])**

*iType*:

The type of page history to be checked:

0 - full history (default)

1 - back history

2 - forward history

## Return Value

1 if page history of specified type is empty, or 0 if it is not empty.

## Related Functions

[PageBack](#), [PageForward](#), [PageHistoryDspMenu](#)

## See Also

[Page Functions](#)

### PageHome

Displays the predefined home page in the window.

## Syntax

**PageHome([*sCluster*])**

*sCluster*:

Optional parameter to the Cluster to associate the page being opened with. Default value "".

## Return Value

No error(0) on success. Bad handle specified (269) if current window handle does not correspond to a valid window. Bad handle specified (274) if INI parameter [\[Page\]HomePage](#) is not set.

## See Also

[Page Functions](#)

### PageInfo

Gets information about the current page.

---

**Note:** This function is not supported in the server process in a multiprocessor environment. Calling this function from the server process results in a hardware alarm being raised.

---

## Syntax

**PageInfo(*nType*)**

*nType*:

The type of page information required.

0 — Page name.

- 1 — Page number.
- 2 — Page title.
- 3 — Display file name.
- 4 — Symbol file name.
- 5 — Next page name.
- 6 — Previous page name
- 7 — Previous display count, incremented at each page scan. The page scan rate defaults to the value of the Citect.ini parameter [Page]ScanTime, and can be overridden per page by changing the scan time setting in the General tab of the page properties in Graphics Builder.
- 8 — Parent window number. Returns -1 if there is no parent.
- 9 — First child window number. Returns -1 if there are no children.
- 10 — Next child in child link. Returns -1 for the end of the list.
- 11 — Window mode (set by the WinNewAt() function).
- 12 — Width of window. If the target is a pinned window, the return value will represent the width of the window as it is on the unscaled version of the page that hosts it.
- 13 — Height of window. If the target is a pinned window, the return value will represent the height of the window as it is on the unscaled version of the page that hosts it.
- 14 — X position of window. If the target is a pinned window, the value will reflect the coordinates for the window based on its location on the unscaled version of the page that hosts it.
- 15 — Y position of window. If the target is a pinned window, the value will reflect the coordinates for the window based on its location on the unscaled version of the page that hosts it.
- 16 — Dynamic window horizontal scale.
- 17 — Dynamic window vertical scale.
- Types 16 and 17 return a real number between 0 and 1 (as a STRING) and will be identical, as the dynamic scaling does not allow a change in the aspect ratio.
- 18 — Flashing color state. Type 18 returns one of the following:
- "0" — the palette does not flash.
  - "1" — the palette is primary now.
  - "2" — the palette is secondary now.
- 19 — In animation cycle. Returns a 1 (true) or 0 (false).
- 20 — In communications cycle. Returns a 1 (true) or 0 (false).
- 21 — Width of background page.
- 22 — Height of background page.
- 23 — Returns the highest AN.
- 24 — Returns the number of ANs.
- 25 — Indicates when the page's "On Page Shown" event has been triggered. Returns 1 if triggered, 0 if it has not.
- 26 — The cluster that has been specified to host the page. Returns the cluster name, or an empty string if no cluster has been specified.
- 27 — Indicates whether the Cicode library used by the page is different from the currently loaded library. Returns 1 if different, 0 if the versions are the same.

- 28 — Return X Coordinate of Client rectangle origin.
- 29 — Return Y Coordinate of Client rectangle origin.
- 30 — Returns the name of the monitor the current page is displayed on at runtime. For example, in a project where three monitors "Screen 1", "Primary", and "Screen 2" have been configured as part of a multi-monitor screen profile, PageInfo(30) has been set on the monitor named "Left" which means "Left" would be displayed at runtime. For more information refer to the topic [Screen Profiles](#) in the main help.
- 31 — Returns the "Content Type" configured for that page.

## Return Value

The information (as a string).

## Related Functions

[PageDisplay](#), [PageTransformCoords](#)

## Example

```
! If currently on page "MIMIC1";
Variable=PageInfo(0);
! Sets Variable to "MIMIC1".
```

**Note:** Before Plant SCADA version 5.0, page records could be edited in the Project Editor. One of the fields available for configuration was "Page Number". The value entered for a page could then be used in runtime with the Page Cicode functions such as PageDisplay(), PageGoto(), and PageInfo(1).

For example, PageDisplay("1") can be used to display the page that has "1" (without the quotes) set in the **PageNumber** field. PageInfo(1) returns the Page Number of the current page.

From version 5.0 on, this feature is only backwards-supported. The "Alias" field in the project Pages.DBF file still contains the Page Numbers from upgraded projects; however, the Pages database records are no longer available for direct editing in Plant SCADA.

## See Also

[Page Functions](#)

## PageLast

Displays the graphics page that was last displayed. With this function, you can successively recall the last ten pages that were displayed.

Graphics pages displayed using this command cannot be subsequently recalled.

You cannot call this function from the Exit command field (see [Edit the Properties for a Page](#)) or a Cicode Object.

**Note:** This function is not supported in the server process in a multiprocessor environment. Calling this function from the server process results in a hardware alarm being raised.

## Syntax

**PageLast()**

## Return Value

0 (zero) if the page is successfully displayed, otherwise an error is returned.

## Related Functions

[PagePeekLast](#), [PagePopLast](#), [PagePushLast](#)

## Example

Buttons

Text	Last Page
Command	PageLast()
Comment	Display the graphics page that was last displayed

```
PageDisplay("MIMIC1");
! Displays page "MIMIC1".
PageDisplay("MIMIC2");
/* Displays page "MIMIC2" and places page "MIMIC1" onto the
page navigation history. */
PageDisplay("10");
! Displays page "10" and places page "MIMIC2" onto the page navigation history. */
PageLast();
/* Displays the last page, that is page "MIMIC2" and
removes it from the
page navigation history. */
PageLast();
/* Displays the last page, that is page "MIMIC1" and
removes it from the
page navigation history. */
PageLast();
/* Returns an "Out of range" error code as there are no more pages in the
page navigation history.*/
```

## See Also

[Page Functions](#)

## PageListCount

Gets number of pages in the page list of the current window.

See the Citect.ini parameter [\[Page\]MaxList](#).

## Syntax

```
PageListCount()
```

## Return Value

Number of pages in the list

## Related Functions

[PageListCurrent](#), [PageListInfo](#), [PageListDisplay](#), [PageListDelete](#)

## Example

```
INT count;
INT index;
INT error;
STRING PageName;

// While 4 entries will be added to page history, only 3 unique pages will be added to page
list
PageDisplay(Page1);
PageDisplay(Page2);
PageDisplay(Page1);
PageDisplay(Page3);

// iterate the pages in the list
count=PageListCount() //count=3
PageName=PageListInfo(0,0); //PageName=Page1
PageName=PageListInfo(1,0); //PageName=Page2
PageName=PageListInfo(2,0); //PageName=Page3
index=PageListCurrent(); //index=2, as Page3 is currently displayed
pageName=PageListInfo(index,0); //PageName=Page3
error=PageListDisplay(1); //recall Page2, error=0
index=PageListCurrent(); //index=1, as current index is moved as part of the recall
PageName=PageInfo(0); //PageName=Page2 as it becomes the current page
error=PageListDelete(index); //remove current page, i.e. Page2, error=0
PageName=PageInfo(0); //PageName=Page3, next page in the list is displayed
index=PageListCurrent(); //index=1, current index is not changed while the list is reduced
count=PageListCount(); //count=2, only 2 pages left in the list
```

## See Also

[Page Functions](#)

### PageListCurrent

Gets Index of the current page in the page list of current window.

## Syntax

```
PageListCurrent()
```

## Return Value

List index (0 to list size -1), or -1 if unable to get index

## Related Functions

[PageListCount](#), [PageListInfo](#), [PageListDisplay](#), [PageListDelete](#)

## Example

```
INT count;
INT index;
INT error;
STRING PageName;

// While 4 entries will be added to page history, only 3 unique pages will be added to page
list
PageDisplay(Page1);
PageDisplay(Page2);
PageDisplay(Page1);
PageDisplay(Page3);

// iterate the pages in the list
count=PageListCount() //count=3
PageName=PageListInfo(0,0); //PageName=Page1
PageName=PageListInfo(1,0); //PageName=Page2
PageName=PageListInfo(2,0); //PageName=Page3
index=PageListCurrent(); //index=2, as Page3 is currently displayed
pageName=PageListInfo(index,0); //PageName=Page3
error=PageListRecall(1); //recall Page2, error=0
index=PageListCurrent(); //index=1, as current index is moved as part of the recall
PageName=PageInfo(0); //PageName=Page2 as it becomes the current page
error=PageListDelete(index); //remove current page, i.e. Page2, error=0
PageName=PageInfo(0); //PageName=Page3, next page in the list is displayed
index=PageListCurrent(); //index=1, current index is not changed while the list is reduced
count=PageListCount(); //count=2, only 2 pages left in the list
```

## See Also

[Page Functions](#)

### PageListInfo

Gets information of a page at the specific index in the page list of the current window.

## Syntax

**PageListInfo(INT index,[ INT type])**

*Index*

Index to the page list (valid range 0 to list size minus 1)

*Type*

Information to return:

0- Page name (default)

1- Configured Page Title

2- Active Page Title

## Return Value

String value of the requested information, or empty string if no valid information can be found

## Related Functions

[PageListCount](#), [PageListCurrent](#), [PageListDisplay](#)

## Example

```
INT count;
INT index;
INT error;
STRING PageName;

// While 4 entries will be added to page history, only 3 unique pages will be added to page
list
PageDisplay(Page1);
PageDisplay(Page2);
PageDisplay(Page1);
PageDisplay(Page3);

// iterate the pages in the list
count=PageListCount() //count=3
PageName=PageListInfo(0,0); //PageName=Page1
PageName=PageListInfo(1,0); //PageName=Page2
PageName=PageListInfo(2,0); //PageName=Page3
index=PageListCurrent(); //index=2, as Page3 is currently displayed
pageName=PageListInfo(index,0); //PageName=Page3
error=PageListDisplay(1); //recall Page2, error=0
index=PageListCurrent(); //index=1, as current index is moved as part of the recall
PageName=PageInfo(0); //PageName=Page2 as it becomes the current page
error=PageListDelete(index); //remove current page, i.e. Page2, error=0
PageName=PageInfo(0); //PageName=Page3, next page in the list is displayed
index=PageListCurrent(); //index=1, current index is not changed while the list is reduced
count=PageListCount(); //count=2, only 2 pages left in the list
```

## See Also

[Page Functions](#)

### PageListDisplay

Recalls (displays) a page at the specific index in the page list of current window, and moves the current index to the page. When a page is recalled, the original parameters (such as cluster context, supergenie associations, PageTask arguments if applicable) used to display the page will be restored.

(See the Citect.ini parameter [\[Page\]MaxList](#).

## Syntax

**PageListDisplay(INT index)**

*Index*

Index to the page list (valid range 0 to list size minus 1)

## Return Value

0 (zero) if the page is successfully displayed, otherwise an error is returned.

## Related Functions

[PageListCount](#), [PageListCurrent](#), [PageListInfo](#), [PageListDelete](#)

## Example

```
INT count;
INT index;
INT error;
STRING PageName;

// While 4 entries will be added to page history, only 3 unique pages will be added to page
list
PageDisplay(Page1);
PageDisplay(Page2);
PageDisplay(Page1);
PageDisplay(Page3);

// iterate the pages in the list
count=PageListCount() //count=3
PageName=PageListInfo(0,0); //PageName=Page1
PageName=PageListInfo(1,0); //PageName=Page2
PageName=PageListInfo(2,0); //PageName=Page3
index=PageListCurrent(); //index=2, as Page3 is currently displayed
pageName=PageListInfo(index,0); //PageName=Page3
error=PageListDisplay(1); //recall Page2, error=0
index=PageListCurrent(); //index=1, as current index is moved as part of the recall
```

```
PageName=PageInfo(0); //PageName=Page2 as it becomes the current page
error=PageListDelete(index); //remove current page, i.e. Page2, error=0
PageName=PageInfo(0); //PageName=Page3, next page in the list is displayed
index=PageListCurrent(); //index=1, current index is not changed while the list is reduced
count=PageListCount(); //count=2, only 2 pages left in the list
```

## See Also

[Page Functions](#)

### PageListDelete

Removes a page at the specific index from the page list of the current window. This function will return an error if only one page is in the list. If the page is currently displayed, the next page will be displayed. If there is no next page, the previous page will be displayed.

## Syntax

```
PageListDelete(INT index)
Index
Index to the page list (valid range 0 to list size minus 1)
```

## Return Value

0 (zero) if the page is successfully removed, otherwise an error is returned.

## Related Functions

[PageListCount](#), [PageListCurrent](#), [PageListInfo](#), [PageListDisplay](#)

## Example

```
INT count;
INT index;
INT error;
STRING PageName;

// While 4 entries will be added to page history, only 3 unique pages will be added to page
list
PageDisplay(Page1);
PageDisplay(Page2);
PageDisplay(Page1);
PageDisplay(Page3);

// iterate the pages in the list
count=PageListCount() //count=3
PageName=PageListInfo(0,0); //PageName=Page1
PageName=PageListInfo(1,0); //PageName=Page2
```

```
PageName=PageListInfo(2,0); //PageName=Page3
index=PageListCurrent(); //index=2, as Page3 is currently displayed
pageName=PageListInfo(index,0); //PageName=Page3
error=PageListDisplay(1); //recall Page2, error=0
index=PageListCurrent(); //index=1, as current index is moved as part of the recall
PageName=PageInfo(0); //PageName=Page2 as it becomes the current page
error=PageListDelete(index); //remove current page, i.e. Page2, error=0
PageName=PageInfo(0); //PageName=Page3, next page in the list is displayed
index=PageListCurrent(); //index=1, current index is not changed while the list is reduced
count=PageListCount(); //count=2, only 2 pages left in the list
```

[Page Functions](#)

## PageMenu

Displays a menu page with page selection buttons. A page goto button is displayed for each of the first 40 pages defined in the project.

## Syntax

**PageMenu()**

## Return Value

0 (zero) if the page is successfully displayed, otherwise an error is returned.

## Related Functions

[PageGoto](#), [PageLast](#), [PagePrev](#), [PageSelect](#)

## Example

### Buttons

Text	Menu
Command	PageMenu()
Comment	Display the menu page

### System Keyboard

Key Sequence	Menu
Command	PageMenu()
Comment	Display the menu page

## See Also

[Page Functions](#)

### PageNext

Displays the next page as specified in the project.

You cannot call this function from the Exit command field (see [Edit the Properties for a Page](#)) or a Cicode object.

**Note:** This function is not supported in the server process in a multiprocessor environment. Calling this function from the server process results in a hardware alarm being raised.

## Syntax

**PageNext()**

## Return Value

0 (zero) if the page is successfully displayed, otherwise an error is returned.

## Related Functions

[PagePrev](#)

## Example

### Buttons

Text	Page Next
Command	PageNext()
Comment	Display the next page in the browse sequence

### System Keyboard

Key Sequence	PageNext
Command	PageNext()
Comment	Display the next page in the browse sequence

```
/* If graphics page 1 is currently displayed, and the graphics
page 1 has Next Page Name=10. */
PageNext();
! Displays graphics page 10.
```

## See Also

[Page Functions](#)

### Page.PeekCurrent

Return the index in the page navigation history for the current page.

## Syntax

**Page.PeekCurrent()**

## Return Value

Index in the page navigation history for the current page. -1 indicates that current window handle does not correspond to a valid window.

## Related Functions

[Page.PeekLast](#), [Page.PopLast](#), [Page.PopUp](#), [Page.PushLast](#), [Page.Recall](#)

## See Also

[Page Functions](#)

### Page.PeekLast

Gets information about a page at an offset in the page navigation history.

---

**Note:** This function is not supported in the server process in a multiprocessor environment. Calling this function from the server process results in a hardware alarm being raised.

---

## Syntax

**Page.PeekLast(*iOffset* [, *iType*] )**

*iOffset*:

Pages are navigated using page navigation history. *iOffset* is used to indicate the position in that history. An *iOffset* value of "0" represents the currently viewed page. Positive increments of *iOffset* indicate previous pages visited in the navigation history. Negative values of *iOffset* are used to indicate pages in the future of the navigation history (negative *iOffsets* exist only if the user has used the back button to revisit earlier pages in the history).

For example:

If you navigate pages in the sequence A, B, C, D, E, and then remain on Page E. The *iOffset* value indicates the following pages:

*iOffset* value: 4 3 2 1 0

corresponding page: A B C D E

If you then navigate "Back" twice the iOffset value indicates the following pages:

iOffset value: 2 1 0 -1 -2

corresponding page: A B C D E

If you further navigate to pages F then G the iOffset value indicates the following pages:

iOffset value: 4 3 2 1 0

corresponding page: A B C F G

*iType*:

An enumeration representing the type of information required. The default value is 0.

0 - Page Name

1 - Configured Page Title

2 - Active Page Title

## Return Value

String value of the requested information, or empty string if no valid result for given arguments.

## Related Functions

[PagePeekCurrent](#), [PagePopLast](#), [PagePopUp](#), [PagePushLast](#)

## See Also

[Page Functions](#)

## PagePopLast

Gets the Page Name of the last item in the page navigation history and removes the page from the history.

---

**Note:** This function is not supported in the server process in a multiprocessor environment. Calling this function from the server process results in a hardware alarm being raised.

---

## Syntax

`PagePopLast()`

## Return Value

The page name or an empty string if there is no last page.

## Related Functions

[PageLast](#), [PagePeekCurrent](#), [PagePeekLast](#), [PagePopUp](#), [PagePushLast](#)

## Example

```
PageDisplay("MIMIC1");
! Displays page "MIMIC1".
PageDisplay("MIMIC2");
/* Displays page "MIMIC2" and places page "MIMIC1" onto the page navigation history. */
PageDisplay("10");
! Displays page "10" and places page "MIMIC2" onto the page navigation history.
Variable=PagePopLast();
/* Sets Variable to "MIMIC2" and removes "MIMIC2" from the page navigation history. */
PageLast();
! Displays page "MIMIC1".
```

## See Also

[Page Functions](#)

### PagePopUp

Display pop up window at the mouse position. If the mouse position is not known then the pop up will display in the centre of the screen. The window is displayed with no resize and will be closed if the page is changed.

## Syntax

**PagePopUp(*sPage*, [, *sClusterName*])**

*sPage*:

The name of the page (drawn with the Graphics Builder).

*sClusterName*:

The name of the cluster that will accommodate the page at runtime (in quotation marks ""). The specified cluster is used to resolve any tags that have a cluster omitted. If the Page parameter is prefixed with the name of a cluster, this parameter will not be used.

This parameter is optional, however if you omit a cluster context in the Page properties, then any tags which omit an explicit Cluster. TagName will be ambiguous and become unresolved if you have multiple clusters defined in the project. Note that this ambiguity and resulting unresolved state will only occur if the parameter [\[General\]TagDB](#) is set to "0" which disables variable tag database loading.

---

**Note:** Before Plant SCADA version 5.0, page records could be edited in the Project Editor. One of the fields available for configuration was "Page Number". The value entered for a page could then be used in runtime with the Page Cicode functions such as PageDisplay(), PageGoto(), and PageInfo(1).

For example, PageDisplay("1") can be used to display the page that has "1" (without the quotes) set in the **Page Number** field. PageInfo(1) returns the Page Number of the current page.

From version 5.0 on, this feature is only backwards-supported. The "Alias" field in the project Pages.DBF file still contains the Page Numbers from upgraded projects; however, the Pages database records are no longer available for direct editing in Plant SCADA.

---

## Related Functions

[PageLast](#), [PagePeekCurrent](#), [PagePeekLast](#), [PagePopLast](#), [PagePushLast](#)

## See Also

[Page Functions](#)

### PagePrev

Displays the previous page as specified in the project.

You cannot call this function from the Exit command field (see [Edit the Properties for a Page](#)) or a Cicode Object.

**Note:** This function is not supported in the server process in a multiprocessor environment. Calling this function from the server process results in a hardware alarm being raised.

## Syntax

**PagePrev()**

## Return Value

0 (zero) if the page is successfully displayed, otherwise an error is returned.

## Related Functions

[PageNext](#)

## Example

Buttons

Text	Page Previous
Command	PagePrev()
Comment	Display the previous page in the browse sequence

System Keyboard

Key Sequence	PagePrev
Command	PagePrev()
Comment	Display the previous page in the browse sequence

```
/* If graphics page 10 is currently displayed, and graphics page
10 has Prev Page Name=1. */
PagePrev();
! Displays graphics page 1.
```

## See Also

[Page Functions](#)

### PageProcessAnalyst

Displays a Process Analyst page (in the same window) preloaded with the pre-defined Process Analyst View (PAV) file.

## Syntax

```
PageProcessAnalyst(sPage, sPAVFile1 [, iFileLocation1 [, iButtonMask1 [, sObjName1 [, sPAVFile2 [, iFileLocation2  
[, iButtonMask2 [, sObjName2 ]]]]]]])
```

*sPage*:

The name of the page that contains Process Analyst object(s). For example, pages based on the Process Analyst templates found in the Tab\_Style\_Include project.

*sPAVFile1*:

Name of the 1st PAV file

*iFileLocation1*:

PAV file location code for the 1st PAV file, see PA doc LoadFromFile() for details.

*iButtonMask1*:

Bit mask for removing command buttons from the 1st PA, bit flags as shown below:

1 - Load View

2 - Save View

4 - Print

8 - Copy to Clipboard

16 - Copy to File

32 - Add Pens

64 - Remove Pens

128 - Show Properties

256 - Help

*sObjName1*:

Name of the PA object on the given Page where the 1st PAV file will be loaded. If this parameter is not specified or empty string, it is defaulted to the object name used in the tab style templates, that is "\_templatePA1".

*sPAVFile2*:

Name of the 2nd PAV file

*iFileLocation2*:

PAV file location code for the 2nd PAV file

*iButtonMask2*:

Bit mask for removing command buttons from the 2nd PA, refer *iButtonMask1* for details

*sObjName2*:

Name of the PA object on the given Page where the 2nd PAV file will be loaded. If this parameter is not specified or empty string, it is defaulted to the object name used in the tab style templates, that is "\_templatePA2".

## Return Value

Zero (0) if the page is successfully displayed. Otherwise an error is returned.

## Related Functions

[PageProcessAnalystPens](#), [ProcessAnalystLoadFile](#), [ProcessAnalystPopup](#), [ProcessAnalystSelect](#),  
[ProcessAnalystSetPen](#), [ProcessAnalystWin](#), [TrnSetPen](#), [WinNewAt](#)

## See Also

[Page Functions](#)

### PageProcessAnalystPens

Display a page and add the specified pens to the first pane of the specified PA object on the page. If a PAV file is also specified, it will be loaded first, and the pens in the first pane will be removed before the specified pens are created on the PA.

## Syntax

**PageProcessAnalystPens**(*sPage*, *sTag1* [, *sTag2..sTag8* [, *iButtonMask* [, *sObjName* [, *iPane* [, *sPAVFile* [, *iFileLocation* ]]]]])

*sPage*:

The name of the page that displays the PA.

*sTag1..sTag8*:

Up to 8 Trend tags can be added to the PA.

*iButtonMask*:

Mask to remove button(s) from the main tool bar of PA. The following values can be combined to remove multiple buttons:

1 - Load View

2 - Save View

4 - Print

8 - Copy to Clipboard

16 - Copy to File

32 - Add Pens

64 - Remove Pens

128 - Show Properties

256 - Help

***sObjName***

The name of the PA object. If not specified it is defaulted to "\_templatePA1" which is the name used by the built-in templates.

***iPane***

The pane in PA where the trend or variable tags are added. If this is not specified or less than 1, it is defaulted to 1 (the 1st pane). If the specified pane does not exist in the PA object, a new pane will be created.

***sPAVFile:***

Optional Process Analyst View file to be loaded, default ="".

***iFileLocation:***

Optional location of the PAV file. The allowed values are:

- 0 - Analyst Views subfolder in project folder (default)
- 1 - Folders specified in properties primary/standby server path
- 2 - My documents folder

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[PageProcessAnalyst](#), [ProcessAnalystLoadFile](#), [ProcessAnalystPopup](#), [ProcessAnalystSelect](#), [ProcessAnalystSetPen](#),  
[ProcessAnalystWin](#), [TrnSetPen](#), [WinNewAt](#)

## See Also

[Page Functions](#)

## PagePushLast

Places a page at the end of the page navigation history.

**Note:** This function is not supported in the server process in a multiprocessor environment. Calling this function from the server process results in a hardware alarm being raised.

## Syntax

**PagePushLast(*Page*)**

***Page:***

The Page Name or Page Number (of the page) to place at the end of the page navigation history.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[PageLast](#), [PagePeekCurrent](#), [PagePeekLast](#), [PagePopLast](#), [PagePopUp](#)

## Example

```
PageDisplay("MIMIC1");
! Displays page "MIMIC1".
PageDisplay("MIMIC2");
/* Displays page "MIMIC2" and places page "MIMIC1" onto the page navigation history. */
PageDisplay("10");
! Displays page "10" and places page "MIMIC2" onto the page navigation history.
PagePushLast("TREND1");
! Places page "TREND1" onto the page navigation history.
PageLast();
/* Displays the last page, that is page "TREND1" and removes it from the page navigation
history. */
PageLast();
/* Displays the last page, that is page "MIMIC2" and removes it from the page navigation
history. */
```

## See Also

[Page Functions](#)

## PageRecall

Displays the page at a specified depth in the page navigation history.

## Syntax

**PageRecall(*iIndex*)**

*iIndex*:

The index into the page navigation history of the Page to be displayed. To get the index for the currently displayed page, call [PagePeekCurrent\(\)](#). Then increment it to access pages in the forward history, or decrement it to access pages in the backward history. Be reminded that you cannot recall the page that is currently displayed.

## Return Value

No error(0) on success. Bad handle specified (269) if current window handle does not correspond to a valid window. Bad handle specified (274) if index is outside of allowable bounds.

## Related Function

[PagePeekCurrent](#)

## See Also

[Page Functions](#)

### PageRichTextFile

This function creates a rich edit object, and loads a copy of the rich text file *Filename* into that object. The rich text object will be rectangular in shape, with dimensions determined by *nHeight*, and *nWidth*. If you do not specify *nHeight* and *nWidth*, *nAN* will define the position of one corner, and (*AN* + 1) the position of the diagonally opposite corner. This function would often be used as a page entry function.

## Syntax

**PageRichTextFile(*nAN*, *Filename*, *nMode* [, *nHeight*] [, *nWidth*] )**

*nAN*:

The animation point at which to display the rich text object.

*Filename*:

The name of the file to be copied and loaded into the rich text object. The filename needs to be entered in quotation marks "".

If you are loading a copy of an RTF report, the report needs to have already been run and saved to a file.

Remember that the filename for the saved report comes from the File Name field in the Devices form. The location of the saved file needs to also be included as part of the filename. For example, if the filename in the Devices settings listed [Data];RepDev.rtf, then you would need to enter "[Data]\repdev.rtf" as your argument. Alternatively, you can manually enter the path, for example, "c:\MyApplication\data\repdev.rtf".

If you are keeping a number of history files for the report, instead of using the rtf extension, you need to change it to reflect the number of the desired history file, for example, 001.

*nMode*:

The display mode for the rich text object. The mode can be any combination of:

0 - Disabled - should be used if the rich text object is to be used for display purposes only.

1 - Enabled - allows you to select and copy the contents of the RTF object (for instance an RTF report), but you will not be able to make changes.

2 - Read/Write - allows you to edit the contents of the RTF object. Remember, however, that the object needs to be enabled before it can be edited. If it has already been enabled, you can just enter Mode 2 as your argument. If it is not already enabled, you will need to enable it. By combining Mode 1 and Mode 2 in your argument (3), you can enable the object, and make it read/write at the same time.

Because the content of the rich text object is just a copy of the original file, changes will not affect the actual file, until saved using the [DspRichTextSave](#) function.

*nHeight*:

The height of the rich text object in pixels. The height is established by measuring down from the animation point.

If you do not enter a height and width, the size of the object will be determined by the position of *nAN* and *AN+1*.

*nWidth*:

The width of the rich text object in pixels. The width is established by measuring across to the right of the animation point.

If you do not enter a height and width, the size of the object will be determined by the position of *nAN* and *AN+1*.

## Return Value

None

## Related Functions

[DspRichText](#), [DspRichTextLoad](#), [DspRichTextEdit](#), [DspRichTextEnable](#), [DspRichTextGetInfo](#), [DspRichTextPgScroll](#),  
[DspRichTextPrint](#), [DspRichTextSave](#), [DspRichTextScroll](#), [FileRichTextPrint](#)

## Example

```
PageRichTextFile(108,"f:\Plant SCADA\data\richtext.rtf",0);

// This function would produce a rich text object at animation
point 108. Into this object a copy of f:\Plant SCADA\data\richtext.rtf
would then be loaded. Remember, richtext.rtf is the name of the
output file for the report, as specified in the Devices form.
Because 0 was specified as the nMode for this example, the
contents of this object will be display only. //

PageRichTextFile(53,"[Data]\richtext.rtf",1);

//This function would produce a rich text object at animation
point 53. Into this object a copy of [Data]\richtext.rtf would
then be loaded. It will be possible to select and copy the
contents of the object, but not make changes. //
```

## See Also

[Page Functions](#)

## PageSelect

Displays a dialog box with a list of graphics pages defined in the project. AN operator can select a page name for display.

## Syntax

**PageSelect()**

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[PageGoto](#), [PageLast](#), [PagePrev](#), [PageMenu](#)

## Example

Buttons

Text	Page Select
Command	PageSelect()
Comment	Display the page selection dialog box

```
PageSelect();  
! Displays the page selection dialog box.
```

## See Also

[Page Functions](#)

## PageSetInt

Associates an integer variable with a particular page. Page-based variables are stored in an array, local to each display page. This function allows you to save integer variables in temporary storage.

---

**Note:**

- You can dynamically change the setting for [\[Page\]ScanTime](#) parameter, by calling this function as follows:  
PageSetInt(-2, <scantime>).
  - This function is not supported in the server process in a multiprocessor environment. Calling this function from the server process results in a hardware alarm being raised.
- 

## Syntax

**PageSetInt**(*sLabel*, *sVar* [, *iWinNum*])

*sLabel*:

String name of the variable which will contain *sValue*.

*sVar*:

The integer to store.

*iWinNum*:

Window number of the page. Default is current window.

## Return Value

No error(0) on success. 269 if *WinNum* handle does not correspond to a valid window. 274 if Label or Var is not a valid variable.

## Related Functions

[PageGetInt](#), [PageGetStr](#), [PageSetStr](#)

## See Also

[Page Functions](#)

### PageSetStr

Stores a local page-based string and associates the string with the page. Page-based variables are stored in an array, local to each display page. This function allows you to save string variables in temporary storage.

**Note:** This function is not supported in the server process in a multiprocessor environment. Calling this function from the server process results in a hardware alarm being raised.

## Syntax

**PageSetStr(*sLabel*, *sVar* [, *iWinNum*])**

*sLabel*:

String name of the variable which will contain *sVar*.

*sVar*:

The string to store. The string length is 128 characters.

*iWinNum*:

Window number of the page. Default is current window.

## Return Value

No error(0) on success. 269 if WinNum handle does not correspond to a valid window. 274 if Label or Var is not a valid variable.

## Related Functions

[PageGetInt](#), [PageGetStr](#), [PageSetInt](#)

## See Also

[Page Functions](#)

### PageSOE

Displays a category of sequence of events (SOE) entries on the SOE page.

To use this function, you need to have a page in your project that was created using the SOE template. By default, the name of the page is expected to be "SOE". However, you can use an alarm page with different name

by adjusting the setting for the INI parameter [\[Page\]SOEPage](#).

## Syntax

**PageSOE(INT Category, INT Fallback)**

*Category:*

The category number for the alarms you want to display their events

*Fallback:*

Whether to display the Summary page instead if the SOE page does not exist. If not specified it defaults to FALSE (0).

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[PageAlarm](#)

## Example

## See Also

[Page Functions](#)

## PageSummary

Displays a category of alarm summary entries on the alarms summary page.

To use this function, you need to have a page in your project that was created using the Summary template. By default, the name of the page is expected to be "Summary". However, you can use an alarm page with a different name by adjusting the setting for the INI parameter [\[Page\]SummaryPage](#).

---

**Note:**

- The operation of this function has changed. In Version 2.xx this function displayed the built-in summary alarm page from the Include project.
  - This function is not supported in the server process in a multiprocessor environment. Calling this function from the server process results in a hardware alarm being raised.
- 

## Syntax

**PageSummary(Category)**

*Category:*

The category number for the alarms you want to summarise.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[PageAlarm](#)

## Example

System Keyboard

Key Sequence	SummaryPage
Command	PageSummary(0)
Comment	Display alarm summary entries on the alarm page

System Keyboard

Key Sequence	Summary ### Enter
Command	PageSummary(Arg1)
Comment	Display a specified category of alarm summary entries on the alarm page

## See Also

[Page Functions](#)

## PageTask

PageTask() is used for running preliminary Cicode before displaying a page in a window. It makes it possible for the same Cicode to be run if the page is re-entered by navigating forward or back. PageTask() is similar to TaskNew().

PageTask() returns a handle to a code task the first time it is run. The custom Cicode of the *sFunctionName* parameter needs to call PageDisplay() in order to display the page. When the page changes, the function and its parameters will be pushed onto the Page Navigation History. The Cicode fnTask will be called again when the page is navigated to using the PageForward or PageBack functions.

## Syntax

**PageTask(*iWinNum*, *sFunctionName*, *sFunctionArg*)**

*iWinNum*:

The Window number of the window in which to display the page.

*sFunctionName*:

String representing the Cicode function to run each time the page is navigated to using the forward and backward navigation functions.

*sFunctionArg*:

String representing the parameters to use with function fnTask.

## Return Value

A handle to a code task the first time it is run. BAD\_HANDLE (-1) if the function did not complete.

## Related Functions

[PageDisplay](#), [PageBack](#), [PageForward](#)

## Example

```
FUNCTION DisplayAlarmLog()
    PageTask(WinNumber(), "_DisplayAlarmLog", "");
END

FUNCTION _DisplayAlarmLog()
    PageFile("[Data]:AlarmLog.Txt");
    DspFile(21,DspFont("Courier", -10, Black, Transparent), 24, 120);
    WinTitle("@(Alarm History)");
END
```

[Page Functions](#)

## PageTransformCoords

Converts Page coordinates to absolute screen coordinates.

## Syntax

**PageTransformCoords(*hPage*, *iPageX*, *iPageY*, *iDisplayX*, *iDisplayY*, *iType*)**

*hPage*:

Page handle of the relevant Window.

*PageX*:

X coordinate of page coordinate.

*iPageY*:

Y coordinate of page coordinate.

*iDisplayX*:

Output parameter: Transformed X coordinate. Must be a Long type variable.

*iDisplayY*:

Output parameter: Transformed Y coordinate. Must be a Long type variable.

*iType:*

The value of output coordinate:

0 - Absolute screen coordinates

1 - Coordinates relative to Window origin

2 - Coordinates relative to Client rectangle origin

## Return Value

0 – Success

269 – ERROR\_BAD\_HANDLE – hPage is not a valid Page handle

274 – ERROR\_INVALID\_ARG – either DisplayX, DisplayY or Type is invalid.

## See Also

[Page Functions](#)

## PageTrend

Displays a trend page with the specified trend pens. Use this function to display trends in a single cluster system with a single trend page. You need to create the trend page with the Graphics Builder and set the pen names to blank. Then display that page by calling this function and passing the required trend tags. Call this function from a menu of trend pages.

---

**Note:** This function is not supported in the server process in a multiprocessor environment. Calling this function from the server process results in a hardware alarm being raised. For a multi-cluster system use [PageTrendEx](#).

## Syntax

**PageTrend**(*sPage*, *sTag1* [, *sTag2..sTag8*] )

*sPage:*

Name of the trend page (drawn with the Graphics Builder).

*sTag1:*

The first trend tag to display on the page.

*sTag2..sTag8:*

Optionally trend tags 2 to 8 to display on the page.

## Return Value

0 (zero) if successful, otherwise an error is returned.

**Note:** Before Plant SCADA version 5.0, page records could be edited in the Project Editor. One of the fields available for configuration was "Page Number". The value entered for a page could then be used in runtime with the Page Cicode functions such as PageDisplay(), PageGoto(), and PageInfo(1).

For example, PageDisplay("1") can be used to display the page that has "1" (without the quotes) set in the **Page Number** field. PageInfo(1) returns the Page Number of the current page.

From version 5.0 on, this feature is only backwards-supported. The "Alias" field in the project Pages.DBF file still contains the Page Numbers from upgraded projects; however, the Pages database records are no longer available for direct editing in Plant SCADA.

## Related Functions

## Example

Buttons

Text	Process Trend
Command	PageTrend("MyTrend", "PV1", "PV2", "PV3")
Comment	Display the trend page with three trend pens

```
PageTrend("MyTrend", "PV1", "PV2", "PV3")
/* Display three trend tags on a single trend page. */
```

## See Also

[Page Functions](#)

## PageTrendEx

Displays a trend page of a specified cluster in a multi-cluster system with the specified trend pens. Use this function to display trends in a mult-cluster system with a single trend page. You need to create the trend page with the Graphics Builder and set the pen names to blank. Then display that page by calling this function and passing the required trend tags. Call this function from a menu of trend pages. This function can also be used in a single cluster system, the *sCluster* argument is optional in such a case.

**Note:** This function is not supported in the server process in a multiprocessor environment. Calling this function from the server process results in a hardware alarm being raised.

## Syntax

**PageTrendEx(*sPage*, *sCluster*, *sTag1* [*, sTag2..sTag8*] )**

*sPage*:

Name of the trend page (drawn with the Graphics Builder).

*sCluster*:

Name of the cluster in which the trend page is located.

*sTag1:*

The first trend tag to display on the page.

*sTag2..sTag8:*

Optionally trend tags 2 to 8 to display on the page.

## Return Value

0 (zero) if successful, otherwise an error is returned.

**Note:** Before Plant SCADA version 5.0, page records could be edited in the Project Editor. One of the fields available for configuration was "Page Number". The value entered for a page could then be used in runtime with the Page Cicode functions such as PageDisplay(), PageGoto(), and PageInfo(1).

For example, PageDisplay("1") can be used to display the page that has "1" (without the quotes) set in the **Page Number** field. PageInfo(1) returns the Page Number of the current page.

From version 5.0 on, this feature is only backwards-supported. The "Alias" field in the project Pages.DBF file still contains the Page Numbers from upgraded projects; however, the Pages database records are no longer available for direct editing in Plant SCADA.

## Plot Functions

Following are functions relating to plotting data:

<a href="#">PlotClose</a>	Displays and/or prints the plot, then closes the plot.
<a href="#">PlotDraw</a>	Draws a point, line, box, or circle on a plot.
<a href="#">PlotFile</a>	This function is now obsolete.
<a href="#">PlotGetMarker</a>	Gets the marker number of a symbol that is registered as a marker.
<a href="#">PlotGrid</a>	Draws gridlines to be used for plotted lines.
<a href="#">PlotInfo</a>	Gets information about a plot.
<a href="#">PlotLine</a>	Plots a line through a set of data points.
<a href="#">PlotMarker</a>	Draws markers on a plotted line or at a specified point.
<a href="#">PlotOpen</a>	Opens a new plot, sets its output device, and returns a plot handle for use by the other plot functions.
<a href="#">PlotScaleMarker</a>	Draws scale lines (with markers) beside the grid on your plot (if there is one).
<a href="#">PlotSetMarker</a>	Sets (registers) a symbol as a marker.
<a href="#">PlotText</a>	Draws text on a plot.
<a href="#">PlotXYLine</a>	Draws an XY line through a set of data points.

## See Also

[Cicode Function Categories](#)

[Using Cicode Functions](#)

## PlotClose

Displays the plot on screen or sends it to the printer (depending on the output device you specified in the PlotOpen() function), then closes the plot. Once the plot is closed, it cannot be used.

## Syntax

**PlotClose(*hPlot*)**

*hPlot*:

The plot handle, returned from the PlotOpen() function. The plot handle identifies the table where all data on the plot is stored.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[PlotDraw](#), [PlotGetMarker](#), [PlotGrid](#), [PlotInfo](#), [PlotLine](#), [PlotMarker](#), [PlotOpen](#), [PlotScaleMarker](#), [PlotSetMarker](#),  
[PlotText](#), [PlotXYLine](#), [TrnPlot](#)

## Example

See [PlotOpen](#).

## See Also

[Plot Functions](#)

## PlotDraw

Constructs drawings on your plot. Use the coordinates (X1,Y1) and (X2,Y2) to define a point, line, rectangle, square, circle, or ellipse. You can specify the style, color, and width of the pen, and a fill color for a box or circular shape.

you need to call the PlotOpen() function first, to get the handle for the plot (*hPlot*) and to specify the output device.

## Syntax

**PlotDraw(*hPlot*, *Type*, *PenStyle*, *PenCol*, *PenWidth*, *nFill*, *X1*, *Y1*, *X2*, *Y2*)**

*hPlot*:

The plot handle, returned from the PlotOpen() function. The plot handle identifies the table where data on the plot is stored.

*nType*:

The type of drawing:

1 - Rectangle or square

2 - Circle or ellipse

3 - Line

4 - Point

*PenStyle*:

The style of the pen used to draw:

0 - Solid

1 - Dash ( - - - - )

2 - Dot (.....)

- 3 - Dash and dot ( - . - . - . - )
- 4 - Dash, dot, dot ( - . - . - . - - )

5 - Hollow

*PenCol:*

The color of the pen (flashing color is not supported). Select a color from the list of Predefined Color Names and Codes or create an RGB-based color using the function [MakeColour](#).

*PenWidth:*

Pen width in pixels. If the width is thicker than one pixel, you need to use a solid pen (PenStyle = 0). Maximum width is 32.

*nFill:*

The fill color of the rectangle, square, circle, or ellipse (flashing color is not supported). Select a color from the list of predefined color names and codes or create an RGB-based color using the function [MakeColour](#). For a point or line, nFill is ignored.

*X1, Y1:*

X and y coordinates (in pixels) of the upper-left corner of the drawing (the origin).

*X2, Y2:*

X and y coordinates (in pixels) of the lower-right corner of the drawing.

For a point, (X1,Y1) and (X2,Y2) are assumed to be the same, so (X2,Y2) is ignored. To draw a circle or ellipse, enter the coordinates for a square or rectangle; the circle or ellipse is automatically drawn within the box.

If the plot is for display on the screen, coordinates are relative to the AN specified in the PlotOpen() function. If the output device is a printer, coordinates are relative to the point (0,0).

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

## Example

See [PlotOpen](#).

## See Also

[Plot Functions](#)

## PlotGetMarker

Gets the marker number of a symbol. The symbol needs to be a symbol and registered with the PlotSetMarker() function.

## Syntax

**PlotGetMarker(*sSymbolName*)**

*sSymbolName*:

The library name and symbol name ("Library.Symbol") of the symbol that is registered as a marker.

## Return Value

The marker number if successful, otherwise -1 is returned.

## Related Functions

[PlotMarker](#), [PlotScaleMarker](#), [PlotSetMarker](#)

## Example

```
/*Assume that the symbol was registered by PlotSetMarker function */
PlotSetMarker(20,"Global.Hourglass");
/*Later on, this symbol can be used as shown below*/
hPlot = PlotOpen(36,"Display",1);
..
/* Display red hourglass as marker at point (100,200) on AN36. */
MarkerNo = PlotGetMarker("Global.Hourglass");
PlotMarker(hPlot,MarkerNo,red,1,1,100,200);
..
PlotClose(hPlot);
```

## See Also

[Plot Functions](#)

## PlotGrid

Defines a frame and draws horizontal and vertical grid lines within this frame. These grid lines can then be used by the PlotLine(), PlotXYLine(), and PlotScaleMarker() functions. You need to define the frame for a plot before you can plot points with the PlotLine() and PlotXYLine() functions. *nSamples* specifies the maximum number of samples that can be plotted for a single line. If you set *FrameWidth* to 0 (zero), the frame will be defined but not displayed (however, the plot will still be displayed).

You can specify the number of grid lines and their color, as well as the background color which will fill the frame. If *nHorGrid* and *nVerGrid* are set to 0 (zero), then the grid lines will not be drawn.

you need to call the PlotOpen() function, first, to get the handle for the plot (*hPlot*), and to specify the output device. Then call this function to set up the frame and grid. You can then call the PlotScaleMarker() function to draw scale lines beside the frame, and call the PlotLine() or PlotXYLine() to plot a set of data points.

## Syntax

**PlotGrid(*hPlot*, *nSamples*, *X1*, *Y1*, *X2*, *Y2*, *nHorGrid*, *HorGridCol*, *nVerGrid*, *VerGridCol*, *FrameWidth*, *FrameCol*, *nFill*, *nMode*)**

*hPlot*:

Plot handle, returned from the PlotOpen() function. The plot handle identifies the table where data on the plot is stored.

*nSamples*:

The maximum number of samples that can be plotted for a single line in this grid (valid values between 2 and 16000 inclusive). For example, if you set *nSamples* to 10, then plot 2 lines in this grid (using the PlotLine() function), each line will be plotted with a maximum of 10 samples. For this example, a line can possess less than 10 samples, but if it has more, it will be shortened to 10 samples.

*X1*, *Y1*:

The x and y coordinates of the upper-left corner of the frame containing the grid lines.

*X2*, *Y2*:

The x and y coordinates of the lower-right corner of the frame containing the grid lines.

If the plot is for display on the screen, you should set (*X1*,*Y1*) to (0,0). The origin of the frame is then positioned at the AN specified in the PlotOpen() function.

If the output device is a printer, both (*X1*,*Y1*) and (*X2*,*Y2*) are relative to the point (0,0).

*nHorGrid*:

The number of rows (formed by the horizontal grid lines) to draw within the frame. If there is no need of grid lines, set *nHorGrid* to 0 (zero) and *HorGridCol* to 0. *nHorGrid* cannot exceed the pixel width of the plot.

*HorGridCol*:

The color of the horizontal grid lines (flashing color is not supported). Select a color from the list of Predefined Color Names and Codes or create an RGB-based color using the function [MakeColour](#).

*nVerGrid*:

The number of columns (formed by the vertical grid lines) to draw within the frame. If there is no need of grid lines, set *nVerGrid* to 0 (zero) and *VerGridCol* to 0. *nVerGrid* cannot exceed the pixel height of the plot.

*VerGridCol*:

The color of the vertical grid lines (flashing color is not supported). Select a color from the list of Predefined Color Names and Codes or create an RGB-based color using the function [MakeColour](#).

*FrameWidth*:

The width (also called pen width) of the frame enclosing the grid, in pixels. To define the frame without drawing its boundaries, set *FrameWidth* to 0 (zero) and *FrameCol* to 0. The maximum is 32.

*FrameCol*:

The color of the frame enclosing the grid (flashing color is not supported). Select a color from the list of Predefined Color Names and Codes or create an RGB-based color using the function [MakeColour](#).

*nFill*:

The background color for the frame (flashing color is not supported). Select a color from the list of Predefined Color Names and Codes or create an RGB-based color using the function [MakeColour](#).

*nMode*:

The mode of the plot. For future use only - set it to 0 (zero).

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[PlotText](#), [PlotXYLine](#), [TrnPlot](#)

## Example

See [PlotOpen](#)

## See Also

[Plot Functions](#)

## PlotInfo

Gets information about the plot. You can call this function to determine the number of pixels per page or inch, the resolution of a plot, and the size and spacing of characters for a specified text font. You can also check whether a printer can print rotated text. (See [PlotText](#).)

you need to first call the PlotOpen() function to get the handle for the plot (*hPlot*) and specify the output device.

## Syntax

**PlotInfo**(*hPlot*, *Type* [, *sInput*] )

*hPlot*:

The plot handle, returned from the PlotOpen() function. The plot handle identifies the table where all data on the plot is stored.

*nType*:

The type of plot information to get:

- 0 - Horizontal pixels on a printout page
- 1 - Vertical pixels on a printout page
- 2 - Horizontal pixels per inch
- 3 - Vertical pixels per inch
- 4 - Horizontal resolution
- 5 - Vertical resolution
- 6 - Height of the font used
- 7 - External leading of the font used
- 8 - Character width of the font used
- 9 - Rotatable text is allowed or not

10 - Indicates whether or not a font is supported

11 - Horizontal size of a page in millimeters

12 - Vertical size of a page in millimeters

*sInput:*

The font handle (hFont), returned from the [DspFont\(\)](#) function. Useful only for Type 6, 7, 8, or 10.

## Return Value

The attributes of the plot as a string.

## Related Functions

[PlotClose](#), [PlotDraw](#), [PlotGrid](#), [PlotLine](#), [PlotMarker](#), [PlotOpen](#), [PlotScaleMarker](#), [PlotText](#), [PlotXYLine](#), [TrnPlot](#)

## Example

```
hPlot = PlotOpen(36,"Display",1);
:
/* Print text in upward direction but first check if printer
supports text rotation. Set default text orientation to left to
right (just in case). */
Orient = 0;
IF PlotInfo(hPlot,9) THEN
Orient = 1;
END
PlotText(hPlot,hFont,Orient,100,100,"scale");
..
/* Print text "Plant SCADA Graph" centred horizontally at top of page.*/
PageWidth = PlotInfo(hPlot,0); ! Get width of page
hFont = DspFont("Courier",14,black,-1);
TextWidth = PlotInfo(hPlot,8,hFont); ! Get width of each character
TextPosn = (PageWidth - TextWidth * 12) / 2 ! Get start of 1st character
PlotText(hPlot,hFont,0,TextPosn,0,"Plant SCADA Graph");
..
PlotClose(hPlot);
```

## See Also

[Plot Functions](#)

## PlotLine

Draws a line (in the Plant SCADA plot system) for a set of data points. You specify the data points in the table *pTable*, and plot these points between the *LoScale* and *HiScale* values. The line is drawn inside the frame defined by the [PlotGrid\(\)](#) function.

For each line on a plot, you can specify a different pen style, color, and width, and a different marker style and color. You can draw lines either from left to right or from right to left.

You need to first call the [PlotOpen\(\)](#) function to get the handle for the plot (*hPlot*) and specify the output device.

You should then use the PlotGrid() function to set up the frame and grid, before you call this function to plot the line.

## Syntax

**PlotLine(*hPlot*, *PenStyle*, *PenCol*, *PenWidth*, *MarkerStyle*, *MarkerCol*, *nMarker*, *Length*, *pTable*, *LoScale*, *HiScale*, *Mode*)**

*hPlot*:

The plot handle, returned from the PlotOpen() function. The plot handle identifies the table where all data on the plot is stored.

*PenStyle*:

The style of the pen used to draw:

0 - Solid

1 - Dash ( - - - - )

2 - Dot (.....)

3 - Dash and dot ( - . - . - . - )

4 - Dash, dot, dot ( - . - . - . - )

5 - Hollow

*PenCol*:

The color of the pen (flashing color is not supported). Select a color from the list of Predefined Color Names and Codes or create an RGB-based color using the function MakeColour.

*PenWidth*:

The width of the pen, in pixels. If the width is thicker than one pixel, you need to use a solid pen (*PenStyle* = 0). The maximum width is 32.

*MarkerStyle*:

The style of the markers:

0 - No markers

1 - Triangle

2 - Square

3 - Circle

4 - Diamond

5 - Filled triangle

6 - Filled square

7 - Filled circle

8 - Filled diamond

20 - 32000 - User-defined markers. You can register any symbol as a marker with the PlotSetMarker() function. Call the PlotGetMarker() function if the number of markers you have previously registered are unknown.

*MarkerCol*:

The color of the markers (flashing color is not supported). Select a color from the list of predefined color names and codes or create an RGB-based color using the function MakeColour.

*nMarker*:

The number of samples between markers.

*Length:*

The length of the array, that is, the number of points in the table pTable for PlotLine(), or in tables xTable and yTable for PlotXYLine().

For every line you draw with the PlotLine() and PlotXYLine() functions within a plot, you need to add the Length arguments for each call, and pass the total to the PlotGrid() function (in the nSamples argument).

*pTable:*

The points to be plotted (as an array of floating-point values).

*LoScale:*

The lowest value that will be displayed on the plot (that is the value assigned to the origin of your grid). The LoScale and HiScale values determine the scale of your grid. This scale is used to plot values. for example, If LoScale = 0 (zero) and HiScale = 100, a value of 50 will be plotted half way up the Y-axis of your grid. LoScale needs to be in the same units as the values in pTable.

*HiScale:*

The highest value that will be displayed on the plot. The LoScale and HiScale values determine the scale of your grid. This scale is used to plot values. for example, If LoScale = 0 (zero) and HiScale = 100, a value of 50 will be plotted half way up the Y- axis of your grid. HiScale needs to be in the same units as the values in pTable.

*Mode:*

The origin of your grid, and the direction of the plotted line:

- 1 - Origin is bottom-left, x is left to right, y is upwards
- 2 - Origin is bottom-right, x is right to left, y is upwards
- 4 - Origin is top-left, x is left to right, y is downwards
- 8 - Origin is top-right, x is right to left, y is downwards

## Return Value

0 (zero) if successful, otherwise an error is returned.

[PlotText](#), [PlotXYLine](#), [TrnPlot](#)

## Example

See [PlotOpen](#).

## See Also

[Plot Functions](#)

## PlotMarker

Draws markers on a plotted line or at a specified point. You can plot any one of the standard markers, or use a symbol of your choice. (you need to first register your symbol as a marker, by using the PlotSetMarker() function.)

To draw a single marker at a specified point, set *X* and *Y* to the coordinates of the point, and set *Length* to 1.

You can draw markers on a plotted line when you draw the line, that is within the PlotLine() or PlotXYLine() function. You would use the PlotMarker() function only if you need to draw a second set of markers on the same line. Call PlotMarker() immediately after the line is drawn. Set *X* and *Y* to -1 and *Length* to the number of data points (specified in the *Length* argument of the PlotLine() or PlotXYLine() function).

you need to first call the PlotOpen() function to get the handle for the plot (*hPlot*) and specify the output device.

## Syntax

**PlotMarker(*hPlot*, *MarkerStyle*, *MarkerCol*, *nMarker*, *Length*, *X*, *Y*)**

*hPlot*:

The plot handle, returned from the PlotOpen() function. The plot handle identifies the table where data on the plot is stored.

*MarkerStyle*:

The style of the markers:

0 - No markers

1 - Triangle

2 - Square

3 - Circle

4 - Diamond

5 - Filled triangle

6 - Filled square

7 - Filled circle

8 - Filled diamond

20 - 32000: User-defined markers. You can register any symbol as a marker with the PlotSetMarker() function. Call the PlotGetMarker() function if the number of markers you have previously registered are unknown.

*MarkerCol*:

The color of the marker (flashing color is not supported). Select a color from the list of Predefined Color Names and Codes or create an RGB-based color using the function [MakeColour](#).

*nMarker*:

The number of samples between markers.

*Length*:

The length of the array (the number of line points in the table pTable) plotted in the PlotLine() or PlotXYLine() function. To draw only one marker at a specified point, set Length to 1.

*X*, *Y*:

The x and y coordinates, in pixels, of the point where the marker is to be drawn. If the plot is for display on the

screen, the coordinates are relative to the AN specified in the PlotOpen() function. If the output device is a printer, the coordinates are relative to the point (0,0).

To draw the markers on a plotted line, set both X and Y to -1, and set Length to the same value as the Length passed in the PlotLine() or PlotXYLine() function.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[PlotClose](#), [PlotDraw](#), [PlotGetMarker](#), [PlotGrid](#), [PlotInfo](#), [PlotLine](#), [PlotOpen](#), [PlotScaleMarker](#), [PlotSetMarker](#), [PlotText](#), [PlotXYLine](#), [TrnPlot](#)

## Example

```
hPlot=PlotOpen(36,"Display",1);
..
/* Draw a filled red square marker at the point (X=100,Y=200). */
PlotMarker(hPlot,6,red,1,1,100,200);
..
/* Draw 10 black triangles and 5 green cylinders along a plot
line. */
PlotLine(hPlot,0,black,3,5,black,10,100,Buf2[0],0,100,2);
PlotSetMarker(20,"Global.Cylinder");
PlotMarker(hPlot,20,green,5,100,-1,-1)
..
PlotClose(hPlot);
```

## See Also

[Plot Functions](#)

## PlotOpen

Opens a new plot, sets its output device, and returns its plot handle. You can send the plot to any one of your system printers, or display it on screen at the specified AN.

you need to call this function before you can call the other plot functions.

## Syntax

**PlotOpen(*nAN*, *sOutput*, *Mode*)**

*nAN*:

The animation point (AN) where the plot will display. Set the AN to 0 (zero) when *sOutput* is a printer.

Do not use an animation point number at which a graphic object exists as this will prevent the PlotOpen() function from succeeding.

**sOutput:**

The output device where the plot is sent, for example:

"Display" - Display on screen. The plot is recorded in a metafile and displayed (at the specified AN) when the plot system is closed.

- "LPT1:" - Send to printer LPT1.
- "LPT2:" - Send to printer LPT2.
- "\ABC\Printers\Color1" - Send to UNC port (and so on for any output device)

**Mode:**

When a plot is removed or updated, the portion of the background screen beneath it is blanked out. The mode determines how the background screen is restored. The mode of the plot system:

1 - Normal mode

2 - Use for compatibility with the old graph functions

17 - Soft (valid for normal mode). The background screen (a rectangular region beneath the plot) is restored with the original image. Any objects that are within the rectangular region are destroyed when the background is restored.

33 - Hard (valid for normal mode). The background screen (a rectangular region beneath the plot) is painted with the color at the AN.

65 - Persistent (valid for normal mode). The plot is not erased. As the plot is updated, it is re-displayed on top. This mode provides fast updates. Transparent color is supported in this mode.

129 - Opaque animation (valid for normal mode). The plot is not erased. As the plot is updated, it is re-displayed on top. This mode provides the fastest updates. Transparent color is not supported in this mode.

257 - Overlapped animation (valid for normal mode). The background screen (the rectangular region beneath the plot) is completely repainted.

## Return Value

The plot handle if the plot is opened successfully, otherwise -1 is returned. The plot handle identifies the table where all data on the associated plot is stored.

## Related Functions

[PlotClose](#), [PlotDraw](#), [PlotGetMarker](#), [PlotGrid](#), [PlotInfo](#), [PlotLine](#), [PlotMarker](#), [PlotScaleMarker](#), [PlotSetMarker](#),  
[PlotText](#), [PlotXYLine](#), [TrnPlot](#)

## Example

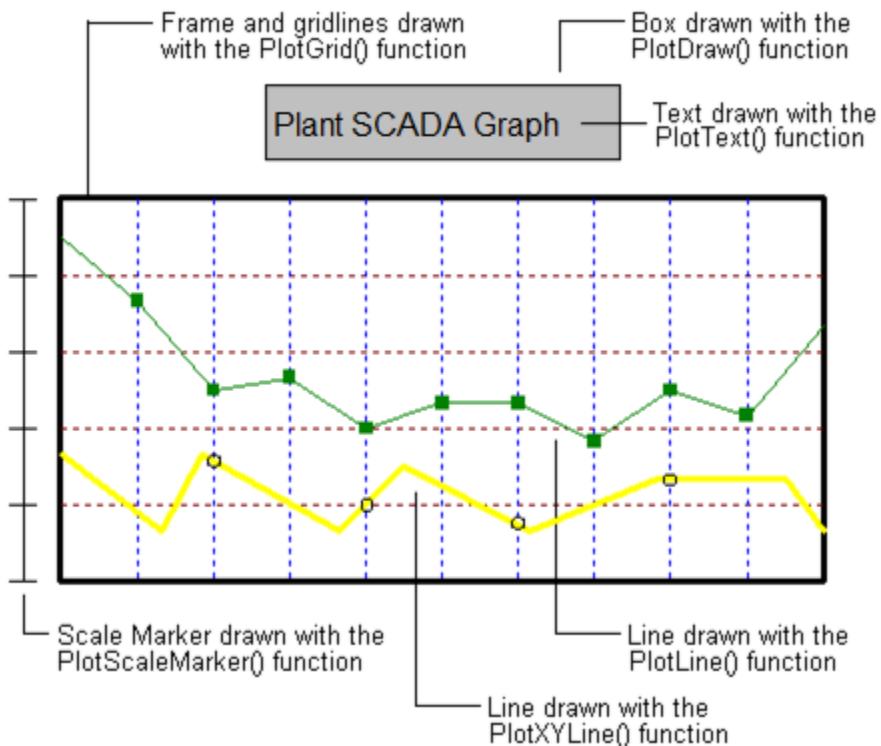

```
hPlot=PlotOpen(0,"LPT2:",1);
IF hPlot <> -1 THEN
    /* Set up a black frame with red & blue grid lines. */
    PlotGrid(hPlot,18,450,800,1850,1600,5,red,10,blue,4,black,white,0);
    /* Draw a scale line to the left of the frame. */
    PlotScaleMarker(hPlot,400,1600,6,1,black,0);
    /* Plot a simple line in green for a table of 10 values. */
    PlotLine(hPlot,0,green,3,6,green,2,10,Buf1,0,100,1);
    /* Plot a line in yellow (with black markers) for tables of 8 X and Y values. */
```

```

PlotXYLine(hPlot,0,yellow,4,3,black,2,8,Buf2,0,150,Buf3,0,100,1);
/* Draw a title box above the plot frame, with the heading "Plant SCADA Graph". */
PlotDraw(hPlot,1,0,black,1,grey,900,250,1400,400);
hFont = DspFont("Times",-60,black,grey);
PlotText(hPlot,hFont,0,950,350,"Plant SCADA Graph");
PlotClose(hPlot);
END

```

The above example prints the following (on the printer):

```

PlotOpen(0,"LPT1:",1) // opens a new plot to be sent to printer
PlotOpen(20,"DISPLAY",17) // normal plot with soft animation
PlotOpen(20,"DISPLAY",257) // normal plot with overlap animation
PlotOpen(20,"DISPLAY",1) // normal plot with overlap animation
(for default animation mode is overlap animation)
PlotOpen(20,"DISPLAY",16) // INVALID
(does not specify whether it is normal or Version 2.xx mode).
PlotOpen(20,"DISPLAY",2) // INVALID for Version 2.xx graph system
(does not support display as output).

```

[Plot Functions](#)

### PlotScaleMarker

Draws scale lines beside the grid on your plot (if there is one) and places markers on them. The height of the scale line is automatically set to the height of the frame set in the PlotGrid() function.

You need to first call the PlotOpen() function to get the handle for the plot (*hPlot*) and specify the output device. You should then use the PlotGrid() function to set up the frame and grid, before you call this function to draw the

scale lines.

## Syntax

**PlotScaleMarker(*hPlot*, *X*, *Y*, *nMarker*, *PenWidth*, *PenCol*, *Mode*)**

*hPlot*:

The plot handle, returned from the PlotOpen() function. The plot handle identifies the table where data on the plot is stored.

*X*, *Y*:

The x and y coordinates of the point where the scale line starts. The end coordinates of the scale line are automatically defined by the size of the frame (set in the PlotGrid() function).

If the plot is for display on the screen, coordinates are relative to the AN specified in the PlotOpen() function. If the output device is a printer, coordinates are relative to the point (0,0).

*nMarker*:

The number of markers on the scale line.

*PenWidth*:

The width of the scale line, in pixels.

*PenCol*:

The color of the pen (flashing color is not supported). Select a color from the list of Predefined Color Names and Codes or create an RGB-based color using the function [MakeColour](#).

*Mode*:

The mode of the markers:

0 - Both sides of the scale line

1 - Left of the scale line

2 - Right of the scale line

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[PlotClose](#), [PlotDraw](#), [PlotGetMarker](#), [PlotGrid](#), [PlotInfo](#), [PlotLine](#), [PlotMarker](#), [PlotOpen](#), [PlotSetMarker](#), [PlotText](#), [PlotXYLine](#), [TrnPlot](#)

## Example

See [PlotOpen](#)

## See Also

[Plot Functions](#)

## PlotSetMarker

Registers a symbol as a marker. You can then draw the new marker at points and on plotted lines, by specifying the *MarkerNo* of the symbol as the *MarkerStyle* in the PlotMarker() function. Call the PlotGetMarker() function if you do not know the number of a marker.

## Syntax

**PlotSetMarker(*MarkerNo*, *sSymbolName*)**

*MarkerNo*:

The number of the marker, to be used as the MarkerStyle in the PlotMarker() function. Your marker numbers need to be greater than or equal to 20 (to a maximum of 32000).

*sSymbolName*:

The name and path of the symbol to be defined as a marker.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[PlotMarker](#), [PlotScaleMarker](#), [PlotGetMarker](#)

## Example

```
hPlot=PlotOpen(30,"Display",1);
..
/* Display red hourglass as marker at point (100,200). */
PlotSetMarker(20,"Global.Hourglass");
PlotMarker(hPlot,20,red,1,1,100,200);
..
PlotClose(hPlot);
```

## See Also

[Plot Functions](#)

## PlotText

Prints text on a plot. You can specify the font, position, and orientation of the text. If you specify an orientation other than 'left-to-right', you need to check that the font (and the printer) supports the orientation.

You need to first call the PlotOpen() function to get the handle for the plot (*hPlot*) and specify the output device. You also need to call the DspFont() function to get a handle for the font (*hFont*).

## Syntax

**PlotText(*hPlot*, *hFont*, *Orientation*, *X*, *Y*, *sText*)**

*hPlot*:

The plot handle, returned from the [PlotOpen\(\)](#) function. The plot handle identifies the table where all data on the plot is stored.

*hFont*:

The font handle, returned from the [DspFont\(\)](#) function. The font handle identifies the table where details of that font are stored.

*Orientation*:

The orientation of the text:

0 - Left-to-right

1 - Upwards

2 - Right-to-left

3 - Downwards

You should check that the font supports rotation (where Orientation = 1, 2, or 3). Most true type and vector fonts support rotation. If the [PlotInfo\(hPlot, 9\)](#) function returns false, you need to specify an Orientation of 0 (zero).

*X*, *Y*:

The x and y coordinates (in pixels) of the start of the text. If the plot is for display on the screen, the coordinates are relative to the AN specified in the [PlotOpen\(\)](#) function. If the output device is a printer, the coordinates are relative to the point (0,0).

*sText*:

The text string to be plotted.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[DspFont](#), [PlotClose](#), [PlotDraw](#), [PlotGrid](#), [PlotInfo](#), [PlotLine](#), [PlotMarker](#), [PlotScaleMarker](#), [PlotXYLine](#), [TrnPlot](#)

## Example

See [PlotOpen](#).

## See Also

[Plot Functions](#)

## PlotXYLine

Plots values from two different tables. Values from one table are considered X coordinates, and values from the other are considered Y coordinates. Points are plotted between the low and high scale values specified for x and y. The line is plotted inside the frame defined by the [PlotGrid\(\)](#) function.

For each line, you can specify a different pen style, color, and width, and a different marker style and color. You can draw lines either from left to right or from right to left. You need to first call the [PlotOpen\(\)](#) function to get the handle for the plot (*hPlot*) and specify the output device. You should then use the [PlotGrid\(\)](#) function to set up the frame and grid, before you call this function to plot the line.

## Syntax

**PlotXYLine(*hPlot*, *PenStyle*, *PenCol*, *PenWidth*, *MarkerStyle*, *MarkerCol*, *nMarker*, *Length*, *xTable*, *LoXScale*, *HiXScale*, *YTable*, *LoYScale*, *HiYScale*, *Mode*)**

*hPlot*:

The plot handle, returned from the [PlotOpen\(\)](#) function. The plot handle identifies the table where all data on the plot is stored.

*PenStyle*:

The style of the pen used to draw:

0 - Solid

1 - Dash ( - - - - )

2 - Dot (.....)

3 - Dash and dot ( - . . - . - . - )

4 - Dash, dot, dot ( - . . - - - - )

5 - Hollow

*PenCol*:

The color of the pen (flashing color is not supported). Select a color from the list of Predefined Color Names and Codes or create an RGB-based color using the function [MakeColour](#).

*PenWidth*:

The width of the pen, in pixels. If the width is thicker than one pixel, you need to use a solid pen (*PenStyle* = 0). The maximum width is 32.

*MarkerStyle*:

The style of the markers:

0 - No markers

1 - Triangle

2 - Square

3 - Circle

4 - Diamond

5 - Filled triangle

6 - Filled square

7 - Filled circle

8 - Filled diamond

20 - 32000 - User-defined markers. You can register any symbol as a marker with the PlotSetMarker() function. Call the PlotGetMarker() function to recall the number of a marker you have previously registered.

*MarkerCol:*

The color of the markers (flashing color is not supported). Select a color from the list of Predefined Color Names and Codes or create an RGB-based color using the function MakeColour.

*nMarker:*

The number of samples between markers.

*Length:*

The length of the array, that is the number of points in the table pTable for PlotLine(), or in tables *xTable* and *yTable* for PlotXYLine().

For every line you draw with the PlotLine() and PlotXYLine() functions within a plot, you need to add the Length arguments for each call, and pass the total to the PlotGrid() function (in the *nSamples* argument).

*xTable:*

The x coordinates for the points in the line, as an array of floating point values.

*LoXScale:*

The lowest X-axis value that will be displayed on the plot (that is the X-coordinate of the origin of your grid). The LoXScale and HiXScale values determine the scale of your grid. This scale is used to plot values. for example, If LoXScale = 0 (zero) and HiXScale = 100, a value of 50 will be plotted half way along the X-axis of your grid.

LoXScale needs to be in the same units as the values in *xTable*.

*HiXScale:*

The highest X-axis value that will be displayed on the plot. The LoXScale and HiXScale values determine the scale of your grid. This scale is used to plot values. for example, If LoXScale = 0 (zero) and HiXScale = 100, a value of 50 will be plotted half way along the X-axis of your grid.

HiXScale needs to be in the same units as the values in *xTable*.

*yTable:*

The y coordinates for the points in the line, as an array of floating point values.

*LoYScale:*

The lowest Y-axis value that will be displayed on the plot (that is the Y-coordinate of the origin of your grid). The LoYScale and HiYScale values determine the scale of your grid. This scale is used to plot values. for example, If LoYScale = 0 (zero) and HiYScale = 100, a value of 50 will be plotted half way up the Y-axis of your grid.

LoYScale needs to be in the same units as the values in *xTable*.

*HiYScale:*

The highest Y-axis value that will be displayed on the plot. The LoYScale and HiYScale values determine the scale of your grid. This scale is used to plot values. for example, If LoYScale = 0 (zero) and HiYScale = 100, a value of 50 will be plotted half way up the Y-axis of your grid.

HiYScale needs to be in the same units as the values in *xTable*.

*Mode:*

The origin of your grid, and the direction of the plotted line:

1 - Origin is bottom-left, x is left to right, y is upwards

2 - Origin is bottom-right, x is right to left, y is upwards

4 - Origin is top-left, x is left to right, y is downwards

8 - Origin is top-right, x is right to left, y is downwards

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Process Analyst Functions

Following are functions relating to [Process Analyst](#):

<a href="#">ProcessAnalystLoadFile</a>	Loads the specified PAV file to a Process Analyst object.
<a href="#">ProcessAnalystPopup</a>	Displays a Process Analyst page (in a new page child window) at the current mouse position.
<a href="#">ProcessAnalystSelect</a>	Allows a set of pens to be selected before displaying the PA page.
<a href="#">ProcessAnalystSetPen</a>	Allows a new pen to be added to a PA display.
<a href="#">ProcessAnalystWin</a>	Displays a Process Analyst page (in a new window) preloaded with the pre-defined Process Analyst View (PAV) file.

## See Also

[Cicode Function Categories](#)

[Using Cicode Functions](#)

## ProcessAnalystLoadFile

Loads the specified PAV file to a Process Analyst object, which is identified by parameter *sObjName*.

## Syntax

**ProcessAnalystLoadFile(*sPAVFile*, *iFileLocation*, *iButtonMask*, *sObjName* )**

*sPAVFile*:

Name of the PAV file

*iFileLocation*:

PAV file location code for the PAV file. Indicates which known location to load the file from.

Member Name	Description	Value
FileLocation_Local	Refers to the project folder	0
FileLocation_Server	Refers to the both the primary/ standby server paths	1
FileLocation_User	Refers to the My Documents folder	2

*iButtonMask*:

Bit mask for removing command buttons from the PA, bit flags as shown below:

1 - Load View

2 - Save View

4 - Print

8 - Copy to Clipboard

16 - Copy to File

32 - Add Pens

64 - Remove Pens

128 - Show Properties

256 - Help

*sObjName*:

Name of the PA object on the given Page where the PAV file will be loaded.

## Return Value

Zero (0) if the function is successfully run. otherwise an error code is returned.

## Related Functions

[PageProcessAnalyst](#), [PageProcessAnalystPens](#), [ProcessAnalystPopup](#), [ProcessAnalystSelect](#),  
[ProcessAnalystSetPen](#), [ProcessAnalystWin](#), [TrnSetPen](#), [WinNewAt](#)

## See Also

[Process Analyst Functions](#)

## ProcessAnalystPopup

Displays a Process Analyst page (in a new page child window) at the current mouse position preloaded with the pre-defined Process Analyst View (PAV) file.

## Syntax

**ProcessAnalystPopup(*sPage* [, *sPAVFile* [, *iFileLocation* [, *iButtonMask* [, *sObjName* [, *iMode* ]]]])**

*sPage*:

The name of the page that contains Process Analyst object(s). For example, pages based on the Process Analyst templates found in the Tab\_Style\_Include project.

*sPAVFile*:

Name of the PAV file

*iFileLocation*:

PAV file location code for the PAV file, see PA doc LoadFromFile() for details.

*iButtonMask*:

Bit mask for removing command buttons from the PA, bit flags as shown below:

1 - Load View

2 - Save View

4 - Print

8 - Copy to Clipboard

16 - Copy to File

32 - Add Pens

64 - Remove Pens

128 - Show Properties

256 - Help

*sObjName*:

Name of the PA object on the given Page where the PAV file will be loaded. If this parameter is not specified or empty string, it is defaulted to the object name used in the tab style templates, that is "\_templatePA1".

*iMode*:

The mode of the window (see WinNewAt() for details).

## Return Value

Window number if the window is successfully displayed. Otherwise -1 is returned.

## Related Functions

[PageProcessAnalyst](#), [PageProcessAnalystPens](#), [ProcessAnalystLoadFile](#), [ProcessAnalystSelect](#),  
[ProcessAnalystSetPen](#), [ProcessAnalystWin](#), [TrnSetPen](#), [WinNewAt](#)

## See Also

[Process Analyst Functions](#)

### ProcessAnalystSelect

Works like the existing Cicode Function `TrnSelect()`. It allows a set of pens to be selected before displaying the PA page. When `PageProcessAnalystPens()` is called after `ProcessAnalystSelect()`, the pens specified by both functions will be available in the final PA display. You can also repeat the call sequence of `ProcessAnalystSelect()` and `ProcessAnalystSetPen()` multiple times to set up multiple PA objects for the same page before displaying the page.

## Syntax

`ProcessAnalystSelect((iWindow, sPage [, sObjName [, sClusterName [, iButtonMask [, sPAVFile [, iFileLocation]]]]]))`

*iWindow*:

The window number (returned from the `WinNumber()` function):

-3 - for the current window

-2 - For the next window displayed

*sPage*:

The name of the page that displays the PA.

*sObjName*:

The name of the PA object. If this is not specified, it is defaulted to "`_TemplatePA1`" which is the name used by the built-in templates.

*sClusterName*:

The name of the cluster that is associated with any trend tag for this PA. This is optional if you have one cluster or are resolving the trend via the current cluster context. The argument is enclosed in quotation marks "".

*iButtonMask*:

Bit mask for removing command buttons from the PA, bit flags as shown below:

1 - Load View

2 - Save View

4 - Print

8 - Copy to Clipboard

16 - Copy to File

32 - Add Pens

64 - Remove Pens

128 - Show Properties

256 - Help

*sPAVFile*:

Name of the PAV file

*iFileLocation:*

PAV file location code for the PAV file, see PA doc LoadFromFile() for details.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[PageProcessAnalyst](#), [PageProcessAnalystPens](#), [ProcessAnalystLoadFile](#), [ProcessAnalystPopup](#),  
[ProcessAnalystSetPen](#), [ProcessAnalystWin](#), [TrnSetPen](#), [WinNewAt](#)

## See Also

[Process Analyst Functions](#)

### ProcessAnalystSetPen

Works like the existing function TrnSetPen(). Allows a new pen to be added to a PA display. The pane defaults to the first pane of the PA if it is not specified.

## Syntax

**ProcessAnalystSetPen((*iPen*, *sTag* [, *sObjName* [, *iPane* [, *iPenType*]]) )**

*iPen:*

Pen number. The allowed values are:

- <0 - new pen
- 0 - the currently selected pen
- existing pen number - change existing pen
- >existing pen number - new pen

Up to 8 pens can be added to the PA using the Cicode function if ObjName is set to "-2".

Be reminded that unlike trend objects, the pen numbers in Process Analyst are not fixed. They are dynamically reassigned when pens are added or deleted. When setting pens to the Process Analyst on the current display, pens are numbered within the scope of the pane they are in. On the other hand, when setting pens for the next display, pens are numbered in a flat scope regardless of pane number specified.

*sTag:*

The trend tag name to be assigned to the pen.

*sObjName:*

The name of the PA object. If this is set to "-2", the pen is set to the next displayed PA page set up by ProcessAnalystSelect(). If the specified ObjName is valid, the changes will be applied to the currently displayed PA. Otherwise, the function will try to set the pen to the specified object on the currently displayed page. If this parameter is not specified or is an empty string, it will default to the object name used in the tab style templates, that is "\_templatePA1".

*iPane*:

Optional number of the pane where the trend or variable tags are added. Please see the same parameter for function PageProcessAnalystPens() for details. Defaulted to 0, that is, the first pane.

*iPenType*:

Pen type for creation. The allowed values are:

0 - Analog Trend (Default)

1 - Digital Trend

2 - Alarm

---

**Note:** This optional parameter is ignored for existing pens. To change pen type, delete a pen and create a new one.

---

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

## ProcessAnalystWin

Displays a Process Analyst page (in a new window) preloaded with the pre-defined Process Analyst View (PAV) file.

## Syntax

**ProcessAnalystWin**(*sPage*, *iX*, *iY*, *iMode* [, *sPAVFile* [, *iFileLocation* [, *iButtonMask* [, *sObjName* ]]]])

*sPage*:

The name of the page that contains Process Analyst object(s). For example, pages based on the Process Analyst templates found in the Tab\_Style\_Include project.

*iX*:

The X pixel coordinate

*iY*:

The Y pixel coordinate

*iMode*:

The mode of the window (see [WinNewAt\(\)](#) for details).

*sPAVFile*:

Name of the PAV file

*iFileLocation*:

PAV file location code for the PAV file, see PA doc [LoadFromFile](#) for details.

*iButtonMask*:

Bit mask for removing command buttons from the PA, bit flags as shown below:

1 - Load View

2 - Save View

4 - Print

8 - Copy to Clipboard

16 - Copy to File

32 - Add Pens

64 - Remove Pens

128 - Show Properties

256 - Help

*sObjName*:

Name of the PA object on the given Page where the PAV file will be loaded. If this parameter is not specified or empty string, it is defaulted to the object name used in the tab style templates, that is "\_templatePA1".

## Return Value

Window number if the window is successfully displayed. Otherwise -1 is returned.

## Quality Functions

The following functions are used to interface with the QUALITY data type.

<a href="#">QualityCreate</a>	Creates a quality value based on the quality fields provided.
<a href="#">QualityGetPart</a>	Extracts a requested part of the Quality value from the QUALITY variable.
<a href="#">QualityIsBad</a>	Returns a value indicating whether the quality is bad.

<a href="#">QualityIsGood</a>	Returns a value indicating whether the quality is good.
<a href="#">QualityIsUncertain</a>	Returns a value indicating whether the quality is uncertain.
<a href="#">QualitySetPart</a>	Sets a Quality part's value to the QUALITY variable.
<a href="#">QualityIsOverride</a>	Returns a value indicating whether the tag is in Override Mode.
<a href="#">QualityIsControlInhibit</a>	Returns a value indicating whether the tag is in Control inhibit mode.
<a href="#">QualityToStr</a>	Returns a textual representation of the Plant SCADA quality.
<a href="#">VariableQuality</a>	Extracts the quality from a given variable.

## See Also

[Cicode Function Categories](#)

[Using Cicode Functions](#)

## QualityCreate

Creates a quality value based on the quality fields provided. When the value of a particular quality field is out of range, the value of its corresponding part in the returned quality remains at 0, and hardware error is generated.

## Syntax

**QualityCreate(INT *generalQuality* [, INT *qualitySubstatus* [, INT *qualityLimit* [, INT *extendedSubstatus* [, INT *bOverride* [, *bControlInhibit* [, INT *datasourceErrorCode* ]]]]]])**

*generalQuality:*

Specifies the general quality.

*qualitySubstatus:*

Specifies the quality substatus.

*qualityLimit:*

The Quality Limit.

*extendedSubstatus:*

Specifies the extended quality substatus.

*bOverride:*

Specifies the Tag Status Override Flag.

*bControlInhibit:*

Specifies the Tag Status Control Inhibit Flag.

***datasourceErrorCode:***

Specifies the data source error code.

For further information on the quality arguments listed above, refer to the [Tag Extensions](#) documentation in the main help.

## Return Value

The Quality value of the element.

## Related Functions

[QualityGetPart](#), [QualityIsBad](#), [QualityIsControlInhibit](#), [QualityIsGood](#), [QualityIsOverride](#), [QualityIsUncertain](#),  
[QualitySetPart](#), [QualityToStr](#)

## Example

```
QUALITY q1;  
q1 = QualityCreate(QUAL_BAD, QUAL_BAD_NON_SPECIFIC, QUAL_LIMITED_HIGH,  
QUAL_EXT_NOT_REPLICATED);
```

## See Also

[Quality Functions](#)

## QualityGetPart

Extracts a requested part of the quality value from a variable tag's quality item.

## Syntax

**QualityGetPart(QUALITY *Quality*, INT *Part*)**

*Quality*:

Specifies the quality variable.

*Part*:

The part to extract:

0 – The General Quality value

1 – Quality Substatus value

2 - The Quality Limit value

3 - The Extended Quality Substatus value

4 – The Tag Status Override flag

5 – The Tag Status Control Inhibit flag

6 - The DataSource error code

7 – The OPC Quality (General + Substatus + Limit)

## Return Value

The value of the requested Quality part (see tables below), or -1 if error.

## Part 0 - General Quality Values

Cicode label name	Value	Description
QUAL_BAD	0x00	Value is not useful for reasons indicated by the Substatus Bit Field.
QUAL_UNCR	0x01	The Quality of the value is uncertain for reasons indicated by the Substatus Bit Field.
QUAL_GOOD	0x03	The Quality of the value is Good.

## Part 1 - Quality Substatus Values

This part returns a value from one of the following substatus groups:

- QUAL\_BAD
- QUAL\_UNCR (uncertain)
- QUAL\_GOOD

To determine which substatus group the return value is from, you need to initially call the General Quality Value (*part* = 0).

- **Quality Substatus Values - QUAL\_BAD**

Cicode label name	Substatus Value	Quality Value	Description
QUAL_BAD_NON_SPECIFIC	0x00	0x00000000	The value is bad but no specific reason is known.
QUAL_BAD_CONFIGURATION_ERROR	0x01	0x00000004	There is some server-specific incorrect configuration. For example, the item in question has been deleted from the configuration.
QUAL_BAD_NOT_CONNECTED	0x02	0x00000008	The input is necessary to be logically connected to something but is not.

Cicode label name	Substatus Value	Quality Value	Description
			This quality may reflect the fact that no value is available at this time, for reasons like the value may not have been provided by the data source.
QUAL_BAD_DEVICE_FAILURE	0x03	0x0000000c	An inoperative device has been detected.
QUAL_BAD_SENSOR_FAILURE	0x04	0x00000010	An inoperative sensor has been detected (the 'Limits' field can provide additional diagnostic information in some situations).
QUAL_BAD_LAST_KNOWN_VALUE	0x05	0x00000014	Communication has been lost, however, the last known value is available. The age of the value may be determined from the TIMESTAMP in the OPCITEMSTATE.
QUAL_BAD_COMM_FAILURE	0x06	0x00000018	Communication has been lost. There is no last known value available.
QUAL_BAD_OUT_OF_SERVICE	0x07	0x0000001C	The block is off scan or otherwise locked. This quality is also used when the active state of the item or the group containing the item is InActive.
QUAL_BAD_WAITING_FOR_INI_DATA	0x08	0x00000020	After items are added to a group, it may take some time for the server to actually obtain values for these items. In such cases, the client might perform a read (from cache), or establish a

Cicode label name	Substatus Value	Quality Value	Description
			ConnectionPoint based subscription and/or execute a refresh on such a subscription before the values are available. This substatus is only available from OPC DA 3.0 or newer servers.

- Quality Substatus Values - QUAL\_UNCR

Cicode label name	Substatus Value	Quality Value	Description
QUAL_UNCR_NON_SPECIFIC	0x00	0x00000040	The value is uncertain but no specific reason is known.
QUAL_UNCR_LAST_USABLE_VALUE	0x01	0x00000044	Whatever was writing this value has stopped doing so. Regard the returned value as 'stale'. This differs from a BAD value with Substatus 5 (0x14) (Last Known Value). This status is associated specifically with a detectable communication error on a 'fetched' value and indicates the failure of some external source to 'put' something into the value within an acceptable period of time. The age of the value can be determined from the TIMESTAMP in OPCITEMSTATE.
QUAL_UNCR_SENSOR_NOT_ACCURATE	0x04	0x00000050	Either the value has 'pegged' at one of the sensor limits (in which case, set the limit field to 1 or 2) or the sensor is otherwise known to be out of calibration via

Cicode label name	Substatus Value	Quality Value	Description
			some form of internal diagnostics (in which case, set the limit field to 0).
QUAL_UNCR_ENG_UNIT_EXCEEDED	0x05	0x00000054	The returned value is outside the limits defined for this parameter. In this case the Limits field indicates which limit has been exceeded but does NOT necessarily imply that the value cannot move farther out of range.
QUAL_UNCR_SUBNORM_AL	0x06	0x00000058	The value is derived from multiple sources and has less than the necessary number of Good sources.

- Quality Substatus Values - QUAL\_GOOD

Cicode label name	Substatus Value	Quality Value	Description
QUAL_GOOD_NON_SPECIFIC	0x00	0x000000c0	The value is good. There are no special conditions.
QUAL_GOOD_LOCAL_OVERRIDE	0x06	0x000000d8	The value has been Overridden. Typically this means the input has been disconnected and a manually entered value has been "forced".

## Part 2 - Quality Limit Values

Cicode label name	Value	Description
QUAL_LIMITED_NOT_LIMITED	0x0	The value is free to move up and down.
QUAL_LIMITED_LOW	0x1	The value has 'pegged' at some lower limit.
QUAL_LIMITED_HIGH	0x2	The value has 'pegged' at some

Cicode label name	Value	Description
		high limit.
QUAL_LIMITED_CONSTANT	0x3	The value is a constant and cannot move.

### Part 3 - Extended Quality Substatus Values

Cicode label name	Value	Description
QUAL_EXT_NON_SPECIFIC	0x00	There is no specific extended substatus value.
QUAL_EXT_SCHEDULED_OFFLINE	0x01	The device is a scheduled device that is offline and no cache value is available.
QUAL_EXT_INVALID_TAG	0x02	The tag configuration is invalid.
QUAL_EXT_INVALID_DATA	0x03	The value of the tag is invalid.
QUAL_EXT_SOFTWARE_ERROR	0x04	An internal software error occurred in the device driver.
QUAL_EXT_TOO_MANY_DEVICES	0x05	Too many devices are attached.
QUAL_EXT_COMM_NO_INIT	0x06	Communication is not initialised.
QUAL_EXT_COMM_BAD	0x07	Bad communication.
QUAL_EXT_TAG_OUT_OF_RANGE	0x08	Tag address is out of range.
QUAL_EXT_WRITE_ONLY	0x09	Tag is not readable.
QUAL_EXT_WRITE_PROTECTED	0x0A	Write operation is not authorised.
QUAL_EXT_NO_CLUSTER_SPECIFIED	0x0B	No cluster is specified within a system or for a given tag.
QUAL_EXT_CLUSTER_NOT_FOUND	0x0C	The requested cluster is not known or no clusters are available.

Cicode label name	Value	Description
QUAL_EXT_CLUSTER_DISABLED	0x0D	The requested cluster is disabled.
QUAL_EXT_SESSION_NOT_CONNECTED	0x0E	Cannot connect to the requested session.
QUAL_EXT_TAG_RESOLVE_TIMEOUT	0x0F	Tag could not be resolved.
QUAL_EXT_VALUE_OUT_OF_RANGE	0x10	Tag value is out of range.
QUAL_EXT_COMM_DEV_BAD	0x11	Communication loss - data source to PLC.
QUAL_EXT_COMM_IOSERVER_BAD	0x12	Communication loss - client to data source.
QUAL_EXT_STALE	0x13	Tag value is "stale".
QUAL_EXT_NOT_REPLICATED	0x14	Tag element value not replicated to every redundant data source.

#### Part 4 - Tag Status Values - Override Flag

Cicode label name	Value	Description
QTS_OVERRIDE	0x01	The tag is in Override mode.

#### Part 5 - Tag Status Values - Control Inhibit Flag

Cicode label name	Value	Description
QTS_CONTROL_INHIBIT	0x02	The tag is in Control Inhibit Mode.

#### Related Functions

[Quality Functions](#)

### QualityIsControlInhibit

Returns a value indicating whether the tag is in Control Inhibit Mode.

## Syntax

**QualityIsControlInhibit(QUALITY *quality*)**

*quality*:

Specifies the QUALITY variable.

## Return Value

0: the tag is not in Control inhibit Mode.

1: the tag is in Control inhibit Mode.

## Related Functions

[QualityGetPart](#), [QualityIsBad](#), [QualityIsGood](#), [QualityIsOverride](#), [QualityIsUncertain](#), [QualitySetPart](#),  
[QualityToStr](#), [QualityCreate](#)

## Example

```
INT controlInhibitEnabled;  
controlInhibitEnabled = QualityIsControlInhibit(Tag1.Field.Q);
```

## See Also

[Quality Functions](#)

### QualityIsBad

This function will return a value indicating whether the general part of quality is bad.

## Syntax

**QualityIsBad(QUALITY *quality*)**

*quality*:

Specifies the QUALITY variable.

## Return Value

0: the quality is not bad.

1: the quality is bad.

## Related Functions

[QualityGetPart](#), [QualityIsControllInhibit](#), [QualityIsGood](#), [QualityIsOverride](#), [QualityIsUncertain](#), [QualitySetPart](#),  
[QualityToStr](#), [QualityCreate](#)

## Example

```
INT bad;  
bad = QualityIsBad(Tag1.Field.Q);
```

## See Also

[Quality Functions](#)

## QualityIsGood

This function will return a value indicating whether the general part of quality is good.

## Syntax

**QualityIsGood(QUALITY *quality*)**

*quality*:

Specifies the QUALITY variable.

## Return Value

0: the quality is not good.

1: the quality is good.

## Related Functions

[QualityGetPart](#), [QualityIsBad](#), [QualityIsControllInhibit](#), [QualityIsOverride](#), [QualityIsUncertain](#), [QualitySetPart](#),  
[QualityToStr](#), [QualityCreate](#)

## Example

```
INT good;
good = QualityIsGood(Tag1.Field.Q);
```

## See Also

[Quality Functions](#)

### QualityIsOverride

Returns a value indicating whether the tag is in Override Mode.

## Syntax

**QualityIsOverride(QUALITY *quality*)**

*quality*:

Specifies the QUALITY variable.

## Return Value

0: the tag is not in Override Mode.

1: the tag is in Override Mode.

## Related Functions

[QualityGetPart](#), [QualityIsBad](#), [QualityIsControlInhibit](#), [QualityIsGood](#), [QualityIsUncertain](#), [QualitySetPart](#),  
[QualityToStr](#), [QualityCreate](#)

## Example

```
INT overrideEnabled;
overrideEnabled = QualityIsOverride(Tag1.Q);
```

## See Also

[Quality Functions](#)

### QualityIsUncertain

This function will return a value indicating whether the general part of quality is uncertain.

## Syntax

**QualityIsUncertain(QUALITY *quality*)**

*quality:*

Specifies the QUALITY variable.

## Return Value

0: the quality is not uncertain.

1: the quality is uncertain.

## Related Functions

[QualityGetPart](#), [QualityIsBad](#), [QualityIsControlInhibit](#), [QualityIsGood](#), [QualityIsOverride](#), [QualitySetPart](#),  
[QualityToStr](#), [QualityCreate](#)

## Example

```
INT uncertain;
uncertain = QualityIsUncertain(Tag1.Field.Q);
```

## See Also

[Quality Functions](#)

## QualitySetPart

Sets a Quality part's value to the QUALITY variable. This function can only be used to manipulate the quality of Cicode variables. The quality item of a variable tag element (for example, 'Tag1.Field.Q') can only be used by QualityGetPart() as it is read only.

## Syntax

**QualitySetPart**(QUALITY *quality*, INT *part*, INT *value*)

*quality:*

Specifies the quality variable.

*part:*

The part to extract:

0 – The General Quality value

1 – Quality Substatus value

2 – The Quality Limit value

3 – The Extended Quality Substatus value

4 – The Tag Status Override flag

5 – The Tag Status Control Inhibit flag

6 – The DataSource error code

7 – The OPC Quality (General + Substatus + Limit)

*value:*

The new value for the given part.

## Return Value

The modified Quality value, or the original value if the given part is not applicable.

## Related Functions

[QualityGetPart](#), [QualityIsBad](#), [QualityIsControlInhibit](#), [QualityIsGood](#), [QualityIsOverride](#), [QualityIsUncertain](#), [QualityToStr](#), [QualityCreate](#)

## Example

```
QUALITY q;  
INT qualityGeneral;  
// insert code here  
q = QualitySetPart(q, 0, qualityGeneral);
```

## See Also

[Quality Functions](#)

## QualityToStr

Returns a textual representation of the quality.

## Syntax

**QualityToStr(QUALITY *quality*, INT *part*, INT *localized*)**

*quality:*

Specifies the QUALITY variable.

*part:*

Specifies the part of quality to obtain the textual representation.

-2: Short representation in the format <General Quality> [- <Quality Substatus>]

-1: Full representation in the format <General Quality> [Override] [Control Inhibit] – <Quality Substatus>

0: <General Quality>

1: <Quality Substatus>

2: <Quality Limit>

3: <Extended Quality Substatus>

4: <Quality Override>

5: <Control Inhibit>

*localized:*

The flag indicating if the returned text should be in native language or in Runtime localized language.

## Return Value

A textual representation of the quality, or an empty string if the part given is not applicable.

## Related Functions

[QualityGetPart](#), [QualityIsBad](#), [QualityIsControlInhibit](#), [QualityIsGood](#), [QualityIsOverride](#), [QualityIsUncertain](#), [QualitySetPart](#), [QualityCreate](#)

## Example

```
QUALITY q;;
STRING str;
q = QualityCreate(QUAL_GOOD, 0, QUAL_LIMITED_NOT_LIMITED,
QUAL_EXT_NON_SPECIFIC, 1, 1, 0);
str = QualityToStr(q, -1, 0);
// The result is: Good [Override] [Control Inhibit]

q = QualityCreate(QUAL_GOOD, QUAL_GOOD_LOCAL_OVERRIDE,
QUAL_LIMITED_NOT_LIMITED, QUAL_EXT_NON_SPECIFIC);
str = QualityToStr(q, 1, 0);
// The result is: Overridden

q = QualityCreate(QUAL_GOOD, 0, QUAL_LIMITED_QL_LOW_LIMITED,
QUAL_EXT_NON_SPECIFIC);
str = QualityToStr(q, 2, 0);
// The result is: Below Low

Login("UserName", "Password", 0, "French(France)");

q = QualityCreate(QUAL_GOOD, 0, QUAL_LIMITED_NOT_LIMITED,
QUAL_EXT_NON_SPECIFIC, 1, 1, 0);
str = QualityToStr(q, -1, 1);
// The result is: Bon [Supplémenté] [Contrôle Inhibé]
// Entries for 'Bon', 'Supplémenté' and 'Contrôle Inhibé'
// needs to have been provided in FRENCH.dbf

Login("UserName", "Password", 0, "English");

q = QualityCreate(QUAL_BAD, QUAL_BAD_CONFIGURATION_ERROR,
QUAL_LIMITED_NOT_LIMITED, QUAL_EXT_NON_SPECIFIC);
str = QualityToStr(q, -1, 0);
// The result is: Bad - Configuration Error

Login("UserName", "Password", 0, "French(France)");

q = QualityCreate(QUAL_BAD, QUAL_BAD_CONFIGURATION_ERROR,
QUAL_LIMITED_NOT_LIMITED, QUAL_EXT_NON_SPECIFIC);
str = QualityToStr(q, -1, 1);
// The result is: Mauvais - Erreur de Configuration
```

```
>Login("UserName", "Password", 0, "English");

q = QualityCreate(QUAL_UNCR, QUAL_UNCR_NON_SPECIFIC,
QUAL_LIMITED_NOT_LIMITED, QUAL_EXT_TAG_OUT_OF_RANGE);
str = QualityToStr(q, 0, 0);
// The result is: Uncertain

q = QualityCreate(QUAL_UNCR, QUAL_UNCR_NON_SPECIFIC,
QUAL_LIMITED_NOT_LIMITED, QUAL_EXT_TAG_OUT_OF_RANGE);
str = QualityToStr(q, 3, 0);
// The result is: Tag Address Out Of Range

q = QualityCreate(QUAL_UNCR, QUAL_UNCR_SUBNORMAL,
QUAL_LIMITED_NOT_LIMITED, QUAL_EXT_NON_SPECIFIC);
str = QualityToStr(q, 1, 0);
// The result is: Subnormal
```

## See Also

[Quality Functions](#)

## VariableQuality

Extracts the quality from a given variable.

**Note:** This function is designed to be used within Cicode; using it on graphical pages may result in displaying an error message instead of an expected quality message when either its argument has not good quality or an execution error is set.

## Syntax

**VariableQuality(*Variable*)**

**Variable:**

The variable from which the quality will be extracted.

## Return Value

The QUALITY of the given variable. If Variable is NULL, it returns quality uncertain (0x40).

Timestamps of uninitialized stack variables, uninitialized code variables and constants are equal to 0 - invalid timestamp, while their qualities are GOOD

## Related Functions

[QualityCreate](#), [QualityGetPart](#), [QualityIsGood](#), [QualitySetPart](#), [QualityIsOverride](#), [QualityIsControlInhibit](#), [QualityToStr](#)

## Example

```
INT codeVariable = 1;
INT
FUNCTION
MyFunction(REAL arg1)
STRING str = "My string";
QUALITY q;
q = VariableQuality(codeVariable); //code variable
q = VariableQuality(arg1); //function argument
q = VariableQuality(str); //stack variable
q = VariableQuality(Tag1); //any tag/local variable

RETURN 1;
END
```

## Report Functions

Following are functions relating to Reports:

<a href="#">RepGetCluster</a>	Retrieves the name of the cluster the report is running on.
<a href="#">RepGetControl</a>	Gets report control information.
<a href="#">Report</a>	Runs a report.
<a href="#">RepSetControl</a>	Sets report control information.

## See Also

[Cicode Function Categories](#)

[Using Cicode Functions](#)

### RepGetCluster

This function retrieves the name of the cluster a report is running on. This function should only be called from a report file.

## Syntax

**RepGetCluster()**

## Return Value

The name of the cluster the report is running on.

## See Also

[Report Functions](#)

## RepGetControl

Gets report control information on a report. This function is a blocking function. It will block the calling Cicode task until the operation is complete.

## Syntax

**RepGetControl(ReportName, Type [, sClusterName])**

*ReportName*:

The name of the report (can be prefixed by the name of the cluster that is ClusterName.ReportName).

*nType*:

The type of report control information to get (send back in the return value):

0 - State of the report - returns one of:

- 0 -Idle
- 1 - Waiting for PLC data for trigger
- 2 - Waiting for PLC data
- 3 - Running

1 - Time of day that the report is due to run next.

2 - The report period, in seconds, or week day, month or year, for example, if the report is weekly, this is the day of the week, 0 (Sunday) to 6 (Saturday).

3 - Synchronisation time of day of the report, for example, 10:00:00 (In seconds from midnight).

4 - Type of report schedule - returns one of:

- 0 - Event triggered
- 1 - Daily
- 2 - Weekly
- 3 - Monthly
- 4 - Yearly

5 - Report state - returns one of:

- 0 - Enabled

- 1 - Disabled

*sClusterName:*

Name of the cluster in which the report resides. This is optional if you have one cluster or are resolving the report server via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

The control information, as an integer.

## Related Functions

[RepSetControl](#), [Report](#)

## Example

```
Next=RepGetControl("SHIFT",1,"ClusterXYZ");
! Sets Next to the time that the report is due to run.
! Display a message at the prompt AN (AN2) if
! the report is running.
IF RepGetControl("SHIFT",0,"ClusterXYZ")=3 THEN
    Prompt("Shift report is running");
END
```

## See Also

[Report Functions](#)

## Report

Runs a report on the Report Server. This function only schedules the report for execution. The running of the report is controlled entirely by the Report Server.

This function will start the specified report on the Reports Server to which the Plant SCADA computer is communicating. If you are using the Reports Servers in Primary/Standy mode, the report can run on the Standby Server. If you call this function on the Standby Server then the report will definitely run on the Standby Server, even if the Primary Server is active.

This function is a blocking function. It will block the calling Cicode task until the operation is complete.

## Syntax

**Report(ReportName [, sClusterName] )**

*ReportName:*

The name of the report to run (can be prefixed by the name of the cluster that is ClusterName.ReportName).

*sClusterName:*

Name of the cluster in which the report resides. This is optional if you have one cluster or are resolving the report server via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[RepSetControl](#), [RepGetControl](#)

## Example

### Buttons

Text: Shift Report

Command: Report("Shift", "ClusterXYZ")

Comment: Runs the Shift Report

### System Keyboard

Key Sequence: Report ##### Enter

Command: Report(Arg1)

Comment: Runs a specified Report

```
Report("SHIFT", "ClusterXYZ");
! Runs the report named "SHIFT".
Report("DAY", "ClusterXYZ");
! Runs the report named "DAY".
/* The "SHIFT" and "DAY" reports are started. The order in which
the reports are run cannot be determined. If you want the "DAY"
report to run after the "SHIFT" report, call Report("DAY") at the
end of the "SHIFT" report. */
```

## See Also

[Report Functions](#)

## RepSetControl

Sets report control information to temporarily override the normal settings for a specified report. You can change the report schedule for a periodic report, and run one-time or event-triggered reports. These new settings are set on both the primary and standby report servers, but are not saved to the database. When you restart your system, Plant SCADA uses the existing settings, defined in the Reports database.

You might need to call this function several times. For example, to change an event-triggered report to run at 6 hourly intervals, you need to change the schedule (Type 4), synchronization time (Type 3), and period (Type 2). If you use incompatible values for these options, you can get unpredictable results. To change more than one option, disable the report, set the options, and then re-enable the report.

This function is a blocking function. It will block the calling Cicode task until the operation is complete.

## Syntax

**RepSetControl(*ReportName*, *Type*, *Data* [, *sClusterName*] )**

*ReportName*:

The name of the report (can be prefixed by the name of the cluster that is ClusterName.ReportName).

*nType*:

The type of report control information to set:

1 - The time of day at which to run the next report in Cicode (date/time) variable type. Subsequent reports are run at the times calculated from the period (Type 2) and synchronisation time (Type 3). Use Type 1 to specify a one-time report. Set the time in Data in seconds from midnight (for example, specify 6 p.m. as TimeMidNight() + (18 \* 60 \* 60) ).

2 - The report period. Set the new period in Data according to the report schedule (Type 4), in seconds from midnight, day of week (0 to 6, Sunday = 0), month (1 to 2), or year.

For a daily report schedule, set the report frequency in Data in seconds from midnight; for example, set Data to 6 \* 60 \* 60 for a 6 hourly shift report. If the report is weekly, set Data to the day of the week, for example, when Data = 2, the day is Tuesday.

3 - Synchronisation time of day of the report. Set the time in Data in seconds from midnight, for example, to synchronize at 10a.m., set Data to 10 \* 60 \* 60.

4 - Type of report schedule. Set Data to one of the following:

- 0 - Event triggered
- 1 - Daily
- 2 - Weekly
- 3 - Monthly
- 4 - Yearly

5 - Report state. Set Data to either:

- 0 - Enabled
- 1 - Disabled

*Data*

The new data value, dependent on the Type.

*sClusterName*:

Name of the cluster in which the report resides. This is optional if you have one cluster or are resolving the report server via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[RepGetControl](#), [Report](#)

## Examples

Run the "Shift" report in 1 minute.

```
RepSetControl("Shift",1,TimeCurrent() + 60,"ClusterXYZ");
```

Change weekly report to 8 hour shift starting at 7 am

```
RepSetControl("Weekly", 5, 1,"ClusterXYZ"); ! disable report  
RepSetControl("Weekly", 4, 1,"ClusterXYZ"); ! change mode to daily  
RepSetControl("Weekly", 3, 7 * 60 * 60,"ClusterXYZ"); ! sync at 7:00:00 am  
RepSetControl("Weekly", 2, 8 * 60 * 60,"ClusterXYZ"); ! run every 8 hours  
RepSetControl("Weekly", 5, 0,"ClusterXYZ"); ! enable report
```

Change yearly report to run on March 10 at 7 am

```
RepSetControl("Yearly", 5, 1,"ClusterXYZ"); ! disable report  
RepSetControl("Yearly", 4, 4,"ClusterXYZ"); ! change mode to yearly  
RepSetControl("Yearly", 3, 7 * 60 * 60,"ClusterXYZ"); ! sync at 7:00:00 am  
RepSetControl("Yearly", 2, 31 + 28 + 10,"ClusterXYZ"); ! run on March 10th  
RepSetControl("Yearly", 5, 0,"ClusterXYZ"); ! enable report
```

## Scheduler Functions

The following functions relate to Scheduler.

<a href="#">SchdClose</a>	Terminates a browsing session and cleans up the resources used by the session.
<a href="#">SchdConfigClose</a>	Terminates a browsing session and cleans up the resources used by the session.
<a href="#">SchdConfigFirst</a>	Places the data browse cursor at the first record.
<a href="#">SchdConfigGetField</a>	Returns the value of the particular field in a record to which the data browse cursor is currently referencing.
<a href="#">SchdConfigNext</a>	Places the data browse cursor at the next available record.
<a href="#">SchdConfigNumRecords</a>	Returns the number of records that match the current filter criteria.
<a href="#">SchdConfigOpen</a>	Initiates a new session for browsing the schedules configured.
<a href="#">SchdConfigPrev</a>	Places the data browse cursor at the previous record.
<a href="#">SchdFirst</a>	Places the data browse cursor at the first record.

<a href="#">SchdGetField</a>	Returns the value of the particular field in a record to which the data browse cursor is currently referencing.
<a href="#">SchdNext</a>	Places the data browse cursor at the next available record.
<a href="#">SchdNumRecords</a>	Returns the number of records that match the current filter criteria.
<a href="#">SchdOpen</a>	Initiates a new session for browsing the runtime schedules.
<a href="#">SchdPrev</a>	Places the data browse cursor at the previous record.
<a href="#">ScheduleItemAdd</a>	Adds a new schedule to the scheduler engine.
<a href="#">ScheduleItemDelete</a>	Deletes an existing schedule.
<a href="#">ScheduleItemModify</a>	Modifies an existing schedule.
<a href="#">ScheduleItemSetRepeat</a>	Adds recurrence information for an existing schedule to the scheduler engine.

## Special Day Functions

<a href="#">SchdSpecialAdd</a>	Adds a new special day group to the scheduler engine.
<a href="#">SchdSpecialClose</a>	Terminates a browsing session and cleans up the resources used in the session.
<a href="#">SchdSpecialDelete</a>	Deletes an existing special day group.
<a href="#">SchdSpecialFirst</a>	Places the data browse cursor at the first record.
<a href="#">SchdSpecialGetField</a>	Returns the value of the particular field in a record to which the data browse cursor is currently referencing.
<a href="#">SchdSpecialItemAdd</a>	Adds a new special day to the scheduler engine.
<a href="#">SchdSpecialItemAddRange</a>	Adds a range of special days in a specified special day group.
<a href="#">SchdSpecialItemClose</a>	Terminates a browsing session and cleans up the resources used in the session.
<a href="#">SchdSpecialItemDelete</a>	Deletes an existing Special day.

SchdSpecialItemDeleteRange	Deletes a range of special days in a specified special day group.
SchdSpecialItemFirst	Places the data browse cursor at the first record.
SchdSpecialItemGetField	Returns the value of the particular field in a record to which the data browse cursor is currently referencing.
SchdSpecialItemModify	Modifies an existing special day.
SchdSpecialItemModifyRange	Modifies a range of special days in a specified special day group.
SchdSpecialItemNext	Places the data browse cursor at the next available record.
SchdSpecialItemNumRecords	Returns the number of records that match the current filter criteria.
SchdSpecialItemOpen	Initiates a new session for browsing the special days.
SchdSpecialItemPrev	Places the data browse cursor at the previous record.
SchdSpecialModify	Modifies an existing special day group.
SchdSpecialNext	Places the data browse cursor at the next available record.
SchdSpecialNumRecords	Returns the number of records that match the current filter criteria.
SchdSpecialOpen	Initiates a new session for browsing the special day groups.
SchdSpecialPrev	Places the data browse cursor at the previous record.

### SchdConfigGetField

The SchdConfigGetField function returns the value of the particular field in a record to which the data browse cursor is currently referencing.

## Syntax

**STRING SchdConfigGetField(LONG Session, STRING Field )**

*Session:*

The handle to a browse session previously returned by the SchdConfigOpen call.

*Field*

A field to retrieve. Refer to [SchdConfigOpen](#) for detailed list of fields.

## Return Value

The value of the specified field as a string. An empty string may or may not be an indication that an error has been detected. The last error should be checked in this instance to determine if an error has actually occurred.

## SchdConfigNext

The SchdConfigNext function places the data browse cursor at the next available record. This function will return an error if called when the data cursor is at end of the records.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

INT **SchdConfigNext**(LONG *Session*)

*Session*:

The handle to a browse session previously returned by the SchdConfigOpen call.

## Return Value

0 (zero) if the browsing session exists, otherwise an error code is returned.

## Related Functions

## SchdConfigNumRecords

The SchdConfigNumRecords function returns the number of records that match the current filter criteria. This function uses iSession as an argument which is previously returned by the SchdConfigOpen function.

## Syntax

```
LONG SchdConfigNumRecords(LONG Session)
```

*Session:*

The handle to a browse session previously returned by the SchdConfigOpen call.

## Return Value

Returns number of records. 0 means no records were found.

## SchdConfigOpen

The SchdConfigOpen function initiates a new session for browsing the schedules configured. It returns a handle for the browsing session which can be used for further browsing operations.

## Syntax

```
LONG SchdConfigOpen([TIMESTAMP Start] [, LONG Duration] [, STRING Filter] [, STRING Fields] [, STRING Clusters] )
```

*Start:*

The start date of the schedules in UTC time to return during the browse. If not specified, today at midnight will be taken as start time. The types of this field is TIMESTAMP. Use [StrToTimestamp](#) or [TimestampCreate](#) Cicode functions to create a TIMESTAMP type.

*Duration:*

The duration of the browse in seconds. The default is 86400 seconds(24 hour).

*Filter:*

A filter expression specifying the records to return during the browse. An empty string indicates that every record will be returned.

All string fields can be filtered based on regular expressions. Using an operator other than = will cause strings to

not match the filter criteria. The following regular expressions are supported \*expr, expr\*, and \*expr\*.

**Fields:**

Specifies via a comma delimited string the columns to be returned during the browse. An empty string indicates that the server will return every available column.

Supported fields are:

**ID:** The unique ID of the schedule within the schedule engine. ID value is the same for all recurring schedules.

**EQUIPMENT:** The equipment name

**STATE:** The state of the schedule

**START:** The start time of the schedule.

**OCCURRENCESTART:** The start of this occurrence. For non-recurring entries will be the same as START.

**END:** The end time of the schedule.

**OCCURRENCEEND:** The end of this occurrence. For non-recurring entries will be the same as END.

**DESC:** The description of the schedule.

**MODIFIEDTIME:** The time when the entry was modified last time.

The following fields are used when a schedule is recurrent. The value of FREQ field -1 means the schedule is not recurrent:

**FREQ:** The type of the recurrence: 4 - daily, 5 - weekly, 6- monthly, 7 - yearly, 8 - special days. -1 means this schedule is non-recurring.

**INTERVAL:** The interval of the recurrence. 1 - every 1 day/week/month etc., 2 - every second day/week/month etc. and so on.

**WEEKDAY:** The first day of the week.

**WEEKDAYMASK:** The day of week mask. Defines day of week where recurrence happens.

- None = 0,
- Sunday = 1,
- Monday = 2,
- Tuesday = 4,
- Wednesday = 8,
- Thursday = 16,
- Friday = 32,
- Saturday = 64,
- Everyday = 127,
- Weekdays = 62,
- Weekendays = 65

Combination of days can be achieved by addition. For example, Tuesdays and Wednesdays would be 12 (4 + 8).

**MAXREC:** The maximum number recurrences (-1 means MAXREC is not specified. If MAXREC is -1 then the recurrence stops on the date specified by RECOUNTIL field. If RECOUNTIL is not specified the recurrence occurs forever).

**RECOUNTIL:** The time until recurrence occurs. -1 means never stops (or finishes after MAXREC occurrences if is specified).

**DAYORD:** Day ordinal. Applicable for monthly and yearly recurrence patterns. Using the values 1 to 4 you can set

the schedule to run on the first, second, third, or fourth occurrence of the DAY in each month (monthly recurrences), or the specified MONTH (yearly recurrences). Use the value -1 for the last week of the month.

**DAY:** The day of month

**MONTH:** The month of the year

**SPECIALINC:** Defined whether the special day is included in the pattern. 0 - none, 1 - all, 2 - selected.

**GROUPIDS** A list of group's ID included in the recurring pattern (used only when SPECIALINC is defined as 2 ("selected")).

*sClusters:*

An optional parameter that specifies via a comma delimited string the subset of the clusters to browse. An empty string indicates that the connected clusters will be browsed.

**Note:** Time values (START, OCCURRENCESTART, END, OCCURRENCEEND, MODIFIEDTIME) are TIMESTAMP type.  
Use [TimestampToStr\(\)](#) Cicode function to convert it to string.

## Return Value

Returns an integer handle to the browse session. Returns -1 when an error is detected.

## Related Functions

## SchdConfigPrev

The SchdConfigPrev function places the data browse cursor at the previous record. This function will return an error if called when the data cursor is at beginning of the records.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**INT SchdConfigPrev(LONG Session)**

*Session:*

The handle to a browse session previously returned by the SchdConfigOpen call.

## Return Value

0 (zero) if the browsing session exists, otherwise an error code is returned.

## Related Functions

## SchdFirst

The SchdFirst function places the data browse cursor at the first record.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**INT SchdFirst(LONG Session)**

*Session:*

The handle to a browse session previously returned by the SchdOpen call.

## Return Value

0 (zero) if the browsing session exists, otherwise an error code is returned.

## SchdGetField

The SchdGetField function returns the value of the particular field in a record to which the data browse cursor is currently referencing.

## Syntax

STRING **SchdGetField**(LONG *Session*, STRING *Field*)

*Session*:

The handle to a browse session previously returned by the SchdOpen call.

*Field*:

Specifies via a comma delimited string the columns to be returned during the browse. An empty string indicates that the server will return every available column. See [SchdOpen](#) for supported fields.

## Return Value

The value of the specified field as a string. An empty string may or may not be an indication that an error has been detected. The last error should be checked in this instance to determine if an error has actually occurred.

## SchdNext

The SchdNext function places the data browse cursor at the next available record. This function will return an error if called when the data cursor is at end of the records.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

INT **SchdNext**(LONG *Session*)

*Session*:

The handle to a browse session previously returned by the SchdOpen call.

## Return Value

0 (zero) if the browsing session exists, otherwise an error code is returned.

## Related Functions

## SchdNumRecords

The SchdNumRecords function returns the number of records that match the current filter criteria.

## Syntax

LONG **SchdNumRecords**(LONG *Session*)

*Session*:

The handle to a browse session previously returned by the SchdOpen call.

## Return Value

The number of records that have matched the filter criteria. A value of 0 denotes that no records have matched. A value of -1 denotes that the browse session is unable to provide a fixed number. This may be the case if the data being browsed changed during the browse session.

## SchdOpen

The SchdOpen function initiates a new session for browsing the runtime schedules. It returns a handle for the browsing session which can be used for further browsing operations.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

LONG **SchdOpen**(STRING *Equipment*[, TIMESTAMP *Start*] [,LONG *Duration*] [,STRING *Filter*] [,STRING *Fields*] [, STRING *Clusters*] )

*Equipment*:

The name of the equipment to browse.

*Start*:

The start date of the schedules. If not specified, today at midnight will be taken as the start time. The types of this field is TIMESTAMP. Use StrToTimestamp or TimestampCreate Cicode functions to create a TIMESTAMP type.

*Duration*:

The duration of the browse in seconds. The default is 86400 seconds(24 hour).

*Filter*:

A filter expression specifying the records to return during the browse. An empty string indicates that every record will be returned.

*Fields*:

Specifies via a comma delimited string the columns to be returned during the browse. An empty string indicates that the server will return every available column. Supported fields are:

**EQUIPMENT**: The equipment name

**STATE**: The state to be set by the schedule

**START**: The start time of the schedule. The time is returned as a Timestamp value. Use StrToTimestamp() to get a TIMESTAMP data value.

**END**: The end time of the schedule. The time is returned as a Timestamp value. Use StrToTimestamp() to get a TIMESTAMP data value.

**INHERITED**: Indicates if the schedule entry is inherited from a schedule defined in a parent equipment higher in the hierarchy.

**DESC**: The description of the schedule.

*Clusters*:

An optional parameter that specifies via a comma delimited string the subset of the clusters to browse. An empty string indicates that the connected clusters will be browsed.

## Return Value

Returns an integer handle to the browse session. Returns -1 when an error is detected.

For errors refer to the topic [Cicode and General Errors](#).

### SchdSpecialAdd

The SchdSpecialAdd adds a new Special Day Group to the Scheduler engine.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

LONG **SchdSpecialAdd**(STRING *Cluster*, STRING *Name*)

*Cluster*:

The name of the cluster.

*Name*:

Name of the special day group.

## Return Value

Returns the ID of the Special Day Group which can be used for modifying and deleting this Special Day Group.

Returns the ID for an existing Special Day group. This function returns -1 if, unsuccessful. Trap the error to get the error returned by this function.

## Related Functions

## SchdSpecialClose

The SchdSpecialClose function terminates a browsing session and cleans up the resources used by the session. This function uses iSession as the argument which is previously returned by the SchdSpecialOpen function.

## Syntax

INT **SchdSpecialClose**(LONG *Session*)

*Session*:

Current special day group browsing session obtained by [SchdSpecialOpen](#).

## Return Value

0 (zero) if the browsing session exists, otherwise an error code is returned.

## Related Functions

### SchdSpecialDelete

The SchdSpecialDelete function deletes an existing special day group.

## Syntax

LONG **SchdSpecialDelete**(STRING *Cluster*, LONG *ID*)

*Cluster*:

Name of the Cluster.

*ID*

Special day group ID.

## Return Value

Returns 0 if successful otherwise it returns an error.

## Related Functions

[SchdSpecialAdd](#), [SchdSpecialModify](#)

## See Also

[Scheduler Functions](#)

### SchdSpecialFirst

The SchdSpecialFirst function places the data browse cursor at the first record. This function uses *Session* as the argument which is previously returned by the SchdSpecialOpen function.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

INT **SchdSpecialFirst**(LONG *Session*)

*Session*:

Current special day group browsing session obtained by [SchdSpecialOpen](#).

## Return Value

0 (zero) if the browsing session exists, otherwise an error code is returned.

## Related Functions

### SchdSpecialGetField

The SchdSpecialGetField function returns the value of a particular field from the record currently referenced by the data browse cursor. This function uses *Session* as an argument which is previously returned by the [SchdSpecialOpen](#) function and the field name of the value to be returned.

## Syntax

STRING **SchdSpecialItemGetField**(LONG *Session*, STRING *Field*)

*Session*

Current special day group browsing session obtained by [SchdSpecialOpen](#).

*Field*

Specifies via a comma delimited string the columns to be returned during the browse. An empty string indicates that the server will return every available column. See [SchdSpecialOpen](#) for supported fields.

## Return Value

The value of the specified field as a string. An empty string may or may not be an indication that an error has been detected. The last error should be checked in this instance to determine if an error has actually occurred.

## Related Functions

### SchdSpecialItemAdd

The SchdSpecialItemAdd function adds a new Special Day to the scheduler engine. It returns the ID of the Special Day which can be used for modifying and deleting the Special Day.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

```
LONG SchdSpecialItemAdd(STRING Cluster, LONG GroupID, STRING Name, TIMESTAMP Day)
```

*Cluster:*

Name of the Cluster.

*GroupID:*

Special day group ID.

*Name:*

Name of special day.

*Day:*

The special day as a timestamp. Use [TimestampCreate](#) or [StrToTimestamp](#) Cicode functions to get a timestamp data value.

## Return Value

Returns the ID for an existing special day or -1 if unsuccessful. Trap the error to get the error returned by this function.

## Related Functions

[SchdSpecialItemModify](#), [SchdSpecialItemDelete](#)

## Example

```
TIMESTAMP tsDate = TimestampCreate(2012,1,2,0,0,0);
.
// Add the new special day
nCatID = SchdSpecialAdd(STRING Cluster, sCategory);
IF (nCatID > -1) THEN
    nSchdID = SchdSpecialItemAdd(STRING Cluster, nCatID, sLabel, tsDate);
    IF (nSchdID > -1) THEN
        // Use the new schedule special day item
    END
END
```

## See Also

[Scheduler Functions](#)

## SchdSpecialItemAddRange

The SchdSpecialItemAddRange function adds a range of special days in the specified special day group (category).

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

```
INT SchdSpecialItemAddRange(STRING Cluster, STRING GroupID, STRING Name, TIMESTAMP FirstDay,  
TIMESTAMP LastDay)
```

*Cluster:*

The name of the cluster.

*GroupID:*

The ID of the special day group.

*Name:*

The name of the special day.

*FirstDay:*

The first day of the special day range as a timestamp. Use TimestampCreate or StrToTimestamp Cicode functions to get a timestamp data value. When creating a timestamp, please use midnight of the required day.

*LastDay:*

Last day (inclusive) of the special day range as a timestamp. Use TimestampCreate or StrToTimestamp Cicode functions to get a timestamp data value. When creating a timestamp, please use midnight of the required day.

## Return Value

0 if successful, otherwise an error code is returned.

## Related Functions

[SchdSpecialItemDeleteRange](#), [SchdSpecialItemModifyRange](#)

## Example

```
// Add the special day range for group id 1  
// 2018-05-06 : 2018-05-10  
  
SchdSpecialItemAddRange("Cluster1", 1,  
TimestampCreate(2018,5,6,0,0,0,0), TimestampCreate(2018,5,10,0,0,0,0));
```

## SchdSpecialItemDelete

This function deletes an existing Special Day.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

```
LONG SchdSpecialItemDelete(STRING Cluster, LONG ID)
```

*Cluster:*

Name of the cluster.

*ID:*

Special day ID.

## Return Value

This function returns 0 if successful otherwise it returns an error.

## Related Functions

[SchdSpecialItemAdd](#), [SchdSpecialItemModify](#)

## SchdSpecialItemDeleteRange

The SchdSpecialItemDeleteRange function removes a range of special days in a specified special day group (category).

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

INT **SchdSpecialItemDeleteRange**(STRING *Cluster*, STRING *GroupID*, TIMESTAMP *FirstDay*, TIMESTAMP *LastDay*)

*Cluster*:

The name of the cluster.

*GroupID*:

The ID of the special day group.

*FirstDay*:

The first day of the special day range as a timestamp. Use TimestampCreate or StrToTimestamp Cicode functions to get a timestamp data value. When creating a timestamp, please use midnight of the required day.

*LastDay*:

Last day (inclusive) of the special day range as a timestamp. Use TimestampCreate or StrToTimestamp Cicode functions to get a timestamp data value. When creating a timestamp, please use midnight of the required day.

## Return Value

0 if successful, otherwise an error code is returned.

## Related Functions

## SchdSpecialItemGetField

This function returns the value of the particular field in a record to which the data browse cursor is currently referencing. This function uses *Session* as an argument which is previously returned by the [SchdSpecialItemOpen](#) function and the field name of the value to be returned.

## Syntax

**STRING SchdSpecialItemGetField(LONG Session, STRING Field)**

*Session*

Current special day group browsing session obtained by [SchdSpecialItemOpen](#).

*Field*

Specifies via a comma delimited string the columns to be returned during the browse. An empty string indicates that the server will return every available column. Supported fields are:

**GROUPNAME:** The group name of the special day

**NAME:** The name of the special day

**DAY:** The special day. The time is returned as a Timestamp value. Use [StrToTimestamp\(\)](#) to get a TIMESTAMP data value

**ID:** The unique ID of the special day. Every special day is assigned a unique ID.

## Return Value

The value of the specified field as a string. An empty string may or may not be an indication that an error has been detected. The last error should be checked in this instance to determine if an error has actually occurred.

## Related Functions

## SchdSpecialItemModify

This function modifies an existing Special Day.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

```
LONG SchdSpecialItemModify(STRING Cluster, LONG ID, STRING Name, TIMESTAMP Day)
```

*Cluster:*

The name of the cluster.

*ID*

ID of the special day to be modified.

*Name*

The name of the special day.

*Day:*

The special day as a timestamp. Use TimestampCreate or StrToTimestamp Cicode functions to get a timestamp data value.

## Return Value

This function returns 0 if successful otherwise it returns an error code.

## Related Functions

[SchdSpecialItemAdd](#), [SchdSpecialItemDelete](#)

### SchdSpecialItemModifyRange

The SchdSpecialItemModifyRange function can be used to modify a range of special days in a specified special day group (category).

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

```
INT SchdSpecialItemAddRange(STRING Cluster, STRING GroupID, TIMESTAMP FirstDay, TIMESTAMP LastDay,  
STRING NewName, TIMESTAMP NewFirstDay, TIMESTAMP NewLastDay)
```

*Cluster*:

The name of the cluster.

*GroupID*:

The ID of the special day group.

*FirstDay*:

The first day of the special day range as a timestamp. Use TimestampCreate or StrToTimestamp Cicode functions to get a timestamp data value. When creating a timestamp, please use midnight of the required day.

*LastDay*:

Last day (inclusive) of the special day range as a timestamp. Use TimestampCreate or StrToTimestamp Cicode functions to get a timestamp data value. When creating a timestamp, please use midnight of the required day.

*NewName*:

A new name for the special days.

*NewFirstDay*:

A new first day for the special day range as a timestamp. Use TimestampCreate or StrToTimestamp Cicode functions to get a timestamp data value. When creating a timestamp, please use midnight of the required day.

*NewLastDay*:

A new last day (inclusive) of the special day range as a timestamp. Use TimestampCreate or StrToTimestamp Cicode functions to get a timestamp data value. When creating a timestamp, please use midnight of the required day.

## Return Value

0 if successful, otherwise an error code is returned.

## Related Functions

[SchdSpecialItemAddRange](#), [SchdSpecialItemDeleteRange](#)

## Example

```
// Modify the existing special day range for group id 1
// from 2018-05-06 : 2018-05-10
// to 2018-06-06 : 2018-06-10

SchdSpecialItemModifyRange("Cluster1", 1, "NewDays",
TimestampCreate(2018,5,6,0,0,0,0), TimestampCreate(2018,5,10,0,0,0,0),
TimestampCreate(2018,6,6,0,0,0,0), TimestampCreate(2018,6,10,0,0,0,0));
```

## See Also

[Scheduler Functions](#)

### SchdSpecialItemNext

This function places the data browse cursor at the next available record. This function uses iSession as the argument which is previously returned by the SchdSpecialItemOpen function. This function will return an EOF error code if called when the data cursor is at end of the records.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

INT **SchdSpecialItemNext**(LONG Session)

*Session:*

Current special day group browsing session obtained by [SchdSpecialItemOpen](#).

## Return Value

0 (zero) if the browsing session exists, otherwise an error code is returned.

## Related Functions

[SchdSpecialItemOpen](#), [SchdSpecialItemClose](#), [SchdSpecialItemFirst](#), [SchdSpecialItemPrev](#),  
[SchdSpecialItemGetField](#)

### SchdSpecialItemNumRecords

The SchdSpecialItemNumRecords function returns the number of records that match the current filter criteria. This function uses iSession as an argument which is previously returned by the SchdSpecialItemOpen function.

## Syntax

LONG **SchdSpecialItemNumRecords**(LONG *Session*)

*Session*:

Current special day group browsing session obtained by [SchdSpecialItemOpen](#).

## Return Value

The number of records that have matched the filter criteria. A value of 0 denotes that no records have matched. A value of -1 denotes that the browse session is unable to provide a fixed number. This may be the case if the data being browsed changed during the browse session.

## Related Functions

[SchdSpecialItemOpen](#), [SchdSpecialItemClose](#), [SchdSpecialItemNext](#), [SchdSpecialItemPrev](#), [SchdSpecialItemFirst](#)

## See Also

[Scheduler Functions](#)

## SchdSpecialItemOpen

This function initiates a new session for browsing the special days. It returns a handle for the browsing session which can be used for further browsing operations.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

LONG **SchdSpecialItemOpen**(STRING *Filter*, STRING *Fields* [, STRING *Clusters*])

*Filter*:

A filter expression specifying the records to return during the browse. An empty string indicates that all records will be returned.

*Fields*:

Specifies via a comma delimited string the columns to be returned during the browse. An empty string indicates that the server will return every available column. See [SchdSpecialItemGetField](#) for the fields supported.

*Clusters*:

An optional parameter that specifies via a comma delimited string the subset of the clusters to browse. An empty string indicates that the connected clusters will be browsed.

## Return Value

Returns an integer handle to the browse session. Returns -1 when an error is detected.

## Related Functions

### SchdSpecialItemPrev

This function places the data browse cursor at the previous record. This function uses iSession as the argument which is previously returned by the SchdSpecialItemOpen function. This function will return an error (EOF) if called when the data cursor is at beginning of the records.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**INT SchdSpecialItemPrev(LONG Session)**

*Session:*

Current special day group browsing session obtained by [SchdSpecialItemOpen](#).

## Return Value

0 (zero) if the browsing session exists, otherwise an error code is returned.

## Related Functions

### SchdSpecialModify

This function modifies an existing special day group.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**LONG SchdSpecialModify(STRING Cluster, LONG ID, STRING NewName)**

*Cluster:*

The name of the cluster.

*ID*:

Existing ID for the current special day group.

*NewName*:

New name of the current special day group.

## Return Value

This function returns 0 if successful otherwise it returns an error.

For error code information codes refer to the topic [Cicode and General Errors](#).

## Related Functions

[SchdSpecialDelete](#), [SchdSpecialAdd](#)

[Scheduler Functions](#)

## SchdSpecialNext

This function places the data browse cursor at the next available record. This function uses *iSession* as the argument which is previously returned by the [SchdSpecialOpen](#) function. This function will return an EOF error code if called when the data cursor is at end of the records.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

INT **SchdSpecialNext**(LONG *Session*)

*Session*:

Current special day group browsing session obtained by [SchdSpecialOpen](#).

## Return Value

0 (zero) if the browsing session exists, otherwise an error code is returned.

## Related Functions

[SchdSpecialOpen](#), [SchdSpecialFirst](#), [SchdSpecialClose](#), [SchdSpecialPrev](#), [SchdSpecialGetField](#),

### SchdSpecialNumRecords

The SchdSpecialNumRecords function returns the number of records that match the current filter criteria. This function uses iSession as an argument which is previously returned by the SchdSpecialOpen function.

## Syntax

LONG **SchdSpecialNumRecords**(LONG *Session*)

*Session*:

Current special day group browsing session obtained by [SchdSpecialOpen](#).

## Return Value

The number of records that have matched the filter criteria. A value of 0 denotes that no records have matched. A value of -1 denotes that the browse session is unable to provide a fixed number. This may be the case if the data being browsed changed during the browse session.

### SchdSpecialOpen

The SchdSpecialOpen function initiates a new session for browsing the special day groups. It returns a handle for the browsing session which can be used for further browsing operations.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

LONG **SchdSpecialOpen**(STRING *Filter*, STRING *Fields*[, STRING *Clusters*])

*Filter*:

A filter expression specifying the records to return during the browse. An empty string indicates that every record will be returned. Multiple filters can be specified and separated with ';'. Where a fieldname is not specified in the filter, it is assumed to be tagname. For example, the filter "AAA" is equivalent to "name=AAA".

*Fields*:

Specifies via a comma delimited string the columns to be returned during the browse. An empty string indicates

that the server will return every available column. Supported fields are:

**NAME:** The name of the special day group.

**ID:** The unique ID of the special day group. Every special day group is assigned a unique ID.

*Clusters:*

An optional parameter that specifies via a comma delimited string the subset of the clusters to browse. An empty string indicates that the connected clusters will be browsed.

## Return Value

Returns an integer handle to the browse session. Returns -1 when an error is detected.

## Related Functions

### ScheduleItemAdd

The ScheduleItemAdd function adds a new schedule to the scheduler engine. It returns the Id of the schedule which can be used for modifying, setting recurrence and deleting this schedule.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

```
LONG ScheduleItemAdd(STRING Cluster, STRING Equipment, STRING State, TIMESTAMP Start, TIMESTAMP End,  
STRING Desc)
```

*Cluster:*

The name of the cluster.

*Equipment:*

The name of the equipment to browse.

*State:*

The state of the schedule.

*Start:*

The start time of the schedule. The type of this parameter is TIMESTAMP. Use TimestampCreate or StrToTimestamp to get a TIMESTAMP value.

*End:*

The end time of the schedule. The type of this parameter is TIMESTAMP. Use TimestampCreate or StrToTimestamp to get a TIMESTAMP value.

*Desc*

The description of the schedule.

## Return Value

The id of the schedule which can be used for modifying, setting recurrence and deleting this schedule. This function returns -1 if unsuccessful. Trap the error to get the error returned by this function.

## Related Functions

[SchdNumRecords](#), [ScheduleItemSetRepeat](#), [ScheduleItemModify](#), [ScheduleItemDelete](#)

## Example

```
//The following example creates a schedule item using state MyState1 for
MyEquipment1, that starts from 3am and ends at 4am on 20th of Nov 2011.
```

```
TIMESTAMP tsStartTime;
TIMESTAMP tsEndTime;
INT iScheduleID;
tsStartTime = TimestampCreate(2011, 11, 20, 3, 0, 0, 0);
tsEndTime = TimestampCreate(2011, 11, 20, 4, 0, 0, 0);
iScheduleID = ScheduleItemAdd("Cluster1",
"MyEquipment1","MyState1",tsStartTime,tsEndTime,"MyScheduleItem1");
```

## See Also

[Scheduler Functions](#)

### ScheduleItemDelete

The ScheduleItemDelete function deletes an existing schedule.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

**LONG ScheduleItemDelete(STRING Cluster, LONG ID)**

*Cluster:*

Name of cluster.

*ID:*

The unique ID of the schedule within the schedule engine.

## Return Value

Returns 0 if successful otherwise it returns an error.

## Related Functions

[SchdClose](#), [SchdConfigOpen](#), [SchdConfigClose](#), [SchdConfigFirst](#), [SchdConfigNext](#), [SchdConfigPrev](#),

[Scheduler Functions](#)

### ScheduleItemModify

The ScheduleItemModify function modifies an existing schedule.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

LONG **ScheduleItemModify**(STRING *Cluster*, LONG *ID*, STRING *State*, TIMESTAMP *Start*, TIMESTAMP *End*, STRING *Desc*)

*Cluster*:

Name of cluster.

*ID*:

The unique ID of the schedule within the schedule engine.

*State*:

The state of the schedule.

*Start*:

The start time of the schedule. The type of this parameter is TIMESTAMP. Use [TimestampCreate](#) or [StrToTimestamp](#) to get a TIMESTAMP value.

*End*:

The end time of the schedule. The type of this parameter is TIMESTAMP. Use [TimestampCreate](#) or [StrToTimestamp](#) to get a TIMESTAMP value.

*Desc*

The description of the schedule.

## Return Value

Returns 0 if successful otherwise it returns an error.

## Related Functions

[SchdClose](#), [SchdConfigOpen](#), [SchdConfigClose](#), [SchdConfigFirst](#), [SchdConfigNext](#), [SchdConfigPrev](#),

[ScheduleItemAdd](#), [ScheduleItemSetRepeat](#), [ScheduleItemDelete](#)

## See Also

[Scheduler Functions](#)

## ScheduleItemSetRepeat

The ScheduleItemSetRepeat function adds recurrence information to an existing schedule to the scheduler engine. The same function is used if the schedule already has recurrence information that need to be changed.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

LONG **ScheduleItemSetRepeat**(STRING *Cluster*, LONG *ID*, LONG *Freq*, LONG *Interval*, LONG *Weekday*, LONG *WeekDayMask*, LONG *MaxRec*, LONG *RecUntil*, LONG *DayOrd*, LONG *Day*, LONG *Month*, LONG *SpecialInc*, STRING

*GroupIds)*

*Cluster*

Name of cluster.

*ID*

The existing schedule id to apply recurrence.

*Freq:*

The type of the recurrence: 4 – daily, 5 – weekly, 6- monthly, 7 – yearly, 8 – special days.

*Interval:*

The interval of the recurrence. 1 – every 1 day/week/month etc., 2 – every second and so on.

*WeekDay:*

The first day of week – Sunday (0) or Monday (1).

*WeekDayMask:*

The day of week mask. Defines day of week where recurrence happens.

None = 0,

Sunday = 1,

Monday = 2,

Tuesday = 4,

Wednesday = 8,

Thursday = 16,

Friday = 32,

Saturday = 64,

Everyday = 127,

Weekdays = 62,

Weekendays = 65

Combination of days can be achieved by addition. For example, Tuesdays and Wednesdays would be 12 (4 + 8).

*MaxRec:*

The maximum number recurrences (-1 means does not stop).

*RecUntil:*

The time specifies the time until recurrence is occurring. The type of this parameter is TIMESTAMP. Use TimestampCreate or StrToTimestamp to get a TIMESTAMP value. To create a recurring schedule that does not end use TimestampCreate(1601, 1, 1, 0, 0, 0, 0, 1).

*DayOrd:*

Day ordinal. Applicable for monthly and yearly recurrence patterns. Can be 1-4 or -1 (every 1, second, third, fourth or last week of a month).

*Day:*

The day of month.

*Month:*

The month of the year.

*SpecialInc:*

Defined whether the special day is included in the pattern. 0 – none, 1 – every, 2 – selected.

*GroupIds* :

A list of group's ID included in the recurring pattern (used only when SpecialIncl is defined as 2 ("selected")).

## Return Value

Returns 0 if successful otherwise it returns an error.

## Security Functions

Following are functions relating to Security:

<a href="#">FullName</a>	Gets the full name of the current operator.
<a href="#">GetLanguage</a>	Gets the language currently used on the display client.
<a href="#">GetPriv</a>	Checks the privilege and area of the current operator.
<a href="#">Login</a>	Logs an operator into the Plant SCADA system. Not available when logged in as Windows user.
<a href="#">LoginForm</a>	Displays a form that allows an operator to log in to the Plant SCADA system.
<a href="#">Logout</a>	Logs an operator out of the Plant SCADA system.
<a href="#">LogoutIdle</a>	Sets an idle time logout for the current operator.
<a href="#">MultiSignatureForm</a>	Displays a form that allows up for 4 users to have their credentials verified in order to approve an operation.
<a href="#">MultiSignatureTagWrite</a>	Displays a form that allows up for 4 users to have their credentials verified in order to approve a write of a specific value to a specific tag.
<a href="#">Name</a>	Gets the user name of the current operator.
<a href="#">UserCreate</a>	Creates a new user record during run time. This function is now deprecated and will be removed in the next release. Use the <a href="#">UserCreateByRole</a> function instead.
<a href="#">UserCreateByRole</a>	Creates a record for a new Plant SCADA user. The user can be assigned to a specified role. Not available when logged in as Windows user.
<a href="#">UserCreateForm</a>	Displays a form to create a record for a new user. Not

	available when logged in as Windows user.
UserDelete	Deletes a new user record during run time. Not available when logged in as Windows user.
UserEditForm	Displays a form for a selected user to create or delete user records during run time. Not available when logged in as Windows user.
UserInfo	Gets information about the operator who is currently logged-in to the system.
UserLogin	Logs an operator into the Plant SCADA system using a secure password string.
UserPassword	Changes a user's password during run time. Not available when logged in as Windows user.
UserPasswordExpiryDays	Returns the number of days left before the user's password is due to expire. Not available when logged in as Windows user.
UserPasswordForm	Displays a form for the operator to change their own password during run time. Not available when logged in as Windows user.
UserSetStr	Sets the value of the given field for the given user record in the project configuration (users.dbf ) on the local machine.
UserUpdateRecord	Triggers a recompile of the local project configuration, then notifies the running system that user configuration has been modified and needs to be reloaded.
UserVerify	Uses the authentication functionality in the user login system.
VerifyPrivilegeForm	Displays a form that allows a single user to enter their credentials.
VerifyPrivilegeTagWrite	Displays a form that allows any single user to enter their credentials in order to approve a write of a specific value to a specific tag.
WhoAmI	Displays the name of the operator who is currently logged-in to the system.

## See Also

[Cicode Function Categories](#)

[Using Cicode Functions](#)

## FullName

Gets the full name of the user who is currently logged on to the system. The user can be a Plant SCADA or a Windows user. For a Plant SCADA user the full name is the one defined in the user settings. For a Windows user the full name is in the format of <DomainName>\<UserName>. When there is no one logged in or the logged in user is a "system user" this function returns an empty string.

## Syntax

**FullName()**

If the user is logged on as a Domain user the name should be the Windows domain name and user account name in the format of <DomainName\UserName>.

If the user is logged on as a local user the name should be the local machine name and user account name in the format of <MachineName\UserName>.

## Return Value

The user name (as a string).

## Related Functions

[NameUserInfo](#)

## Example

```
/* Display the full name of the current user at AN20. */  
DspText(20, 0, FullName());
```

## See Also

[Security Functions](#)

## GetLanguage

Gets the language currently used on the display client.

## Syntax

STRING **GetLanguage(INT iType)**

*iType*

The type of language information to be returned:

0 (default) — the name of the current language as defined in the project. For example, "English (United States)" or "French (France)".

1 — the country language code of the current language. Includes the language code (ISO-639) and country code (ISO-3166). For example:

- "en-US" for English (United States)
- "fr-FR" for French (France).

## Return Value

The specified information describing the language that is currently in use.

## Related Functions

[Login](#), [LoginForm](#), [UserLogin](#)

## Example

```
// login a user -> Login("ConfigUsers","SCADA",1,"German(Germany)")  
STRING sLanguage;  
sLanguage = GetLanguage(0) // will return German(Germany)  
sLanguage = GetLanguage(1) // will return de-DE
```

## See Also

[Security Functions](#)

## GetPriv

Checks if the current user has a privilege for a specified area. With this function, you can write your own Cicode functions to control user access to the system.

## Syntax

**GetPriv(*Priv*, *Area*)**

*Priv*

The privilege level (1..8).

*Area*

The area of privilege (0..255).

## Return Value

Returns 1 if the user has the specified privilege in the area, or 0 (zero) if the user does not have the privilege.

## Related Functions

[SetArea](#)

## Example

```
/* User needs to have privilege 2, or cannot do operation. */
IF GetPriv(2, 0) THEN
    ! Do operation here
ELSE
    Prompt("No privilege for command");
END
```

## See Also

[Security Functions](#)

## Login

Not available when logged in as Windows user.

Logs a user into the Plant SCADA system, using Plant SCADA security and gives users access to the areas and privileges assigned to them in the Users database, and uses the locale language defined for that user. Only one user can be logged into a computer at any one time. If a user is already logged in when a second user logs in, the first user is automatically logged out.

When using Windows security use [UserLogin](#) to limit Windows credentials being exposed as plain text.

At startup, or when the user logs out, a default user is active, with access to area 0 (zero) and privilege 0 (zero) only. Use the [LoginForm\(\)](#) function to display a form for logging in to the system.

## Syntax

**Login**(*sUserName*, *sPassword* [, *bSync*] [, *sLanguage*])

*sUserName*:

The user's name, as defined in the Users database.

*sPassword*:

The user's password, as defined in the Users database.

*bSync*:

Optionally specifies whether the function operates in blocking or non-blocking mode. If set to 1 blocks caller until login is complete. If set to 0 (default) does not block caller.

*sLanguage*:

The specified language needs to be one of the languages defined in the [Languages](#) view in Plant SCADA Studio's [Setup](#) activity. If the specified language is undefined, the default language is used by the login user, and a message "Undefined language" is shown in the prompt line.

An empty string (i.e. "") can be specified to indicate that the default language is used by the login user. The default language defined by [\[Language\]LocalLanguage](#) INI parameter.

The default value of this parameter is "".

## Return Value

0 (zero) if successful.

## Related Functions

[LoginForm](#), [Logout](#), [LogoutIdle](#), [Message](#), [Input](#), [UserLogin](#)

## Example

```
/*
** Log in a user whose user name is "FRED" and whose password
** is "ABC".
**
** The language of the logged in user session will be set to
** the default language.
*/
Login("FRED", "ABC");

/*
** Log in a user whose user name is "FRED" and whose password
** is "ABC".
**
** The language of the logged in user session will be set to
** English.
*/
Login("FRED", "ABC", 0, "English");

/*
** Log in a user whose user name is "FRED" and whose password
** is "ABC".
**
** The language of the logged in user session will be set to
** French.
*/
Login("FRED", "ABC", 0, "French(France)");

/*
** Log in a user whose user name is "FRED" and whose password
** is "ABC".
**
** The language of the logged in user session will be set to
** Chinese.
*/
Login("FRED", "ABC", 0, "Chinese(Simplified, PRC)");
```

## See Also

[Security Functions](#)

### LoginForm

Displays a form in which a user can log in to the Plant SCADA system by entering their name and password and local language. If the login is correct, the user is logged into the Plant SCADA system with the area(s) and privilege(s) assigned to them in the Users database.

---

**Note:** You can only call this function on a client process.

From version 7.10 this form can be pre-filled by the caller. Both Plant SCADA and Windows users are supported.

This function is a blocking function. It will block the calling Cicode task until the operation is complete.

## Syntax

**LoginForm([*sUserName* [, *sPassword* [, *sLanguage*]])**

*sUserName*:

Optionally, the user's name, as defined in the Users database.

*sPassword*:

Optionally, the user's password, as defined in the Users database.

*sLanguage*:

The specified language must be one of the languages defined in the **Languages** view in Plant SCADA Studio's **Setup** activity. If the specified language is undefined, the default language is used by the login user, and a message "Undefined language" is shown in the prompt line.

An empty string (i.e. "") can be specified to indicate that the default language is used by the login user. The default language defined by [\[Language\]LocalLanguage](#) INI parameter.

The default value of this parameter is "".

---

**Note:** If the language is changed a page reload will occur.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[Login](#), [UserLogin](#)

## Example

System Keyboard

Key Sequence	Login
LoginForm	Display the Login form
Comment	Allow user login

#### Buttons

Text	Operator Login
LoginForm	Display the Login form
Comment	Allow user login

## See Also

[Security Functions](#)

## Logout

Logs the current user out of the Plant SCADA system. Plant SCADA continues to run, but with access to area 0 (zero) and privilege 0 (zero) only. If the current page requires access for a specified area (as defined by the page's area property), the system returns to the home page as specified by the parameter [\[Page\]HomePage](#), and if unsuccessful that returns to the startup page. When multiple pages are currently displayed, this occurs for each open window.

Calling this function to logout the logged on user will cause an automatically logged in user to be logged back on. If there is no user logged in, calling this function will return an error. When the logged on user is an automatically logged in user, calling this function will return an error.

## Syntax

**Logout()**

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[Login](#), [LoginForm](#), [LogoutIdle](#), [UserInfo](#), [Message](#), [Input](#)

## Example

```
/* Log the current user out of the system. */  
Logout();
```

## See Also

[Security Functions](#)

### LogoutIdle

Sets an idle time for logging out the current user. If the current user does not execute a command within the specified idle time, a prompt is displayed. If the prompt is ignored, then the user is logged out. For every user to have the same idle time, you would call this function at startup. Otherwise, you can call the function from the Users database to specify an idle time for each user. This function will not log out an automatically logged on user.

Until reset LogoutIdle remains active. To reset call LogoutIdle (-1) from the Exit command of the Users database record.

## Syntax

**LogoutIdle(*Idle*)**

*Idle*:

The number of minutes the user needs to be idle before logout will occur. Set Idle to -1 to disable the current logout timeout.

## Return Value

No return value.

## Related Functions

[Logout](#), [Login](#), [LoginForm](#)

## Example

Users

User Name	Operator1
LoginForm	LogoutIdle(5)
Comment	Logs the user out after five minutes

## See Also

[Security Functions](#)

## MultiSignatureForm

Displays a form that allows up to four users to have their credentials verified in order to approve an operation. The usernames can be Plant SCADA or Windows users.

## Syntax

**MultiSignatureForm**(*sOperationDescription*, *sLogDevice*, *sUser1*, *sUser2*, *sUser3*, *sUser4*)

*sOperationDescription*:

A description of the operation that requires approval. This string will be displayed on the signature form and logged to the log device if the operation is approved.

*sLogDevice*:

The name of a log device if logging is required, otherwise pass an empty string.

*sUser1..4*:

Each *sUser* argument needs to be either a Plant SCADA user name, a Windows user name (including domain\ prefix) or a blank string. Even though the *sUser* arguments are numbered 1 through 4, this only controls the order in which users are displayed on the multi-signature form. You can pass empty strings for any of these arguments, but at least one user needs to be specified.

## Return Value

TRUE (1) if the operation approved (that is all users' credentials were verified and the operator clicked the "Approve" button, otherwise FALSE (0).

## Related Functions

[FormSecurePassword](#), [MultiSignatureTagWrite](#), [VerifyPrivilegeForm](#), [VerifyPrivilegeTagWrite](#)

## Example

```
// This example sets the page integer to indicate the approval status, but
// it can be used to perform any logic necessary to trigger the operation
// that was approved.
PageSetInt(1, MultiSignatureForm("Shut down plant", "ApprovalLog", "shiftsupervisor",
"DOMAIN\mike.manager", "", ""));
```

[Form Functions](#)

## MultiSignatureTagWrite

Displays a form that allows up to four users to have their credentials verified in order to approve a write of a specific value to a specific tag. If all users are verified successfully, the write to the tag is performed by this

function before it returns. The usernames can be Plant SCADA or Windows users.

## Syntax

**MultiSignatureTagWrite(*sTagName*, *sValueToWrite*, *sLogDevice*, *sUser1*, *sUser2*, *sUser3*, *sUser4*)**

*sTagName*:

The name of the tag to which a write needs to be approved.

*sValueToWrite*:

The value to write to the tag if approval succeeds.

*sLogDevice*:

The name of a log device if logging is required, otherwise pass an empty string.

*sUser*:

Each *sUser* argument needs to be either a Plant SCADA user name, a Windows user name (including domain\prefix) or an empty string. Even though the *sUser* arguments are numbered 1 through 4, this only controls the order in which users are displayed on the multi-signature form. You can pass empty strings for any of these arguments, but at least one user needs to be specified.

## Return Value

TRUE (1) if the operation was approved (that is all users' credentials were verified and the operator clicked the "Approve" button, otherwise FALSE (0).

## Related Functions

[FormSecurePassword](#), [MultiSignatureForm](#), [VerifyPrivilegeForm](#), [VerifyPrivilegeTagWrite](#)

## Example

```
// This example generates a form to request two users to approve the tag write operation.  
// When approved, the PLC_VAR1 tag is written with the value 123 and a page string  
// is set to indicate the approval status.  
IF  
  MultiSignatureTagWrite("PLC_VAR1", "123", "", "John Smith", "Angela Huth", "", "")  
THEN  
  PageSetStr(1, "TagWrite Successful");  
ELSE  
  PageSetStr(1, "TagWrite Not Successful");  
END
```

## Name

Gets the name of the operator who is currently logged on to the display system. The user can be a Plant SCADA or a windows user. If this function is called on a server, it returns the name of the local operator. If there is no one logged on, or the logged on user is a "system user" this function returns an empty string.

## Syntax

**Name**([*bIncludeDomain*])

*bIncludeDomain*:

- *bIncludeDomain* = 0: Return Windows user name only
- *bIncludeDomain* = 1: (Default) Return Windows user name with domain name

---

**Note:** This parameter is ignored when a normal Plant SCADA account.

---

## Return Value

The name of the user as a string. If the user is logged on as a Windows user the name will be the Windows user account name.

## Related Functions

[FullName](#), [Login](#), [LoginForm](#)

## Example

```
/* Display the user name of the current user at AN20. */  
DspText(20,0,Name());
```

## See Also

[Security Functions](#)

## UserCreate

This function is now deprecated and will be removed in the next release. Use the [UserCreateByRole](#) function instead.

Not available for a Windows user.

Creates a record for a new Plant SCADA user. The name of the user needs to be unique.

The user can be of a specified **Type** or assigned to a specified **Role**, depending on the current setting for the parameter [\[Security\]CreateUserByRole](#).

---

**Note:** Only users assigned an administrator role can create a user. Other users attempting to run this will encounter an error.

An alarm server needs to be configured and running in the project, so that all clients are notified that an online change to the users configuration has been completed.

In order to perform user configuration changes online in a system with multiple computers running SCADA nodes using these functions, you will need to use the RUN and COPY parameters to check the updates are distributed throughout the system, and that the functions are called from the computer which uses the COPY path as its RUN path.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**UserCreate(*sName*, *sFullName*, *sPassword*, *sType/sRole*)**

*sName*:

The name of the user.

*sFullName*:

The full name of the user.

*sPassword*:

The password of the user.

The *sPassword* argument is optional. If not passed, this argument defaults to an empty string which is subsequently ignored. It is included for the purposes of handling duplicate user names and separate password identification compatibility.

*sType*:

The generic type of user. The type needs to be defined in the general properties for a user in Plant SCADA Studio's Security activity (see [Add a Plant SCADA User](#)).

*sRole*:

The role to which the user will be assigned. The role needs to be defined in Plant SCADA Studio's Security activity (see [Roles](#)).

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[UserDelete](#), [UserEditForm](#), [UserPassword](#), [UserPasswordForm](#), [UsercreateForm](#)

## Example

```
/* Create a new user */
UserCreate("Fred", "Fred Jones", "secret", "Operator");
```

## UserCreateByRole

This function is not available for a Windows user.

Creates a record for a new Plant SCADA user. The user can be assigned to a specified role (see [Roles](#)). The name of the user needs to be unique.

---

**Note:** Only users assigned an administrator role can create a user. Other users attempting to run this will encounter an error.

---

An alarm server needs to be configured and running in the project, so that all clients are notified that an online change to the users configuration has been completed.

In order to perform user configuration changes online in a system with multiple computers running SCADA nodes using these functions, you will need to use the RUN and COPY parameters to check the updates are distributed throughout the system, and that the functions are called from the computer which uses the COPY path as its RUN path.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**UserCreateByRole(*sName*, *sFullName*, *sPassword*, *sRole*)**

*sName*:

The name of the user.

*sFullName*:

The full name of the user.

*sPassword*:

The password of the user.

The *sPassword* argument is optional. If not passed, this argument defaults to an empty string which is subsequently ignored. It is included for the purposes of handling duplicate user names and separate password identification compatibility.

*sRole*:

The role(s) to which the user will be assigned. If required, you can enter multiple roles as a comma separated list. The role(s) you specify need to be defined in Plant SCADA Studio's **Security** activity (see [Roles](#)).

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[UserDelete](#), [UserEditForm](#), [UserPassword](#), [UserPasswordForm](#), [UsercreateForm](#)

## Example

```
/* Create a new user */  
UserCreateByRole("Fred", "Fred Jones", "secret", "Operator");
```

[Security Functions](#)

## UserInfo

Gets information about the operator who is currently logged-in to the system.

## Syntax

**UserInfo(*nType*)**

*nType*:

The type of user information:

0 - Flag to indicate whether any user other than a view-only user is logged in

1 - The login name of the user

2 - The full name of the user

3 - The time the user logged in

4 - The time the user entered the last command

5 - The number of commands entered by the user

6 - The type of login:

- "0" indicates that the current user is a view-only user.

- "1" indicates there is Plant SCADA or Windows non-default user explicitly logged in.

- "2" indicates the logged on user is a Plant SCADA default user (control client auto login Plant SCADA user).

- "3" indicates the logged on user is a Windows default user (control client auto login windows user).

## Return Value

The information (as a string). If an error is detected, an empty string is returned.

## Related Functions

[Login](#)

## Example

```
/* Check if a user has logged on. If so, get the user's full name and the number of
commands they have performed. */
String sName;
String sCount;
IF UserInfo(0) = "1" THEN
    sName = UserInfo(2);
    sCount = UserInfo(5);
END
```

## See Also

[Security Functions](#)

## UserLogin

Logs a user into the Plant SCADA system, using either Windows integrated security or Plant SCADA security and gives users access to the areas and privileges assigned to them in the Users database, and uses the locale language defined for that user. Only one user can be logged into a computer at any one time. If a user is already logged in when a second user logs in, the first user is replaced by the newly logged on user. When a newly logged in user does not have access to view the current page (as defined by the page's area), the system returns to the home page as specified by the parameter[Page]HomePage, and if unsuccessful that returns to the startup page. When multiple pages are currently displayed, this occurs for each open window.

To call this function at user login, the password argument passed needs to be in secure string format.

At startup, or when the user logs out, a default user is active, with access to area 0 (zero) and privilege 0 (zero) only. Use the [LoginForm\(\)](#) function to display a form for logging in to the system.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**UserLogin(sUserName, sPassword, [sLanguage])**

**sUserName:**

The user's name as defined in the Users database, or the Windows User account name, in plain text.

**sPassword:**

The user's password, as defined in the Users database or Windows account formatted as a secure string.

To improve the user credentials protection provides a system built-in user login function that takes the user

name and secure password as the arguments. This reduces the chance that the user's password can be exposed in plain text from the runtime system

*sLanguage:*

The specified language needs to be one of the languages defined in the Languages view in Plant SCADA Studio's Setup activity. If the specified language is undefined, the default language is used by the login user, and a message "Undefined language" is shown in the prompt line.

An empty string (i.e. "") can be specified to indicate that the default language is used by the login user. The default language defined by [\[Language\]LocalLanguage](#) INI parameter.

The default value of this parameter is "".

## Return Value

0 (zero) if successful.

## Related Functions

[LoginForm](#), [Logout](#), [LogoutIdle](#), [Message](#), [Input](#)

## Example

```
/*
** FUNCTION NAME:LoginForm
**
** This function displays the login form, get the user name, password and
** the language of the user session and then trys to log the user in.
** If the login does not succeed it will retry until login is ok or user
** presses the cancel button.
*/
INT
FUNCTION

### UserPassword

Not available for a Windows user.

Changes the password for the user. Changes are written to both the Users database and the runtime database in memory.

An alarm server needs to be configured and running in the project, so that all clients are notified that an online change to the users configuration has been completed.

If you use this function to perform user configuration changes across an online system with multiple computers running SCADA nodes, you will need to use the [\[CtEdit\]Run](#) and [\[CtEdit\]Copy](#) parameters to distribute the updated files throughout the system.

You will also need to execute the UserPassword function on:

- The computer where the master/source Users.dbf and \_Users.rdb files are located.  
Or:
- The computer to which [CtEdit]Copy is pointing.  
Or:
- The computer from which [CtEdit]Copy is copying files.

UserPassword can only work for users that are contained in the main project.

---

**Note:** Only those users assigned a role with "Manage User" privilege set to True can set a user password without knowing the existing password. Other users attempting to run will encounter an error.

---

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**UserPassword(*sName* [, *sPassword*] [, *sOldPassword*] )**

*sName:*

The name of the user.

*sPassword:*

The password of the user.

The *sPassword* argument is optional. If not passed, this argument defaults to an empty string which is subsequently ignored. It is included for the purposes of handling duplicate user names and separate password identification compatibility.

*sOldPassword:*

The password assigned to the user before the `UserPassword()` function is run.

The *sOldPassword* argument is optional. If passed, Plant SCADA will only permit the password change (and consequent re-setting of the expiry period) when the old password is correctly entered. If the *sOldPassword* parameter is not passed, the password change will proceed without restriction.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[UserPasswordForm](#), [UserCreate](#), [UserEditForm](#)

## Example

```
/* Change Fred's password */  
UserPassword("Fred", "secret");
```

## See Also

## UserPasswordExpiryDays

Not available for a Windows user.

Returns the number of days left before the user's password is due to expire.

To use this function, you can build a form page by using Cicode that takes the user name and password as inputs and output the number of days that return by `UserPasswordExpiryDays`.

## Syntax

**UserPasswordExpiryDays(*sUserName* [, *sPassword*] )**

*sUserName:*

The name of the user.

*sPassword:*

The password of the user.

The *sPassword* argument is optional. If not passed, this argument defaults to an empty string which is subsequently ignored. It is included for the purposes of handling duplicate user names and separate password identification compatibility.

## Return Value

The return value contains either the number of days before password expiry, or one of two exception conditions:

- 0 to 365 - number of days
- -1 - no expiry
- -2 - user not found or password wrong

## Related Functions

[UserPassword](#)

### UserSetStr

Sets the value of the given field for the given user record in the project configuration (users.dbf ) on the local machine.

After this function has been called, use the function [UserUpdateRecord](#) to update the user record on the running system.

An alarm server needs to be configured and running in the project, so that all clients are notified that an online change to the users configuration has been completed.

In order to perform user configuration changes online in a system with multiple computers running SCADA nodes using these functions, you will need to use the RUN and COPY parameters to check the updates are distributed throughout the system, and that the functions are called from the computer which uses the COPY path as its RUN path.

---

**Note:** Only those users assigned the role with "Manage User" privilege set to True can update other users details. The current logged in user can only update their own details. Other users attempting to run will encounter an error.

---

## Syntax

**UserSetStr**(*sName*, *sField*, *sData*)

*sName*:

The name of the user who's configuration record we wish to modify.

*sField*:

The name of the field in users.dbf to modify.

*sData*:

The new value of the field.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[UserDelete](#), [UserEditForm](#), [UserPassword](#), [UserPasswordForm](#), [UserCreateForm](#)

## Example

```
UserSetStr("Fred", "Comment", "Fred is an engineer");
UserUpdateRecord();
```

## See Also

[Security Functions](#)

## UserUpdateRecord

Triggers a recompile of the local project configuration, then notifies the running system that user configuration has been modified and needs to be reloaded.

Use this function in conjunction with [UserSetStr](#) to modify user configuration online.

An alarm server needs to be configured and running in the project, so that all clients are notified that an online change to the users configuration has been completed.

In order to perform user configuration changes online in a system with multiple computers running SCADA nodes using these functions, you will need to use the RUN and COPY parameters to check the updates are distributed throughout the system, and that the functions are called from the computer which uses the COPY path as it's RUN path.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

```
UserUpdateRecord()
```

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[UserDelete](#), [UserEditForm](#), [UserPassword](#), [UserPasswordForm](#), [UserCreateForm](#)

## Example

```
UserSetStr("Fred", "Comment", "Fred is an engineer");
UserUpdateRecord();
```

[Security Functions](#)

### UserVerify

Verifies a given user by authenticating the user's credential, verifies the user privileges and areas against those specified in the functions parameters. Successful verification however does not log the user into the Plant SCADA runtime system.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**UserVerify**(*sName*, *sPassword* [, *sAccess*] [, *sPrivGlobal*] [, *sPriv1..sPriv8*] )

*sName*:

The name of the user.

*sPassword*:

The password of the user. The *sPassword* argument needs to be passed as a secure string.

*sAccess*:

Specifies the required user's viewable areas.

*sPrivGlobal*:

Specifies the required user's global privilege.

*sPriv1-8*:

Specifies the required areas for privileges 1 - 8. That is, *sPriv1* contains the areas (1,2,3,4,...,255) where the user has Privilege 1.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

The successful verification has to meet the following conditions:

- The selected user credentials can be authenticated
- The required user privileges are included in the authenticated user's total privileges.

## Related Functions

[UserDelete](#), [UserEditForm](#), [UserPassword](#), [UserPasswordForm](#), [UserCreateForm](#)

## Example

```
INT FUNCTION UserVerifyTest()
  STRING sName;
  STRING sPassword;

```

```
INT nStatus;
bDone = FALSE;
WHILE bDone = FALSE DO
    FormNew("@(Login Form)", 30, 5, 5);
    FormInput(1, 0, "@(Name)" + " ", sName, 16);
    FormSecurePassword(1, 2, "@(Password)" + " ", sPassword, 16);
    FormButton( 1, 4, " " + "@(OK)" + " ", 0, 1);
    FormButton(17, 4, "@(Cancel)", 0, 2);
    IF FormRead(0) = 0 THEN
        IF UserVerify(sName, sPassword) = 0 THEN
            bDone = TRUE;
            nStatus = 0;
            Message("Info", "Verification successful", 0)
        ELSE
            sPassword = "";
            Message("Info", "Verification not successful", 0)
        END
    ELSE
        bDone = TRUE;
        nStatus = 298;
    END
END
RETURN nStatus;
END
```

### VerifyPrivilegeForm

Displays a form that allows a single user to enter their credentials. These credentials are checked against a specified set to ensure the user has the required privileges before allowing the operation to proceed.

The user can be a Plant SCADA or Windows user.

## Syntax

**VerifyPrivilegeForm(*sOperationDescription*,*sLogDevice*, *sAccess*, *sGlobalPriv*, *sPriv1*, *sPriv2*, *sPriv3*, *sPriv4*, *sPriv5*,  
*sPriv6*, *sPriv7*, *sPriv8*)**

*sOperationDescription*:

A description of the operation that requires approval.

*sLogDevice*:

The name of a log device if logging is required, otherwise pass an empty string.

*sAccess*:

The required user viewable areas, or pass an empty string for none.

*sGlobalPriv*:

The required global privilege, otherwise pass an empty string.

*sPriv1..8*:

Specifies the required areas for privileges 1 - 8. That is, *sPriv1* contains the areas (1,2,3,4,...,255) where the user has Privilege 1. Each argument needs to be either specified or an empty string for none.

## Return Value

The name of the user that met the required privileges, otherwise ""

## Related Functions

[FormSecurePassword](#), [MultiSignatureForm](#), [MultiSignatureTagWrite](#), [VerifyPrivilegeTagWrite](#)

## Example

```
// This example generates a form to request a user to approve an operation.  
// This user needs the global privilege level of 8.  
// When approved, the operation is completed and a page string  
// is set to indicate the approval status.  
IF (VerifyPrivilegeForm("Shut Down Plant", "ApprovalLog",  
"PlantWide", "8", "", "", "", "", "", "", "")<>"") THEN  
    // Do operation  
    PageSetStr(1, "Operation approved");  
ELSE  
    PageSetStr(1, "Operation not approved");  
END
```

## See Also

[Security Functions](#)

[Form Functions](#)

## VerifyPrivilegeTagWrite

Displays a form that allows any single user to enter their credentials in order to approve a write of a specific value to a specific tag. These credentials are checked against a specified set to ensure the user has the required privileges before allowing the operation to proceed.

The usernames can be Plant SCADA or Windows users.

## Syntax

**VerifyPrivilegeTagWrite**(*sTagName*, *sValueToWrite*, *sLogDevice*, *sAccess*, *sGlobalPriv*, *sPriv1*, *sPriv2*, *sPriv3*,  
*sPriv4*, *sPriv5*, *sPriv6*, *sPriv7*, *sPriv8*)

*sTagName*:

The name of the tag to which a write needs to be approved.

*sValuetowrite*:

The value to write to the tag if approval succeeds.

*sLogDevice*:

The name of a log device if logging is required, otherwise pass an empty string.

*sAccess:*

The required user viewable areas, or pass an empty string for none.

*sGlobalPriv:*

The required global privilege, otherwise pass an empty string.

*sPriv1..8:*

Specifies the required areas for privileges 1 - 8. That is, *sPriv1* contains the areas (1,2,3,4,...,255) where the user has Privilege 1. Each argument needs to be either specified or an empty string for none.

## Return Value

Name of user that met the required privileges (and therefore the value was written to the specified tag), otherwise ""

## Related Functions

[FormSecurePassword](#), [MultiSignatureForm](#), [MultiSignatureTagWrite](#), [VerifyPrivilegeForm](#)

## Example

```
// This example generates a form to request a user to approve the tag write operation.  
// This user needs privilege levels of 6 and 3.  
// When approved, the PLC_VAR1 tag is written with the value 123 and a page string  
// is set to indicate the approval status.  
IF (VerifyPrivilegeTagWrite("PLC_VAR1", "123", "ApprovalLog",  
"PlantWide", "", "6", "3", "", "", "", "", "")<>"") THEN  
    PageSetStr(1, "TagWrite Successful");  
ELSE  
    PageSetStr(1, "TagWrite Not Successful");  
END
```

## Sequence of Events (SOE) Functions

Following are functions relating to sequence of events:

<a href="#">SOEventAdd</a>	Inserts a new event into the event journal
<a href="#">SOEArchive</a>	Archives event journals
<a href="#">SOEMount</a>	Mounts archive volume
<a href="#">SOEDismount</a>	Dismount archive volume

## See Also

[Cicode Function Categories](#)

[Using Cicode Functions](#)

## SOEArchive

Use this function to archive event journals. To use this function you need to log in with a user assigned to a role that has full privileges (privilege 1..8).

**Note:** When you call this function, archiving will commence according to the values defined for the Plant SCADA parameters "ArchiveAfter" and "KeepOnlineFor". For more information, see the topic [Configure the Archiving Parameters](#) in the main help.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**INT SOEArchive(STRING Path[, STRING ClusterName])**

*Path: (optional)*

The path set for SOEArchive (for example, "C:\temp\SOEArchive").

If a path is not entered, the default archive path for the alarm server configuration will be used.

*sClusterName:*

Optional cluster on which to perform mounting operation. If not specified, the operation will be performed on all clusters.

---

**Note:** The volume where data is to be saved should be labeled. This includes any removable storage devices. If this is not the case, archiving will not succeed and a message will display on the SOE page.

---

## Return Value

0 (zero) if successful, otherwise an error code is returned.

### Examples

SOEArchive(<path>, <ClusterName>) <-- Archiving specific Cluster of SOE and Summary Data to a specific location

SOEArchive("", <ClusterName>) <-- Archiving specific Cluster of SOE and Summary Data to the default Archive Path defined in Alarm Server configuration (form)

SOEArchive(<path>) <-- Archiving all Clusters of SOE and Summary Data to a specific location

SOEArchive() <-- Archiving all Clusters of SOE and Summary Data to the default Archive Path defined in Alarm Server configuration (form)

## See Also

[Sequence of Events \(SOE\) Functions](#)

## SOEDismount

Use this function to dismount archive volume. To use this function you will need to log in with a role (e.g.Engineer) who has full privilege (privilege 1..8).

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**INT SOEDisMount([, STRING ClusterName])**

*sClusterName:*

Optional cluster on which to perform mounting operation. If not specified, the operation will be performed on all clusters.

## Example

```
SOEDismount() <-- Dismounting all Clusters of SOE and Summary Data  
SOEDismount(<ClusterName>) <-- Dismounting specific Cluster of SOE and Summary Data
```

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## See Also

[Sequence of Events \(SOE\) Functions](#)

## SOEventAdd

Use this function to insert an event into the Event Journal.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

```
INT SOEventAdd(TIMESTAMP TimeStamp, STRING Message[,STRING Tag, STRING Cluster])
```

*TimeStamp*:

The time of the inserted event.

*Message*:

The message for the event.

*Tag*:

Alarm tag associated with the event. This can be Cluster.Tag or Tag if running on a single cluster system. If not specified the event is classed as a 'User' event.

*Cluster*:

Specify if running on a multi-cluster system and Tag has been specified. If Tag has not been specified and the Cluster is blank, the User event will be broadcast to all of the clusters to which the client is currently connected.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

---

**Note:** If you have installed Plant SCADA on an English operating system and want to add events messages at runtime using a Unicode language (such as Korean, Russian or Chinese), you will need to change the Windows™ Region setting for the runtime computer. To do this, go to **Control Panel** and open the **Region** dialog box. On the **Administrative** tab, use the **Change system locale** button to select the required system locale. Be aware that you will have to restart your computer. When you launch runtime, select the matching **Language** on the login form. Your event messages will be recorded using the specified language characters.

---

[Sequence of Events \(SOE\) Functions](#)

## SOEMount

Use this function to mount an archive volume. Archived data from the volume can be displayed on the Alarm Summary and Sequence of events page. To use this function you will need to log in with a role (e.g.Engineer) who has full privilege (privilege 1..8).

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

`INT SOEMount(STRING sPath [, STRING ClusterName])`

*sClusterName:*

Optional cluster on which to perform mounting operation. If not specified, the operation will be performed on all clusters.

**Note:** Check the archive output is mounted on the correct cluster. If the archive output is mounted on the wrong cluster, the incorrect data may be presented for user.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Examples

```
SOEMount(<path>, <ClusterName>) <-- Mounting specific Cluster of SOE and Summary Data from a specific location
```

```
SOEMount(<path>) <-- Mounting all Clusters of SOE and Summary Data from a specific location
```

## Server Functions

Following are functions relating to servers.

<a href="#">ServerBrowseClose</a>	The ServerBrowseClose function terminates an active data browse session and cleans up resources associated with the session.
<a href="#">ServerBrowseFirst</a>	The ServerBrowseFirst function places the data browse cursor at the first record.

<a href="#">ServerBrowseGetField</a>	The ServerBrowseGetField function retrieves the value of the specified field from the record the data browse cursor is currently referencing.
<a href="#">ServerBrowseNext</a>	The ServerBrowseNext function moves the data browse cursor forward one record.
<a href="#">ServerBrowseNumRecords</a>	The ServerBrowseNumRecords function returns the number of records that match the filter criteria.
<a href="#">ServerBrowseOpen</a>	The ServerBrowseOpen function initiates a new browse session and returns a handle to the new session that can be used in subsequent data browse function calls.
<a href="#">ServerBrowsePrev</a>	The ServerBrowsePrev function moves the data browse cursor back one record.
<a href="#">ServerGetProperty</a>	Returns information about a specified server and can be called from any client.
<a href="#">ServerInfo</a>	Gets client and server information.
<a href="#">ServerInfoEx</a>	Gets client and server information from a specified process in a multiprocessor environment.
<a href="#">ServerIsOnline</a>	The ServerIsOnline function checks if the given server can be contacted by the client for giving the online/offline status of the server.
<a href="#">ServerReload</a>	Reloads the server specified by cluster and server name.
<a href="#">ServerRestart</a>	Restart any specific alarm, report, trend or I/O server from any Cicode node in system, without affecting other server processes running on the same machine.
<a href="#">ServerRPC</a>	Calls a remote procedure on the Plant SCADA server specified by the <i>ServerName</i> argument.

## See Also

[Using Cicode Functions](#)

### ServerBrowseClose

The ServerBrowseClose function terminates an active data browse session and cleans up resources associated

with the session.

## Syntax

**ServerBrowseClose(*iSession*)**

*iSession*:

Handle to a browse session previously opened by a [ServerBrowseOpen](#) call.

## Return Value

0 (zero) if the server browse session exists, otherwise an error code is returned.

## Related Functions

[ServerBrowseFirst](#), [ServerBrowseGetField](#), [ServerBrowseNext](#), [ServerBrowseNumRecords](#), [ServerBrowseOpen](#), [ServerBrowsePrev](#)

## Example

```
INT iRetVal = ServerBrowseClose(hServers);
```

## See Also

[Server Functions](#)

## ServerBrowseOpen

The [ServerBrowseOpen](#) function initiates a new browse session and returns a handle to the new session that can be used in subsequent data browse function calls.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**ServerBrowseOpen(STRING *Filter* , STRING *Fields* , STRING *Clusters*)**

*Filter*:

A semicolon delimited list of field name=field value pairs, specifying the records to return during the browse. An empty string indicates that all records will be returned.

The following regular expressions are supported: \*expr, expr\*, and \*expr\*. To specify an exclusion filtering condition, use the NOT keyword after the = operator.

*Fields*:

Specifies via a comma-delimited string the columns to be returned during the browse. An empty string indicates that the server will return available columns. Supported fields are:

NAME, TYPE, COMMENT, CLUSTER, MODE, NETADDR, PORT.

See [Browse Function Field Reference](#) for information about fields.

*Clusters:*

An optional parameter that specifies via a comma delimited string the subset of clusters to browse. An empty string indicates that connected clusters will be browsed.

## Return Value

An integer handle to the browse session. Returns -1 on error.

The returned entries will be ordered alphabetically by name.

## Related Functions

[ServerBrowseClose](#), [ServerBrowseFirst](#), [ServerBrowseGetField](#), [ServerBrowseNext](#), [ServerBrowseNumRecords](#),  
[ServerBrowsePrev](#)

## Example

```
INT hServers = ServerBrowseOpen("Type=alarm;Mode=1", "Name", "");
```

## See Also

[Server Functions](#)

## ServerBrowseFirst

The ServerBrowseFirst function places the data browse cursor at the first record.

## Syntax

**ServerBrowseFirst(*iSession*)**

*iSession:*

Handle to a browse session previously opened by a [ServerBrowseOpen](#) call.

## Return Value

0 (zero) if the server browse session exists, otherwise an error code is returned.

## Related Functions

[ServerBrowseClose](#), [ServerBrowseGetField](#), [ServerBrowseNext](#), [ServerBrowseNumRecords](#), [ServerBrowseOpen](#),  
[ServerBrowsePrev](#)

## Example

```
INT iReturn = ServerBrowseFirst(hServers);
```

## See Also

[Server Functions](#)

### ServerBrowseNext

The ServerBrowseNext function moves the data browse cursor forward one record. If you call this function after you have reached the end of the records, error 412 is returned (Databrowse session EOF).

## Syntax

**ServerBrowseNext(*iSession*)**

*iSession*:

Handle to a browse session previously opened by a [ServerBrowseOpen](#) call.

## Return Value

0 (zero) if the server browse session exists, otherwise an error code is returned.

## Related Functions

[ServerBrowseClose](#), [ServerBrowseFirst](#), [ServerBrowseGetField](#), [ServerBrowseNumRecords](#), [ServerBrowseOpen](#),  
[ServerBrowsePrev](#)

## See Also

[Server Functions](#)

### ServerBrowsePrev

The ServerBrowsePrev function moves the data browse cursor back one record. If you call this function after you have reached the beginning of the records, error 412 is returned (Databrowse session EOF).

## Syntax

**ServerBrowsePrev(*iSession*)**

*iSession*:

Handle to a browse session previously opened by a [ServerBrowseOpen](#) call.

## Return Value

0 (zero) if the server browse session exists, otherwise an error code is returned.

## Related Functions

[ServerBrowseClose](#), [ServerBrowseFirst](#), [ServerBrowseGetField](#), [ServerBrowseNext](#), [ServerBrowseNumRecords](#),  
[ServerBrowseOpen](#)

## See Also

[Server Functions](#)

## ServerBrowseGetField

The ServerBrowseGetField function retrieves the value of the specified field from the record the data browse cursor is currently referencing.

## Syntax

**ServerBrowseGetField(*iSession*, *sFieldName*)**

*iSession*:

Handle to a browse session previously opened by a [ServerBrowseOpen](#) call.

*sFieldName*:

The name of the field that references the value to be returned. Supported fields are:

NAME, TYPE, COMMENT, CLUSTER, MODE, NETADDR, PORT.

See [Browse Function Field Reference](#) for information about fields.

## Return Value

The value of the specified field as a string. An empty string may or may not be an indication that an error has been detected. The last error should be checked in this instance to determine if an error has actually occurred.

## Related Functions

[ServerBrowseClose](#), [ServerBrowseFirst](#), [ServerBrowseNext](#), [ServerBrowseNumRecords](#), [ServerBrowseOpen](#),  
[ServerBrowsePrev](#)

## Example

```
STRING ServName = ServerBrowseGetField(hServers, "NAME");
```

## See Also

[Server Functions](#)

### ServerBrowseNumRecords

The ServerBrowseNumRecords function returns the number of records that match the filter criteria.

## Syntax

**ServerBrowseNumRecords(*iSession*)**

*iSession*:

Handle to a browse session previously opened by a [ServerBrowseOpen](#) call.

## Return Value

The number of records that matched the filter criteria. A value of 0 denotes that no records matched. A value of -1 denotes that the browse session is unable to provide a fixed number. This could be the case if the data being browsed changed during the browse session.

## Related Functions

[ServerBrowseClose](#), [ServerBrowseFirst](#), [ServerBrowseGetField](#), [ServerBrowseNext](#), [ServerBrowseOpen](#),  
[ServerBrowsePrev](#)

## Example

```
INT iNumRecords = ServerBrowseNumRecords(hServers);
```

## See Also

[Server Functions](#)

### ServerGetProperty

This function returns information about a specified server and can be called from any client.

---

**Note:** This function can only be called for Alarm, Report and Trend Servers.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**STRING ServerGetProperty(STRING *Server*, STRING *Property* [, STRING *Cluster*]).**

*sServer*:

The name of the server to be queried in quotations marks "". Can be prefixed by the name of the host cluster,

that is "ClusterName.ServerName".

*sProperty:*

The name of the requested property. Can be one of the following:

"LastReloadError" - Error Code from the latest reload

"LibRDBMemTime" - Date and time of currently loaded cicode library (\_library.RDB)

"LibRDBDiskTime" - Date and time of cicode library on disk (\_library.RDB)

"RDBDiskTime" - Returns the date and time of RDB on disk (compiled)

"RDBMemTime" - Returns the date and time of currently loaded RDB (in-memory)

"ReloadStatus" - Returns 1 if the server is reloading, 0 if not

"ReloadProgress" - Reload Progress (in percent) Range: 0 – 100

"ServerStartState" - Returns the start up state of the server. Returns 0 if the server is starting, 1 if it is running.

"SyncStatus" - Returns the startup synchronization status:

- 0 – the server has been synchronized with its redundant peer.
- 1 – the server is not connected to peer server.
- 2 – the server is synchronizing with its redundant peer.

"SyncProgress" - The percentage of the server synchronization progress: Range: 0-100

*sCluster:*

The cluster of the server to be queried in quotation marks "". This parameter is optional. However, if the Server Name is not local or not specified in ClusterName.ServerName format an error code is returned.

**Note:** The "ServerStartState" property is only supported for alarm servers. The "SyncStatus" and "SyncProgress" properties are only supported for trend and alarm servers.

## Return Value

The value of the server property requested.

## Related Functions

[ServerInfo](#), [ServerInfoEx](#), [ServerIsOnline](#), [ServerReload](#), [ServerRestart](#)

## Example

```
ServerGetProperty("AlarmServer1", "ReloadStatus", "Cluster12");
```

## See Also

[Server Functions](#)

## ServerInfo

Gets status information on clients and servers.

**Note:** This function is a non-blocking function and can only access data contained within the calling process;

---

consequently it cannot return data contained in a different server process. This function is not redirected automatically by Plant SCADA runtime. If you want to make a call from one process to return data in another, use `MsgRPC()` to make a remote procedure call on the other process. Alternatively, use the [ServerInfoEx](#) function that allows you to specify the name of the component from which you want to retrieve data.

---

## Syntax

`STRING ServerInfo(STRING Name, INT Type [, STRING ClusterName] )`

**Name:**

The name of the client or server, either "Client", "Server", "Alarm", "Trend", or "Report".

You can also pass a number instead of the name (but it still needs to be enclosed in quotes). The number represents the target client. For example, if there are 12 clients, passing "3" will get information on the 3rd client.

If this server is an Alarm, Trend, Report, and I/O server then each client will be attached 4 times. So 12 clients would mean there are 3 Plant SCADA computers using this server - one of which is itself.

**Type:**

The type of information required (depends on the **Name** you specify):

**"Alarm", "Trend", or "Report" name:**

0 - Active flag (returns 1 if this is the active server, 0 if an inactive server).

1 - Number of clients attached to this server.

2 - If this client is attached to the primary or standby server for the specified server name. If Name is "Alarm" and if this client is attached to the primary alarm server, the return value is 0. If this client is attached to the standby, the return value is 1.

3 - The status of the client connection to the specified server name. If Name is "Report" and the client is talking to a report server (either primary or standby), the return value is 1. If not, the return value is 0.

4 - Alarm DB Status for the alarm server. Returns 1 if initializing, 2 if main, 3 if standby and 4 if invalid.

**"Client" name:**

- 0 - The computer name, as specified by [LAN]Node.
- 1 - Not supported.
- 2 - Not supported.
- 3 - Not supported.

For modes 1,2 and 3, use [ServerInfoEx](#) instead.

**"Server" name:**

- 0 - Not supported.
- 1 - The number of clients attached to this server. This is the total number of Alarm, Trend Report, and I/O server clients.

**"<number>":**

- 0 - The name of the server this client is talking to. For example, "Alarm", "Trend", "Report", or "IOServer".
- 1 - The login name of the client. This may be an empty string if the client has not logged in.
- 2 - The Plant SCADA computer name of the client computer.
- 3 - The time the client logged in.

- 4 - The number of messages received from this client.
- 5 - The number of messages sent to this client.
- 6 - If this client has a licence (1) from this server or not (0).
- 7 - The type of the licence; full licence (0), View-only Client (1), or Control Client (2).
- 8 - If the client is remote (1) or local (0).

*ClusterName:*

The name of the cluster that the server belongs to. This is only relevant if:

- The Name is "alarm", "report", or "trend"; AND
- The type of information required, *nType*, is 2 or 3.

**Note:**

**Alarm Server:** When an alarm server is active, it writes entries to the alarm log device(s). However, this alarm server may not be the 'Main' alarm server. The 'Main' alarm server stores data in the primary archive used for displaying the 'Sequence of Events' and 'Summary' pages. Currently an alarm server may be 'active' for the log devices, but 'standby' for the primary archive.

**Trend Server:** Trend server redundancy does not have the concept of "active". For trend servers, Type=0 will return 1 if the process is running on the computer defined as "Primary", and zero (0) if the process is running on the machine defined as "Secondary".

## Return Value

Status information specified by *nnType*.

## Related Functions

[ServerGetProperty](#), [ServerInfoEx](#), [ServerIsOnline](#), [ServerReload](#), [ServerRestart](#)

## Example

```
sSrvInfo=ServerInfo("Report",0);
IF sSrvInfo THEN
    ! This is a primary report server.
ELSE
    ! This is a stand-by report server.
END
/* Get and store the names of clients attached to this server */
iCount = 0;
iClients = ServerInfo("Server", 1);
WHILE iCount < iClients DO
    sName[iCount] = ServerInfo(IntToStr(iCount), 2);
    iCount = iCount + 1;
END
```

## See Also

[Server Functions](#)

## ServerInfoEx

Gets status information on clients and servers from a specified component in a multiprocess runtime environment.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

When this function is called, the system redirects the call to the process that contains the specified component. If the specified component is in the calling process, the call is not redirected. If the specified component is not one of the servers listed in the *sComponent* argument description (see below), or if the system cannot find the component from the connected local processes, a hardware alarm is raised.

## Syntax

```
STRING ServerInfoEx(STRING Name, INT Type, STRING Component [, STRING ClusterName] [, STRING ServerName] )
```

*Name*:

The name of the client or server, either "Client", "Server", "Alarm", "Trend", or "Report".

You can also pass a number instead of the name (but it still needs to be enclosed in quotes). The number represents the target client. For example, if there are 12 clients, passing "3" will get information on the 4th client.

If this server is an Alarm, Trend, Report, and I/O server then each client will be attached 4 times. So 12 clients would mean there are 3 Plant SCADA computers using this server - one of which is itself.

*Type*:

The type of information required (depends on the *Name* you specify):

When *Name* is set to "Alarm", "Trend", or "Report":

0 - Active flag (returns 1 if this is the active server, 0 if an inactive server).

When an alarm server is active, it writes entries to the alarm log device(s). However, this alarm server may not be the 'Main' alarm server. The 'Main' alarm server stores data in the primary archive used for displaying the 'Sequence of Events' and 'Summary' pages. Currently an alarm server may be 'active' for the log devices, but 'standby' for the primary archive.

Trend server redundancy does not have the concept of "active". For trend servers, *Type*=0 will return 1 if the process is running on the computer defined as "Primary", and zero (0) if the process is running on the machine defined as "Secondary".

1 - Number of clients attached to this server.

2 - If this client is attached to the primary or standby server for the specified server name. If *Name* is "Alarm" and if this client is attached to the primary alarm server, the return value is 0. If this client is attached to the standby, the return value is 1.

If the *Component* is "IOServer" and the *Name* is "Client", Types 1 and 2 return an empty string, as the concept of primary and standby servers does not apply to I/O servers.

3 - The status of the client connection to the specified server name. If *Name* is "Report" and the client is talking to a report server (either primary or standby), the return value is 1. If not, the return value is 0.

Since v7.30, the Client connection to the alarm server is not permanently maintained, and is reopened for each new user. The client connection to the trend servers is permanent, and is not affected by the new user login process.

4 - Alarm DB Status for the alarm server. Returns 1 if initializing, 2 if main, 3 if standby and 4 if invalid.

If *Name* is set to "**Client**"

- 0 - The computer name, as specified by [LAN]Node.
- 1 - The primary server name, as specified in the server configuration settings.
- 2 - The secondary server name, as specified , as specified in the server configuration settings.
- 3 - The name of the INI file being used, for example, Citect.INI.

If *Name* is set to "**Server**":

- 0 - The server name, as specified in the server configuration settings.
- 1 - The number of clients attached to this server. This is the total number of Alarm, Trend Report, and I/O server clients.

If *Name* uses an ordinal option "**<number>**":

- 0 - The name of the server this client is talking to. For example, "Alarm", "Trend", "Report", or "IOServer".
- 1 - The login name of the client. This may be an empty string if the client has not logged in.
- 2 - The Plant SCADA computer name of the client computer.
- 3 - The time the client logged in.
- 4 - The number of messages received from this client.
- 5 - The number of messages sent to this client.
- 6 - Determines the licensing relationship between the target client (specified by "<number>") and the server (specified by *Component*). '0' indicates there is no licensing relationship, '1' indicates the server has provided the target client with a license, '2' indicates the server received a license from the target client (acting as the license server). If the server is running in multi-process mode, you will need to iterate through all the server processes on the computer using mode 6 to detect if a license is being issued from that computer.
- 7 - The type of the licence; full licence (0), View-only Client (1), or Control Client (2). If the client has not obtained a license from the listed server component (i.e. ServerInfoEx mode 6 has returned 0), then this will not be defined and always return 0.
- 8 - If the client is remote (1) or local (0). "Remote" means the client is not in the same process as the server. For example, the client could be in another process on the same computer as the server, or even on another computer. "Local" means the client is in the same process as the server.

Be aware that ServerInfoEx has been enhanced so that when using the ordinal option (*Name* is "<number>") the number representing *Type* can be supplied in a 100-based format so that all connections between server and client will be considered in evaluating that type. Not using 100-based format may mean only a subset of connections will be evaluated.

For example, using *Type* 106 will search all connections to determine whether the client has a licence from the server, whereas using 6 will ignore some connections.

Please note the enhanced 100-based format should be used with v8.30 or above to avoid missing connections. Do not mix the enhanced 100-based mode with the normal mode. For example, if your Cicode uses mode 106 rather than 6 to query whether the client has a licence from the server, then it should use 107 rather than 7 to enquire about the type of licence.

*Component*:

Specifies the component name from which to retrieve the status information:

- " "- An empty string causes the function to run on the calling process.
- "Alarm" - Redirects the function to the alarm server process.

- "Trend" - Redirects the function to the trend server process.
- "Report" - Redirects the function to the report server process.
- "IOMServer" - Redirects the function to the I/O server process.

If *Name* is "Client", the function will not be redirected to the component specified by *Component*. Instead, the function gets information of type *Type* from the current client connection to the component specified by *Component*.

#### ClusterName:

The name of the cluster that the server belongs to. This is only relevant if:

The Name is "alarm", "report", or "trend"; AND

The type of information required, *nType*, is 2 or 3.

#### ServerName:

Specifies the name of the the I/O Server. This parameter is only required if you are running more than one I/O server process from the same cluster on the same computer and need to instruct the system which process to redirect to. The argument is enclosed in quotation marks "".

## Return Value

Status information specified by *nType*.

## Related Functions

[ServerGetProperty](#), [ServerInfo](#), [ServerIsOnline](#), [ServerReload](#), [ServerRestart](#)

## Example

This example gets the server information from the report process.

```
sSrvInfo=ServerInfoEx("Report",0, "Report");
IF sSrvInfo THEN
    ! This is a primary report server.
ELSE
    ! This is a stand-by report server.
END
/* Get and store the names of clients attached to the report server */
iCount = 1;
iClients = ServerInfoEx("Server", 1, "Report");
WHILE iCount <= iClients DO
    sName[iCount] = ServerInfoEx(IntToStr(iCount), 2, "Report");
    iCount = iCount + 1;
END
```

## See Also

[Server Functions](#)

## ServerIsOnline

The ServerIsOnline function checks if the given server can be contacted by the client for giving the online/offline status of the server.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

```
INT ServerIsOnline(STRING ServerName[, STRING Clusters][, INT bLocal])
```

*ServerName*:

The name of the server to be queried in quotations marks "".

*Cluster*:

The cluster of the server to be queried in quotation marks "". An empty string indicates that the default cluster will be used.

*bLocal*:

The mode of the server status check.

A value of "1" results in a local check of the server status, checking if the current computer can connect to the server directly. In local mode, this function will return a value immediately, without blocking the Cicode.

A value of "0" (default) indicates that a remote check of the server status is required to confirm if the server can be reached through its peer. In remote mode, this function will block the Cicode while waiting for a response to the query.

## Return Value

An integer value of online/offline status. Returns 1 for online, 0 for offline.

## Related Functions

[ServerGetProperty](#), [ServerInfo](#), [ServerInfoEx](#), [ServerReload](#), [ServerRestart](#)

## Example

```
ServerIsOnline("AlarmServer1", "Cluster12");
```

## See Also

[Server Functions](#)

## ServerReload

This function can only be called for Alarm, Report and Trend Servers and reloads the server specified by cluster and server name. If the server is not found an error code is returned. ServerReload can be used in blocking or non-blocking modes using the bSync parameter. When used in non-blocking mode, the server status can be returned using the [ServerGetProperty](#) function.

To call this function successfully a valid user needs to be logged in as the client and you need to set the [\[LAN\]AllowRemoteReload](#) parameter in the Citect.ini file to "1" on the computer where the receiving server is running.

It is recommended that the ServerGetProperty Cicode function be used with the *LibRDBMemTime* and *LibRDBDiskTime* properties to check if there is a change to the Cicode library before attempting a reload. Following a reload please check the corresponding server's syslog.dat file for any reload messages. The Cicode changes will not be reloaded, therefore a restart may be more appropriate.

## WARNING

### UNINTENDED EQUIPMENT OPERATION

Restart the server process if a "Cicode library timestamp differs" error is detected. A library mismatch is indicated on the server in either the hardware alarm or the server's syslog.dat file.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** A message in the Syslog.dat file and hardware alarm of "Cicode library timestamp differs" (error code 454) will be raised if the Cicode library used by one or more server runtime databases is different from the one in memory. The timestamps will be different if the project has been fully recompiled (with or without Cicode modification), or if the project has been incrementally recompiled after any Cicode has been modified.

## Syntax

**INT ServerReload(STIRNG Server [, STRING Cluster] [, INT Sync] )**

*sServer:*

The name of the server to be reloaded in quotations marks "". Can be prefixed by the name of the host cluster, that is "ClusterName.ServerName".

*sCluster:*

The cluster of the server to be reloaded in quotation marks "". This parameter is optional. However, if the server name is not local or not specified in ClusterName.ServerName format, an error code is returned.

*bSync:*

Specifies whether the function operates in blocking or non-blocking mode. If bSync is set to 1, the function will not return until the server reload is complete. The reload is complete when all the records of all rdb files have been processed and updated. Blocking mode cannot be used from a foreground task (for example on graphic pages). When bSync is set to 0, the function operates in non-blocking mode. You can get the latest status of the reload using the ServerGetProperty function. Default value is 0.

## Return Value

0 (zero) if the function was successful. Returns an error if unsuccessful. Outline of errors:

- 418 - Server is not found or if the client is not allowed to visit the cluster described in "sCluster".
- 281 - Server is sitting on a remote machine to the client and the connection towards the server is not available.
- 519 - Server connection was available but interrupted.
- 451 - Server is busy with previous load request.

## Related Functions

## Example

```
ServerReload("AlarmServer1", "Cluster1", 0);
```

## See Also

[Server Functions](#)

### ServerRestart

Allows you to restart any specific alarm, report, trend or I/O server from any Cicode node in a system, without affecting other server processes running on the same machine. To call this function, a valid user needs to be logged in.

For this function to operate successfully, you need to make the following Citect.ini parameter settings:

- [\[Shutdown\]NetworkStart](#) = "1" on the computer where the issuing client is running.
- [\[Shutdown\]NetworkIgnore](#) = "0" (zero) on the computer where the server is running.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

```
INT error = ServerRestart (STRING sServerName, STRING sCluster = "")
```

*sServerName*:

The name of the server to restart

*sCluster*:

The cluster the server belongs to. This parameter is optional. If *sCluster* is not specified the current system cluster is used.

## Return Value

0 (zero) if successful, otherwise one of the following error codes is returned:

- 256 - General software error
- 292 - Invalid function
- 403 - Cluster not found
- 418 - No server of type on cluster
- 512 - Time out error
- 513 - Access denied error

## SQL Functions

Following are functions related to SQL operations.

## Miscellaneous functions

<a href="#">ExecuteDTSPkg</a>	Loads and executes a Data Transformation Services package which initiates data transfer between OLE DB data sources.
-------------------------------	--

## Connection functions

<a href="#">SQLClose</a>	Closes a SQL connection between the DB connection object and a database.
<a href="#">SQLConnect</a>	Makes a connection to a database system for execution of SQL statements.
<a href="#">SQLCreate</a>	Creates an internal DB connection object.
<a href="#">SQLDisconnect</a>	Closes a database connection.
<a href="#">SQLDispose</a>	Disposes the DB connection object.
<a href="#">SQLInfo</a>	Gets information about a database connection.
<a href="#">SQLOpen</a>	Opens an SQL connection between the DB connection object and the database.

## Transaction functions

<a href="#">SQLBeginTran</a>	Starts a database transaction.
<a href="#">SQLCommit</a>	Commits a transaction to the database.
<a href="#">SQLRollBack</a>	Rolls back (or cancels) the last database transaction.

## Statement functions

<a href="#">SQLAppend</a>	Appends a text string to the SQL buffer.
<a href="#">SQLCall</a>	Executes an SQL query on a database.
<a href="#">SQLEnd</a>	Terminates an SQL query.
<a href="#">SQLExec</a>	Executes an SQL query on a database.
<a href="#">SQLGetRecordset</a>	Executes an SQL query on a database.
<a href="#">SQLGetScalar</a>	Executes an SQL query on a database.
<a href="#">SQLSet</a>	Sets a statement string in the SQL buffer.

## Multiple queries functions

<a href="#">SQLQueryCreate</a>	Creates a new query and returns its handle.
<a href="#">SQLQueryDispose</a>	Disposes a query.

## Recordset functions

<a href="#">SQLCancel</a>	Cancels both the current operation on the given connection and all other pending operations on the given connection.
<a href="#">SQLFieldInfo</a>	Gets information about the fields or columns selected in an SQL query.
<a href="#">SQLGetField</a>	Gets field or column data from a database record.
<a href="#">SQLIsNullField</a>	Checks presence of null value in field from a recordset.
<a href="#">SQLNext</a>	Gets the next database record from a SQL query.
<a href="#">SQLNoFields</a>	Gets the number of fields or columns that were returned by the last SQL statement.

<a href="#">SQLNumChange</a>	Gets the number of records that were modified in the last insert, update, or delete SQL statement.
<a href="#">SQLNumFields</a>	Gets the number of fields or columns that were returned by the last SQL statement.
<a href="#">SQLPrev</a>	Gets the previous database record from an SQL query.
<a href="#">SQLRowCount</a>	Gets the number of rows in the recordset.

## Error and tracing functions

<a href="#">SQLErrMsg</a>	Returns an error message from the SQL system.
<a href="#">SQLTraceOff</a>	Turns off the debug trace.
<a href="#">SQLTraceOn</a>	Turns on the debug trace.

## Parametrized queries functions

<a href="#">SQLParamsClearAll</a>	Remove all parameters associated with a particular connection object.
<a href="#">SQLParamsSetAsInt</a>	Adds or replaces a parameterized query's parameter and its value in the specified connection. The value of the parameter is given as an int.
<a href="#">SQLParamsSetAsReal</a>	Adds or replaces a parameterized query's parameter and its value in the specified connection. The value of the parameter is given as a real.
<a href="#">SQLParamsSetAsString</a>	Adds or replaces a parameterized query's parameter and its value in the specified connection. The value of the parameter is given as a string.

## See Also

[Cicode Function Categories](#)

[Using Cicode Functions](#)

## ExecuteDTSPkg

Loads and executes a DTS (Data Transformation Services) package which initiates data transfer and transformations between OLE DB data sources.

A DTS package is created using the DTS utility provided in Microsoft SQL Server 7.0. It can be saved in a COM structured file, a Microsoft Repository, or in an SQL Server Database.

All except the first of this function's parameters are optional, and their use will depend on your needs.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**ExecuteDTSPkg(*sFileOrSQLSvrName* [, *sPkgName*] [, *sParam1*, ..., *sParam5*] [, *sPkgPwd*] [, *sPkgVer*] [, *sLogFile*] [, *sSQLSvrUsr*] [, *sSQLSvrPwd*])**

*sFileOrSQLSvrName*:

The path and name of the file containing the package (for file-based packages), or the SQL Server name (for SQL Server stored packages).

*sPkgName*:

The package name.

For file-based packages where only one package is stored in a file, you can ignore this parameter, as the package name defaults to the name of the file.

If the package has been named differently to the file, or a file contains more than one package, you need to specify the package name. You need to also specify the package name for SQL Server stored packages.

*sParam1*, *sParam5*:

Five optional variables which may be used as global variables within the DTS package. The variables need to be named Param1, Param2, Param3, Param4, and Param5.

*sPkgPwd*:

The package password.

The creator of the DTS package may have implemented a password so that unauthorized users cannot access it. In this case, you need to specify the package password. If no password has been implemented, you can omit this parameter.

*sPkgVer*:

The package version. If you don't specify a version, the most recent version is used.

*sLogFile*:

An optional path and name for a log file. The log file can track activity such as:

File DTS package detected

SQL DTS package detected

Package initialized successfully

Package executed successfully

Package execution was not successful

*sSQLSvrUsr*:

The user name providing access to the SQL Server where the DTS package is stored. A user's account on the SQL Server consists of this user name and, in most cases, a password.

This parameter also determines which method is used to load the package.

If *sSQLSvrUsr* is specified, the package is assumed to be an SQL Server stored package. In this case, the package is loaded using the *LoadFromSQLServer()* method. Otherwise, the package is file-based and *LoadFromStorageFile()* is called.

*sSQLSvrPwd*:

The password providing access to the SQL Server, if the user's account on the server requires a password.

## Return Value

0 (zero) if the package was executed successfully, otherwise a DTS error number is returned.

## Example

```
/* File-based package with one package per file, where the package
name is the same as the file name.*/
iResult = ExecuteDTSPkg("c:\dtspackages\package.dts");
/*SQL Server stored package with additional parameters */
iResult = ExecuteDTSPkg("Server1", "TestPackage", "Param1", "Param2", "Param3",
"Param4", "Param5", "Fred", "1", "c:\packages\PkgLog.txt", "jsmith", "secret");
```

## See Also

[SQL Functions](#)

## SQLAppend

Appends a query string to the SQL buffer. Cicode cannot send an SQL query that is longer than 255 characters. If you have an SQL query that is longer than the 255 character limit, you can split the query into smaller strings, and use this function to append the query in the SQL buffer.

This function can be called in the foreground or background.

Queries which are built on the basis of user data, for example inputed by users via graphics pages or forms, may be prone to SQL Injection attacks. In such case, try to limit the risk by using CiCode functions from parameterized queries group and refer to a professional advice in this matter.

### NOTICE

#### SECURITY BREACH VIA SQL INJECTION

- Validate all textbox entries using validation controls, regular expressions and code
- Use parameterized SQL or stored procedures
- Use a limited access account to connect to the database

**Failure to follow these instructions can result in equipment damage.**

Building queries from pieces (SQLSet, SQLAppend) or adding parameters to either queries or connections (SQLParam functions) requires a few calls to respective CiCode functions. If a few functions try to manipulate the same connection in the same time some conflicts and unintended operations may occur. It is a typical multithreading problem.

To avoid this, instead of manipulating connections, consider using locally created and locally disposed queries. For example:

```
int function SAFE_SQL_CICODE_MULTITHREAD_USE()
//locally created query
int hStmt = SQLQueryCreate(hConnection);

//Set the query
```

```
SQLSet(hStmt, "select * from TAB where NAME=@Name");

//Add parameters to the query
SQLParamsSetAsString(hStmt, "Name", "Aaa");

//Execute the query
SQLGetRecordset(hStmt, "");

//the locally created query is disposed
SQLQueryDispose(hStmt);
End
```

## Syntax

**SQLAppend(*hGeneral*, *String*)**

*hGeneral*:

The handle either to the DB connection object (returned from either SQLCreate() or SQLConnect() function) or to the query handle (returned from SQLQueryCreate()). When it is the connection handle, the operation is performed on the default query in that DB connection object. When it is the query handle, the operation is performed on that query through the DB object which is associated to it.

*String*:

The query string to append to the SQL buffer.

## Return Value

0 (zero) if successful, otherwise an error number is returned. (For details of the 307 error code, call the [SQLErrMsg](#) function).

## Related Functions

[SQLSet](#), [SQLBeginTran](#), [SQLCommit](#), [SQLConnect](#), [SQLDisconnect](#), [SQLEnd](#), [SQLErrMsg](#)

## Example

See [SQLSet](#)

## See Also

[SQL Functions](#)

## SQLBeginTran

Starts a database transaction. When you make a transaction, your changes are not written to the database until you call the SQLCommit() function. Alternatively, you can use the SQLRollBack() function to discard all changes made during the transaction.

After you begin a transaction, you need to call either SQLCommit() to save the changes or SQLRollBack() to discard the changes. You need to use one of these functions to complete the transaction and release all database

locks.

A single database connection can only handle one transaction at a time. After you call SQLBeginTran(), you need to complete that transaction before you can call SQLBeginTran() again.

If you disconnect from a database while a transaction is active (not completed), the transaction is automatically "rolled back" any changes you made to the database in that transaction are discarded.

You do not need to begin a transaction to modify a database. Any changes you make to a database before you call the SQLBeginTran() are automatically committed, and no database locks are held.

The SQLBeginTran() function is not supported by all databases. If the function is not performing as you expect, check that both your database and/or DB provider support transactions. Refer to the documentation for your database for more information on transactions.

This function is a blocking function and should not be called from a foreground task.

## Syntax

**SQLBeginTran(*hSQL*)**

*hSQL*:

The handle to the DB connection object, returned from either SQLCreate() or SQLConnect() function. The handle identifies the DB connection object where details of the associated SQL connection are stored.

## Return Value

0 (zero) if successful, otherwise an error number is returned. (For details of the 307 error code, call the [SQLErrMsg](#) function).

## Related Functions

[SQLCommit](#), [SQLConnect](#), [SQLDisconnect](#), [SQLEnd](#), [SQLErrMsg](#), [SQLExec](#), [SQLFieldInfo](#), [SQLGetField](#), [SQLInfo](#), [SQLNext](#), [SQLNoFields](#), [SQLNumChange](#), [SQLRollBack](#), [SQLTraceOff](#), [SQLTraceOn](#)

## Example

```
/* Increase each employee's salary and superannuation by a
specified amount. If any errors occur, the changes are aborted */
INT
FUNCTION
PayIncrease(STRING sIncrease)
    INT hSQL;
    INT Count1;
    INT Count2;
    hSQL = SQLConnect("DRV=QEDBF");
    SQLBeginTran(hSQL);
    SQLExec(hSQL, "UPDATE C:\DATA\EMPLOYEE SET Salary = Salary + " +sIncrease);
    Count1 = SQLNumChange(hSQL);
    SQLExec(hSQL, "UPDATE C:\DATA\EMPLOYEE SET Super = Super + " +sIncrease);
    Count2 = SQLNumChange(hSQL);
    IF Count1 = Count2 THEN
        SQLCommit(hSQL);
    ELSE
```

```
    SQLRollBack(hSQL);
END
SQLEnd(hSQL);
SQLDisconnect(hSQL);
END
```

## See Also

[SQL Functions](#)

### SQLCall

Executes an SQL query on a database. The function returns the number of rows affected by the executed query. With this function, you can execute any SQL query or command supported by the SQL database. If it returns some data (as for SELECT query), the data is ignored.

This function is a blocking function and should not be called from a foreground task.

Queries which are built on the basis of user data, for example inputed by users via graphics pages or forms, may be prone to SQL Injection attacks. In such case, try to limit the risk by using CiCode functions from parameterized queries group and refer to a professional advice in this matter.

#### NOTICE

#### SECURITY BREACH VIA SQL INJECTION

- Validate all textbox entries using validation controls, regular expressions and code
- Use parameterized SQL or stored procedures
- Use a limited access account to connect to the database

**Failure to follow these instructions can result in equipment damage.**

## Syntax

**SQLCall(*hGeneral*, *sSelect*)**

*hGeneral*:

The handle either to the DB connection object (returned from either SQLCreate() or SQLConnect() function) or to the query handle (returned from SQLQueryCreate()). When it is the connection handle and *sSelect* is an empty string, the operation is performed on the first query in that DB connection object. When it is the query handle, the operation is performed on that query through the DB object which is associated to it.

*sSelect*:

The SQL query to be sent to the SQL database.

## Return Value

The number of affected records or -1 if an error is detected. (For details call the SQLErrMsg() function). The presence of error code can be tested by calling the [IsError](#) CiCode function.

## Related Functions

[SQLCreate](#), [SQLOpen](#), [SQLClose](#), [SQLDispose](#), [SQLConnect](#), [SQLDisconnect](#), [SQLInfo](#), [SQLSet](#), [SQLAppend](#), [SQLExec](#), [SQLGetRecordset](#), [SQLCall](#), [SQLGetScalar](#), [SQLEnd](#)

## See Also

[SQL Functions](#)

### SQLCancel

This function cancels both the current operation on the given connection and all other pending operations on the given connection. The cancellation means that the current operation on the SCADA side is immediately finished. The cancelled operation returns error code 299 and its state on the database side should be considered as undefined, that is, it is not known that it either succeeded, partially succeeded, or was unsuccessful.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete. It can be called in the foreground or background.

## Syntax

**SQLCancel(*hConnection*)**

*hConnection*:

The handle to the connection.

## Return Value

0 (zero) if successful, otherwise an error code is returned. (For details of the 307 error code, call the [SQLErrMsg\(\)](#) function).

## Related Functions

[SQLCreate](#), [SQLOpen](#), [SQLClose](#), [SQLDispose](#), [SQLConnect](#), [SQLDisconnect](#), [SQLInfo](#)

## See Also

[SQL Functions](#)

### SQLClose

Closes a SQL connection between the DB connection object specified by the function's parameter and a database. The DB connection object is not deleted from the memory until calling [SQLDispose](#) function.

This function is a blocking function and should not be called from a foreground task.

## Syntax

**SQLClose(*hSQL*)**

*hSQL*:

The handle to the DB connection object, returned from the SQLCreate() function. The handle identifies the DB connection object where details of the associated SQL connection are stored.

## Return Value

0 if success, otherwise an error code (for details call the [SQLErrMsg\(\)](#) function).

## Related Functions

[SQLCreate](#), [SQLOpen](#), [SQLClose](#), [SQLDispose](#), [SQLConnect](#), [SQLDisconnect](#), [SQLInfo](#)

## Example

See [SQLCreate](#).

## See Also

[SQL Functions](#)

## SQLCommit

Commits (to the database) all changes made within a transaction. If you call the [SQLBeginTran\(\)](#) function to begin a transaction, you need to call the SQLCommit() function to save the changes you make to the database during that transaction (with the Insert, Delete, and Update SQL commands).

The SQLCommit() and [SQLRollBack\(\)](#) functions both complete a transaction and release all database locks. But while the SQLCommit() function saves all changes made during the transaction, the SQLRollBack() function discards these changes. Unless you call the SQLCommit() function before you disconnect the database, the transaction is automatically rolled back any changes you made to the database in that transaction are discarded.

The SQLCommit() function could affect different databases in different ways. If the function is not performing as you expect, check that your database is able to service transactions. Refer to the documentation for your database for information on committing transactions.

This function is a blocking function and should not be called from a foreground task.

## Syntax

**SQLCommit(*hSQL*)**

*hSQL*:

The handle to the DB connection object, returned from either [SQLCreate\(\)](#) or [SQLConnect\(\)](#) function. The handle identifies the DB connection object where details of the associated SQL connection are stored.

## Return Value

0 (zero) if successful, otherwise an error number is returned. (For details of the 307 error code, call the SQLErrMsg() function).

## Related Functions

[SQLBeginTran](#), [SQLConnect](#), [SQLDisconnect](#), [SQLEnd](#), [SQLErrMsg](#), [SQLExec](#), [SQLFieldInfo](#), [SQLGetField](#), [SQLInfo](#), [SQLNext](#), [SQLNoFields](#), [SQLNumChange](#), [SQLRollBack](#), [SQLTraceOff](#), [SQLTraceOn](#)

## Example

See [SQLBeginTran](#).

## See Also

[SQL Functions](#)

## SQLConnect

Creates an internal database connection object and tries to connect it to a database specified by the connection string. Returns a handle to the database connection object for use by the other database functions.

You only require one database connection object for each database system to be accessed (for example, Oracle, dBASE, Excel, etc.).

It is recommended not to use an SQL database for storage of real-time data (such as alarms), because SQL databases do not provide real-time performance when accessing database data. Only use an SQL database where data transfer is not a priority (for example, recipes or reports). If you try to use SQL to store real time data, Plant SCADA's performance could be greatly decreased.

Each database connection object created by SQLConnect should be released by calling SQLDisconnect with handle to the object. The releasing operation should be performed even when the SQL connection to database is no longer active; for example automatically dropped by a remote database or manually closed by SQLClose. Memory leaks can occur if the handles are not properly released.

---

### Note:

Currently there are certain configurations of providers, connection strings and database systems which can automatically close connections in order to save the database systems' resources; for example MS SQL Server dedicated provider with activated pooling closes the connection to MS SQL Server when there is no data exchange between the client and the database server for some predefined time. If such behaviour is observed and is not desired from the system design point of view, it can be either:

- Switched off by finding and using respective attributes in the connection string (if existing and supported by database) or
- By actively checking error codes returned from SQL Cicode functions and reconnecting by using SQLOpen if the connection is dropped.

The actual state of connections can be checked by [SQLInfo](#) with type 5.

---

This function is a blocking function and should not be called from a foreground task.

## Syntax

**SQLConnect(*sConnect*)**

*sConnect*:

The connection string, in the format:

`<attribute>=<value>[;<attribute>=<value>...]`

Acceptable attributes and their values vary accordingly to the provider and/or the database system, so please refer to your database documentation. For example, connecting to a SQL Server via ODBC usually requires giving the computer name and the database name which can be done by defining "Server" and "Database" attributes. The same connection via OleDB requires defining the computer as "Data Source" and the database as "Initial Catalog".

Providing username and password as a plain text in the connection string may lead to a security breach on the database side. Please consider using other forms of authentication instead of username/password login, for example Windows Authentication. If this is not possible, try to limit the database account rights and not use the same username and password for other vital parts of the system such as for SCADA.

### NOTICE

#### SECURITY BREACH VIA SQL INJECTION

- Validate all textbox entries using validation controls, regular expressions and code
- Use parameterized SQL or stored procedures
- Use a limited access account to connect to the database

**Failure to follow these instructions can result in equipment damage.**

Some simple examples are shown below:

ODBC provider

```
"Driver={SQL Server};Server=(local);Trusted_Connection=Yes; Database=MyDatabase;"  
"Driver={Microsoft ODBC for Oracle};Server=ORACLE8i7;Persist Security  
Info=False;Trusted_Connection=Yes"  
"Driver={Microsoft Access Driver (*.mdb)};DBQ=c:\doc\MyDatabase.mdb"  
"Driver={Microsoft Excel Driver (*.xls)};DBQ=c:\doc\MySheet.xls"  
"SCADA Data Provider=Odbc;Driver={Microsoft Text Driver (*.txt; *.csv)};DBQ=c:\doc"  
"DSN=MyDSNname"
```

OleDB provider

```
"SCADA Data Provider=OleDb;Provider=MSDAORA; Data Source=ORACLE8i7;Persist Security  
Info=False;Integrated Security=Yes"  
"SCADA Data Provider=OleDb;Provider=Microsoft.Jet.OLEDB.4.0; Data Source=c:\bin\  
LocalAccess40.mdb"  
"SCADA Data Provider=OleDb;Provider=SQLOLEDB;Data Source=(local);Integrated Security=SSPI"
```

SQLClient Provider

```
"SCADA Data Provider=SQLClient;Persist Security Info=False;Integrated Security=true;Initial  
Catalog=MyCatalog;server=(local)"
```

SCADA Data Provider

The provider to be used to communicate to a database. Allowed values are as follows:

	ODBC – ODBC provider, default one if no provider specified, OLEDB – OLEDB provider, SQLClient – MS SQL Server dedicated provider
SCADA Connection Timeout	The timeout in seconds for establishing connections.
SCADA Query Timeout	The timeout in seconds for executing queries. This attribute overwrites the [SQL]QueryTimeout INI parameter.

## Return Value

The handle to the database connection object if the connection is successful, otherwise -1 is returned. (For details call the SQLErrMsg() function). The handle identifies the database connection object where details of the associated SQL connection to a DB are stored.

## Related Functions

[SQLCreate](#), [SQLOpen](#), [SQLClose](#), [SQLDispose](#), [SQLConnect](#), [SQLDisconnect](#), [SQLInfo](#)

## Example

```
/* Make a connection to an SQL server and select the name field from each record in the
employee database. */
UNCTION
ListNames()
    INT hSQL;
    STRING sName;
    INT Status;
    hSQL = SQLConnect("DSN=MyDatabase;UID=billw;SRVR=CI1");
    IF hSQL <> -1 THEN
        Status = SQLExec(hSQL, "SELECT NAME FROM EMPLOYEE");
        IF Status = 0 THEN
            WHILE SQLNext(hSQL) = 0 DO
                sName = SQLGetField(hSQL, "NAME");
                ..
            END
            SQLEnd(hSQL);
        ELSE
            Message("Information", SQLErrMsg(), 48);
        END
        SQLDisconnect(hSQL);
    ELSE
        Message("Information", SQLErrMsg(), 48);
    END
END
```

## See Also

[SQL Functions](#)

### SQLCreate

Creates an internal DB connection object and returns a handle to the object for use by the other DB functions. The object is in disconnected state and can be connected to a database by executing the [SQLOpen](#) function.

You only require one DB connection object for each database system to be accessed (for example, Oracle, dBASE, Excel, etc.).

Each DB connection object created by SQLCreate should be released by calling [SQLDispose](#) with the handle to the object. The releasing operation should be performed even when the SQL connection to DB is no longer active; for example, automatically dropped by a remote DB. Memory leaks can occur if the handles are not properly released.

This function can be called in the foreground or background.

## Syntax

**SQLCreate(sConnect)**

*sConnect:*

The connection string, in the format:

<attribute>=<value>[ ;<attribute>=<value> . . . ]

Acceptable attributes and their values vary accordingly to the provider and/or the database system, so please refer to your database documentation. For example, connecting to a SQL Server via ODBC usually requires giving the computer name and the database name which can be done by defining "Server" and "Database" attributes. The same connection via OleDB requires defining the computer as "Data Source" and the database as "Initial Catalog".

Providing username and password as a plain text in the connection string may lead to a security breach on the database side. Please consider use of other forms of authentication instead of username/password login as for example Windows Authentication. If not possible, try to limit the database account rights and not use the same username and password as for other vital part of the system as for example for SCADA.

#### NOTICE

#### SECURITY BREACH VIA SQL INJECTION

- Validate all textbox entries using validation controls, regular expressions and code

```

**SQLClient Provider**

```
"SCADA Data Provider=SQLClient;Persist Security Info=False;Integrated Security=true;Initial
Catalog=MyCatalog;server=(local)"
```

SCADA Data Provider	The provider to be used to communicate to a DB. Allowed values are as follows: ODBC - ODBC provider, default one if no provider specified, OLEDB - OLEDB provider, SQLClient - MS SQL Server dedicated provider
SCADA Connection Timeout	The timeout for establishing connections.
SCADA Query Timeout	The timeout for executing queries. This attribute overwrites the [SQL]QueryTimeout INI parameter.

**Return Value**

The handle to the DB connection object if the connection is successful, otherwise -1 is returned. (For details call the SQLErrMsg() function). The handle identifies the DB connection object where details of the associated SQL connection to a DB are stored.

**Related Functions**

[SQLOpen](#), [SQLClose](#), [SQLDispose](#), [SQLConnect](#), [SQLDisconnect](#), [SQLInfo](#)

**Example**

```
/* Make a connection to an SQL server and select the name field
from each record in the employee database. */
FUNCTION
ListNames()
    INT hSQL;
    STRING sName;
    INT Status;
    INT hRec;
    INT nColumns;
    INT nRows;
    INT i;
```

```
hSQL = SQLCreate("DSN=MyDatabase;UID=billw;SRVR=CI1");
IF hSQL <> -1 THEN
    Status = SQLOpen(hSQL);
    IF Status = 0 THEN
        hRec = SQLGetRecordset(hSQL, "SELECT NAME FROM EMPLOYEE");
        IF hRec <> -1 THEN
            nRows = SQLRowCount(hRec);
            FOR i=0 TO nRows - 1 DO
                sName = SQLGetField(hRec, "NAME", i);
                ..
            END
            SQLEnd(hRec);
        ELSE
            Message("Information", SQLErrMsg(), 48);
        END
        SQLClose(hSQL);
    ELSE
        Message("Information", SQLErrMsg(), 48);
    END
    SQLDispose(hSQL);
END
END
```

## See Also

[SQL Functions](#)

## SQLDisconnect

Closes the SQL connection to a database and disposes the DB connection object specified by the function parameter.

This function is a blocking function and should not be called from a foreground task.

## Syntax

**SQLDisconnect(*hSQL*)**

*hSQL*:

The handle to the DB connection object, returned from the [SQLConnect\(\)](#) function. The handle identifies the DB connection object where details of the associated SQL connection are stored.

## Return Value

0 if success, otherwise an error code (for details call the [SQLErrMsg\(\)](#) function).

## Related Functions

[SQLCreate](#), [SQLOpen](#), [SQLClose](#), [SQLDispose](#), [SQLConnect](#), [SQLDisconnect](#), [SQLInfo](#)

## Example

See [SQLConnect](#).

## See Also

[SQL Functions](#)

## SQLDispose

Disposes the DB connection object specified by its parameter. If there is an active SQL connection to a database, the SQL connection has to be closed before disposal.

This function can be called in the foreground or background.

## Syntax

**SQLDispose(*hSQL*)**

*hSQL*:

The handle to the DB connection object, returned from either the [SQLCreate\(\)](#) or [SQLConnect\(\)](#) function. The handle identifies the DB connection object where details of the associated SQL connection are stored.

## Return Value

0 – if success, otherwise an error code (For details call the [SQLErrMsg\(\)](#) function).

## Related Functions

[SQLCreate](#), [SQLOpen](#), [SQLClose](#), [SQLDispose](#), [SQLConnect](#), [SQLDisconnect](#), [SQLInfo](#)

## Example

See [SQLCreate](#).

## See Also

[SQL Functions](#)

## SQLEnd

The function can be called with:

- The connection handle, in which case the function releases resources allocated for the default recordset for this connection. Generally, SCADA does the operation automatically each time when a new query is executed through [SQLExec](#) on the connection, but the operation can be also triggered manually. However, using the [SQLEnd](#) function aids efficiency and creates good programming standards. [SQLEnd](#) releases the memory that

was allocated when the last query was executed via SQLExec.

- The recordset handle, in which case the function then removes the disconnected recordset associated with the handle from the system. This operation has to be done each time when the recordset is no longer necessary. Not removing recordsets from the system can result in consuming all available memory and halting SCADA and other applications on a computer.

This function is a blocking function and should not be called from a foreground task.

## Syntax

**SQLEnd(*hGeneral*)**

*hGeneral*:

The handle either to:

The DB connection object, returned from either [SQLCreate](#) or [SQLConnect](#) function. The handle identifies the DB connection object where details of the associated SQL connection are stored.

Or:

The recordset.

## Return Value

0 (zero) if successful, otherwise an error code is returned. (For details on the 307 error code, call the [SQLErrMsg\(\)](#) function).

## Related Functions

[SQLCreate](#), [SQLOpen](#), [SQLClose](#), [SQLDispose](#), [SQLConnect](#), [SQLDisconnect](#), [SQLInfo](#), [SQLSet](#), [SQLAppend](#),  
[SQLExec](#), [SQLGetRecordset](#), [SQLCall](#), [SQLGetScalar](#), [SQLEnd](#)

## Example

See [SQLConnect](#).

## See Also

[SQL Functions](#)

## SQLErrMsg

Returns an error message from either a particular data object or entire data system. If a 307 error code occurs when one of the SQL functions is called, an SQL error message is generated. Call this function to get that error message.

This function can be called in the foreground or background.

## Syntax

**SQLErrMsg(*hGeneral*)**

*hGeneral*:

The handle to any data object either to the database connection object, recordset or query. The default value is -1 and then the function returns the error message for entire SQL system.

## Return Value

The error message (as a string).

## Related Functions

[SQLTraceOff](#).

## Example

See [SQLConnect](#).

## See Also

[SQL Functions](#)

## SQLExec

Executes an SQL query on a database. With this function, you can execute any SQL query or command supported by the SQL database.

---

**Note:** All types of fields can be requested in statements, but SCADA has to convert values of the fields to MBCS 8-bit strings which is not always possible. For example either single byte database strings or numbers can be converted to MBCS 8-bit strings, multi-byte strings can be converted to MBCS (their proper presentation depends on correct setup of SCADA and OS), while blobs cannot be encoded at all.

---

Data obtained by this function is stored in the default recordset. The default recordset is always a connected recordset. Connected recordsets fetch only small portion of data when the query is executed, but later they have to fetch further portions when recordset functions are used. This kind of recordset needs open connections to DB, but they need little memory.

The SQLNext() function needs to be called after the SQLExec() function before you can access data in the first record.

Only one query can be active at a time, so there is no need to end one query before you execute another query; each time you call SQLExec(), the previous query (through a previous SQLExec() call) is automatically ended. It means that each query executed from SQLExec cleans the default recordset.

Queries are queued for execution and a result from one query overwrites the result from preceding one. Similarly, Plant SCADA automatically ends the latest query when it disconnects the database, even if you have not called SQLEnd(). However, the SQLEnd() function aids efficiency; SQLEnd() releases the memory that was allocated when the latest query was executed.

This function is a blocking function and should not be called from a foreground task.

Queries which are built on the basis of user data, for example inputed by users via graphics pages or forms, may be prone to SQL Injection attacks. In such case, try to limit the risk by using CiCode functions from parameterized queries group and refer to a professional advice in this matter.

---

**Note:****SECURITY BREACH VIA SQL INJECTION**

- Validate all textbox entries using validation controls, regular expressions, code
  - Use parameterized SQL or stored procedures
  - Use a limited access account to connect to the database.
- 

## Syntax

**SQLExec(*hGeneral*, *sSelect*)**

*hGeneral*:

The handle either to the DB connection object (returned from either SQLCreate() or SQLConnect() function) or to the query handle (returned from SQLQueryCreate()). When it is the connection handle and *sSelect* is an empty string, the operation is performed on the first query in that DB connection object. When it is the query handle, the operation is performed on that query through the DB object which is associated to it.

*sSelect*:

The SQL query to be sent to the SQL database.

## Return Value

0 (zero) if successful, otherwise an error number is returned. (For details of the 307 error code, call the SQLErrMsg() function).

## Related Functions

[SQLCreate](#), [SQLOpen](#), [SQLClose](#), [SQLDispose](#), [SQLConnect](#), [SQLDisconnect](#), [SQLInfo](#), [SQLSet](#), [SQLAppend](#), [SQLExec](#), [SQLGetRecordset](#), [SQLCall](#), [SQLGetScalar](#), [SQLEnd](#)

## Example

These examples assume that the following tables are setup in a SQL server (with the name configured in Windows Control Panel) and opened with the SQLConnect() function:

### PEOPLE

SURNAME	FIRSTNAME	OCCUPATION	DEPARTMENT
MARTIAN	MARVIN	ENGINEER	MANAGEMENT
CASE	CARRIE	SUPPORT	SCADA
LIGHT	LARRY	PROGRAMMER	SCADA
BOLT	BETTY	ENGINEER	SYSTEMS

**PHONE**

SURNAME	NUMBER
MARTIAN	5551000
CASE	5551010
BOLT	5551020
LIGHT	5551030

Each SQL string (sSQL) should be encased within the SQLExec function, for example:

```
SQLExec(hSQL, sSQL);
To add a record to a table:
sSQL = "INSERT INTO PEOPLE (SURNAME, FIRSTNAME, OCCUPATION, DEPARTMENT)
        VALUES('ALLEN','MATTHEW','PROGRAMMER','SCADA')";
```

This SQL command changes the PEOPLE table to:

**PEOPLE**

SURNAME	FIRSTNAME	OCCUPATION	DEPARTMENT
MARTIAN	MARVIN	ENGINEER	MANAGEMENT
CASE	CARRIE	SUPPORT	SCADA
LIGHT	LARRY	PROGRAMMER	SCADA
BOLT	BETTY	ENGINEER	SYSTEMS
ALLEN	MATTHEW	PROGRAMMER	SCADA

To remove records from a table:

```
sSQL = "DELETE FROM (PEOPLE, PHONE) WHERE SURNAME='MARTIAN'";
SQLBeginTran(hSQL);
SQLExec(hSQL,sSQL);
IF (Message("Alert", "Do you really want to DELETE MARTIAN", 33) = 0) THEN
    SQLCommit(hSQL);
ELSE
    SQLRollback(hSQL);
END
```

Assuming that OK was clicked on the Message Box, the tables change to:

**PEOPLE**

SURNAME	FIRSTNAME	OCCUPATION	DEPARTMENT
CASE	CARRIE	SUPPORT	SCADA
LIGHT	LARRY	PROGRAMMER	SCADA
BOLT	BETTY	ENGINEER	SYSTEMS

## PHONE

SURNAME	NUMBER
CASE	5551010
BOLT	5551020
LIGHT	5551030

**To change a record:**

```
sSQL = "UPDATE PEOPLE SET OCCUPATION='SUPPORT' WHERE FIRSTNAME='LARRY'" ;
```

This SQL command changes the PEOPLE table to:

**PEOPLE**

SURNAME	FIRSTNAME	OCCUPATION	DEPARTMENT
MARTIAN	MARVIN	ENGINEER	MANAGEMENT
CASE	CARRIE	SUPPORT	SCADA
LIGHT	LARRY	SUPPORT	SCADA
BOLT	BETTY	ENGINEER	SYSTEMS

**To select a group of records from a table:**

```
sSQL = "SELECT SURNAME FROM PEOPLE WHERE OCCUPATION='ENGINEER'" ;
```

This SQL command will return the following table back to Plant SCADA. The table can then be accessed by the SQLNext() function and the SQLGetField() functions.

Plant SCADA table for hSQL

SURNAME
MARTIAN
BOLT

You can also select data using a much more complete SQL string, for example:

```
sSQL = "SELECT (SURNAME, OCCUPATION, NUMBER) FROM (PEOPLE, PHONE)  
WHERE DEPARTMENT='SCADA' AND PEOPLE.SURNAME = PHONE.SURNAME" ;
```

This SQL command retrieves the following table:

SURNAME	OCCUPATION	NUMBER
CASE	SUPPORT	5551010
LIGHT	PROGRAMMER	5551030

**To extract information from a table:**

```
STRING sInfo[3][10]  
int i = 0;  
WHILE ((SQLNext(hSQL) = 0) and (i < 10)) DO
```

```

sInfo[0][i] = SQLGetField(hSQL, "SURNAME");
sInfo[1][i] = SQLGetField(hSQL, "OCCUPATION");
sInfo[2][i] = SQLGetField(hSQL, "NUMBER");
END

```

This code example leaves the information in the sInfo two dimensional array as follows:

### SInfo

	<b>0</b>	<b>1</b>	<b>2</b>
0	CASE	SUPPORT	5551010
1	LIGHT	PROGRAMMER	5551030
2			
3			
4			
...			

## See Also

[SQL Functions](#)

### SQLFieldInfo

Gets information about the fields or columns selected by a SQL query. The function returns the name and width of the specified field. If you call the function within a loop, you can return the names and sizes of all the fields in the database.

When the *hGeneral* is the connection handle, the function returns information about the default recordset.

When the *hGeneral* is the recordset handle, the function returns information about the recordset itself.

Keywords such as "DATE", "TIME", and "DESC" cannot be used as field names by some database systems. To use fields with these names, you need to append underscores to the names (for example, "TIME\_", "DATE\_", "DESC\_").

This function can be called in the foreground or background.

Some combinations of database drivers and databases can return no name for certain classes of fields/columns, for example for aggregation queries such as "select SUM". In those cases such fields can be either explicitly named in the query itself, or accessed via a unified name in the format of "Field{ColumnNumber}" where {ColumnNumber} is the number of the requested field/column in the recordset.

## Syntax

**SQLFieldInfo(*hGeneral*, *hField*, *sName*, *Width*)**

*hGeneral*:

The handle either to:

The DB connection object, returned from either [SQLCreate](#) or [SQLConnect](#) function. The handle identifies the DB

connection object where details of the associated SQL connection are stored.

Or:

The recordset.

*hField*:

The field (or column) handle, indicating the position of the field in the database.

*sName*:

Output Parameter: A string in which the function stores the field name. The argument is returned by the function. Must be a String type variable.

*Width*:

Output Parameter: An integer in which the function stores the maximum number of characters in the field. The argument is returned by the function. Must be an Integer type variable.

## Return Value

0 (zero) if successful, otherwise an error number is returned. (For details of the 307 error code, call the [SQLErrMsg](#) function).

## Related Functions

[SQLSet](#), [SQLAppend](#), [SQLExec](#), [SQLGetRecordset](#), [SQLCall](#), [SQLGetScalar](#), [SQLEnd](#), [SQLNumChange](#), [SQLNoFields](#), [SQLNumFields](#), [SQLGetField](#), [SQLIsNullField](#), [SQLRowCount](#), [SQLNext](#), [SQLPrev](#)

## Example

```
! Lists all fields in the Employee database
FUNCTION
ListFields()
    INT hSQL;
    STRING sField;
    INT Count;
    INT Width;
    INT Index;
    SQLTraceOn("C:\DATA\TRACE.LOG");
    hSQL = SQLConnect("DRV=QEDBF");
    SQLExec(hSQL, "SELECT * FROM C:\DATA\EMPLOYEE");
    Count = SQLNoFields(hSQL);
    Index = 0;
    WHILE Index < Count DO
        SQLFieldInfo(hSQL,Index,sField,Width);
        ..
    END
    SQLEnd(hSQL);
    SQLDisconnect(hSQL);
    SQLTraceOff();
END
```

## See Also

[SQL Functions](#)

### SQLGetField

Gets field or column data from a database field. To get to a specific record in the recordset, use either the [SQLNext\(\)](#) or [SQLPrev\(\)](#) functions or, in case of disconnected recordsets, the *nRowIndex* argument.

When the *hGeneral* is the connection handle, the function returns information from the default recordset. When the *hGeneral* is the recordset handle, the function returns information from the recordset itself.

---

**Note:** All types of fields can be requested in statements, but SCADA has to convert values of the fields to MBCS 8-bit strings which is not always possible. For example either single byte database strings or numbers can be converted to MBCS 8-bit strings, multi-byte strings can be converted to MBCS (their proper presentation depends on correct setup of SCADA and OS), while blobs cannot be encoded at all.

---

Keywords such as "DATE", "TIME", and "DESC" cannot be used as field names by some database systems. To use fields with these names, you need to append underscores to the names (for example, "TIME\_", "DATE\_", "DESC\_").

This function can be called in the foreground or background.

Some combinations of database drivers and databases can return no name for certain classes of fields/columns, for example for aggregation queries such as "select SUM". In those cases such fields can be either explicitly named in the query itself, or accessed via a unified name in the format of "Field{ColumnNumber}" where {ColumnNumber} is the number of the requested field/column in the recordset.

## Syntax

**SQLGetField(*hGeneral*, *sField*, *nRowIndex*)**

*hGeneral*:

The handle either to:

The DB connection object, returned from either [SQLCreate\(\)](#) or [SQLConnect\(\)](#) function. The handle identifies the DB connection object where details of the associated SQL connection are stored.

Or:

The recordset.

*sField*:

The name of the field or column.

*nRowIndex*:

If *hGeneral* is a connection handle and *nRowIndex* is not equal -1, then the function returns an empty string.

## Return Value

The field or column data (as a string).

The maximum length of the return data is 255 characters. If the returned data is longer than this, the function will return error 306 (can be checked using the [IsError\(\)](#) Cicode function).

## Related Functions

[SQLSet](#), [SQLAppend](#), [SQLExec](#), [SQLGetRecordset](#), [SQLCall](#), [SQLGetScalar](#), [SQLEnd](#), [SQLNumChange](#), [SQLNoFields](#), [SQLNumFields](#), [SQLFieldInfo](#), [SQLGetField](#), [SQLIsNullField](#), [SQLRowCount](#), [SQLNext](#), [SQLPrev](#)

## Example

See [SQLConnect](#).

## See Also

[SQL Functions](#)

### SQLGetRecordset

Executes an SQL query on a database and returns a handle to any resulting disconnected recordset. All recordsets created in this way should be closed by the [SQLEnd\(\)](#) function. If unsuccessful, the function returns an invalid handle and an error code is returned (can be tested by [IsError\(\)](#)). In case of no data returned, the function returns an invalid handle and no error. With this function, you can execute any SQL query or command supported by the SQL database, but it is designed mainly to work with queries returning data like for example `SELECT`. Queries which don't return database data, like `INSERT` or `UPDATE`, should be executed via [SQLCall](#).

Recordsets produced by this function are disconnected. The disconnected recordsets fetch the data from the DB when the query is executed and thus they don't need an open connection when recordset functions are used. This kind of recordset improves speed of access to data after executing the query, but may consume significant amounts of memory.

Creating disconnected recordsets without releasing them may lead to utilizing all available memory, which can result in degraded performance.

#### NOTICE

#### EXCESSIVE MEMORY USAGE

Limit the number of disconnected recordsets using the [\[SQL\]MaxConnections](#) parameter. Release unused disconnected recordsets. Test projects using disconnected recordsets prior to deployment in production.

**Failure to follow these instructions can result in equipment damage.**

**Note:** All types of fields can be requested in statements, but SCADA has to convert values of the fields to MBCS 8-bit strings which is not always possible. For example either single byte database strings or numbers can be converted to MBCS 8-bit strings, multi-byte strings can be converted to MBCS (their proper presentation depends on correct setup of SCADA and OS), while blobs cannot be encoded at all.

This function is a blocking function and should not be called from a foreground task.

Queries which are built on the basis of user data, for example inputed by users via graphics pages or forms, may be prone to SQL Injection attacks. In such case, try to limit the risk by using CiCode functions from parameterized queries group and refer to a professional advice in this matter.

#### NOTICE

#### SECURITY BREACH VIA SQL INJECTION

- Validate all textbox entries using validation controls, regular expressions and code
- Use parameterized SQL or stored procedures
- Use a limited access account to connect to the database

**Failure to follow these instructions can result in equipment damage.**

## Syntax

**SQLGetRecordset(*hGeneral*, *sSelect*)**

*hGeneral*:

The handle either to the DB connection object (returned from either [SQLCreate\(\)](#) or [SQLConnect\(\)](#) function) or to the query handle (returned from [SQLQueryCreate\(\)](#)). When it is the connection handle and *sSelect* is an empty string, the operation is performed on the first query in that DB connection object. When it is the query handle, the operation is performed on that query through the DB object which is associated to it.

*sSelect*:

The SQL query to be sent to the SQL database.

## Return Value

The handle to a recordset holding the result of the query. If unsuccessful an invalid handle and an error code are returned (for details call the [SQLErrMsg\(\)](#) function). If no data is returned, an invalid handle and no error message are returned. The presence of an error can be tested by calling the [IsError\(\)](#) Cicode function

## Related Functions

[SQLCreate](#), [SQLOpen](#), [SQLClose](#), [SQLDispose](#), [SQLConnect](#), [SQLDisconnect](#), [SQLInfo](#), [SQLSet](#), [SQLAppend](#), [SQLExec](#), [SQLCall](#), [SQLGetScalar](#), [SQLEnd](#)

## Example

See [SQLCreate](#).

## See Also

[SQL Functions](#)

## SQLGetScalar

Executes an SQL query on a database. The value from the first column of the first row is returned. With this function, you can execute any SQL query or command supported by the SQL database. If it doesn't return any data (like INSERT or UPDATE), a respective error code is set which can be tested by calling [IsError\(\)](#).

**Note:** All types of fields can be requested in statements, but SCADA has to convert values of the fields to MBCS 8-bit strings which is not always possible. For example either single byte database strings or numbers can be

---

converted to MBCS 8-bit strings, multi-byte strings can be converted to MBCS (their proper presentation depends on correct setup of SCADA and OS), while blobs cannot be encoded at all.

---

This function is a blocking function and should not be called from a foreground task.

Queries which are built on the basis of user data, for example inputed by users via graphics pages or forms, may be prone to SQL Injection attacks. In such case, try to limit the risk by using CiCode functions from parameterized queries group and refer to a professional advice in this matter.

#### NOTICE

#### SECURITY BREACH VIA SQL INJECTION

- Validate all textbox entries using validation controls, regular expressions and code
- Use parameterized SQL or stored procedures
- Use a limited access account to connect to the database

**Failure to follow these instructions can result in equipment damage.**

## Syntax

**SQLGetScalar(*hGeneral*, *sSelect*, *isNull*)**

*hGeneral*:

The handle either to the DB connection object (returned from either [SQLCreate](#) or [SQLConnect](#) function) or to the query handle (returned from [SQLQueryCreate](#)). When it is the connection handle and *sSelect* is an empty string, the operation is performed on the first query in that DB connection object. When it is the query handle, the operation is performed on that query through the DB object which is associated to it.

*sSelect*:

The SQL query to be sent to the SQL database.

*isNull*:

Output Parameter: Indicated whether the returned variable is NULL. The argument is returned by the function.

## Return Value

String representing a value from the first column and the first row of the result of executing the SQL query. If the value is NULL, the string is empty and *isNull* parameter is set to TRUE. If there are no records in the result, the string is empty and the error code is set to 294. For details of the 307 error code, call the [SQLErrMsg\(\)](#) function. The presence of error code can be tested by calling the [IsError\(\)](#) CiCode function.

## Related Functions

[SQLCreate](#), [SQLOpen](#), [SQLClose](#), [SQLDispose](#), [SQLConnect](#), [SQLDisconnect](#), [SQLInfo](#), [SQLSet](#), [SQLAppend](#), [SQLExec](#), [SQLGetRecordset](#), [SQLCall](#), [SQLEnd](#)

## See Also

[SQL Functions](#)

## SQLInfo

Gets information about a database connection, recordset or query properties.

This function can be called in the foreground or background.

## Syntax

**SQLInfo(*hGeneral*, *Type*)**

*hGeneral*:

The handle either to:

The DB connection object, returned from either [SQLCreate](#) or [SQLConnect](#) function. The handle identifies the DB connection object where details of the associated SQL connection are stored.

Or:

The recordset.

Or:

The query.

*nType*:

The type of information to get:

0 - The connection string.

1 - The current SQL query for connection handles and query handles or the source SQL query for recordset handles.

2 - The current database filename (only works with SQL device).

3 - No longer supported.

4 - No longer supported. Now returns an empty string and sets the SQL error to 'Invalid Type'.

5 - The DB connection object's state: Closed (The connection is closed), Open (The connection is open), Connecting (The connection object is connecting to the data source. For future release), Executing (The connection object is executing a command. For future release), Fetching (The connection object is retrieving data. For future release), Broken (The connection to the data source is broken. This can occur only after the connection has been opened. A connection in this state may be closed and then re-opened. For future release). An empty string means either error occurred or the handle is invalid.

6 - The handle to the connection if used on either recordset or query handle.

7 - Checks whether a new transaction can be opened. The function perform a check how many transaction levels have been already opened and returns TRUE if a new one can be opened, otherwise FALSE. The function doesn't check ability of the external DB to open transactions. The functions returns FALSE for recordset handles.

---

**Note:** There is no guarantee that the objects behind the connection handles still exist in the system.

---

## Return Value

The information (as a string).

## Related Functions

[SQLCreate](#), [SQLOpen](#), [SQLClose](#), [SQLDispose](#), [SQLConnect](#), [SQLDisconnect](#)

## Example

```
SQLInfo(1,2);
```

## See Also

[SQL Functions](#)

## SQLIsNullField

Checks presence of null value in field from a recordset. To get to a specific record in the recordset, use either the [SQLNext\(\)](#)/[SQLPrev\(\)](#) functions or the *nRowIndex* argument.

When the *hGeneral* is the connection handle, the function returns information from the default recordset. When the *hGeneral* is the recordset handle, the function returns information from the recordset itself.

This function can be called in the foreground or background.

## Syntax

**SQLIsNullField**(*hGeneral*, *sField*, *nRowIndex*=-1)

*hGeneral*:

The handle either to:

The DB connection object, returned from either [SQLCreate](#) or [SQLConnect](#) function. The handle identifies the DB connection object where details of the associated SQL connection are stored.

Or:

The recordset.

*sField*:

The name of the field or column.

*nRowIndex*:

The number of the row which data is requested. The first row has index 0. -1 means that an internal pointer is used instead. The pointer can be moved forward and backward by executing [SQLNext\(\)](#) or [SQLPrev\(\)](#) functions.

## Return Value

TRUE if the value is NULL, FALSE otherwise.

## Related Functions

[SQLSet](#), [SQLAppend](#), [SQLExec](#), [SQLGetRecordset](#), [SQLCall](#), [SQLGetScalar](#), [SQLEnd](#), [SQLNumChange](#), [SQLNoFields](#), [SQLNumFields](#), [SQLFieldInfo](#), [SQLGetField](#), [SQLIsNullField](#), [SQLRowCount](#), [SQLNext](#), [SQLPrev](#)

## See Also

[SQL Functions](#)

### SQLNext

Gets the next database record from an SQL query. Use the [SQLExec/SQLGetRecordset](#) function to select a number of records or rows from the SQL database, and then use the [SQLNext](#) function to step through each record separately.

When the *hGeneral* is the connection handle, the function moves in the default recordset. When the *hGeneral* is the recordset handle, the function moves in the recordset itself.

This function can be called in the foreground or background.

## Syntax

**SQLNext(*hGeneral*)**

*hGeneral*:

The handle either to:

The DB connection object, returned from either [SQLCreate](#) or [SQLConnect](#) function. The handle identifies the DB connection object where details of the associated SQL connection are stored.

Or:

The recordset.

## Return Value

0 (zero) if successful, otherwise an error number is returned. (For details of the 307 error code, call the [SQLErrMsg](#) function).

## Related Functions

[SQLSet](#), [SQLAppend](#), [SQLExec](#), [SQLGetRecordset](#), [SQLGetScalar](#), [SQLEnd](#), [SQLNumChange](#), [SQLNoFields](#), [SQLNumFields](#), [SQLFieldInfo](#), [SQLGetField](#), [SQLIsNullField](#), [SQLRowCount](#), [SQLPrev](#)

## Example

See [SQLConnect](#).

## See Also

[SQL Functions](#)

### SQLNoFields

When the *hGeneral* is the connection handle, the function returns the number of fields or columns that were

returned by the last SQL statement. When the *hGeneral* is the recordset handle, the function returns the number of fields or columns in the recordset itself.

---

**Note:** This function is deprecated and may be removed in future releases.

This function can be called in the foreground or background.

## Syntax

**SQLNoFields(*hGeneral*)**

*hGeneral*:

The handle either to:

The DB connection object, returned from either [SQLCreate\(\)](#) or [SQLConnect\(\)](#) function. The handle identifies the DB connection object where details of the associated SQL connection are stored.

Or:

The recordset.

## Return Value

The number of fields. A value of 0 is returned if no fields were returned or if an error has been detected. (For details of an error code, call the [SQLErrMsg](#) function).

## Related Functions

[SQLSet](#), [SQLAppend](#), [SQLExec](#), [SQLGetRecordset](#), [SQLCall](#), [SQLGetScalar](#), [SQLEnd](#), [SQLNumChange](#), [SQLNoFields](#), [SQLNumFields](#), [SQLFieldInfo](#), [SQLGetField](#), [SQLIsNullField](#), [SQLRowCount](#), [SQLNext](#), [SQLPrev](#)

## Example

See [SQLFieldInfo](#).

## See Also

[SQL Functions](#)

## SQLNumChange

Gets the number of records that were modified in the last SQL Insert, Update, or Delete statement.

This function can be called in the foreground or background.

## Syntax

**SQLNumChange(*hSQL*)**

*hSQL*:

The handle to the DB connection object, returned from either [SQLCreate\(\)](#) or [SQLConnect\(\)](#) function. The handle

identifies the DB connection object where details of the associated SQL connection are stored.

## Return Value

The number of records that were modified. A value of 0 is returned if no fields were returned or if an error has occurred. (For details of an error code, call the [SQLErrMsg](#) function).

## Related Functions

[SQLSet](#), [SQLAppend](#), [SQLExec](#), [SQLGetRecordset](#), [SQLCall](#), [SQLGetScalar](#), [SQLEnd](#), [SQLNoFields](#), [SQLNumFields](#), [SQLFieldInfo](#), [SQLGetField](#), [SQLIsNullField](#), [SQLRowCount](#), [SQLNext](#), [SQLPrev](#)

## Example

See [SQLBeginTran](#).

## See Also

[SQL Functions](#)

## SQLNumFields

When *hGeneral* is the connection handle, the function returns the number of fields or columns that were returned by the last SQL statement. When *hGeneral* is the recordset handle, the function returns the number of fields or columns in the recordset itself.

This function can be called in the foreground or background.

## Syntax

**SQLNumFields(*hGeneral*)**

*hGeneral*:

The handle either to:

The DB connection object, returned from either [SQLCreate\(\)](#) or [SQLConnect\(\)](#) function. The handle identifies the DB connection object where details of the associated SQL connection are stored.

Or:

The recordset.

## Return Value

The number of fields. A value of 0 is returned if no fields were returned or if an error has been detected. (For details of an error code, call the [SQLErrMsg](#) function).

## Related Functions

[SQLSet](#), [SQLAppend](#), [SQLExec](#), [SQLGetRecordset](#), [SQLCall](#), [SQLGetScalar](#), [SQLEnd](#), [SQLNumChange](#), [SQLNoFields](#), [SQLNumFields](#), [SQLFieldInfo](#), [SQLGetField](#), [SQLIsNullField](#), [SQLRowCount](#), [SQLNext](#), [SQLPrev](#)

## Example

See [SQLFieldInfo](#).

## See Also

[SQL Functions](#)

## SQLOpen

Opens an SQL connection between the DB connection object specified by the function's parameter and the database defined by the connection string given before as the parameter to either [SQLCreate](#) or [SQLConnect](#) function.

---

### Note:

Currently there are certain configurations of providers, connection strings and database systems which can automatically close connections for the sake of saving the database systems' resources; for example MS SQL Server dedicated provider with activated pooling closes the connection to MS SQL Server when there is no data exchange between the client and the DB server for some predefined time. If such behaviour is observed and is not desired from the system design point of view, it can be either:

- Switched off by finding and using respective attributes in the connection string (if existing and supported by DB) or
- By actively checking error codes returned from SQL CiCode functions and reconnecting by using SQLOpen if the connection is dropped.

The actual state of connections can be checked by SQLInfo with type 5.

---

This function is a blocking function and should not be called from a foreground task.

## Syntax

**SQLOpen(*hSQL*)**

*hSQL*:

The handle to the DB connection object, returned from either the [SQLCreate\(\)](#) or [SQLConnect\(\)](#) function. The handle identifies the DB connection object where details of the associated SQL connection are stored.

## Return Value

0 if success, otherwise an error code (For details call the [SQLErrMsg\(\)](#) function)

## Related Functions

[SQLCreate](#), [SQLOpen](#), [SQLClose](#), [SQLDispose](#), [SQLConnect](#), [SQLDisconnect](#), [SQLInfo](#)

## Example

See [SQLCreate](#).

## See Also

[SQL Functions](#)

### SQLParamsClearAll

Remove all parameters associated with a particular connection object.

Each database provider (Odbc, OleDb, SQL Server) uses parameterized queries in a different way. It is recommended that you look at documentation and examples included with your database.

This function is a blocking function and should not be called from a foreground task.

Building queries from pieces (SQLSet, SQLAppend) or adding parameters to either queries or connections (SQLParam functions) requires a few calls to respective CiCode functions. If a few functions try to manipulate the same connection in the same time some conflicts and unintended operations may occur. It is a typical multithreading problem.

To avoid this, instead of manipulating connections, consider using locally created and locally disposed queries.  
For example:

```
int function SAFE_SQL_CICODE_MULTITHREAD_USE()
//locally created query
int hStmt = SQLQueryCreate(hConnection);

//Set the query
SQLSet(hStmt, "select * from TAB where NAME=@Name");

//Add parameters to the query
SQLParamsSetAsString(hStmt, "Name", "Aaa");

//Execute the query
SQLGetRecordset(hStmt, "");

//the locally created query is disposed
SQLQueryDispose(hStmt);
End
```

## Syntax

**SQLParamsClearAll(*hSQL*)**

*hSQL*:

The handle to the DB connection object, returned from either [SQLCreate\(\)](#) or [SQLConnect\(\)](#) function. The handle identifies the DB connection object where details of the associated SQL connection are stored.

## Return Value

0 (zero) if successful, otherwise an error number is returned. (For details of the 307 error code, call the

[SQLErrMsg](#) function.)

## Related Functions

[SQLSet](#), [SQLAppend](#), [SQLExec](#), [SQLGetRecordset](#), [SQLCall](#), [SQLGetScalar](#), [SQLEnd](#), [SQLParamsSetAsInt](#),  
[SQLParamsSetAsReal](#), [SQLParamsSetAsString](#)

## Example

See [SQLParamsSetAsInt](#).

## See Also

[SQL Functions](#)

### SQLParamsSetAsInt

Adds or replace a parameterized query parameter and its value in the specified connection. The value of the parameter is given as integer.

Each database provider (Odbc, OleDb, SQL Server) uses parameterized queries in a different way. It is recommended that you look at documentation and examples included with your database.

Building queries from pieces (SQLSet, SQLAppend) or adding parameters to either queries or connections (SQLParam functions) requires a few calls to respective CiCode functions. If a few functions try to manipulate the same connection in the same time some conflicts and unintended operations may occur. It is a typical multithreading problem.

To avoid this, instead of manipulating connections, consider using locally created and locally disposed queries. For example:

```
int function SAFE_SQL_CICODE_MULTITHREAD_USE()
    //locally created query
    int hStmt = SQLQueryCreate(hConnection);
    //Set the query
    SQLSet(hStmt, "select * from TAB where NAME=@Name");
    //Add parameters to the query
    SQLParamsSetAsString(hStmt, "Name", "Aaa");
    //Execute the query
    SQLGetRecordset(hStmt, "");
    //the locally created query is disposed
    SQLQueryDispose(hStmt);
End
```

This function is a blocking function and should not be called from a foreground task.

## Syntax

**SQLParamsSetAsInt**(*hSQL*, *ParamName*, *ParamValue*)

*hSQL*:

The handle to the DB connection object, returned from either [SQLCreate\(\)](#) or [SQLConnect\(\)](#) function. The handle identifies the DB connection object where details of the associated SQL connection are stored.

**ParamName:**

The name of the parameter to add or change.

**ParamValue:**

The value of the parameter as an integer.

## Return Value

0 (zero) if successful, otherwise an error number is returned. (For details of the 307 error code, call the [SQLErrMsg](#) function).

## Related Functions

[SQLSet](#), [SQLAppend](#), [SQLExec](#), [SQLGetRecordset](#), [SQLCall](#), [SQLGetScalar](#), [SQLEnd](#), [SQLParamsSetAsReal](#), [SQLParamsSetAsString](#), [SQLParamsClearAll](#)

## Examples

The following examples assume that the following table is setup and opened for the three data providers, ODBC, OleDb and SQLClient, respectively:

```
PEOPLE
SURNAME FIRSTNAME AGE HEIGHT
MARTIAN MARVIN 27 1.78
CASE CARRIE 18 1.73
```

### ODBC

A parameter is identified by a character "?" in the SQL query. Since the protocol uses a sequential approach for statement parameterization, the parameters order matters. In that case, to confirm that the correct parameters are picked up by the query, it is suggested to clear all the parameters after a query is executed and configure new ones in a correct order for another query unless the parameters are exactly the same in terms of value and position in the sequence between the two queries:

```
INT nError = 0;
STRING sValue0 = "";
STRING sValue1 = "";
INT nIsNull = 0;
INT hQueryDelete = SQLQueryCreate(hSQL);
SQLSet(hQueryDelete, "delete from PEOPLE where SURNAME=? and FIRSTNAME=?");
SQLParamsClearAll(hSQL);
//the name of the parameter does not matter
SQLParamsSetAsString(hSQL, "sName", "CASE");
SQLParamsSetAsString(hSQL, "fName", "CARRIE");
SQLCall(hQueryDelete, "");
SQLParamsClearAll(hSQL);
SQLParamsSetAsString(hSQL, "sName", "JACKSON");
SQLParamsSetAsString(hSQL, "fName", "DAVID");
SQLParamsSetAsInt(hSQL, "nAge", 28);
SQLParamsSetAsReal(hSQL, "nHeight", 1.85);
SQLCall(hSQL, "insert into PEOPLE (SURNAME, FIRSTNAME, AGE, HEIGHT) values (?,?,?,?)");
SQLParamsClearAll(hSQL);
SQLParamsSetAsString(hSQL, "fName", "DAVID");
SQLParamsSetAsString(hSQL, "sName", "JACKSON");
```

```
sValue0 = SQLGetScalar(hSQL, "select AGE from PEOPLE where FIRSTNAME=? and SURNAME=?",
nIsNull);
sValue1 = SQLGetScalar(hSQL, "select HEIGHT from PEOPLE where FIRSTNAME=? And SURNAME=?",
nIsNull);
```

**OleDb**

Same to ODBC, the association and later substitution is based on order of the parameters in a query statement and "?" is used as the mark. Thus the last example for ODBC also works for general cases of OleDb. Additionally, for some databases, i.e. Microsoft Access, user may have another option: parameter name with "@" prefix. Following examples are specific for communicating with Microsoft Access through OleDb data protocol.

```
INT nError = 0;
STRING sValue0 = "";
STRING sValue1 = "";
INT nIsNull = 0;
INT hQueryDelete = SQLQueryCreate(hSQL);
SQLSet(hQueryDelete, "delete from PEOPLE where SURNAME=@sName and FIRSTNAME=@fName");
SQLParamsClearAll(hSQL);
SQLParamsSetAsString(hSQL, "sName", "CASE");
SQLParamsSetAsString(hSQL, "fName", "CARRIE");
SQLCall(hQueryDelete, "");
SQLParamsClearAll(hSQL);
SQLParamsSetAsString(hSQL, "sName", "JACKSON");
SQLParamsSetAsString(hSQL, "fName", "DAVID");
SQLParamsSetAsInt(hSQL, "nAge", 28);
SQLParamsSetAsReal(hSQL, "nHeight", 1.85);
SQLCall(hSQL, "insert into PEOPLE (SURNAME, FIRSTNAME, AGE, HEIGHT) values (@sName, @fName,
@sName, @nHeight)");
SQLParamsClearAll(hSQL);
SQLParamsSetAsString(hSQL, "fName", "DAVID");
SQLParamsSetAsString(hSQL, "sName", "JACKSON");
sValue0 = SQLGetScalar(hSQL, "select AGE from PEOPLE where FIRSTNAME=@fName and
SURNAME=@sName", nIsNull);
sValue1 = SQLGetScalar(hSQL, "select HEIGHT from PEOPLE where FIRSTNAME=@fName And
SURNAME=@sName", nIsNull);
```

**Note:** If you want to use a parameter more than once in the same query, there is no need to define it multiple times. However, the parameters have to be prepared in proper order based on their occurrence order in the query statement.

**Example**

```
INT nError = 0;
STRING sValue0 = "";
STRING sValue1 = "";
INT nIsNull = 0;
INT hQueryInsert = SQLQueryCreate(hSQL);
SQLSet(hQueryInsert, "insert into TABLE (COLUMN0, COLUMN1, COLUMN2, COLUMN3, COLUMN4)
values (@param0, @param0, @param1, @param1, @param0");
SQLParamsClearAll(hSQL);
SQLParamsSetAsString(hSQL, "param0", "Value0");
SQLParamsSetAsString(hSQL, "param1", "Value1");
SQLCall(hQueryInsert, "");
The result will be:
TABLE
COLUMN0 COLUMN1 COLUMN2 COLUMN3 COLUMN4
Value0 Value0 Value1 Value1 Value0
```

**SQLClient**

SQL server uses a named parameter approach for parameterization. Parameters in queries are preceded by the '@' character. The order of the parameters does not matter.

```
INT nError = 0;
STRING sValue0 = "";
STRING sValue1 = "";
INT nIsNull = 0;
INT hQueryDelete = SQLQueryCreate(hSQL);
SQLSet(hQueryDelete, "delete from PEOPLE where SURNAME=@sName and FIRSTNAME=@fName");
SQLParamsSetAsString(hSQL, "sName", "CASE");
SQLParamsSetAsString(hSQL, "fName", "CARRIE");
SQLCall(hQueryDelete, "");
//Order does not matter
SQLParamsSetAsInt(hSQL, "nAge", 28);
SQLParamsSetAsReal(hSQL, "nHeight", 1.85);
//If a parameter has been defined already, setting the value again //will replace the old
value.
SQLParamsSetAsString(hSQL, "sName", "JACKSON");
SQLParamsSetAsString(hSQL, "fName", "DAVID");
SQLCall(hSQL, "insert into PEOPLE (SURNAME, FIRSTNAME, AGE, HEIGHT) values (@sName, @fName,
@nAge, @nHeight)");
sValue0 = SQLGetScalar(hSQL, "select AGE from PEOPLE where FIRSTNAME=@fName and
SURNAME=@sName", nIsNull);
sValue1 = SQLGetScalar(hSQL, "select HEIGHT from PEOPLE where FIRSTNAME=@fName And
SURNAME=@sName", nIsNull);
```

By the given Cicode examples, the table will be updated to:

```
PEOPLE
SURNAME FIRSTNAME AGE HEIGHT
MARTIAN MARVIN 27 1.78
JACKSON DAVID 28 1.85
```

### SQLParamsSetAsReal

Adds or replaces a parameterized query's parameter and its value in the specified connection. The value of the parameter is given as a real.

Each database provider (Odbc, OleDb, SQL Server) uses parameterized queries in a different way. It is recommended that you look at documentation and examples included with your database.

This function is a blocking function and should not be called from a foreground task.

Building queries from pieces (SQLSet, SQLAppend) or adding parameters to either queries or connections (SQLParam functions) requires a few calls to respective CiCode functions. If a few functions try to manipulate the same connection in the same time some conflicts and unintended operations may occur. It is a typical multithreading problem.

To avoid this, instead of manipulating connections, consider using locally created and locally disposed queries. For example:

```
int function SAFE_SQL_CICODE_MULTITHREAD_USE()
//locally created query
int hStmt = SQLQueryCreate(hConnection);
```

```
//Set the query
SQLSet(hStmt, "select * from TAB where NAME=@Name");

//Add parameters to the query
SQLParamsSetAsString(hStmt, "Name", "Aaa");

//Execute the query
SQLGetRecordset(hStmt, "");

//the locally created query is disposed
SQLQueryDispose(hStmt);
End
```

## Syntax

**SQLParamsSetAsReal(*hSQL*, *ParamName*, *ParamValue*)**

*hSQL*:

The handle to the DB connection object, returned from either SQLCreate() or SQLConnect() function. The handle identifies the DB connection object where details of the associated SQL connection are stored.

*ParamName*:

The name of the parameter to add or change.

*ParamValue*:

The value of the parameter as a real.

## Return Value

0 (zero) if successful, otherwise an error number is returned. (For details of the 307 error code, call the [SQLErrMsg](#) function).

## Related Functions

[SQLSet](#), [SQLAppend](#), [SQLExec](#), [SQLGetRecordset](#), [SQLCall](#), [SQLGetScalar](#), [SQLEnd](#), [SQLParamsSetAsInt](#), [SQLParamsSetAsString](#), [SQLParamsClearAll](#)

## Example

See [SQLParamsSetAsInt](#).

[SQL Functions](#)

## SQLParamsSetAsString

Adds or replaces a parameterized query's parameter and its value in the specified connection. The value of the

parameter is given as a string.

Each database provider (Odbc, OleDb, SQL Server) uses parameterized queries in a different way. It is recommended that you look at documentation and examples included with your database.

Building queries from pieces (SQLSet, SQLAppend) or adding parameters to either queries or connections (SQLParam functions) requires a few calls to respective CiCode functions. If a few functions try to manipulate the same connection in the same time some conflicts and unintended operations may occur. It is a typical multithreading problem.

To avoid this, instead of manipulating connections, consider using locally created and locally disposed queries. For example:

```
int function SAFE_SQL_CICODE_MULTITHREAD_USE()
//locally created query
int hStmt = SQLQueryCreate(hConnection);

//Set the query
SQLSet(hStmt, "select * from TAB where NAME=@Name");

//Add parameters to the query
SQLParamsSetAsString(hStmt, "Name", "Aaa");

//Execute the query
SQLGetRecordset(hStmt, "");

//the locally created query is disposed
SQLQueryDispose(hStmt);
End
```

This function is a blocking function and should not be called from a foreground task.

## Syntax

**SQLParamsSetAsString(*hSQL*, *ParamName*, *ParamValue*, *nStrType*)**

*hSQL*:

The handle to the DB connection object, returned from either SQLCreate() or SQLConnect() function. The handle identifies the DB connection object where details of the associated SQL connection are stored.

*ParamName*:

The name of the parameter to add or change.

*ParamValue*:

The value of the parameter as a string.

*nStrType*:

The index specifying the type of the string:

0 - Allowing ADO engine to use the default string type of the protocol. For SQLClient, OleDb and ODBC, the default string type is NVarChar (A variable-length stream of Unicode characters ranging between 1 and 4,000 characters);

1 - Forcing the string type to be NVarChar;

2 - Forcing the string type to be NChar (A fixed-length stream of Unicode characters ranging between 1 and 4,000 characters);

3 - Forcing the string type to be VarChar (A variable-length stream of non-Unicode characters ranging between 1

and 8,000 characters. VarChar is used when the database column is varchar(max));  
4 - Forcing the string type to be Char (A fixed-length stream of non-Unicode characters ranging between 1 and 8,000 characters).  
The default value of nStrType is 0.

## Return Value

0 (zero) if successful, otherwise an error number is returned. (For details of the 307 error code, call the [SQLErrMsg](#) function).

## Related Functions

[SQLSet](#), [SQLAppend](#), [SQLExec](#), [SQLGetRecordset](#), [SQLCall](#), [SQLGetScalar](#), [SQLEnd](#), [SQLParamsSetAsInt](#), [SQLParamsSetAsReal](#), [SQLParamsClearAll](#)

## Example

See [SQLParamsSetAsInt](#)

## See Also

[SQL Functions](#)

## SQLPrev

Gets the previous database record from an SQL query. The function works only with disconnected recordsets. Use the [SQLGetRecordset\(\)](#) function to select a number of records or rows from the SQL database, and then use the [SQLNext\(\)](#)/[SQLPrev\(\)](#) function to step through each record separately.

This function can be called in the foreground (only for disconnected recordsets) or background.

## Syntax

**SQLPrev(*hGeneral*)**

*hGeneral*:

The handle to the disconnected recordset.

## Return Value

0 (zero) if successful, otherwise an error number is returned. (For details of the 307 error code, call the [SQLErrMsg](#) function).

## Related Functions

[SQLSet](#), [SQLAppend](#), [SQLExec](#), [SQLGetRecordset](#), [SQLCall](#), [SQLGetScalar](#), [SQLEnd](#), [SQLNumChange](#), [SQLNoFields](#),

[SQLNumFields](#), [SQLFieldInfo](#), [SQLGetField](#), [SQLIsNullField](#), [SQLRowCount](#), [SQLNext](#)

## Example

See [SQLConnect](#)

## See Also

[SQL Functions](#)

### SQLQueryCreate

The function creates a new query and returns its handle. The query is empty and has to be set by using [SQLSet\(\)](#) and/or [SQLAppend\(\)](#) functions. The query handle can be used with the statement functions as [SQLExec\(\)](#) or [SQLGetRecordset\(\)](#).

Queries allocated by [SQLQueryCreate](#) should be disposed by [SQLQueryDispose](#) when no longer necessary. Each DB connection object has one default query which is created and disposed automatically. The default query need not be disposed by the function [SQLQueryDispose](#).

This function can be called in the foreground or background.

## Syntax

**SQLQueryCreate(*hSQL*)**

*hSQL*:

The handle to the DB connection object, returned from either [SQLCreate\(\)](#) or [SQLConnect\(\)](#) function. The handle identifies the DB connection object where details of the associated SQL connection are stored.

## Return Value

The handle to the query if successful, otherwise the invalid handle.

## Related Functions

[SQLSet](#), [SQLAppend](#), [SQLExec](#), [SQLGetRecordset](#), [SQLCall](#), [SQLGetScalar](#), [SQLEnd](#), [SQLQueryDispose](#),  
[SQLNumChange](#), [SQLNumFields](#), [SQLFieldInfo](#), [SQLGetField](#), [SQLIsNullField](#), [SQLRowCount](#), [SQLNext](#), [SQLPrev](#)

## See Also

[SQL Functions](#)

### SQLQueryDispose

The function disposes the query which handle is given as the argument.

Queries allocated by [SQLQueryCreate](#) should be disposed by [SQLQueryDispose](#) when no longer necessary. Each

DB connection object has one default query which is created and disposed automatically. The default query need not be disposed by the function SQLQueryDispose.

This function can be called in the foreground or background.

## Syntax

**SQLQueryDispose(*hQuery*)**

*hQuery*:

The handle to the query, returned from SQLQueryCreate() function.

## Return Value

0 (zero) if successful, otherwise an error code is returned. (For details of the 307 error code, call the [SQLErrMsg\(\)](#) function).

## Related Functions

[SQLSet](#), [SQLAppend](#), [SQLExec](#), [SQLGetRecordset](#), [SQLCall](#), [SQLGetScalar](#), [SQLEnd](#), [SQLQueryCreate](#),  
[SQLQueryDispose](#), [SQLNumChange](#), [SQLNoFields](#), [SQLNumFields](#), [SQLFieldInfo](#), [SQLGetField](#), [SQLIsNullField](#),  
[SQLRowCount](#), [SQLNext](#), [SQLPrev](#)

## See Also

[SQL Functions](#)

## SQLRollBack

Rolls back (discards) all changes made to the database within the current transaction. If you call the [SQLBeginTran\(\)](#) function to begin a transaction, you are not committed to changes to the database made by the Insert, Delete, and Update commands until you call the [SQLCommit\(\)](#) function. You can discard these changes by calling the [SQLRollBack\(\)](#) function.

You can only call the [SQLRollBack\(\)](#) function if you have called [SQLBeginTran\(\)](#) to begin a transaction. You do not need to begin a transaction to modify a database, but any changes you make to a database outside of a transaction are automatically committed.

The [SQLRollBack\(\)](#) function could affect different databases in different ways. If the function is not performing as you expect, check that your database is able to service transactions. Refer to the documentation for your database for more information on rolling back transactions.

This function is a blocking function and should not be called from a foreground task.

## Syntax

**SQLRollBack(*hSQL*)**

*hSQL*:

The handle to the DB connection object, returned from either [SQLCreate\(\)](#) or [SQLConnect\(\)](#) function. The handle

identifies the DB connection object where details of the associated SQL connection are stored.

## Return Value

0 (zero) if successful, otherwise an error number is returned. (For details of the 307 error code, call the [SQLErrMsg](#) function).

## Related Functions

[SQLCreate](#), [SQLOpen](#), [SQLClose](#), [SQLDispose](#), [SQLConnect](#), [SQLDisconnect](#), [SQLInfo](#), [SQLBeginTran](#), [SQLCommit](#)

## Example

See [SQLBeginTran](#).

## See Also

[SQL Functions](#)

## SQLRowCount

Gets the number of rows in the recordset.

This function can be called in the foreground or background.

## Syntax

**SQLRowCount(*hGeneral*)**

*hGeneral*:

The handle either to:

The DB connection object, returned from either [SQLCreate\(\)](#) or [SQLConnect\(\)](#) function. The handle identifies the DB connection object where details of the associated SQL connection are stored.

Or:

The recordset.

## Return Value

The number of rows in the given recordset for disconnected recordsets. For the connected recordset, the function returns always -1.

## Related Functions

[SQLSet](#), [SQLAppend](#), [SQLExec](#), [SQLGetRecordset](#), [SQLCall](#), [SQLGetScalar](#), [SQLEnd](#), [SQLNumChange](#), [SQLNoFields](#), [SQLNumFields](#), [SQLFieldInfo](#), [SQLGetField](#), [SQLIsNullField](#), [SQLRowCount](#), [SQLNext](#), [SQLPrev](#)

## Example

See [SQLCreate](#).

## See Also

[SQL Functions](#)

## SQLSet

Sets a query string in the SQL buffer. Cicode cannot send an SQL query that is longer than 255 characters. If you have an SQL query that is longer than the 255 character limit, you can split the query into smaller strings, and use this function and the [SQLAppend\(\)](#) function to append the query in the SQL buffer.

This function can be called in the foreground or background.

Queries which are built on the basis of user data, for example inputed by users via graphics pages or forms, may be prone to SQL Injection attacks. In such case, try to limit the risk by using Cicode functions from parameterized queries group and refer to a professional advice in this matter.

### NOTICE

#### SECURITY BREACH VIA SQL INJECTION

- Validate all textbox entries using validation controls, regular expressions and code
- Use parameterized SQL or stored procedures
- Use a limited access account to connect to the database

**Failure to follow these instructions can result in equipment damage.**

Building queries from pieces (SQLSet, SQLAppend) or adding parameters to either queries or connections (SQLParam functions) requires a few calls to respective CiCode functions. If a few functions try to manipulate the same connection in the same time some conflicts and unintended operations may occur. It is a typical multithreading problem.

To avoid this, instead of manipulating connections, consider using locally created and locally disposed queries. For example:

```
int function SAFE_SQL_CICODE_MULTITHREAD_USE()
//locally created query
int hStmt = SQLQueryCreate(hConnection);

//Set the query
SQLSet(hStmt, "select * from TAB where NAME=@Name");

//Add parameters to the query
SQLParamsSetAsString(hStmt, "Name", "Aaa");

//Execute the query
SQLGetRecordset(hStmt, "");

//the locally created query is disposed
SQLQueryDispose(hStmt);
```

End

## Syntax

**SQLSet(*hGeneral*, *sString*)**

*hGeneral*:

The handle either to the DB connection object (returned from either [SQLCreate\(\)](#) or [SQLConnect\(\)](#) function) or to the query handle (returned from [SQLQueryCreate\(\)](#)). When it is the connection handle, the operation is performed on the first query in that DB connection object. When it is the query handle, the operation is performed on that query through the DB object which is associated to it.

*sString*:

The query string to set in the SQL buffer. The string needs to contain the first part of an SQL query.

## Return Value

0 (zero) if successful, otherwise an error number is returned. (For details of the 307 error code, call the [SQLErrMsg\(\)](#) function).

## Related Functions

### Example

```
hSQL = SQLConnect("DSN=QEDBF");
nError = SQLBeginTran(hSQL);
nError = SQLSet(hSQL, "SELECT *");
nError = SQLAppend(hSQL, " FROM EMP");
nError = SQLAppend(hSQL, " ORDER BY last_name");
hRec = SQLGetRecordset(hSQL, "");
```

## See Also

[SQL Functions](#)

## SQLTraceOff

Turns off the debug trace. Use this function to stop tracing function calls that are made to the database. The trace can be turned off globally for all connections or for a specific one.

This function can be called in the foreground or background.

## Syntax

**SQLTraceOff(*hSQL*)**

*hSQL*:

The handle to the DB connection object: INVALID HANDLE - The trace is deactivated for all DB connections (default), otherwise - The trace is deactivated for this specific DB connection object.

## Return Value

0 (zero) if successful, otherwise an error number is returned. (For details of the 307 error code, call the [SQLErrMsg](#) function).

## Related Functions

[SQLErrMsg](#)

## Example

See [SQLFieldInfo](#).

## See Also

[SQL Functions](#)

## SQLTraceOn

Turns on a debug trace. Use this function to begin tracing function calls that are made to the database. The information is written to TraceLog.dat file (the strFileName argument is currently ignored). The trace can be turned on globally for all connections or for a specific connection.

---

**Note:** Currently the SQL tracing functionality uses the standard SCADA logging mechanism. All SQL traces are Information logs and can be written to TraceLog.dat file only if appropriate logging ini parameters are set respectively, for example [\[Debug\]SeverityFilterMode](#).

---

This function can be called in the foreground or background.

## Syntax

**SQLTraceOn(*sFileName*, *hSQL*, *nTraceLevel*)**

*sFileName*:

The output file name for the debug trace. Currently ignored.

*hSQL*:

The handle to the DB connection object: INVALID HANDLE - The trace is activated for all DB connections (default), otherwise - The trace is activated for this specific DB connection object.

*nTraceLevel*:

Defines the level of details written to the trace file. The following values are allowed:

0 - as per 1, but without values (default).

1 - the highest level of details including values of read cells

## Return Value

0 (zero) if successful, otherwise an error number is returned. (For details of the 307 error code, call the

[SQLErrMsg](#) function).

## Related Functions

[SQLErrMsg](#), [SQLTraceOff](#)

## Example

## SPC Functions

Following are functions relating to Statistical Process Control:

<a href="#">SPCAlarms</a>	Returns the status of the specified SPC alarm.
<a href="#">SPCClientInfo</a>	Returns SPC data for the given SPC tag.
<a href="#">SPCGetHistogramTable</a>	Returns an array containing the frequency of particular ranges for the given SPC tag.
<a href="#">SPCGetSubgroupTable</a>	Returns an array containing the specified subgroup's elements with the mean, range and standard deviation.
<a href="#">SPCPlot</a>	Generates a single page print showing three separate trends of the SPC Mean, Range, and Standard Deviation.
<a href="#">SPCProcessXRSGet</a>	Gets the process mean, range and standard deviation overrides.
<a href="#">SPCProcessXRSSet</a>	Sets the process mean, range and standard deviation overrides.
<a href="#">SPCSelLimit</a>	Sets the upper or lower control limits of X-bar, range, or standard deviation charts.
<a href="#">SPCSpecLimitGet</a>	Gets the upper and lower specification limits for the specified tag.
<a href="#">SPCSpecLimitSet</a>	Sets the upper and lower specification limits for the specified tag.
<a href="#">SPCSubgroupSizeGet</a>	Gets the size of a subgroup for the specified SPC tag.

SPCSubgroupSizeSet	Sets the subgroup size for the specified SPC tag.
--------------------	---

## See Also

[Cicode Function Categories](#)

[Using Cicode Functions](#)

## SPCAlarms

Returns the status of the specified SPC alarm. This function is used to configure SPC alarms, by defining alarms with this trigger in Advanced Alarms.

This function can only be used if the Alarm Server is on the current machine. When the Alarm Server is not in the calling process, this function will become blocking and cannot be called from a foreground task. In this case, the return value will be undefined and a Cicode hardware alarm will be raised.

## Syntax

**SPCAlarms(*sSPCTag*, *AlarmType*)**

*sSPCTag*:

The SPC Tag name as defined in SPC Tags.

*AlarmType*:

The description of the alarm type. The following types are valid:

XFreak

XOutsideCL

XAboveUCL

XBelowLCL

XOutsideWL

XGradualUp

XGradualDown

XUpTrend

XDownTrend

XErratic

XStratification

XMixture

ROutsideCL

RAboveUCL

RBelowLCL

## Return Value

Alarm status, ON (1) or OFF (0).

## Related Functions

[AlarmAck](#)

## Example

Advanced Alarm

Alarm Tag	Feed_SPC_XBLCL
Alarm Desc	Process mean below LCL
Expression	SPCALarms("Feed_SPC", XBelowLCL)
Comment	Trigger an alarm when XBelowLCL condition becomes true.

Advanced Alarm

Alarm Tag	Temp_SPC_GRADUP
Alarm Desc	Mean is drifting up
Expression	SPCALarms("Temp_SPC", XGradualUp)
Comment	Trigger an alarm if mean drifts up.

[SPC Functions](#)

### SPCClientInfo

Returns SPC data for the given SPC tag. The information retrieved through this function is from the cache maintained by the client. This function will give a faster response than the related functions which access the SPC (trend) server.

This function can only be called while the SPC tag is being displayed on an SPC page.

## Syntax

**SPCClientInfo(*sSPCTag*, *iType*)**

*sSPCTag*:

The SPC Tag name as defined in SPC Tags.

*iType*:

The information to be returned:

1 - Subgroup Size

2 - No. of Subgroups

- 3 - Process Mean (x double bar)
- 4 - Process Range
- 5 - Process Standard Deviation
- 6 - Lower Specification Limit (LSL)
- 7 - Upper Specification Limit (USL)
- 8 - Cp - Process Capability Actual
- 9 - Cpk - Process Capability Potential
- 10 - Process Skewness
- 11 - Process kurtosis

## Return Value

The requested data specified by iType. It is of type REAL.

## Related Functions

[SPCSpecLimitGet](#), [SPCProcessXRSGet](#), [SPCSubgroupSizeGet](#)

## Example

```
/* This function will check the capability of a particular SPC tag.*/
REAL
FUNCTION
CheckCapability(STRING sTAG)
    REAL rReturn;
    rReturn = SPCClientInfo(sTag, 8);
    !rReturn holds the inherent capability value
    IF rReturn > 1.0 THEN
        Message(sTag + "Assessment","The process is Capable.",64);
    ELSE
        Message(sTag + "Assessment","The process is not Capable.",64);
    END
    Return rReturn;
END
```

## See Also

[SPC Functions](#)

### SPCGetHistogramTable

Returns an array containing the frequencies of particular ranges for the given SPC tag. The histogram structure is implied in the order of the table as follows - the first array element is the data less than -3 sigma. The second value is the data between -3 sigma and -3 sigma plus the bar width etc. The last value is the data greater than +3 sigma.

This function can only be called while the SPC tag is being displayed on an SPC page.

## Syntax

**SPCGetHistogramTable(*sSPCTag*, *iNoBars*, *TableVariable*)**

*sSPCTag*:

The SPC Tag name as defined in SPC Tags.

*iNoBars*:

The number of bars in the table. The valid range is restricted to values from 7 to 100. This also indicates the size of the array to be returned.

*TableVariable*:

The Cicode array that will store the histogram data. The number of elements in the array needs to be equal to (or greater than) *iNoBars*. Must be a Real type global array variable.

## Return Value

0 (zero) if successful, otherwise an error number is returned. The histogram table is written to *TableVariable*.

## Related Functions

TableMath

## Example

```
/* This function will get the maximum frequency present in the
histogram of a particular SPC tag.*/
REAL iFrequency[7];
! This variable needs to be global to the file so is declared outside
of the function
INT
FUNCTION
GetMaxFreq(STRING sTAG)
    INT iError;
    INT iMax = -1;
    iError = SPCGetHistogramTable(sTag, 7, iFrequency);
    !The elements of iFrequency now hold the histogram table frequencies.
    IF iError = 0 THEN
        ! Get maximum
        iMax = TableMath(iFrequency,7,1,0);
    END
    Return iMax;
END
```

## See Also

[SPC Functions](#)

## SPCGetSubgroupTable

Returns an array containing the specified subgroup's elements with the mean, range and standard deviation. The data will be in the following order:

Element0, Element1, ... , Element(**n**-1), Mean, Range, StdDev

where **n** is the subgroup size.

This function can only be called while the SPC tag is being displayed on an SPC page.

## Syntax

**SPCGetSubgroupTable**(*sSPCTag*, *iSubgroup*, *TableVariable*)

*sSPCTag*:

The SPC Tag name as defined in SPC Tags.

*iSubgroup*:

The number of the subgroup being displayed whose data is to be retrieved. Zero ('0') represents the latest subgroup.

*TableVariable*:

The first element of the Cicode array that will store the sample data. The number of elements in the array needs to be equal to (or greater than) the subgroup size + 3. Must be a Real type global array variable.

## Return Value

0 (zero) if successful, otherwise an error number is returned. The subgroup's data is written to *TableVariable*.

## Related Functions

[TableMath](#)

## Example

```
/* This function will get the minimum value present in the sample
data of a particular SPC tag.*/
REAL rSubgroup[8]; ! 5 samples + mean + range + stddev.
! This variable needs to be global to the file, so is declared outside
of the function
REAL
FUNCTION
GetMinSample(STRING sTAG)
INT iError;
REAL iMin = 0;
iError = SPCGetSubgroupTable(sTag, 7, rSubgroup);
!The elements of rSubgroup now hold the group samples, mean, range and stddev.
IF iError = 0 THEN
! Get minimum. Be aware that the range of data is 5
iMin = TableMath(rSubgroup,5,0,0);
END
Return iMin;
```

**END**

## See Also

[SPC Functions](#)

### SPCPlot

This function is designed to work only on an SPCXRSChart page. It prints a single page showing three separate trends of the SPC Mean, Range, and Standard Deviation. The Mean needs to be at *nAN*, the Range at *AN + 1*, and the Standard Deviation at *AN + 2*. You can specify a title and a comment for the plot, and whether it is printed in color or in black and white.

## Syntax

**SPCPlot(*sPort*, *nAN* [, *sTitle*] [, *sComment*] [, *nMode*] )**

*sPort*:

The name of the printer port to which the plot will be printed. This name needs to be enclosed within quotation marks. For example LPT1:, to print to the local printer, or \\Pserver\canon1 using UNC to print to a network printer.

*nAN*:

The animation point at which the Mean chart is currently situated. The Range and Standard Deviation charts need to be on the next two consecutive animation numbers. For example, if the Mean chart is at animation point 40, the Range chart needs to be at animation point 41, and the Standard Deviation chart needs to be at animation point 42.

*sTitle*:

The title of the trend plot.

*sComment*:

The comment that is to display beneath the title of the trend plot. You do not have to enter a comment.

*nMode*:

The color mode of the printer.

0 - Black and White (default)

1 - Color

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TrnPlot](#), [TrnComparePlot](#), [TrnPrint](#), [PlotOpen](#)

## Example

```
/* This function will print the Mean trend (currently displayed at
animation point 40), the Range trend (currently at animation point
41), and the Standard Deviation trend (currently at animation
point 42). The result is a one page, black and white combination
of all three trends, printed to LPT1. */
SPCPlot("LPT1:",40, "Plant SCADA SPC Chart","Gradually increasing trend",0);
```

## See Also

[SPC Functions](#)

### SPCProcessXRSGet

Gets the process mean, range, and standard deviation overrides for the specified SPC tag. The values that are returned are the values that are currently being used by the SPC (trend) server, not necessarily the values specified in the SPC Tag definition.

This function is a blocking function. It will block the calling Cicode task until the operation is complete.

This function can only be called while the SPC tag is being displayed on an SPC page.

## Syntax

**SPCProcessXRSGet(*sSPCTag*, *XVariable*, *RVariable*, *SVariable* [, *sClusterName*] )**

***sSPCTag*:**

The SPC Tag name as defined in SPC Tags.

***XVariable*:**

The Cicode variable that stores the process mean (X double bar). A constant is not allowed. Must be a Real type global variable.

***RVariable*:**

The Cicode variable that stores the range (R). A constant is not allowed. Must be a Real type global variable.

***SVariable*:**

The Cicode variable that stores the standard deviation (S). A constant is not allowed. Must be a Real type global variable.

***sClusterName*:**

Specifies the name of the cluster of the SPC tag.

## Return Value

0 (zero) if successful, otherwise an error number is returned. The process mean is written to XVariable, the process range to RVariable, and the standard deviation to SVariable.

## Related Functions

[SPCClientInfo](#), [SPCProcessXRSSet](#)

## Example

```
/* This function will set a new override value for Mean, without
overwriting the values already in place for Standard Deviation and
Range */
REAL rOldMean;
REAL rRange;
REAL rStdDev;
! These variables need to be global to the file, so are declared
outside of the function
INT
FUNCTION
Tank1SPCNewMean(REAL rNewMean)
    INT iError;
    iError = SPCProcessXRSGet("TANK_1_TEMP", rOldMean, rRange, rStdDev);
    ! If no error, rOldMean, rRange and rStdDev now hold the current values of XRS.
    IF iError = 0 THEN
        iError = SPCProcessXRSSet("TANK_1_TEMP", rNewMean, rRange, rStdDev);
    END
    Return iError;
END
```

## See Also

[SPC Functions](#)

### SPCProcessXRSSet

Sets the process mean, range and standard deviation overrides for the specified SPC tag. The values entered here will override Plant SCADA's automatic calculations, and the overrides specified in the SPC Tags definition.

This function is a blocking function. It will block the calling Cicode task until the operation is complete.

This function can only be called while the SPC tag is being displayed on an SPC page.

## Syntax

**SPCProcessXRSSet(*sSPCTag*, *rMean*, *rRange*, *rStdDev* [, *sClusterName*] )**

*sSPCTag*:

The SPC Tag name as defined in SPC Tags.

*rMean*:

The new value of process mean (x double bar) to set.

*rRange*:

The new value of process range to set.

*rStdDev*:

The new value of process standard deviation to set.

*sClusterName*:

Specifies the name of the cluster of the SPC tag.

## Return Value

0 (zero) if successful, otherwise an error number is returned.

## Related Functions

[SPCProcessXRSGet](#)

## Example

See [SPCProcessXRSGet](#).

## See Also

[SPC Functions](#)

## SPCSetLimit

Sets the upper or lower control limits of X-bar, range, or standard deviation charts. Using this function will only set the controller limits on the Client display which will not affect the SPC Alarms. To set the server control limits, use the SPCProcessXRSSet function.

## Syntax

**SPCSetLimit(*nAN*, *Type*, *Value*, *Setting*)**

*nAN*:

The AN where the SPC chart is located.

*nType*:

The SPC type:

1 - X-bar upper control limit

2 - X-bar lower control limit

3 - Range upper control limit

4 - Range lower control limit

5 - Standard deviation upper control limit

6 - Standard deviation lower control limit

7 - X-bar centre line

8 - Range centre line

9 - Standard deviation centre line

**Value:**

The value for the control limit.

**Setting:**

Automatic calculation or manual setting of control limits:

0 - Automatic

1 - Manual

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Example

```
SPCSetLimit(40,1,250,1);
! Sets X-bar upper control limit to 250 at AN40.
```

## See Also

[SPC Functions](#)

## SPCSpecLimitGet

Gets the process Upper and Lower Specification Limits (USL and LSL) for the specified SPC tag. The values that are returned are the values that are currently being used by the SPC (trend) server, not necessarily the values specified in the SPC Tag definition.

This function is a blocking function. It will block the calling Cicode task until the operation is complete.

## Syntax

```
SPCSpecLimitGet(sSPCTag, LSLVariable, USLVariable [, sClusterName] )
```

***sSPCTag:***

The SPC Tag name as defined in SPC Tags.

***LSLVariable:***

The Cicode variable that stores the Lower Specification Limit (LSL). Do not specify a constant in this field. Must be a Real type global variable.

***USLVariable:***

The Cicode variable that stores the Upper Specification Limit (USL). Do not specify a constant in this field. Must be a Real type global variable.

***sClusterName:***

Specifies the name of the cluster of the SPC tag.

## Return Value

0 (zero) if successful, otherwise an error number is returned. The LSL is written to LSLVariable, while the USL is written to USLVariable.

## Related Functions

[SPCClientInfo](#), [SPCSpecLimitSet](#)

## Example

```
/* This function will increase the current USL and LSL of the
specified Tag by 10 percent.*/
REAL rLSL;
REAL rUSL;
! These variables need to be global to the file, so are declared
outside of the function
INT
FUNCTION
ExpSLbyPercent(STRING sTAG)
    REAL rIncPercent = 1.1;
    REAL rDecPercent = 0.9;
    INT iError;
    iError = SPCSpecLimitGet(sTag, rLSL, rUSL);
! If no error, rLSL and rUSL now hold the current values of
    LSL and USL for sTAG
    rLSL = rLSL * rDecPercent;
    rUSL = rUSL * rIncPercent;
    IF iError = 0 THEN
        iError = SPCSpecLimitSet(sTAG, rLSL, rUSL);
    END
    Return iError;
END
```

The function would be called as follows:

Page Button

Button Text	Expand Temperature Limits
Expression	ExpSLby10Percent("TANK_1_TEMP");

## See Also

[SPC Functions](#)

### SPCSpecLimitSet

Sets the process Upper and Lower Specification Limits (USL and LSL) for the specified SPC tag. The values entered here will override those specified in the SPC Tags definition.

This function is a blocking function. It will block the calling Cicode task until the operation is complete.

## Syntax

**SPCSpecLimitSet(*sSPCTag*, *rLSL*, *rUSL* [, *sClusterName*] )**

*sSPCTag*:

The SPC Tag name as defined in SPC Tags.

*rLSL*:

The new value of Lower Specification Limit (LSL) to set.

*rUSL*:

The new value of Upper Specification Limit (USL) to set.

*sClusterName*:

Specifies the name of the cluster of the SPC tag.

## Return Value

0 (zero) if successful, otherwise an error number is returned.

## Related Functions

[SPCSpecLimitGet](#)

## Example

See [SPCSpecLimitGet](#).

## See Also

[SPC Functions](#)

## SPCSubgroupSizeGet

Gets the subgroup size for the specified SPC tag. The value that is returned is the value that is currently being used by the SPC (trend) server, not necessarily the value specified in the SPC Tag definition.

This function is a blocking function. It will block the calling Cicode task until the operation is complete.

This function can only be called while the SPC tag is being displayed on an SPC page.

## Syntax

**SPCSubgroupSizeGet(*sSPCTag*, *SizeVariable* [, *sClusterName*] )**

*sSPCTag*:

The SPC Tag name as defined in SPC Tags.

*SizeVariable*:

The Cicode variable that stores the subgroup size. This variable needs to be defined as a global of type INT. A

constant is not allowed. Must be a Long type variable.

*sClusterName*:

Specifies the name of the cluster of the SPC tag.

## Return Value

0 (zero) if successful, otherwise an error number is returned. The subgroup size is written to *SizeVariable*.

## Related Functions

[SPCClientInfo](#), [SPCSubgroupSizeSet](#)

## Example

See [SPCSubgroupSizeSet](#).

## See Also

[SPC Functions](#)

## SPCSubgroupSizeSet

Sets a new subgroup size for the specified SPC tag. The new subgroup size becomes the new size as long as the SPC (trend) server is running. The subgroup size is updated first in the SPC server, which then informs the clients to update. This will force re-calculation of SPC values (UCL and LCL) across the span of any displayed charts.

This function is a blocking function. It will block the calling Cicode task until the operation is complete.

This function can only be called while the SPC tag is being displayed on an SPC page.

## Syntax

**SPCSubgroupSizeSet(*sSPCTag*, *iSize* [, *sClusterName*] )**

*sSPCTag*:

The SPC Tag name as defined in SPC Tags.

*iSize*:

The new size of the subgroup to set.

*sClusterName*:

Specifies the name of the cluster of the SPC tag.

## Return Value

0 (zero) if successful, otherwise an error number is returned.

## Related Functions

[SPCSubgroupSizeGet](#)

## Example

```
/* This function increments the subgroup size for FEED_RATE_1 by
the specified amount. */
INT iSize;
! This variable needs to be global to the file, so is declared outside
of the function
INT
FUNCTION
IncSubgroupSize(INT iIncrement)
    INT iError;
    iError = SPCSubgroupSizeGet("FEED_RATE_1", iSize);
    ! If no error, iSize now contains the current subgroup size of FEED_RATE_1
    iSize = iSize + iIncrement;
    IF iError = 0 and (isize > 1) THEN
        iError = SPCSubgroupSizeSet("FEED_RATE_1", iSize );
    END
    Return iError;
END
```

## String Functions

String functions allow you to manipulate strings in various ways. You can extract characters or substrings from a string, convert strings into other data types, format strings, search for strings, and perform other operations.

Following are functions relating to Strings:

<a href="#">CharToStr</a>	Converts an ASCII code into a string.
<a href="#">HexToStr</a>	Converts a number into a hexadecimal string.
<a href="#">IntToStr</a>	Converts an integer variable into a string.
<a href="#">PathToStr</a>	Converts a Plant SCADA path into a string.
<a href="#">RealToStr</a>	Converts a floating-point variable into a string.
<a href="#">StrCalcWidth</a>	Retrieves the pixel width of a string using a particular font.
<a href="#">StrClean</a>	Removes control characters from a string.
<a href="#">StrEndsWith</a>	Verifies whether the given string ends with a specific

	string.
StrFill	Fills a string with characters.
StrFormat	Formats a variable into a string.
StrGetChar	Gets a single character from a string or buffer.
StrLeft	Gets the left-hand characters from a string.
StrLength	Gets the length of a string.
StrListContainsItem	Checks whether the string passed is an item contained in a delimited list of strings.
StrLower	Converts a string to lower-case.
StrMid	Gets characters from the middle of a string.
StrPad	Pads a string to the required length.
StrReplace	Replaces a substring in a string with replacement substring.
StrRight	Gets the right-hand characters from a string.
StrSearch	Searches for a string within a string.
StrSetChar	Sets a single character into string or buffer.
StrSplit	Checks whether the string passed is an item contained in a delimited list of strings.
StrToBool	Converts a string value to a Boolean value.
StrToChar	Converts a string to an ASCII code.
StrToDate	Converts a string into a date variable.
StrToFmt	Converts a string into format fields.
StrToGrp	Converts a string into a group.
StrToHex	Converts a hexadecimal string into an integer.
StrToInt	Converts a string into an integer variable.
StrToLines	Converts a string into lines of limited length.
StrToLocalText	Converts a string from Native language to Local language.
StrToPeriod	Converts a string into a (time) period.

<a href="#">StrToReal</a>	Converts a string into a floating-point variable.
<a href="#">StrToTime</a>	Converts a string into a time variable.
<a href="#">StrToValue</a>	Converts a string into a floating-point variable.
<a href="#">StrTrim</a>	Trims spaces from a string.
<a href="#">StrTruncFont</a>	Returns the truncated string using a particular font (specified by name) or the specified number of characters.
<a href="#">StrTruncFontHnd</a>	Returns the truncated string using a particular font (specified by font number) or the specified number of characters.
<a href="#">StrTruncFontTooltip</a>	Returns a truncated string with ellipsis, and sets an AN with a tooltip containing the complete string if a truncation occurs.
<a href="#">StrUpper</a>	Converts a string to upper-case.
<a href="#">StrWord</a>	Gets a word from a string.

## CharToStr

Converts an ASCII code into a string.

## Syntax

**CharToStr(ASCIICode)**

*ASCIICode:*

The ASCII code to convert.

## Return Value

A string containing the converted ASCII code.

## Related Functions

[StrSetChar](#)

## Example

```
str = CharToStr(65);
! Sets str to "A".
```

## See Also

[String Functions](#)

## HexToStr

Converts a number into a hexadecimal string. The string is the width specified (padded with zeros).

## Syntax

**HexToStr(Number, Width)**

*Number:*

The number to convert.

*Width:*

The width of the string (0 to 8).

---

**Note:** The function does not truncate the result if it is longer than the value specified.

---

## Return Value

A string containing the converted number.

## Related Functions

[StrToHex](#), [IntToStr](#)

## Example

```
Variable=HexToStr(123, 4);
! Sets Variable to "007b".
Variable = HexToStr(0x12ABFE, 8);
! Sets Variable to "0012abfe"
```

## See Also

[String Functions](#)

## IntToStr

Converts a number into a string.

## Syntax

**IntToStr(*Number*)**

*Number*:

The number to convert.

## Return Value

A string containing the converted number.

## Related Functions

[StrFormat](#)

## Example

```
Variable=IntToStr(5);
! Sets Variable to "5".
```

## See Also

[String Functions](#)

[Converting and Formatting Cicode Variables](#)

## PathToStr

Converts a Plant SCADA path into a string. The path string can contain one of the standard Plant SCADA path operators, BIN, DATA, RUN, USER or a user-configured path. If the string does not contain a Plant SCADA path, it is unchanged.

## Syntax

**PathToStr(*sPath*)**

*sPath*:

The Plant SCADA path to convert.

## Return Value

A string containing the converted path.

## Example

```
Variable=PathToStr("[data]:test.txt");
! Sets Variable to "c:\MyApplication\data\test.txt".
! assuming that DATA=C:\MyApplication\DATA
```

## See Also

[String Functions](#)

### RealToStr

Converts a floating-point number into a string.

## Syntax

**RealToStr(*Number*, *Width*, *Places*[, *Separator*])**

*Number*:

The floating-point number to convert.

*Width*:

The width of the string.

*Places*:

The number of decimal places contained in the string.

*Separator*:

Optionally, the decimal separator contained in the string. Defaults to empty string.

- "." - period
- "," - comma
- "" - empty string

If an empty string or an invalid separator is passed as a parameter, the string will contain the decimal separator used in the current locale.

## Return Value

The floating-point number (as a string).

## Related Functions

[StrToReal](#)

## Example

```
Variable=RealToStr(12.345,10,1);
! Sets Variable to " 12.3" (10 characters long).
```

## See Also

[String Functions](#)

## StrCalcWidth

Retrieves the pixel width of a string using a particular font.

## Syntax

**StrCalcWidth(*sText, iFont*)**

*sText:*

The text to determine the pixel width of

*iFont:*

The font number used to calculate the pixel width of the text. (To use the default font, set to -1).

## Return Value

The pixel width of a string using the particular font.

## Related Functions

[StrTruncFont](#), [StrTruncFontHnd](#), [DspFont](#), [DspFontHnd](#)

## See Also

[String Functions](#)

[Using the Caret Escape Sequence Character](#)

## StrClean

Removes control characters from a string. Any character that is not a displayable ASCII character is removed from the string.

## Syntax

**StrClean(*String*)**

*String:*

The source string.

## Return Value

The string with all control characters removed.

## Related Functions

[StrTrim](#)

## Example

```
Variable=StrClean("*****Text*****");
/* Sets Variable to "Text" (the "*" character in this example
represents an unprintable character). */
```

## See Also

[String Functions](#)

[Using the Caret Escape Sequence Character](#)

## StrEndsWith

Verifies whether the given string ends with a specific string.

## Syntax

**StrEndsWith(STRING *sSource*, STRING *sSearchTerm*)**

*sSource*

The source string to check.

*sSearchTerm*

The string to search for in the source string.

## Return Value

Returns TRUE if *sSource* ends with *sSearchTerm*, otherwise returns FALSE.

## Example

```
STRING sTest = "MyPage_UHD4K";
INT bResult = StrEndsWith("MyPage_UHD4K", "_UHD4K");
```

[String Functions](#)

## StrFill

Fills a string with a number of occurrences of another string.

## Syntax

**StrFill(*String*, *Length*)**

*String*:

The string to be repeated.

*Length*:

The length of the string.

## Return Value

The filled string.

## Related Functions

[StrPad](#)

## Example

```
Variable=StrFill("abc",10);
! Sets Variable to "abcabca".
Variable=StrFill("x",10);
! Sets Variable to "xxxxxxxxxx".
```

## See Also

[String Functions](#)

[Using the Caret Escape Sequence Character](#)

## StrFormat

Converts a variable into a formatted string. This function is the equivalent of the Cicode " ##### " operator.

## Syntax

**StrFormat(*Variable*, *Width*, *DecPlaces*, *EngUnits*)**

*Variable*:

The variable to format into a string.

*Width*:

The width of the variable after it has been converted to string format.

*DecPlaces*:

The number of decimal places in the converted string.

*EngUnits*:

The engineering units of the variable.

## Return Value

The variable (as a formatted string).

## Related Functions

[StrToReal](#), [StrToInt](#), [RealToStr](#), [IntToStr](#)

## Example

```
Variable=StrFormat(10.345,5,2,"%");
! Sets Variable to "10.35%".
```

## See Also

[String Functions](#)

[Using the Caret Escape Sequence Character](#)

## StrGetChar

Gets a single character from a string or buffer. Use this function to read a string, character by character.

## Syntax

**StrGetChar**(*String*, *iOffset*)

*String*:

The source string. Must be a String type variable.

*iOffset*:

The offset in the string, commencing at 0.

## Return Value

The character at the offset in the string.

## Related Functions

[StrSetChar](#)

## Example

```
FOR i = 0 To length DO
char = StrGetChar(str, i);
! Get char from string
END
```

## See Also

[String Functions](#)

[Using the Caret Escape Sequence Character](#)

## StrLeft

Gets the left-most characters from a string.

## Syntax

**StrLeft(*String*, *N*)**

*String*:

The source string.

*N*:

The number of characters to get from the source string.

## Return Value

A string containing the left-most *N* characters of *String*.

## Related Functions

[StrRight](#), [StrMid](#), [StrLength](#)

## Example

```
Variable=StrLeft("ABCDEF",2);
! Sets Variable to "AB".
```

## See Also

[String Functions](#)

[Using the Caret Escape Sequence Character](#)

## StrLength

Gets the length of a string.

## Syntax

**StrLength(*String*)**

*String*:

The source string.

## Return Value

The length of the string (as an integer).

## Related Functions

[StrRight](#), [StrMid](#), [StrLeft](#)

## Example

```
Variable=StrLength("ABCDEF");
! Sets Variable to 6.
```

## See Also

[String Functions](#)

[Using the Caret Escape Sequence Character](#)

## StrListContainsItem

Checks whether the string passed is an item contained in a delimited list of strings. String comparison is case insensitive. Leading and trailing spaces are removed before comparing.

## Syntax

**StrListContainsItem**(STRING *sItem*, STRING *sList*, STRING *sDelim*)

*sItem*

Item that you wish to search for.

*sList*

List to search within.

*sDelim*

The string to use as a delimiter. If this is not specified, a comma (,) is used.

## Return Value

Returns TRUE if the item is found in the list, otherwise returns FALSE

## Related Functions

[StrEndsWith](#), [StrSplit](#), [StrTruncFontTooltip](#)

## See Also

[String Functions](#)

### StrLower

Converts a string to lowercase.

## Syntax

**StrLower(*String*)**

*String*:

The source string.

## Return Value

The string (as lowercase).

## Related Functions

[StrUpper](#)

## Example

```
Variable=StrLower("ABCDEF");
! Sets Variable to "abcdef".
Variable=StrLower("AbCdEf");
! Sets Variable to "abcdef".
```

## See Also

[String Functions](#)

[Using the Caret Escape Sequence Character](#)

### StrMid

Gets characters from the middle of a string.

## Syntax

**StrMid(*String, Offset, Characters*)**

*String*:

The source string.

*Offset*:

The offset in the string, commencing at 0.

*Characters:*

The number of characters to get, commencing at the offset.

## Return Value

A string containing the number of characters from the offset.

## Related Functions

[StrLeft](#), [StrLength](#), [StrRight](#)

## Example

```
Variable=StrMid("ABCDEF",1,3);
! Sets Variable to "BCD".
Variable=StrMid("ABCDEF",4,1);
! Sets Variable to "E".
```

## See Also

[String Functions](#)

[Using the Caret Escape Sequence Character](#)

## StrPad

Pads a string with a number of occurrences of another string. Padding can be added to the left or to the right of a string. If the string is already longer than the required string length, the string is truncated.

## Syntax

**StrPad**(*String*, *PadString*, *Length*)

*String:*

The source string.

*PadString:*

The padding string.

*Length:*

The length of the string. If a positive length is specified, padding will be added to the right of the string. If a negative length is specified, padding will be added to the left of the string.

## Return Value

A padded string.

## Related Functions

[StrFill](#)

## Example

```
Variable=StrPad("Test", " ",10);
! Sets Variable to "Test ".
Variable=StrPad("Test","abc",-14);
! Sets Variable to "abcabcaTest".
```

## See Also

[String Functions](#)

[Using the Caret Escape Sequence Character](#)

## StrReplace

Replaces a substring in a string with replacement substring.

## Syntax

**StrReplace(*sString*, *sFindSubstring* [, *sReplaceSubstring* [, *sTerminators*]])**

*sString*:

The source string.

*sFindSubstring*:

The substring to search for.

*sReplaceSubstring*:

The replacement substring. If this is not specified, it defaults to an empty string, that is, the matched substring will be removed from the original string.

*sTerminators*:

Optional set of characters to terminate the substring. If this is not specified, it defaults to an empty string. When it is specified, the substring is only considered a match if it is enclosed by one of the characters specified by this argument.

## Return Value

The replaced string.

## Example

```
// Replaces argument "abc" with 12. Use the sTerminators for higher precision
StrReplace("func(abcde, abc)", "abc", "12"); // func(12de, 12), incorrect
StrReplace("func(abcde, abc)", "abc", "12", " ,()") // func(abcde, 12), correct
```

## See Also

[String Functions](#)

[Using the Caret Escape Sequence Character](#)

## StrRight

Gets the rightmost characters from a string.

## Syntax

**StrRight(*String*, *N*)**

*String*:

The source string.

*N*:

The number of characters to get from the source string.

## Return Value

A string containing the rightmost *N* characters of *String*.

## Related Functions

[StrLeft](#), [StrMid](#), [StrLength](#)

## Example

```
Variable=StrRight("ABCDEF",2);  
! Sets Variable to "EF".
```

## See Also

[String Functions](#)

[Using the Caret Escape Sequence Character](#)

## StrSearch

Searches for a string within a string, commencing at a specified offset. The result of the search is the index in the source string, where the first character of the sub-string is found. Index 0 is the first character in the string, index 1 is the second, and so on.

## Syntax

**StrSearch(*Offset*, *String*, *Substring*)**

*Offset:*

The offset in the string, commencing at 0.

*String:*

The source string.

*Substring:*

The substring to search for.

## Return Value

The index in the search string, or -1 if the sub-string does not exist in the string.

## Related Functions

[StrLength](#)

## Example

```
Variable=StrSearch(1,"ABCDEF","CD");
! Sets Variable to 2.
Variable=StrSearch(4,"ABCDEF","CD");
! Sets Variable to -1.
Variable=StrSearch(5,"ABCDEF","F");
! Sets Variable to 5.
```

## See Also

[String Functions](#)

[Using the Caret Escape Sequence Character](#)

## StrSetChar

Sets a single character into a string or buffer. Use this function to build up a string, character by character, and terminate the string with the end-of-string character 0 (zero). (If you use a string without a terminator in a function that expects a string, or in a Cicode expression, you could get invalid results.) To use the string to build up a buffer, you do not need the terminating 0 (zero).

## Syntax

**StrSetChar**(*sText*, *iOffset*, *Char*)

*sText:*

The destination string. Must be a String type variable.

*iOffset:*

The offset in the string, commencing at 0.

*Char:*

The ASCII character to set into the string.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[StrGetChar](#)

## Example

```
! Set chars in buffer, Buf is NOT a valid string
! and cannot be used where a normal string would be used.
FOR i = 0 To length DO
    StrSetChar(Buf, i, 30 + i);
END
StrSetChar(sStr, 0, 13); ! put CR into string
StrSetChar(sStr, 1, 0); ! terminate so may be used as a normal string
```

## See Also

[String Functions](#)

[Using the Caret Escape Sequence Character](#)

## StrSplit

Splits a string into sub-strings based on the specified delimiter. Sub-strings are stored in a new array and a handle to this array is returned. The returned array contains the exact number of split strings. You can use the ArrayCount function to determine the number of strings into which the source was split.

consecutive delimiters are treated as a single delimiter. By default, leading and trailing white space is trimmed from sub-strings.

## Syntax

`StrSplit(STRING sSource, STRING sDelim, INT bNoTrim)`

*sSource*

The source string to split.

*sDelim*

The string to use as a delimiter. If not specified, a comma (,) is used.

*bNoTrim*

Optional flag to disable the trimming of white space from sub-strings. Trimming will occur by default.

## Return Value

Returns a handle to the array containing all sub-strings.

## Example

```
STRING sNames = "Phil, Michael, Bradley"
STRING sName;
INT aNames
INT iItem = 0;
aNames = StrSplit(sNames, ",");
WHILE (sName <> "") DO
sName = ArrayGetString(aNames, iItem);
iItem = iItem + 1;
END
ArrayDestroy(aNames);
```

## Related Functions

[StrEndsWith](#), [StrListContainsItem](#), [StrTruncFontTooltip](#)

## See Also

[String Functions](#)

## StrToInt

Converts a string value to an integer value.

## Syntax

**StrToInt(sVal)**

*sVal:*

Boolean value as a string. Allowable values are: TRUE, FALSE or any numeric value.

## Return Value

Boolean value of 0 or 1.

## Example

```
StrToInt("TRUE"); // returns 1 which is TRUE
StrToInt("false"); // returns 0 which is FALSE
StrToInt("5"); // returns 1
StrToInt("Orange"); // returns 0
StrToInt("0"); // returns 0
```

## See Also

[String Functions](#)

## StrToChar

Gets the ASCII code of the first character in a string.

## Syntax

**StrToChar(*String*)**

*String*:

The source string.

## Return Value

The ASCII code of the first character in *String*.

## Related Functions

[StrGetChar](#)

## Example

```
Variable=StrToChar("ABC");
! Sets Variable to 65 (ASCII "A").
```

## See Also

[String Functions](#)

[Using the Caret Escape Sequence Character](#)

## StrToDate

Converts a "date" string into a time/date variable. This variable is the same as returned from the TimeCurrent() function. To set the order of the day, month, and year, and the delimiter, use the Windows Control panel.

Time/date functions can only be used with dates from 1980 to 2035. You should check that the date you are using is valid with the following Cicode:

```
IF StrToDate(Arg1)>0 THEN
  ...
ELSE
  ...
END
```

## Syntax

**StrToDate(*String*)**

*String:*

The source string.

## Return Value

A time/date variable, or 274 if the time/date is out of range.

## Related Functions

[StrToPeriod](#), [StrToTime](#)

## Example

```
! Australian format (dd/mm/yy) is set in the Windows Control panel.  
DateVariable=DateAdd(StrToDate("3/11/95"),86400);  
NewDate= TimeToStr(DateVariable, 2);  
! Adds 24 hours to 3/11/95 and sets NewDate to "4/11/95".
```

## See Also

[String Functions](#)

[Using the Caret Escape Sequence Character](#)

## StrToFmt

Converts a string into field data for a format template. This function is useful for splitting a string into separate strings. After the string is converted, you can call the [FmtGetField\(\)](#) function to extract the individual data from the template fields.

## Syntax

**StrToFmt(*hFmt*, *String*)**

*hFmt:*

The format template handle, returned from the [FmtOpen\(\)](#) function. The handle identifies the table where all data on the associated format template is stored.

*String:*

The source string.

## Return Value

The string (formatted as template field data).

## Related Functions

[FmtOpen](#), [FmtGetField](#)

## Example

```
StrToFmt(hFmt, "CV101 Raw Coal Conveyor");
Name=FmtGetField(hFmt, "Name");
! Sets Name to "CV101".
```

## See Also

[String Functions](#)

[Using the Caret Escape Sequence Character](#)

## StrToGrp

Converts a string into a group and places it into a group number. Any existing values in the group are cleared before the new values are inserted. The group string is a series of numbers separated by " , " to list individual values or " .. " to specify a range of values.

## Syntax

**StrToGrp(*hGrp*, *Str*)**

*hGrp*:

The group handle, returned from the [GrpOpen\(\)](#) function. The group handle identifies the table where all data on the associated group is stored.

*Str*:

The string to convert.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[GrpOpen](#)

## Example

```
hGrp=GrpOpen("MyGrp",1);
! Set group to 1 ... 10 and 20, 30 and 40.
StrToGrp(hGrp,"1..10,20,30,40");
```

## See Also

[String Functions](#)

[Using the Caret Escape Sequence Character](#)

## StrToHex

Converts a hexadecimal string into an integer. This function will search the string for the first non-blank character, and then start converting until it finds the end of the string or a non-hexadecimal numeric character. If the first non-blank character is not one of the following hexadecimal characters, the return value is 0 (zero):

- **(0-9, a-f, A-F);**
- **A space;**
- A "+" (plus) or a "-" (minus) sign.

## Syntax

**StrToHex(*String*)**

*String*:

The string to convert.

## Return Value

An integer (converted from *String*).

## Related Functions

[StrToReal](#), [StrToValue](#), [HexToStr](#)

## Example

```
Variable=StrToHex("123");
! Sets Variable to hex 123, decimal 291
Variable=StrToHex("F2");
! Sets Variable to hex F2, decimal 242
Variable=StrToHex("G45");
! Sets Variable to 0.
Variable=StrToHex("-FG");
! Sets Variable to hex, -F decimal -15.
```

## See Also

[String Functions](#)

[Using the Caret Escape Sequence Character](#)

## StrToInt

Converts a string into an integer. This function will search the string for the first non-blank character, and then start converting until it finds the end of the string or a non-numeric character. If the first non-blank character is not a numeric character (0-9), a space, a " + " or a " - " sign, the return value is 0 (zero).

## Syntax

**StrToInt(*String*)**

*String*:

The string to convert.

## Return Value

An integer (converted from *String*).

## Related Functions

[StrToReal](#), [StrToValue](#)

## Example

```
Variable=StrToInt("45");
! Sets Variable to 45.
Variable=StrToInt("45.23");
! Sets Variable to 45.
Variable=StrToInt("A45");
! Sets Variable to 0.
```

## See Also

[String Functions](#)

[Using the Caret Escape Sequence Character](#)

[Converting and Formatting Cicode Variables](#)

## StrToLines

Converts a string into separate lines that contain no more than the number of characters specified in the *MaxChars* argument.

The function splits the string by inserting newline characters into the text string, thus dividing it into separate lines. The string will be split at a whitespace character if possible, and that whitespace will be replaced by the newline character. If no whitespace characters are available then the insertion will be made at the maximum number of characters from the previous line break.

## Syntax

**StrToLines(*String*, *MaxChars*, *nLines*)**

*String*:

The string to convert.

*MaxChars*:

The maximum number of characters permitted in each new line produced by the StrToLines() function.

*nLines*:

Output Parameter: Returns the number of lines produced by the StrToLines() function from the input string. This should be a Cicode INT type variable.

## Return Value

A string containing the input string with new line characters inserted into it.

## Example

```
BrokenString=StrToLines("Was that a real Stegosaur?", 5, nLines);
!The function returns the value 6 in nLines, and Broken String now contains:
Was
that
a
real
Stego
saur?
BrokenString=StrToLines("It breaks the string by inserting newline characters into
the text.", 16, nLines);
!The function returns the value 6 in nLines, and Broken String now contains:
It breaks the
string by
inserting
newline
characters into
the text.
```

## See Also

[String Functions](#)

[Using the Caret Escape Sequence Character](#)

## StrToLocalText

Converts a native string into the local version of that string. (The string needs to be contained within quotation marks, as shown in the example below.) The local version is taken from the current language database(as specified using the [Language]LocalLanguage parameter).

**StrToLocalText(*sText*)**

*sText*:

The string for which you would like the local translation returned. This string needs to be enclosed in quotation marks. For example:

```
"@(Motor Overload)"
```

## Return Value

The local version of the text if it was found, otherwise the native text or "#MESS" is returned, depending on the setting of the [\[Language\]DisplayError](#) parameter.

## Related Functions

[LanguageFileTranslate](#)

## Example

```
StrToLocalText("@(Motor Overload)");
! Returns the Local translation of Motor Overload.
```

## See Also

[String Functions](#)

[Using the Caret Escape Sequence Character](#)

## StrToPeriod

Converts a string into a time period. You would normally use this function to convert operator input, for example, to set a trend period.

A valid period string is in the format HH:MM:SS, MM:SS or SS, where HH is the hours, MM is the minutes and SS is the seconds. The colon character (':') represents the time delimiter for these fields, which will be the current system time delimiter as set in the Windows Control Panel.

If minutes are specified, seconds need to be in the range 0-59. If hours are specified, minutes need to be in the range 0-59.

## Syntax

**StrToPeriod(*String*)**

*String*:

The string to convert.

## Return Value

A period (converted from *String*), or -1 if no conversion can be performed.

## Related Functions

[StrToTime](#), [StrToDate](#)

## Example

```
Variable=StrToPeriod("200");
! Sets Variable to 200 (seconds).
Variable=StrToPeriod("200:40");
! Sets Variable to 12040 (12000 + 40 seconds).
Variable=StrToPeriod("48:00:40");
! Sets Variable to 172840 (172800 + 40 seconds).
```

## See Also

[String Functions](#)

[Using the Caret Escape Sequence Character](#)

## StrToInt

Converts a string into a floating-point number. This function will search the string for the first non-blank character, and then start converting until it finds the end of the string or a non-numeric character. If the first non-blank character is not a numeric character (0-9), a space, a decimal point, a "+" or a "-" sign, the return value is 0 (zero).

## Syntax

**StrToInt(*String*)**

*String*:

The string to convert.

## Return Value

A floating-point number (converted from *String*).

## Related Functions

[StrToInt](#), [StrToValue](#)

## Example

```
Variable=StrToInt("45");
! Sets Variable to 45.
Variable=StrToInt("45.23");
! Sets Variable to 45.23
Variable=StrToInt("A45");
```

```
! Sets Variable to 0.
```

## See Also

[String Functions](#)

[Using the Caret Escape Sequence Character](#)

[Converting and Formatting Cicode Variables](#)

## StrToTime

Converts a "time" string into a time/date variable. The value returned is the number of seconds from midnight. You can add this value to the date to get the current time value. To set the time delimiter, use the Windows Control Panel.

A valid time string is in the format HH:MM:SS or HH:MM:SS tt, where HH is the hour in the range 0-23, MM is the minute in the range 0-59, SS is the second in the range 0-59 and tt is the time extension; for example,, am or pm. The colon character ':' represents the time delimiter for these fields, which will be the current system time delimiter as set in the Windows control panel.

Times may also be passed in the for HH or HH:MM. In other words, you may omit the right-hand fields if they are 0.

---

**Note:** When you call the StrToTime function, it does not have any context of the day or date. This means it does not take into account daylight savings transitions. To accommodate days where a daylight savings time transition occurs, you need to use alternative Cicode functions that accept both date and time as arguments (such as [StrToTimestamp](#) or [TimestampToTimeInt](#)).

---

## Syntax

**StrToTime(String)**

*String:*

The string to convert.

## Return Value

A time/date variable, or -1 if no conversion can be performed.

## Related Functions

[Time, Date](#)

## Example

```
Variable=StrToTime("11:43:00");
! Sets Variable to (11*3600+43*60+0) seconds.
Variable=StrToTime("9:02");
! Sets Variable to (9*3600+2*60) seconds.
Variable=StrToTime("2");
```

```
! Sets Variable to (2*3600) seconds.
```

## See Also

[String Functions](#)

[Using the Caret Escape Sequence Character](#)

## StrToValue

Converts a string into a floating-point number. This function is similar to the [StrToReal\(\)](#) function except that the function halts if it is passed an invalid string. The function will search the string for the first non-blank character, and then start converting until it finds the end of the string or a non-numeric character. If the first non-blank character is not a numeric character (0-9), a space, a decimal point, a "+" or a "-" sign, the function will halt.

Use this function to check keyboard input from the operator by setting control points (for example, it minimizes the likelihood of a setpoint being set to 0 if the operator presses ENTER or enters invalid data by mistake).

## Syntax

**StrToValue(*String*)**

*String*:

The string to convert.

## Return Value

A floating-point number (converted from *String*).

## Related Functions

[StrToReal](#), [StrToInt](#)

## Example

System Keyboard

Key Sequence	F3 ##### Enter
Command	SP123 = StrToValue(Arg1);
Comment	Set setpoint 123 to value unless value is invalid

**Note:** If value is invalid the Cicode is halted. Any other Cicode after the StrToValue() function will not execute.

## See Also

[String Functions](#)

[Using the Caret Escape Sequence Character](#)

## StrTrim

Removes leading and trailing spaces from a string. Internal spaces are not removed from the string.

## Syntax

**StrTrim(*String*)**

*String*:

The source string.

## Return Value

*String* with leading and trailing spaces removed.

## Related Functions

[StrPad](#), [StrFill](#)

## Example

```
Variable=StrTrim(" Test String ");
! Sets Variable to "Test String".
```

## See Also

[String Functions](#)

## StrTruncFont

Returns the truncated string using a particular font (specified by name) or the specified number of characters.

## Syntax

**StrTruncFont(*sText*, *sFont* [, *iLength*] [, *iLengthMode*])**

*sText*:

The text to truncate

*sFont*:

The name of the font that is used to display the text. The Font Name needs to be defined in the Fonts database. If the font is not found, the default font is used.

*iLength*:

Length of the Text to display, either in characters or pixels depending on *iLengthMode* (default -1, no truncation)

*iLengthMode*:

The length mode of the text string:

- 0 - Length as pixels truncated (default)
- 1 - Length as pixels truncated with ellipsis
- 2 - Length interpreted as characters.

## Return Value

A truncated string or the original one.

## Related Functions

[StrCalcWidth](#), [StrTruncFontHnd](#)

## See Also

[String Functions](#)

[Using the Caret Escape Sequence Character](#)

## StrTruncFontHnd

Returns the truncated string using a particular font (specified by font number) or the specified number of characters.

## Syntax

**StrTruncFontHnd**(*sText*, *hFont* [, *iLength*] [, *iLengthMode*])

*sText*:

The text to truncate

*hFont*:

The font handle used to calculate the pixel width of the text. (To use the default font, set to -1).

*iLength*:

Length of the Text to display, either in characters or pixels depending on *iLengthMode* (default -1, no truncation)

*iLengthMode*:

The length mode of the text string:

- 0 - Length as pixels truncated (default)
- 1 - Length as pixels truncated with ellipsis
- 2 - Length interpreted as characters.

## Return Value

A truncated string or the original one.

## Related Functions

[StrCalcWidth](#), [StrTruncFont](#), [DspFont](#), [DspFontHnd](#)

## See Also

[String Functions](#)

## StrTruncFontTooltip

Returns a truncated string with ellipsis, and sets an AN with a tooltip containing the complete string if a truncation occurs.

## Syntax

**StrTruncFontTooltip(INT *nANForTooltip*, STRING *sText*, STRING *sFont*, INT *nPixels*)**

*nANForTooltip*

The AN for which the tooltip needs to be set.

*sText*

The text to truncate.

*sFont*

The name of the font that is used to display the text. The font name needs to be defined in the Fonts database. If the font is not found, the default font is used.

*nPixels*

Number of pixels that the text can display before truncation occurs.

## Return Value

Returns the truncated string.

## Example

```
StrTruncFontTooltip(10, "My really, really, really long string", "SA_ButtonFont", 50)
```

## Related Functions

## StrUpper

Converts a string to uppercase.

## Syntax

**StrUpper(*String*)**

*String*:

The source string.

## Return Value

The string (as uppercase).

## Related Functions

[StrLower](#)

## Example

```
Variable=StrUpper("abcdef");
! Sets Variable to "ABCDEF".
Variable=StrUpper("AbCdEf");
! Sets Variable to "ABCDEF".
```

## See Also

[String Functions](#)

[Using the Caret Escape Sequence Character](#)

## StrWord

Gets the first word from a string. The word is removed from the string to allow the function to be repeated. Word separators can be a space, newline, carriage return, or tab character.

## Syntax

**StrWord(*String*)**

*String*:

The source string.

## Return Value

A string containing the first word from *String*.

## Related Functions

[StrSearch](#)

## Example

```
Str="THIS IS A STRING";
Variable=StrWord(Str);
! Sets Variable to "THIS".
Variable=StrWord(Str);
! Sets Variable to "IS".
Variable=StrWord(Str);
! Sets Variable to "A".
Variable=StrWord(Str);
! Sets Variable to "STRING".

## Super Genie Functions

The Super Genie functions allow you to use Super Genies in your runtime system.

Following are functions relating to Super Genies:

<a href="#">Ass</a>	Associates a variable tag with a Super Genie.
<a href="#">AssChain</a>	Chains the associations from the current Super Genie to a new Super Genie.
<a href="#">AssChainPage</a>	Chains the associations from the current Super Genie to a new Super Genie, and displays the new Super Genie (in the current window).
<a href="#">AssChainPopUp</a>	Chains the associations from the current Super Genie to a new Super Genie, and displays the new Super Genie in a new popup window.
<a href="#">AssChainWin</a>	Chains the associations from the current Super Genie to a new Super Genie, and displays the new Super Genie in a new window. The new window will be of the same type as the current window.
<a href="#">AssChainWinFree</a>	Stores the tag associations on an existing Super Genie, closes it, then assigns the tags to a new window.
<a href="#">AssEquipParameters</a>	Associates a set of equipment parameters defined in Plant SCADA Studio's System Model   Equipment

	Runtime Parameters with a page.
AssEquipReferences	Creates Super Genie associations for each piece of equipment referenced by the specified equipment.
AssGetProperty	Gets association information about the current Super Genie from the datasource
AssGetScale	Gets scale information about the associations of the current Super Genie from the datasource
AssInfo	Gets association information about the current Super Genie (that is information about a variable tag that has been substituted into the Super Genie).
AssInfoEx	Gets association information about the current Super Genie (that is information about a variable tag that has been substituted into the Super Genie). Replacement for AssInfo supporting online changes.
AssMetadata	Performs Super Genie associations using the "Name" and "Value" fields.
AssMetadataPage	Uses the metadata information from the current animation point for the page associations for a new Super Genie page, and displays the new Super Genie in the current page.
AssMetadataPopUp	Uses the metadata information from the current animation point for the associations for a new Super Genie page, and displays the new Super Genie in a new pop up window.
AssMetadataWin	Uses the metadata information from the current animation point for the associations for a new Super Genie page, and displays the new Super Genie in a new window.
AssPage	Associates up to eight variable tags with a Super Genie and displays the Super Genie in the current window.
AssPopUp	Associates up to eight variable tags with a Super Genie and displays the Super Genie in a popup window.
AssScaleStr	Gets scale information about the associations of the current Super Genie (that is scale information about a variable tag that has been substituted into the Super Genie).
AssTag	Associates a variable tag with the current Super Genie. The association will be created for the current Super

	Genie only, and will only come into effect after you re-display the Super Genie.
<a href="#">AssTitle</a>	Sets the runtime window title to the tag name of the first variable substituted into the Super Genie.
<a href="#">AssVarTags</a>	Associates up to eight variable tags with a Super Genie. This association is only made for the next Super Genie you display (either in the current window or in a new window). You can use this function repeatedly to associate more than 8 variable tags to a Super Genie.
<a href="#">AssWin</a>	Associates up to eight variable tags with a Super Genie, and displays the Super Genie in a new window.
<a href="#">AssWinReplace</a>	This function removes the associations on a specified Super Genie window and applies any pending associations.

[Cicode Function Categories](#)

[Using Cicode Functions](#)

## Ass

Associates a variable tag or equipment with a Super Genie. This association is only made for the next Super Genie you display (either in the current window or in a new window). You cannot create an association for a Super Genie that is already displayed. You need to call this function once for every Super Genie substitution string in the Super Genie, otherwise the variable (substitution string) will remain uninitialized and it will be displayed as #ASC.

---

**Note:** If you need to replace an association for a Super Genie that is already displayed, you can use the function [AssWinReplace](#).

This function provides the lowest level of support for associating Super Genie variables with physical tags. The higher level functions (listed below) are simpler to use.

## Syntax

**Ass(*hWin*, *nArg*, *sTag*, *nMode* [, *sClusterName*] )**

*hWin*:

The association will be created for the next Super Genie to display in the window specified here; enter the window number or:

- -3 - for the current window when the page is changed. The page can be changed by using Page Cicode functions like PageDisplay, PageGoto, etc.
- -2 - for the next new window or page displayed.

**nArg:**

The argument number or name (substitution string number or name) of the Super Genie string to be replaced by sTag. For example, to replace ?INT 3? with sTag, set nArg to 3 ,or ?Level? set nArg to Level.

**sTag:**

Variable tag, or equipment and item name reference of a variable tag (using equipment.item notation) that will replace the Super Genie association. Partial tag names or equipment.item tag references can also be used.

The name of the tag can be prefixed by the name of the cluster for example, "*ClusterName.Tag*" or "*ClusterName.Equipment.Item*".

---

**Note:** If the tag name exceeds the length limit of 254 characters the hardware alarm "Tag name exceed length limit" will be raised.

---

**nMode:**

The mode of the association. Set to 0.

**sClusterName:**

Specifies the name of the cluster in which the Variable Tag resides. This is optional if you have one cluster or are resolving the tag via the page's current cluster context. The argument is enclosed in quotation marks "".

Resolution of the tag's cluster context occurs when the page is displayed. It is resolved to the page's cluster context, not the context in force when this function is called.

## Return Value

0 (zero) if successful, otherwise an error code is returned. When using partial associations, an error 274 or 289 may be returned even though the association is successful, and can be ignored.

## Related Functions

[AssChain](#), [AssMetadata](#), [AssMetadataPage](#), [AssMetadataPopUp](#), [AssMetadataWin](#), [AssChainPage](#),  
[AssChainPopUp](#), [AssChainWin](#), [AssChainWinFree](#), [AssGetProperty](#), [AssGetScale](#), [AssInfo](#), [AssInfoEx](#), [AssPage](#),  
[AssPopUp](#), [AssScaleStr](#), [AssTag](#), [AssTitle](#), [AssVarTags](#), [AssWin](#)

## Example

```
//Using a string identifier for the substitution parameter
    Ass(-2,"Level", "MI1K_LEVEL",0);
// Associate variable tag PV123 with the next Genie to display in the current window
Ass(-3, 5, "PV123", 0);
```

## See Also

[Super Genie Functions](#)

## AssChain

Chains the associations from the current Super Genie to a new Super Genie. Use this function to display a new Super Genie when you already have one displayed. The new Super Genie will inherit the associations of the first Super Genie.

This function provides the lowest level of support for chaining associations from one Super Genie to another. You should call the higher level functions [AssChainPage\(\)](#), [AssChainWin\(\)](#), and [AssChainPopUp\(\)](#) - these functions are simpler to use.

## Syntax

**AssChain(*hDest*, *hSource*, *nMode*)**

*hDest*:

The next Super Genie to display in the window specified here will inherit the associations of the current Super Genie - enter the window number, or:

- -3: for the current window when the page is changed. The page can be changed by using the Page Cicode functions like PageDisplay, PageGoto, etc.
- 2: for the next new window or page displayed.

*hSource*:

The number of the window containing the source Super Genie (that is the Super Genie from which the associations will be inherited).

*nMode*:

The mode of the association. Set to 0.

## Return Value

Returns the number of associations copied.

## Related Functions

[Ass](#), [AssMetadata](#), [AssMetadataPage](#), [AssMetadataPopUp](#), [AssMetadataWin](#), [AssChainPage](#), [AssChainPopUp](#), [AssChainWin](#), [AssChainWinFree](#), [AssGetProperty](#), [AssGetScale](#), [AssInfo](#), [AssInfoEx](#), [AssPage](#), [AssPopUp](#), [AssScaleStr](#), [AssTag](#), [AssTitle](#), [AssVarTags](#), [AssWin](#)

## Example

```
// Copy associations from the current Super Genie to !NewGenie
AssChain(WinNumber(), WinNumber(), 0);
PageDisplay("!NewGenie");
```

## See Also

[Super Genie Functions](#)

## AssChainPage

Chains the associations from the current Super Genie to a new Super Genie, and displays the new Super Genie (in the current window). Use this function to display a new Super Genie when you already have one displayed. The new Super Genie will inherit the associations of the first Super Genie.

## Syntax

**AssChainPage(*sPage*)**

*sPage*:

The page name of the Super Genie. If you prefixed your Super Genie page name with an exclamation mark (!), remember to include it here.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[Ass](#), [AssChain](#), [AssMetadata](#), [AssMetadataPage](#), [AssMetadataPopUp](#), [AssMetadataWin](#), [AssChainPopUp](#), [AssChainWin](#), [AssChainWinFree](#), [AssGetProperty](#), [AssGetScale](#), [AssInfo](#), [AssInfoEx](#), [AssPage](#), [AssPopUp](#), [AssScaleStr](#), [AssTag](#), [AssTitle](#), [AssVarTags](#), [AssWin](#)

## Example

```
// Display new Super Genie in current window, using current associations
AssChainPage("!NewGenie");
```

## See Also

[Super Genie Functions](#)

## AssChainPopUp

Chains the associations from the current Super Genie to a new Super Genie, and displays the new Super Genie in a new popup window. Use this function to display a new Super Genie in a new popup window when a Super Genie is already displayed. The new Super Genie will inherit the associations of the first.

**Note:** This function helps to prevent the Super Genie from being opened more than once (at the same time). However, the same Super Genie with different associations can be opened.

## Syntax

**AssChainPopUp(*sPage*)**

*sPage*

The page name of the Super Genie. If you prefixed your Super Genie page name with an exclamation mark (!), remember to include it here.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[Ass](#), [AssChain](#), [AssMetadata](#), [AssMetadataPage](#), [AssMetadataPopUp](#), [AssMetadataWin](#), [AssChainPage](#), [AssChainWin](#), [AssChainWinFree](#), [AssGetProperty](#), [AssGetScale](#), [AssInfo](#), [AssInfoEx](#), [AssPage](#), [AssPopUp](#), [AssScaleStr](#), [AssTag](#), [AssTitle](#), [AssVarTags](#), [AssWin](#)

## Example

```
// Display new Super Genie in new popup using current associations
AssChainPopUp("!NewGenie");
```

## See Also

[Super Genie Functions](#)

## AssChainWin

Chains the associations from the current Super Genie to a new Super Genie, and displays the new Super Genie in a new window. The new window will be of the same type as the current window. Use this function to display a new Super Genie in a new window when a Super Genie is already displayed. The new Super Genie will inherit the associations of the first.

## Syntax

**AssChainWin(*sPage*, *X*, *Y*, *Mode*)**

*sPage*:

The page name of the Super Genie. If you prefixed your Super Genie page name with an exclamation mark (!), remember to include it here.

*X*:

The x pixel coordinate of the top left corner of the window.

*Y*:

The y pixel coordinate of the top left corner of the window.

*Mode*:

The mode of the window:

0 - Normal page.

1 - Page child window. The window is closed when a new page is displayed, for example, when the PageDisplay() or PageGoto() function is called. The parent is the current active window.

2 - Window child window. The window is closed automatically when the parent window is freed with the WinFree() function. The parent is the current active window.

4 - No re-size. The window is displayed with thin borders and no maximize/minimize icons. The window cannot be re-sized.

8 - No icons. The window is displayed with thin borders and no maximize/minimize or system menu icons. The window cannot be re-sized.

16 - No caption. The window is displayed with thin borders, no caption, and no maximize/minimize or system menu icons. The window cannot be re-sized.

32 - Echo enabled. When enabled, keyboard echo, prompts, and error messages are displayed on the parent window. This mode should only be used with child windows (for example, Mode 1 and 2).

64 - Always on top.

128 - Open a unique window. This mode helps to prevent this window from being opened more than once.

256 - Display the entire window. This mode helps to ensure that no parts of the window will appear off the screen

512 - Open a unique Super Genie. This mode helps to prevent a Super Genie from being opened more than once (at the same time). However, the same Super Genie with different associations can be opened.

1024 - Disables dynamic resizing of the new window, overriding the setting of the [Page]DynamicSizing parameter.

You can select multiple modes by adding modes together (for example, set *Mode* to 9 to open a page child window without maximize, minimize, or system menu icons).

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[Ass](#), [AssChain](#), [AssMetadata](#), [AssMetadataPage](#), [AssMetadataPopUp](#), [AssMetadataWin](#), [AssChainPage](#), [AssChainPopUp](#), [AssChainWinFree](#), [AssGetProperty](#), [AssGetScale](#), [AssInfo](#), [AssInfoEx](#), [AssPage](#), [AssPopUp](#), [AssScaleStr](#), [AssTag](#), [AssTitle](#), [AssVarTags](#), [AssWin](#)

## Example

```
// Displays a new super genie in a new window using the current associations
AssChainWin("!NewGenie", 100, 200, 1 + 8);
```

## See Also

[Super Genie Functions](#)

## AssChainWinFree

Stores the associations on an existing Super Genie, closes it, then assigns the tags to a new window. This allows a Super Genie popup window to call another popup window, and close the parent popup.

This function is effectively the same as the AssChainWin() function, but frees the current Super Genie.

## Syntax

**AssChainWinFree(*sPage*, *X*, *Y*, *Mode*)**

*sPage*:

The page name of the Super Genie. If you prefixed your Super Genie page name with an exclamation mark (!), remember to include it here.

X:

The x pixel coordinate of the top left corner of the window.

Y:

The y pixel coordinate of the top left corner of the window.

*Mode*:

The mode of the window:

0 - Normal page.

1 - Page child window. The window is closed when a new page is displayed, for example, when the PageDisplay() or PageGoto() function is called. The parent is the current active window.

2 - Window child window. The window is closed automatically when the parent window is freed with the WinFree() function. The parent is the current active window.

4 - No re-size. The window is displayed with thin borders and no maximize/minimize icons. The window cannot be re-sized.

8 - No icons. The window is displayed with thin borders and no maximize/minimize or system menu icons. The window cannot be re-sized.

16 - No caption. The window is displayed with thin borders, no caption, and no maximize/minimize or system menu icons. The window cannot be re-sized.

32 - Echo enabled. When enabled, keyboard echo, prompts, and error messages are displayed on the parent window. This mode should only be used with child windows (for example, Mode 1 and 2).

64 - Always on top.

128 - Open a unique window. This mode helps to prevent this window from being opened more than once.

256 - Display the entire window. This mode helps to ensure that no parts of the window will appear off the screen

512 - Open a unique Super Genie. This mode helps to prevent a Super Genie from being opened more than once (at the same time). However, the same Super Genie with different associations can be opened.

1024 - Disables dynamic resizing of the new window, overriding the setting of the [Page]DynamicSizing parameter.

You can select multiple modes by adding modes together (for example, set *Mode* to 9 to open a page child window without maximize, minimize, or system menu icons).

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

## Example

```
// Close the current genie window and display a new genie using the current associations  
AssChainWinFree("!GeniePopup", 200, 300, 1 + 8);
```

## See Also

[Super Genie Functions](#)

### AssEquipParameters

Associates a set of equipment parameters defined in Plant SCADA Studio **System Model | Equipment | Runtime Parameters** with a page. This association is only made for the next page you display (either in the current window or in a new window). You cannot create an association for a page that is already displayed.

## Syntax

**AssEquipParameters(*hWin*, *sClusterName*, *sEquipmentName* )**

*hWin*:

The association will be created for the next page to display in the window specified here; enter the window number or:

- -3 for the current window when the page is changed. The page can be changed by using the Page Cicode functions like PageDisplay, PageGoto, etc.
- -2 for the next new window or page displayed.

*sClusterName*:

Specifies the name of the cluster in which the equipment resides. The cluster name is optional if you have one cluster or are resolving the tag via the page's current cluster context. The argument is enclosed in quotation marks "".

Resolution of the tag's cluster context occurs when the page is displayed. It is resolved to the page's cluster context, not the context in force when this function is called.

The value field of the Equipment Runtime Parameters table can work like a tag reference when the Is Tag column is set to true or default.

It can contain Variable tag, or equipment and item name reference of a variable tag (using equipment.item notation) that will replace the Super Genie association. Partial tag names or equipment.item tag references can also be used.

The name of the tag can be prefixed by the name of the cluster for example, "*ClusterName.Tag*" or "*ClusterName.Equipment.Item*".

## Return Value

0 (zero) if successful, otherwise an error code is returned. When using partial associations, an error 274 or 289 may be returned even though the association is successful, and can be ignored.

## Related Functions

## Example

```
// Associate equipment runtime parameters for equipment on Cluster1 called Pump1 with the
next window
AssEquipParameters(-2, "Cluster1", "Pump1");
```

## See Also

[Super Genie Functions](#)

## AssEquipReferences

Creates Super Genie associations for each piece of equipment referenced by the specified equipment.

## Syntax

**AssEquipReferences** (INT *hwin*, STRING *sClusterAndEquipment*, STRING *sCategory*)

*hWin*:

The association will be created for the next Super Genie to display in the window specified here; enter the window number or:

- -3 - for the current window when the page is changed. The page can be changed by using Page Cicode functions like PageDisplay and PageGoto.
- -2 - for the next new window or page displayed.

*sClusterAndEquipment*

The cluster and prefixed equipment name

*sCategory*

The category of reference to create associations for.

If no association name exists then the equipment reference will be skipped.

## Example

```
AssEquipReferences(-3, "Cluster1.Pump1", "MyCategory");
```

This example creates associations on the next page displayed in current window (-3 = same as other Ass Cicode functions) for references from "Pump1" on "Cluster1" with the category "MyCategory".

## See Also

[Super Genie Functions](#)

### AssGetProperty

This function gets association information about the current Super Genie from the data source (that is, information about a variable tag that has been substituted into the Super Genie). You can only call this function on a Super Genie after the associations are completed.

Use this function to display association information as part of the Super Genie. For example, if you have a Super Genie that is a loop controller, you could display the name of the loop at the top of the loop controller box. Each time the Super Genie is used with different associations (specifically a different tag name association) the correct loop name will be displayed.

If a constant value is associated, then only the constant value can be retrieved through the *TagName* property. The remaining properties are not valid.

This function replaces [AssInfo](#).

## Syntax

**AssGetProperty**(*sArg*, *sProperty* [, *iCachedMode*] )

*sArg*:

The argument number or name (integer or string) of the association from which to get information.

When you associate a partial variable tag name (or partial equipment.item to reference variable tag) a prefix or suffix needs be added to the association to form a valid tag reference. The Argument *sArg* needs to be parsed as a string when partial tag names are used for the association, such as "[a]?1?[b]".

For example, where the substitution is a valid equipment reference and ?INT 1?.HourRun is a valid 'equipment.item' reference to a tag, set *sArg* to:

"?INT 1?.HourRun"

*sProperty*:

The property to read. Property names are case sensitive. Supported properties are:

Address - The configured address of the referenced tag (as specified in the Variable Tags properties).

ArraySize - Array size of the referenced tag. Returns 1 for non-array types.

AssFullName - Full name of the referenced tag in the form cluster.tagname even if the tag is not resolved.

ClusterName - Name of the cluster the referenced tag resides on.

DataBitWidth - Number of bits used to store the value.

Description - Description of the referenced tag.

EngUnitsHigh - Maximum scaled value.

EngUnitsLow - Minimum scaled value.

Equipment - Name of the equipment.

Format - Format bit string. The format information is stored in the integer as follows:

- Bits 0-7 - format width
- Bits 8-15 - number of decimal places
- Bits 16 - zero-padded
- Bit 17 - left-justified
- Bit 18 - display engineering units
- Bit 20 - exponential (scientific) notation.

ErrorValUsed - Returns 1 if the defined error value was used for the SuperGenie association. This means that tag name is invalid/unresolved or the substitutions are not complete. This is only relevant for named Super Genies. Returns zero (0) if the association string provided a value, or a default value was not defined.

FormatDecPlaces - Number of decimal places for default format.

FormatWidth - Number of characters used in default format.

FullName - Full name of the referenced tag in the form cluster.tagname If the referenced tag is not resolved, returns an empty string.

Item - Name of the equipment item associated with the Tag. If the tag is not resolved, returns an empty string.

Literal - Returns 1 if the substitution is a literal value, returns 0 if the substitution is a tag name.

RangeHigh - Maximum unscaled value.

RangeLow - Minimum unscaled value.

TagName - Name of the tag for the specified association. Will retrieve the tag name regardless if you used equipment.item to reference the tag.

Type - General type of associated tag. Allowed values are:

- 0 - Digital
- 1 - Byte
- 2 - Integer16
- 3 - UInteger16
- 4 - Long
- 5 - Real
- 6 - String
- 7 - ULong
- 8 - Undefined

Units - Engineering Units for example, %, mm, Volts.

Custom1 ... Custom8 - User-defined strings.

*iCachedMode*:

Optional parameter that specifies from where to retrieve the value for the property.

- -1 - The mode is determined by the INI parameter [\[Client\]TagReadCachedMode](#).
- 0 - The property value is retrieved direct from the server in blocking mode and an error code is returned if it is not on the server (or the server is unavailable).
- 1 - The property value is retrieved from the cache and an error code is returned if the cache is not loaded yet.
- 2 - The property value is retrieved from the local configuration and an error code is returned if it is not available (this is the traditional behavior).

- 3 - The property value is retrieved from the cache, if the cache is loaded, and from the local configuration, if the cache is not loaded yet.

Default value is -1.

**Note:** When retrieving bit width ("DataBitWidth" property) or array size ("ArraySize" property) from the local configuration (iCachedMode 2), the value is related to the data structure in the device. For example, MODNET, is a 16 bit device and does not have native LONG and REAL numbers. So when you have a LONG variable, an array of 2 INTEGERS are needed to store it. In the example, the property "DataBitWidth" against the variable will return 16 and property "ArraySize" will return 2. The combination of these two return values will add up to the correct bits.

## Return Value

String representation of the property of the referenced tag. On detection of an error, an empty string and an error are set.

## Related Functions

[Ass](#), [AssChain](#), [AssMetadata](#), [AssMetadataPage](#), [AssMetadataPopUp](#), [AssMetadataWin](#), [AssChainPage](#), [AssChainPopUp](#), [AssChainWin](#), [AssChainWinFree](#), [AssGetScale](#), [AssInfo](#), [AssInfoEx](#), [AssPage](#), [AssPopUp](#), [AssScaleStr](#), [AssTag](#), [AssTitle](#), [AssVarTags](#), [AssWin](#), [TagGetProperty](#), [TagGetScale](#), [TagScaleStr](#), [TagInfo](#)

## Example

```
//Using a string identifier for the substitution parameter
AssGetProperty("MILK_LEVEL", "TagName", 0);
// Get the engineering full scale value for the 2nd
// argument of the association of the current Super Genie
EngFullScale = AssGetProperty(2, "EngUnitsHigh", 0);
// Get the cached engineering units for the 3rd argument
// of the association of the current Super Genie
MeasureUnits = AssGetProperty(3, "Units", 1);
```

## See Also

[Super Genie Functions](#)

## AssGetScale

Gets scale information about the tag references for the current Super Genie from the datasource (that is scale information about a variable tag that has been substituted into the Super Genie). You can only call this function on a Super Genie after the associations are completed.

Use this function to display association scale information as part of the Super Genie. For example, if you have a bar graph illustrating output, you could indicate zero, 50%, and full scale output on the vertical axis of the graph. Each time the Super Genie is used with different associations the correct scale values will be displayed.

The value is returned as a formatted string using the association format specification and (optionally) the engineering units.

This function replaces [AssScaleStr](#).

## Syntax

**AssGetScale(sArg, iPercent, iEngUnits [, iCached] )**

*sArg:*

The argument number or name of the association from which to get information.

When you associate a partial variable tag name (or partial equipment.item to reference variable tag) a prefix or suffix needs be added to the association to form a valid tag reference. The Argument sArg needs to be parsed as a string when partial tag names are used for the association ie "[a]?1?[b]".

For example, where the substitution is a valid equipment reference and ?INT 1?.HourRun is a valid equipment.item reference to a tag.

```
set sArg to "?INT 1?.HourRun"
```

*iPercent:*

The percentage of full scale of the returned value.

*iEngUnits:*

Flag to determine if the value is returned with engineering units:

0 - Return the value without engineering units

1 - Return the value with engineering units

*iCached:*

Optional flag to attempt to retrieve the cached value for the property rather than the current value. This makes the function non-blocking. If the property has not yet been cached, an error is set.

0 - Do not force cached read. Cicode is blocking

1 - Force cached read. Cicode is non-blocking

Default value is 1 (true).

## Return Value

The scale of the referenced tag (as a string).

## Related Functions

[Ass](#), [AssChain](#), [AssMetadata](#), [AssMetadataPage](#), [AssMetadataPopUp](#), [AssMetadataWin](#), [AssChainPage](#), [AssChainPopUp](#), [AssChainWin](#), [AssChainWinFree](#), [AssGetProperty](#), [AssInfo](#), [AssInfoEx](#), [AssPage](#), [AssPopUp](#), [AssScaleStr](#), [AssTag](#), [AssTitle](#), [AssVarTags](#), [AssWin](#), [TagGetProperty](#), [TagGetScale](#), [TagScaleStr](#), [TagInfo](#)

## Example

```
//Using a string identifier for the substitution parameter
AssGetScale("MILK_LEVEL", 50, 1, 0);

// Display the zero, 50% and full scale of the 2nd argument
// of the association of the current Super Genie
```

```
DspText(31,0,AssGetScale(2, 0, 1));
DspText(32,0,AssGetScale(2, 50, 1));
DspText(33,0,AssGetScale(2, 100, 1));
```

## See Also

[Super Genie Functions](#)

### AssInfo

Gets association information about the current Super Genie (that is information about a variable tag that has been substituted into the Super Genie). You can only call this function on a Super Genie after the associations are completed.

Use this function to display association information as part of the Super Genie. For example, if you have a Super Genie that is a loop controller, you could display the name of the loop at the top of the loop controller box. Each time the Super Genie is used with different associations (specifically a different tag name or equipment.item association) the correct loop name will be displayed.

**Note:** In some cases it may be beneficial to replace AssInfo with either the [AssGetProperty](#) or the [AssInfoEx](#) function. If the Tag properties are updated, AssInfo does not get the updated values whereas AssGetProperty does. In addition, the function [AssInfoEx](#) has been introduced to make it easier to make legacy Cicode compatible with online changes. In a large number of cases AssInfo can be replaced with AssInfoEx using Find and Replace (see [Using Find and Replace](#)). Please be aware that if you are replacing an instance of AssInfo with AssInfoEx in a loop, you may want to make AssInfoEx blocking using the *iCached* argument to verify you are using the correct value for the Tag in your logic.

## Syntax

**AssInfo(sArg, nType [, iCachedMode])**

**sArg:**

When you associate variable tags (can use equipment.item to reference the variable tag) with Super Genies, the Super Genie substitution strings are replaced by variable tags. The sArg argument allows you to get information about one of those variable tags. What you need to know is which substitution string it replaced when the association was performed.

Enter the argument number or name (substitution string number or name) of the relevant substitution string. For example, if you want information about the variable that replaced substitution string

?INT 3?

set sArg to 3.

Or

?Level?

set sArg to Level

When you associate a partial variable tag name (or partial equipment.item to reference variable tag) a prefix or suffix needs be added to the association to form a valid tag reference. The Argument sArg needs to be parsed as a string when partial tag names are used for the association ie "[a]?1?[b]".

eg where the substitution is a valid equipment reference and ?INT 1?.HourRun is a valid equipment.item reference to a tag.

set sArg to "?INT 1?.HourRun"

*nType:*

The type of information to get:

0 - Tag reference as defined in sArg. If the referenced tag is not resolved, returns an empty string.

1 - Engineering units

2 - Raw zero scale

3 - Raw full scale

4 - Engineering zero scale

5 - Engineering full scale

6 - Width of the format

7 - Number of decimal places of format

8 - The Tag format as a long integer. The format information is stored in the integer as follows:

- Bits 0-7 - format width
- Bits 8-15 - number of decimal places
- Bits 16 - zero-padded
- Bit 17- left-justified
- Bit 18 - display engineering units
- Bit 20 - exponential (scientific) notation

9 - Logical Unit Number - I/O device number (for internal use)

10 - Raw Type - Protocol's raw data type number for this tag. Type numbers are:

- 0 - Digital
- 1 - Integer
- 2 - Real
- 3 - BCD
- 4 - Long
- 5 - Long BCD
- 6 - Long Real
- 7 - String
- 8 - Byte
- 9 - Void
- 10 - Unsigned integer

11 - Bit Width - Tag's size in bits. For example, an INT is 16 bits

12 - Unit Type - Protocol's unit type number for this tag

13 - Unit Address - Tag's address after the protocol DBF's template is applied.

14 - Unit Count - Array size. For example, if the tag's address is I1[50], the unit count is 50.

15 - Record Number - Tag's record number in variable.DBF - 1. That is, the first tag has a record number of 0.

16 - Comment - As defined in the variable tags list.

17 - ClusterName of the tag. If the referenced tag is not resolved, returns an empty string.

18 - Full name (*cluster.tagname*) of the referenced tag. If the tag is not resolved, returns an empty string.

19 - Full name (*cluster.tagname*) of the referenced tag even if the tag is not resolved.

20 - Configured Address of the tag. If the tag is not resolved, returns an empty string.

21 - Network Number - I/O device number (as defined by the Number field of the I/O Devices dialog).

22 - Name of the equipment associated with the Tag. If the referenced tag is not resolved, returns an empty string.

23 - General Type.

- 0 - Digital
- 1 - Byte
- 2 - Integer16
- 3 - UInteger 16
- 4 - Long
- 5 - Real
- 6 - String
- 7 - ULONG
- 8 - Undefined

24 - Reserved for internal use.

25 - Name of the equipment item associated with the Tag. If the tag is not resolved, returns an empty string.

If the tag is a local variable, mode 9 error code 348 is retrieved when cache mode is 0,1,2,3. Modes 12, 13, 14 and 15 will return an empty string (error 274 is trapped).

Type 8 - 16 are only supported when *iCachedMode* equals to 2 or 3.

26 - Custom 1 - a user-defined string.

27 - Custom 2 - a user-defined string.

28 - Custom 3 - a user-defined string.

29 - Custom 4 - a user-defined string.

30 - Custom 5 - a user-defined string.

31 - Custom 6 - a user-defined string.

32 - Custom 7 - a user-defined string.

33 - Custom 8 - a user-defined string.

#### *iCachedMode:*

Optional parameter that specifies from where to retrieve the value for the property.

- -1 - The mode is determined by the INI parameter [Client]TagReadCachedMode.
- 0 - The property value is retrieved direct from the server in blocking mode and an error code is returned if it is not on the server (or the server is unavailable).
- 1 - The property value is retrieved from the cache and an error code is returned if the cache is not loaded yet.
- 2 - The property value is retrieved from the local configuration and an error code is returned if it is not available (this is the traditional behavior).
- 3 - The property value is retrieved from the cache, if the cache is loaded, and from the local configuration, if the cache is not loaded yet.

Default value is -1.

---

**Note:** When retrieving bit width (Type 11) or unit count (Type 14) from local configuration (iCachedMode 2), the value is related to the data structure in the device. For example, MODNET, This is a 16 bit device does not have native LONG and REAL numbers. So when you have a LONG variable, then 2 INTEGERS are needed to store it. In the case, Type 11 against the variable will return 16 and Type 14 will return 2. The combination of these two return values will add up to the correct bits.

---

## Return Value

The value of the information as a string.

## Related Functions

[Ass](#), [AssChain](#), [AssMetadata](#), [AssMetadataPage](#), [AssMetadataPopUp](#), [AssMetadataWin](#), [AssChainPage](#), [AssChainPopUp](#), [AssChainWin](#), [AssChainWinFree](#), [AssGetProperty](#), [AssGetScale](#), [AssInfoEx](#), [AssPage](#), [AssPopUp](#), [AssScaleStr](#), [AssTag](#), [AssTitle](#), [AssVarTags](#), [AssWin](#), [TagGetProperty](#), [TagGetScale](#), [TagScaleStr](#), [TagInfo](#)

## Example

```
//Using a string identifier for the substitution parameter
AssInfo("MILK_LEVEL", 1); (to get Engineering Units of the association )

sTag = AssInfo(1, 0); // Get the name of association 1
sEngLow = AssInfo(1, 4); // get the low engineering scale of association 1

sTag = AssInfo("?INT 1?.HourRun", 0) //Get the name where the super genie association is
only part of the tag name
```

## See Also

[Super Genie Functions](#)

## AssInfoEx

Gets association information about the current Super Genie (that is information about a variable tag that has been substituted into the Super Genie). You can only call this function on a Super Genie after the associations are completed.

Use this function to display association information as part of the Super Genie. For example, if you have a Super Genie that is a loop controller, you could display the name of the loop at the top of the loop controller box. Each time the Super Genie is used with different associations (specifically a different tag name association) the correct loop name will be displayed.

---

**Note:** When replacing an instance of AssInfo with AssInfoEx in a loop, you may want to make AssInfoEx blocking using the iCached argument to verify you are using the correct value for the Tag in your logic.

---

## Syntax

**AssInfoEx(sArg, nType [, iCachedMode] )**

*sArg:*

When you associate variable tags with super Genies, the Super Genie substitution strings are replaced by variable tags. The sArg argument allows you to get information about one of those variable tags. What you need to know is which substitution string it replaced when the association was performed.

Enter the argument number (substitution string number) of the relevant substitution string. For example, if you want information about the variable that replaced substitution string

?INT 3?

set sArg to 3.

When you associate a partial variable tag name (or partial equipment.item to reference variable tag) a prefix or suffix needs be added to the association to form a valid tag reference. The Argument sArg needs to be parsed as a string when partial tag names are used for the association ie "[a]?1?[b]".

eg where the substitution is a valid equipment reference and ?INT 1?.HourRun is a valid equipment.item reference to a tag.

set sArg to "?INT 1?.HourRun"

*nType:*

The type of information to get:

0 - The referenced tag from the variables table. This is the same as sName argument. (Returned to be compatible with the AssInfo() function).

1 - Engineering units

2 - Raw zero scale

3 - Raw full scale

4 - Engineering zero scale

5 - Engineering full scale

6 - Width of the format

7 - Number of decimal places of format

8 - The Tag format as a long integer. The format information is stored in the integer as follows:

- Bits 0-7 - format width

- Bits 8-15 - number of decimal places

- Bits 16 - zero-padded

- Bit 17- left-justified

- Bit 18 - display engineering units

- Bit 20 - exponential (scientific) notation

9 - Logical Unit Number - I/O device number (for internal use)

10 - Raw Type - Protocol's raw data type number for this tag. Type numbers are:

- 0 - Digital

- 1 - Integer

- 2 - Real

- 3 - BCD

- 4 - Long

- 5 - Long BCD

- 6 - Long Real

- 7 - String
- 8 - Byte
- 9 - Void
- 10 - Unsigned integer

11 - Bit Width - Tag's size in bits. For example, an INT is 16 bits

12 - Unit Type - Protocol's unit type number for this tag

13 - Unit Address - Tag's address after the protocol DBF's template is applied.

14 - Unit Count - Array size. For example, if the tag's address is I1[50], the unit count is 50.

15 - Record Number - Tag's record number in variable.DBF - 1. That is, the first tag has a record number of 0.

16 - Comment - As defined in the variable tags list.

17 - ClusterName of the tag.

18 - Full name (*cluster.tagname*) of the tag.

19 - Full name (*cluster.tagname*) of the referenced tag even if the tag is not resolved.

20 - Configured Address of the tag. If the tag is not resolved, returns an empty string.

21 - Network Number - I/O device number (as defined by the Number field of the I/O Devices dialog).

22 - Name of the equipment associated with the Tag. If the association tag is not resolved, returns an empty string.

If the tag is a local variable, mode 9 error code 348 is retrieved when cache mode is 0,1,2,3. Modes 12, 13, 14 and 15 will return an empty string (error 274 is trapped).

23 - General Type.

- 0 - Digital
- 1 - Byte
- 2 - Integer16
- 3 - UInteger 16
- 4 - Long
- 5 - Real
- 6 - String
- 7 - ULong
- 8 - Undefined

24 - Reserved for internal use.

25 - Name of the equipment item associated with the Tag. If the tag is not resolved, returns an empty string.

26 - Custom 1 - a user-defined string.

27 - Custom 2 - a user-defined string.

28 - Custom 3 - a user-defined string.

29 - Custom 4 - a user-defined string.

30 - Custom 5 - a user-defined string.

31 - Custom 6 - a user-defined string.

32 - Custom 7 - a user-defined string.

33 - Custom 8 - a user-defined string.

***iCachedMode:***

Optional parameter that specifies from where to retrieve the value for the property.

-1 - The mode is determined by the INI parameter [\[Client\]TagReadCachedMode](#).

0 - The property value is retrieved direct from the server in blocking mode and an error code is returned if it is not on the server (or the server is unavailable).

1 - The property value is retrieved from the cache and an error code is returned if the cache is not loaded yet.

2 - The property value is retrieved from the local configuration and an error code is returned if it is not available (this is the traditional behaviour).

3 - The property value is retrieved from the cache, if the cache is loaded, and from the local configuration, if the cache is not loaded yet.

Default value is -1.

**Note:** When retrieving bit width (Type 11) or unit count (Type 14) from local configuration (*iCachedMode* 2), the value is related to the data structure in the device. For example, MODNET, This is a 16 bit device does not have native LONG and REAL numbers. So when you have a LONG variable, then 2 INTEGERS are needed to store it. In the case, Type 11 against the variable will return 16 and Type 14 will return 2. The combination of these two return values will add up to the correct bits.

## Return Value

The value of the information as a string. If an error is detected an empty string is returned. The error code can be obtained by calling the [IsError](#) Cicode function.

## Related Functions

[AssChainPopUp](#), [AssChainWin](#), [AssChainWinFree](#), [AssGetProperty](#), [AssGetScale](#), [AssInfo](#), [AssPage](#), [AssPopUp](#),  
[AssScaleStr](#), [AssTag](#), [AssTitle](#), [AssVarTags](#), [AssWin](#), [TagGetProperty](#), [TagGetScale](#), [TagScaleStr](#), [TagInfo](#)

## Example

```
//Using a string identifier for the substitution parameter
AssInfoEx("MILK_LEVEL", 1, 0); //to get Engineering units, no cache read)
sTag = AssInfoEx(1, 0); // Get the name of association 1 in non-blocking mode
sEngLow = AssInfoEx(1, 4, 0); // get the low engineering scale of association 1,
block until data is available

sTag = AssInfoEx("?INT 1?.HourRun", 0) //Get the name where the super genie association is
only part of the tag name
```

## See Also

[Super Genie Functions](#)

## AssMetadata

This non-blocking function performs Super Genie associations using the "Name" and "Value" fields defined on

the Object Properties - Metadata tab, and matches it to the 'Name' field in the page associations table. While performing associations any additional metadata entries are ignored.

## Syntax

**AssMetadata(*hWin* [, *nAn*])**

*hWin*:

The associations will be created for the next Super Genie to display in the window specified. Enter the window number or:

- -3: for the current window when the page is changed. The page can be changed by using the Page Cicode functions like PageDisplay, PageGoto, etc.
- -2: for the next new window or page displayed.

*nAN*:

An animation number that uniquely identifies an object. This object contains the list of metadata definitions that will be used to perform the association operations. This parameter is optional with -2 being the default value. When -2 is specified, it is equivalent to [DspGetAnCur\(\)](#) which returns the animation number of the current active command cursor, please refer [DspGetAnCur\(\)](#) for usage and limitations.

### UNINTENDED EQUIPMENT OPERATION

If called after other Cicode functions in a command expression field, retrieve the animation number first, then pass it through the *nAN* parameter.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

## Return Value

0 (zero) if successful, otherwise an error code is returned. When using partial associations, an error 274 may be returned even though the association is successful, and can be ignored.

## Example

```
/* Example of calling AssMetadata after other cicode functions */
An = DspGetAnCur();
SomeVal = TagRead("SomeTag"); // do additional work
AssMetadata(-2, An);
PageOpen("!TestSG");
```

## See Also

[Super Genie Functions](#)

### AssMetadataPage

Uses the metadata information from the current object for the page associations for a new Super Genie page, and displays the new Super Genie (in the current page).

## Syntax

**AssMetadataPage(*sPage* [,*nAN*])**

*sPage*:

The name of the Super Genie page to open.

*nAN*:

An animation number that uniquely identifies an object. This object contains the list of metadata definitions that will be used to perform the association operations. This parameter is optional with -2 being the default value. When -2 is specified, it is equivalent to DspGetAnCur() which returns the animation number of the current active command cursor, please refer DspGetAnCur() for usage and limitations.

#### UNINTENDED EQUIPMENT OPERATION

If called after other cicode functions in a command expression field, retrieve the animation number first, then pass it through the *nAN* parameter.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Example

```
/* Example of calling AssMetadataPage after other cicode functions */
An = KeyGetCursor();
SomeVal = TagRead("SomeTag"); // do additional work
AssMetadataPage("!TestSG", An);
```

[Super Genie Functions](#)

### AssMetadataPopUp

Uses the metadata information from the current animation point for the associations for a new Super Genie page, and displays the new Super Genie in a pop up window.

## Syntax

**AssMetadataPopUp(*sPage* [,*nAN*])**

*sPage*

The name of the Super Genie page to open.

*nAN*:

An animation number that uniquely identifies an object. This object contains the list of metadata definitions that will be used to perform the association operations. This parameter is optional with -2 being the default value. When -2 is specified, it is equivalent to [DspGetAnCur\(\)](#) which returns the animation number of the current active command cursor, please refer [DspGetAnCur\(\)](#) for usage and limitations.

#### UNINTENDED EQUIPMENT OPERATION

If called after other cicode functions in a command expression field, retrieve the animation number first, then pass it through the *nAN* parameter.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Example

```
/* Example of calling AssMetadataPopUp after other cicode functions */
An = DspGetAnCur();
SomeVal = TagRead("SomeTag"); // do additional work
AssMetadataPopUp("!TestSG", An);
```

## Related Functions

## See Also

[Super Genie Functions](#)

### AssMetadataWin

Uses the metadata information from the current animation-point for the associations for a new Super Genie page, and displays the new Super Genie in a new window.

## Syntax

**AssMetadataWin(*sPage*, INT *x*, INT *y*, INT *mode* [,*nAN*])**

*sPage*:

The name of the Super Genie page to open.

*X*:

The x pixel coordinate of the top left corner of the window. Default value is 0.

*Y*:

The y pixel coordinate of the top left corner of the window. Default value is 0.

*Mode*:

The mode of the window:

0 - Normal page (default value).

1 - Page child window. The window is closed when a new page is displayed, for example, when the PageDisplay() or PageGoto() function is called. The parent is the current active window.

2 - Window child window. The window is closed automatically when the parent window is freed with the WinFree() function. The parent is the current active window.

4 - No re-size. The window is displayed with thin borders and no maximize/minimize icons. The window cannot be re-sized.

8 - No icons. The window is displayed with thin borders and no maximize/minimize or system menu icons. The window cannot be re-sized.

16 - No caption. The window is displayed with thin borders, no caption, and no maximize/minimize or system menu icons. The window cannot be re-sized.

32 - Echo enabled. When enabled, keyboard echo, prompts, and error messages are displayed on the parent window. This mode should only be used with child windows (for example, Mode 1 and 2).

64 - Always on top.

128 - Open a unique window. This mode stops this window from being opened more than once.

256 - Display the entire window. This mode commands that no parts of the window will appear off the screen

512 - Open a unique Super Genie. This mode stops a Super Genie from being opened more than once (at the same time). However, the same Super Genie with different associations can be opened.

1024 - Disables dynamic resizing of the new window, overriding the setting of the [\[Page\]DynamicSizing](#) parameter.

4096 - Allows the window to be resized without maintaining the current aspect ratio. The aspect ratio defines the relationship between the width and the height of the window, which means this setting allows you to stretch

or compress the window to any proportions. This option overrides the setting of the [Page]MaintainAspectRatio parameter.

8192 - Text on a page will be resized in proportion with the maximum scale change for a resized window. For example, consider a page that is resized to three times the original width, and half the original height. If this mode is set, the font size of the text on the page will be tripled (in proportion with the maximum scale). This option overrides the setting of the [\[Page\]ScaleTextToMax](#) parameter.

16384 - Hide the horizontal scroll bar.

32768 - Hide the vertical scroll bar.

65536 - Disable horizontal scrolling.

131072 - Disable vertical scrolling.

You can select multiple modes by adding modes together (for example, set Mode to 9 to open a page child window without maximize, minimize, or system menu icons).

nAN:

An animation number that uniquely identifies an object. This object contains the list of metadata definitions that will be used to perform the association operations. This parameter is optional with -2 being the default value. When -2 is specified, it is equivalent to [DspGetAnCur\(\)](#) which returns the animation number of the current active command cursor, please refer [DspGetAnCur\(\)](#) for usage and limitations.

## WARNING

### UNINTENDED EQUIPMENT OPERATION

If called after other Cicode functions in a command expression field, retrieve the animation number first, then pass it through the nAN parameter.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Example

```
/* Example of calling AssMetadataWin after other cicode functions */
An = DspGetAnCur();
SomeVal = TagRead("SomeTag"); // do additional work
AssMetadataWin("!TestSG", 50, 50, 1, An);
```

## Related Functions

[Ass](#), [AssChain](#), [AssMetadata](#), [AssMetadataPage](#), [AssMetadataPopUp](#), [AssMetadataWin](#), [AssChainPage](#), [AssChainPopUp](#), [AssChainWin](#), [AssChainWinFree](#), [AssGetProperty](#), [AssGetScale](#), [AssInfo](#), [AssInfoEx](#), [AssPage](#), [AssPopUp](#), [AssScaleStr](#), [AssTag](#), [AssTitle](#), [AssVarTags](#), [AssWin](#)

## See Also

[Super Genie Functions](#)

## AssPage

Associates up to eight variable tags or equipment.item tag references with a Super Genie and displays the Super Genie in the current window. Partial tag names and equipment.item tag references can also be used. The first variable tag (*sTag1*) replaces Super Genie substitution string 1. The second variable tag (*sTag2*) replaces substitution string 2, and so on.

This function has the same effect as calling Ass() or AssTag() eight times, and then calling the PageDisplay() function. The AssPage() function provides a quick way of associating eight Super Genie variables and displaying the Super Genie - at the same time.

If you want to associate more than eight tags with the Super Genie, it is strongly recommended you call the AssVarTags(), AssTag(), or Ass() function to create the associations before you call this function.

## Syntax

**AssPage(*sPage*, *sTag1*, [*sTag2..8*] )**

*sPage*:

The page name of the Super Genie. If you prefixed your Super Genie page name with an exclamation mark (!), remember to include it here.

*sTag1..sTag8*:

The first eight physical tags to be associated with the Super Genie. For any given Super Genie, the variable tags will replace the Super Genie substitution strings as follows:

Variable tag	replaces substitution string
<i>sTag1</i>	1
<i>sTag2</i>	2
<i>sTag3</i>	3
<i>sTag4</i>	4
<i>sTag5</i>	5
<i>sTag6</i>	6
<i>sTag7</i>	7
<i>sTag8</i>	8

Because there is a strict correlation between the variable tag numbers and the substitution string numbers, you need to know how your Super Genie substitutions are numbered. For example, if your Super Genie has three unique substitution strings, numbered 1, 3, & 4, you need to enter a blank ("") for *sTag2*.

The name of the tag can be prefixed by the name of the cluster for example, "*ClusterName.Tag*".

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[Ass](#), [AssChain](#), [AssMetadata](#), [AssMetadataPage](#), [AssMetadataPopUp](#), [AssMetadataWin](#), [AssChainPage](#),  
[AssChainPopUp](#), [AssChainWin](#), [AssChainWinFree](#), [AssGetProperty](#), [AssGetScale](#), [AssInfo](#), [AssInfoEx](#), [AssPage](#),  
[AssPopUp](#), [AssScaleStr](#), [AssTag](#), [AssTitle](#), [AssVarTags](#), [AssWin](#)

## Example

```
// Associate 3 tags with the Super Genie then display the Super Genie
AssPage("!MyGenie", "PV123", "OP123", "SP123");
```

## See Also

[Super Genie Functions](#)

## AssPopUp

Associates up to eight variable tags or equipment.item tag references with a Super Genie and displays the Super Genie in a popup window. Partial tag names or equipment.item tag references can also be used. The first variable tag (*sTag1*) replaces Super Genie substitution string 1. The second variable tag (*sTag2*) replaces substitution string 2, and so on.

This function has the same effect as calling the [Ass\(\)](#) function or the [AssTag\(\)](#) function eight times, and then calling the [WinNewAt\(\)](#) function to create a window at the position of the mouse. The [AssPopUp\(\)](#) function is a quick way of associating eight Super Genie variables and displaying the Super Genie in a new window at the same time.

If you want to associate more than eight tags with the Super Genie, you need to call the [AssVarTags\(\)](#), [AssTag\(\)](#), or [Ass\(\)](#) function to create the associations before you call this function.

---

**Note:** This function helps to prevent the Super Genie from being opened more than once (at the same time). However, the same Super Genie with different associations can be opened.

---

## Syntax

**AssPopUp(*sPage*, *sTag1*, [*sTag2..8*] )**

*sPage*:

The page name of the Super Genie. If you prefixed your Super Genie page name with an exclamation mark (!), remember to include it here.

*sTag1..sTag8*:

The first 8 physical tags to be associated with the Super Genie. For any given Super Genie, the variable tags will replace the Super Genie substitution strings as follows:

Variable tag	replaces substitution string
sTag1	1
sTag2	2
sTag3	3
sTag4	4
sTag5	5
sTag6	6
sTag7	7
sTag8	8

Because there is a strict correlation between the variable tag numbers and the substitution string numbers, you need to know how your Super Genie substitutions are numbered. For example, if your Super Genie has three unique substitution strings, numbered 1, 3, & 4, you have to enter a blank ("") for sTag2.

The name of the tag can be prefixed by the name of the cluster for example, "*ClusterName.Tag*".

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[Ass](#), [AssChain](#), [AssMetadata](#), [AssMetadataPage](#), [AssMetadataPopUp](#), [AssMetadataWin](#), [AssChainPage](#), [AssChainPopUp](#), [AssChainWin](#), [AssChainWinFree](#), [AssGetProperty](#), [AssGetScale](#), [AssInfo](#), [AssInfoEx](#), [AssPage](#), [AssScaleStr](#), [AssTag](#), [AssTitle](#), [AssVarTags](#), [AssWin](#)

## Example

```
// Associate 3 tags with the Super Genie then display it
AssPopUp("!MyGenie", "PV123", "OP123", "SP123");
```

## See Also

[Super Genie Functions](#)

## AssScaleStr

Gets scale information about the associations of the current Super Genie (that is scale information about a variable tag that has been substituted into the Super Genie). You can only call this function on a Super Genie after the associations are completed.

Use this function to display association scale information as part of the Super Genie. For example, if you have a

bar graph illustrating output, you could indicate zero, 50%, and full scale output on the vertical axis of the graph. Each time the Super Genie is used with different associations the correct scale values will be displayed.

The value is returned as a formatted string using the association format specification and (optionally) the engineering units.

---

**Note:** This function is being deprecated and is replaced by the [AssGetScale](#) function. If the Tag properties are updated AssScaleStr does not get the updated values whereas AssGetScale does.

---

## Syntax

STRING **AssScaleStr**(STRING *Arg*, INT *Percent*, INT *EngUnits*[,INT *CachedMode*])

*sArg*:

When you associate variable tags with Super Genies, the Super Genie substitution strings are replaced by variable tags. The *nArg* argument allows you to get scale information about a particular variable tag. You need to know which substitution string the tag replaced when the association was performed.

Enter the argument number or name (substitution string number or name) of the relevant substitution string. For example, if you want scale information about the variable that replaced substitution string:

?INT 3?

set *nArg* to 3.

or

?Level?

set *nArg* to Level

When you associate a partial variable tag name (or partial equipment.item to reference variable tag) a prefix or suffix needs be added to the association to form a valid tag reference. The Argument *sArg* needs to be parsed as a string when partial tag names are used for the association ie "[a]?1?[b]".

For example, where the substitution is a valid equipment reference and ?INT 1?.HourRun is a valid equipment.item reference to a tag.

set *sArg* to "?INT 1?.HourRun"

*Percent*:

The percentage of full scale of the returned value.

*EngUnits*:

Determines if the value is returned with engineering units:

0 - Do not return the value with engineering units

1 - Return the value with engineering units

*CachedMode*:

Optional parameter that specifies from where to retrieve the value for the property.

-1 - The mode is determined by the INI parameter [\[Client\]TagReadCachedMode](#).

0 - The property value is retrieved direct from the server in blocking mode and an error code is returned if it is not on the server (or the server is unavailable).

1 - The property value is retrieved from the cache and an error code is returned if the cache is not loaded yet.

2 - The property value is retrieved from the local configuration and an error code is returned if it is not available (this is the traditional behaviour).

3 - The property value is retrieved from the cache, if the cache is loaded, and from the local configuration, if the cache is not loaded yet.

Default value is -1.

## Return Value

The scale of the referenced tag(as a string).

## Related Functions

[AssChainPopUp](#), [AssChainWin](#), [AssChainWinFree](#), [AssGetProperty](#), [AssGetScale](#), [AssInfo](#), [AssInfoEx](#), [AssPage](#),  
[AssPopUp](#), [AssTag](#), [AssTitle](#), [AssVarTags](#), [AssWin](#)

## Example

```
//Using a string identifier for the substitution parameter
AssScaleStr("MILK_LEVEL", 50, 1);

// Display the zero, 50% and full scale of the variable that was substituted for
Super Genie arg no. 3DspText(31,0,AssScaleStr(3, 0, 1));DspText(32,0,AssScaleStr(3, 50,
1));DspText(33,0,AssScaleStr(3, 100, 1));
```

## See Also

[Super Genie Functions](#)

## AssTag

Associates a variable tag or equipment.item tag reference with a Super Genie. The association will only be created for the next Super Genie you display in the current window, and will only come into effect after you re-display the Super Genie. You need to call this function once for every substitution string in the current Super Genie, or the super-genie variable (substitution string) will remain uninitialized and it will display as #ASC. You cannot use this function to create associations for variables that will display in new windows.

## Syntax

**AssTag**(*nArg*, *sTag* [, *sClusterName*] )

*nArg*:

The argument name (substitution string name) of the Super Genie string to be replaced by *sTag*. For example, to replace ?INT equip? with *sTag*, set *nArg* to equip.

*sTag*:

The variable tag or equipment.item tag reference that will replace the Super Genie substitution string. Partial tag names or equipment.item tag references can also be used.

The name of the tag can be prefixed by the name of the cluster for example, "ClusterName.Tag" or "ClusterName.equipment.item".

***sClusterName:***

Specifies the name of the cluster in which the Variable Tag resides. This is optional if you have one cluster or are resolving the tag via the current cluster context. The argument is enclosed in quotation marks "".

Resolution of the tag's cluster context occurs when the page is displayed. It is resolved to the page's cluster context, not the context in force when this function is called.

**Return Value**

0 (zero) if successful, otherwise an error code is returned. When using partial associations, an error 274, or 289 may be returned even though the association is successful, and can be ignored.

**Related Functions**

**Example**

```
// Associate variable tag PV123 and PV124 with !MyGenie
AssTag(1, "PV123");
AssTag(2, "PV124");
// Re-display the current Super Genie
PageDisplay("!MyGenie");
```

**See Also**

[Super Genie Functions](#)

**AssTitle**

Sets the runtime window title to the tag name of the first variable substituted into the Super Genie.

---

**Note:** This function only supports associations using tag names or equipment.item references.

See [Page Properties - General](#) for information regarding using named associations in the Window Title field.

**Syntax**

**AssTitle( [Mask] [, Prefix] [, Suffix])**

***Mask:***

The number of characters to mask (hide) from the right of the title string (optional).

***Prefix:***

A string to add to the beginning of the title string (optional).

***Suffix:***

A string to add to the end of the title string (optional).

## Return Value

0 (zero) if successful, otherwise an error code is returned.

[AssPopUp](#), [AssScaleStr](#), [AssTag](#), [AssVarTags](#), [AssWin](#)

## See Also

[Super Genie Functions](#)

## AssVarTags

Associates up to eight variable tags or equipment.item tag references with a Super Genie. Partial tag names or equipment.item tag references can also be used. This association is only made for the next Super Genie you display (either in the current window or in a new window). This function has an offset that allows you to specify which substitution string the first variable tag will replace. This means that if you have a Super Genie with more than 8 substitution strings, you can use this function repeatedly (while increasing the offset), until you have associated the necessary variable tags.

This function has the same effect as calling the Ass() function or the AssTag() function eight times. The AssVarTags() function is a quick way of associating up to eight Super Genie variables at the same time.

**Note:** This function does not support named associations. To use named associations refer to [AssMetadata](#).

## Syntax

**AssVarTags(*hWin*, *nOffset*, *sTag1*, [*sTag2..8*] )**

*hWin*:

The association will be created for the next Super Genie to display in the window specified here - enter the window number or:

- -3 - for the current window when the page is changed. The page can be changed by using the Page Cicode functions like PageDisplay, PageGoto, etc.
- -2 - for the next new window or page displayed.

*nOffset*:

By default, the first variable tag (*sTag1*) will replace substitution string 1, and *sTag2* will replace substitution string 2, and so on. Enter an offset to change this so that *sTag1* replaces a substitution string other than the first. For example, an offset of 8 means that *sTag1* replaces string 9 instead of the default string 1 (8+1=9), and *sTag2* replaces string 10 instead of string 2 (8+2=10) etc. This means that you can use this function repeatedly to associate more than eight variables.

*sTag1..8*:

The physical variable tags (up to eight) to be associated with the Super Genie. For any given Super Genie, the variable tags will replace the Super Genie substitution strings as follows:

If <i>nOffset</i> is 0...	<i>sTag1</i> will replace the substitution string 1,
	<i>sTag2</i> will replace the substitution string 2, etc.
If <i>nOffset</i> is 8...	<i>sTag1</i> will replace the substitution string 9,
	<i>sTag2</i> will replace the substitution string 10, etc.

Because there is a strict correlation between the variable tag numbers and the substitution string numbers, you need to know how your Super Genie substitutions are numbered. For example, if your Super Genie has three unique substitution strings, numbered 1, 3, & 4, you need to enter a blank ("") for *sTag2*.

The name of the tag can be prefixed by the name of the cluster for example, "*ClusterName.Tag*".

## Return Value

No value is returned.

## Related Functions

[Ass](#), [AssChain](#), [AssMetadata](#), [AssMetadataPage](#), [AssMetadataPopUp](#), [AssMetadataWin](#), [AssChainPage](#), [AssChainPopUp](#), [AssChainWin](#), [AssChainWinFree](#), [AssGetProperty](#), [AssGetScale](#), [AssInfo](#), [AssInfoEx](#), [AssPage](#), [AssPopUp](#), [AssScaleStr](#), [AssTag](#), [AssTitle](#), [AssWin](#)

## Example

```
// Associate 12 variables to the Super Genie
AssVarTags(WinNumber(), 0, "PV123", "SP123", "OP123", "PV124", "SP124", "OP124",
            "PV125", "SP125");
AssVarTags(WinNumber(), 8, "OP125", "PV126", "SP126", "OP126");
PageDisplay("!MyGenie"); // Display the Super Genie
```

## See Also

[Super Genie Functions](#)

## AssWin

Associates up to eight variable tags or equipment.item tag references with a Super Genie, and displays the Super Genie in a new window. This function has the same effect as calling the [Ass\(\)](#) or [AssTag\(\)](#) function eight times, and then calling the [WinNewAt\(\)](#) function. The [AssWin\(\)](#) function is a quick way of associating eight Super Genie variables and creating a new window - at the same time.

If you want to associate more than eight tags with the Super Genie you need to call the [AssVarTags\(\)](#), [AssTag\(\)](#), or [Ass\(\)](#) function to create the associations before you call this function.

## Syntax

**AssWin(*sPage*, *X*, *Y*, *Mode*, *sTag1*, [*sTag2..8*])**

*sPage:*

The page name of the Super Genie. If you prefixed your Super Genie page name with an exclamation mark (!), remember to include it here.

X

The x pixel coordinate of the top left corner of the window.

Y

The y pixel coordinate of the top left corner of the window.

*Mode:*

The mode of the window:

0 - Normal page.

1 - Page child window. The window is closed when a new page is displayed, for example, when the PageDisplay() or PageGoto() function is called. The parent is the current active window.

2 - Window child window. The window is closed automatically when the parent window is freed with the WinFree() function. The parent is the current active window.

4 - No re-size. The window is displayed with thin borders and no maximize/minimize icons. The window cannot be re-sized.

8 - No icons. The window is displayed with thin borders and no maximize/minimize or system menu icons. The window cannot be re-sized.

16 - No caption. The window is displayed with thin borders, no caption, and no maximize/minimize or system menu icons. The window cannot be re-sized.

32 - Echo enabled. When enabled, keyboard echo, prompts, and error messages are displayed on the parent window. This mode should only be used with child windows (for example, Mode 1 and 2).

64 - Always on top.

128 - Open a unique window. This mode stops this window from being opened more than once.

256 - Display the entire window. This mode commands that no parts of the window will appear off the screen

512 - Open a unique Super Genie. This mode stops a Super Genie from being opened more than once (at the same time). However, the same Super Genie with different associations can be opened.

1024 - Disables dynamic resizing of the new window, overriding the setting of the [\[Page\]DynamicSizing](#) parameter.

You can select multiple modes by adding modes together (for example, set Mode to 9 to open a page child window without maximize, minimize, or system menu icons).

*sTag1..8:*

The first eight physical tags to be associated with the Super Genie. For any given Super Genie, the variable tags will replace the Super Genie substitution strings as follows:

Variable tag...	replaces substitution string...
sTag1	1
sTag2	2
sTag3	3
sTag4	4

sTag5	5
sTag6	6
sTag7	7
sTag8	8

Because there is a strict correlation between the variable tag numbers and the substitution string numbers, you need to know how your Super Genie substitutions are numbered. For example, if your Super Genie has three unique substitution strings, numbered 1, 3, & 4, you need to enter a blank ("") for sTag2.

The variable tags that you specify here need to be the same data type as that specified by the relevant Super Genie substitution strings. For example, only a digital tag could replace the substitution string ?DIGITAL 4?. If the substitution string does not specify a type (for example, ?5?), you can use any type except STRING.

The name of the tag can be prefixed by the name of the cluster for example, "*ClusterName.Tag*".

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[Ass](#), [AssChain](#), [AssMetadata](#), [AssMetadataPage](#), [AssMetadataPopUp](#), [AssMetadataWin](#), [AssChainPage](#), [AssChainPopUp](#), [AssChainWin](#), [AssChainWinFree](#), [AssGetProperty](#), [AssGetScale](#), [AssInfo](#), [AssInfoEx](#), [AssPage](#), [AssPopUp](#), [AssScaleStr](#), [AssTag](#), [AssTitle](#), [AssVarTags](#)

## Example

```
// Associate 3 tags with the Super Genie
// then display the new window at (100,200) in mode 9
AssWin("!MyGenie", 100, 200, 1 + 8, "PV123", "OP123", "SP123");
```

## See Also

[Super Genie Functions](#)

## AssWinReplace

This function removes the associations on a specified Super Genie window and applies any pending associations. This may be a useful alternative to calling [PageDisplay](#) or [WinNewAt](#) to update associations, as a full page reload is not required.

You need to call this function once for every Super Genie substitution string in the specified window, otherwise the variable (substitution string) will remain uninitialized and will be displayed as #ASC.

## Syntax

**AssWinReplace(*nTargetWindow*)**

*nTargetWindow*:

The number of the window where associations will be replaced.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Example

```
Ass(-3, "Level", "MILK_LEVEL", 0);
AssWinReplace(2);
```

[Super Genie Functions](#)

## Table (Array) Functions

Table functions perform mathematical functions on entire tables (or arrays), such as the calculation of minimum, maximum, average, and standard deviation values.

---

**Note:** This function only supports arrays declared in Cicode and not variable tag arrays.

---

Following are functions relating to Tables:

<a href="#">TableLookup</a>	Gets a value from a table.
<a href="#">TableMath</a>	Performs mathematical operations on a table, for example, average, maximum, minimum, etc.
<a href="#">TableShift</a>	Shifts a table, left or right.

## See Also

[Cicode Function Categories](#)

[Using Cicode Functions](#)

## TableLookup

Searches for a value in a table, and returns the position (offset) of the value in the table. Be aware that the first item in a table is offset 0 (zero), the next item is offset 1, etc.

**Note:** This function only supports arrays declared in Cicode and not variable tag arrays.

## Syntax

**TableLookup(*Table*, *Size*, *Value*)**

*Table*:

The table to search. The table needs to be an array of real numbers. Must be a Real type variable.

*Size*:

The maximum number of items in the table.

*Value*:

The value to locate.

## Return Value

The offset to the table value, or -1 if the value does not exist.

## Related Functions

[TableMath](#)

## Example

```
REAL Levels[5]=10,15,50,100,200;  
Variable=TableLookup(Levels,5,50);  
! Sets Variable to 2.  
Variable=TableLookup(Levels,5,45);  
! Sets Variable to -1.
```

## See Also

[Table \(Array\) Functions](#)

## TableMath

Performs mathematical operations on a table of real (floating-point) numbers. This function supports minimum, maximum, average, standard deviation, and total operations on a table of values. Use this function for operating on tables returned from the trend system with the [TrnGetTable\(\)](#) function. You can set the *Mode* to either accept or ignore invalid or gated data returned from [TrnGetTable\(\)](#).

**Note:**

- This function cannot check the length of any arrays passed to it. If the array is shorter than the size argument,

unpredictable results can occur, such as data in memory being overwritten, or a general protection fault.

- This function only supports arrays declared in Cicode and not variable tag arrays.

## **WARNING**

### **UNINTENDED EQUIPMENT OPERATION**

Always confirm that arrays are of appropriate length before passing them to the TableMath function.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

## **Syntax**

**TableMath(Table, Size, Command [, Mode] )**

*Table:*

Any table of floating-point numbers. Must be a Real type variable.

*Size:*

The maximum number of items in the table.

*Command:*

The mathematical operation to perform on the table:

0 - Minimum

1 - Maximum

2 - Average

3 - Standard deviation

4 - Total

*Mode:*

The mode of the operation:

0 - Operate on all data - default

1 - Ignore invalid or gated data returned from the TrnGetTable() function

## **Return Value**

Returns the value related to the requested mathematical operation performed on the table (Minimum, Maximum, Average, Standard deviation or Total).\\

## **Related Functions**

[TableLookup](#) [TrnGetTable](#)

## **Example**

```
REAL Array[5]=10,15,50,100,200;  
REAL Min,Avg;  
! Get the minimum value.
```

```
Min=TableMath(Array, 5, 0, 0); ! Sets Min to 10.  
! Get the average value.  
Avg=TableMath(Array, 5, 2, 0); ! Sets Avg to 75.
```

## See Also

[Table \(Array\) Functions](#)

## TableShift

Shifts table items in a table by a number of positions. You can shift the table left or right. Items shifted off the end of the table are lost. Items within a table that are not replaced by other items (that have moved) are set to 0.

---

**Note:** This function only supports arrays declared in Cicode and not variable tag arrays.

---

## Syntax

**TableShift**(*Table*, *Size*, *Count*)

*Table*:

The table to shift, an array of real numbers. Must be a Real type variable.

*Size*:

The maximum number of items in the table.

*Count*:

The number of positions to shift the table items. A negative Count moves items to the right and a positive Count moves items to the left.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TableMath](#), [TableLookup](#)

## Example

```
REAL Levels[5]=10,15,50,100,200;  
TableShift(Levels,5,2);  
/* Shifts the table items by 2 positions to the left, that is  
Levels[0]=50  
Levels[1]=100  
Levels[2]=200  
Levels[3]=0  
Levels[4]=0 */
```

[Table \(Array\) Functions](#)

## Tag Functions

The Tag Functions allow you to read the values of variables in I/O devices such as PLCs, and to write data into these I/O device variables. These functions also allow you to control I/O devices and to display information about I/O devices.

Following are functions relating to tags:

<a href="#">SubscriptionAddCallback</a>	Adds a callback function to a tag subscription.
<a href="#">SubscriptionGetAttribute</a>	Reads an attribute value of a tag subscription.
<a href="#">SubscriptionGetInfo</a>	Reads the specified text information about a subscribed tag.
<a href="#">SubscriptionGetQuality</a>	Reads quality of a subscribed tag.
<a href="#">SubscriptionGetTag</a>	Reads a value, quality and timestamps of a subscribed tag.
<a href="#">SubscriptionGetTimestamp</a>	Reads the specified timestamp of a subscribed tag.
<a href="#">SubscriptionGetValue</a>	Reads a value of a subscribed tag.
<a href="#">SubscriptionRemoveCallback</a>	Removes a callback function from a tag subscription.
<a href="#">TagBrowseClose</a>	Terminates an active data browse session and cleans up all resources associated with the session.
<a href="#">TagBrowseFirst</a>	Places the data browse cursor at the first record.
<a href="#">TagBrowseGetField</a>	Retrieves the value of the specified field from the record the data browse cursor is currently referencing.
<a href="#">TagBrowseNext</a>	Moves the data browse cursor forward one record.
<a href="#">TagBrowseNumRecords</a>	Gets the number of records for a given browsing session.
<a href="#">TagBrowseOpen</a>	Initiates a new browse session and returns a handle to the new session that can be used in subsequent data browse function calls.
<a href="#">TagBrowsePrev</a>	Moves the data browse cursor back one record.
<a href="#">TagDebug</a>	Displays a dialog which allows you to select any configured tag to read or change (write) its value.

<a href="#">TagDebugForm</a>	Displays a dialog that allows you to select a variable tag and perform some basic read/write operations.
<a href="#">TagEventFormat</a>	Returns a handle to the format of the data used by the TagEventQueue().
<a href="#">TagEventQueue</a>	Opens the tag update event queue.
<a href="#">TagGetProperty</a>	Gets a property for a variable tag from the datasource.
<a href="#">TagGetScale</a>	Gets the value of a tag at a specified scale from the datasource.
<a href="#">TagGetValue</a>	Gets the value, quality and timestamp of a tag based on the tag subscription.
<a href="#">TagInfo</a>	Gets information about a variable tag.
<a href="#">TagInfoEx</a>	Gets information about a variable tag.
<a href="#">TagRamp</a>	Increments a tag by a percentage amount.
<a href="#">TagRDBReload</a>	Reloads the variable tag database so when TagInfo is called it picks up online changes to the tag database.
<a href="#">TagRead</a>	Reads a variable from an I/O Device.
<a href="#">TagReadEx</a>	Reads the value, quality and timestamp of a particular tag element.
<a href="#">TagResolve</a>	Increments a reference count on a tag to keep it resolved.
<a href="#">TagScaleStr</a>	Gets the value of a tag at a specified scale.
<a href="#">TagSetOverrideBad</a>	Sets a quality Override element for a specified tag to Bad Non Specific.
<a href="#">TagSetOverrideGood</a>	Sets a quality Override element for a specified tag to Good Non Specific.
<a href="#">TagSetOverrideUncertain</a>	Sets a quality Override element for a specified tag to Uncertain Non Specific.
<a href="#">TagSetOverrideQuality</a>	Sets a quality Override element for a specified tag.
<a href="#">TagSubscribe</a>	Subscribes a tag for periodic monitoring and event handling.
<a href="#">TagUnsubscribe</a>	Unsubscribes a tag for periodic monitoring and event handling.

<a href="#">TagUnresolve</a>	Unresolves a reference count implemented on a tag by TagResolve().
<a href="#">TagWrite</a>	Writes to an I/O Device variable.
<a href="#">TagWriteEventQue</a>	Opens the tag write event queue.
<a href="#">TagWriteIntArray</a>	Writes an array of integers to a tag.
<a href="#">TagWriteRealArray</a>	Writes an array of reals to a tag.

## See Also

[Cicode Function Categories](#)

[Using Cicode Functions](#)

## SubscriptionAddCallback

Adds a function callback to a tag subscription. When the value change for a subscribed tag is detected, a callback function can be called. This implements change based Cicode and avoids continuously polling a tag value to monitor changes.

Multiple callbacks are possible to the same subscription.

To remove a callback from a subscription use the [SubscriptionRemoveCallback](#) function.

## Syntax

**SubscriptionAddCallback(*iHandle*, *sCallback*)**

*iHandle*

Integer handle of the subscription to add a callback to.

*sCallback*

String stating the name of a function to call when the value is updated. The function should have the structure:

```
FUNCTION evtHandler(INT subsHandle)
```

..

End

Where *subsHandle* is the subscription that raised the event.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TagSubscribe](#), [TagUnsubscribe](#), [SubscriptionGetAttribute](#), [SubscriptionRemoveCallback](#)

## See Also

[Tag Functions](#)

### SubscriptionGetAttribute

Reads the specified attribute value of a subscribed tag. Similar to TagRead.

**Note:** This function has been superseded and may be deprecated in a future release. Please use the following functions: [SubscriptionGetInfo](#), [SubscriptionGetTimestamp](#), [SubscriptionGetQuality](#), [SubscriptionGetValue](#) or [SubscriptionGetTag](#) as substitutions in new projects.

## Syntax

**SubscriptionGetAttribute**(*iHandle*, *sAttribute* [, *iOffset*] )

*iHandle*

Integer handle of the subscription to read from.

*sAttribute*

Attribute of the tag to read. Supported Attributes are:

**ClusterName** - Returns the resultant cluster context of the subscription. For example, for the tag subscribed as "cluster1.tagname", the return value is "cluster1".

There are several possible outcomes where no cluster is specified in the subscription:

- If the tag is a local tag, an empty string will be returned.
- If the tag is a variable tag and the system only contains one cluster, this cluster will be returned.
- If the tag is a variable tag and there is a default cluster being run in the Cicode, the default cluster will be returned.
- If none of these options are true, an empty string will be returned.

**FullName** - Return the full subscription name. For example, for the tag subscribed as "cluster1.tagname", return value is "cluster1.tagname". If the tag was subscribed without a cluster the return value will be the tagname.

**TagName** - Return the tagname for the subscription. For example, for the tag subscribed as "cluster1.tagname", return value is "tagname".

**Value** - The current value of the tag.

**ValueQuality** - An indication of the current quality of the tag as an integer number.

**Note:** The return value is not compatible with the QUALITY data type or the quality Cicode functions. Use [SubscriptionGetQuality](#).

**ValueTimestamp** - The time when the tag last changed. It is returned as an integer value compatible with a time/data variable.

**Note:** The return value is not compatible with the TIMESTAMP data type. Use [SubscriptionGetTimestamp](#).

**ValueTimestampMS** - The millisecond part of the time when the tag last changed.

*iOffset*

Optional integer expressing the zero based index of an array attribute. This is only valid for the Value attribute. Default value is 0.

## Return Value

String representation of the cached value for a subscribed tag. On error, an empty string and an error is set.

## Related Functions

[SubscriptionGetInfo](#), [SubscriptionGetTimestamp](#), [SubscriptionGetQuality](#), [SubscriptionGetValue](#),  
[SubscriptionGetTag](#)

## See Also

[Tag Functions](#)

### SubscriptionGetInfo

Reads the specified text information about a subscribed tag.

## Syntax

**SubscriptionGetInfo**(*iHandle*, *sAttribute* )

*iHandle*

Integer handle of the subscription to read from.

*sAttribute*

Attribute of the tag to read. Supported Attributes are:

**ClusterName** - Return the cluster context of the subscription. For example, for the tag subscribed as "cluster1.tagname", return value is "cluster1". If the tag was subscribed without a cluster the return value will be an empty string.

**FullName** - Return the full subscription name. For example, for the tag subscribed as "cluster1.tagname.field", return value is "cluster1.tagname.field". If the tag was subscribed without a cluster, the return value will be the tag name and/or element name. If the tag was subscribed without an element, the return value will be the tag name and/or cluster name.

**TagName** - Return the tagname for the subscription. For example, for the tag subscribed as "cluster1.tagname", return value is "tagname".

**ElementName** - Retrieve the element name of the subscription.

## Return Value

String representation of the requested information for a subscribed tag. On error, returns an empty string and an error is set.

## Related Functions

[SubscriptionGetTimestamp](#), [SubscriptionGetQuality](#), [SubscriptionGetValue](#), [SubscriptionGetTag](#)

## Example

```
STRING TagName = SubscriptionGetInfo(hSub, "TagName");
```

## See Also

[Tag Functions](#)

### SubscriptionGetQuality

Reads quality of a subscribed tag.

## Syntax

**SubscriptionGetQuality(*iHandle*)**

*iHandle*

Integer handle of the subscription to read from.

## Return Value

The quality for a subscribed tag. On error, QUAL\_BAD.

## Related Functions

[SubscriptionGetInfo](#), [SubscriptionGetTimestamp](#), [SubscriptionGetValue](#), [SubscriptionGetTag](#)

## Example

```
QUALITY theQuality = SubscriptionGetQuality(hSub);
```

## See Also

[Tag Functions](#)

### SubscriptionGetTag

Reads a value, quality and timestamps of a subscribed tag.

## Syntax

**SubscriptionGetTag(*iHandle*, *sOffset*)**

*iHandle*

Integer handle of the subscription to read from.

*sOffset*

Optional integer expressing the zero based index of an array attribute. This is only valid for the Value attribute. Default value is 0.

## Return Value

Returns a value, quality and timestamps of a subscribed tag. The type of the returned value depends on a type of the subscribed tag. The quality and timestamps of the subscribed tag are read and passed with the returned value.

Using [SubscriptionGetValue](#) gives similar results as using direct reference to a tag without item ex. tag1, tag1.Field.

On error, returns either 0 for numerical data types or an empty string for strings.

## Related Functions

[SubscriptionGetTimestamp](#), [SubscriptionGetQuality](#), [SubscriptionGetInfo](#), [SubscriptionGetValue](#)

## Example

```
INT Value = SubscriptionGetTag(hSub);
```

## See Also

[Tag Functions](#)

## SubscriptionGetTimestamp

Reads the specified timestamp of a subscribed tag.

## Syntax

**SubscriptionGetTimestamp(*iHandle*, *sAttribute* )**

*iHandle*

Integer handle of the subscription to read from.

*sAttribute*

Attribute of the tag to read. Supported Attributes are:

**Timestamp** - The timestamp when the tag last changed. It is default value used when this argument is not specified.

**QualityTimestamp** - The timestamp when quality of the tag last changed.

**ValueTimestamp** - The timestamp when value of the tag last changed.

## Return Value

The requested timestamp for a subscribed tag. On error, 0 (INVALID TIMESTAMP).

## Related Functions

[SubscriptionGetInfo](#), [SubscriptionGetQuality](#), [SubscriptionGetValue](#), [SubscriptionGetTag](#)

## Example

```
TIMESTAMP theTime = SubscriptionGetTimestamp(hSub, "ValueTimestamp");  
TIMESTAMP theTime = SubscriptionGetTimestamp(hSub);
```

## See Also

[Tag Functions](#)

## SubscriptionGetValue

Reads a value of a subscribed tag.

## Syntax

**SubscriptionGetValue(*iHandle*, *sOffset*)**

*iHandle*

Integer handle of the subscription to read from.

*sOffset*

Optional integer expressing the zero based index of an array attribute. Default value is 0.

## Return Value

Returns a value of a subscribed tag. The type of the returned variable depends on a type of the subscribed tag. The quality and timestamps of the subscribed tag are not read i.e. quality of the returned value can be consider as GOOD and its timestamps as 0 (INVALID TIMESTAMP).

Using [SubscriptionGetValue](#) gives similar results as using direct reference to tag's v item ex. tag1.v, tag1.Field.v.

On error, returns either 0 for numerical data types or an empty string for strings.

## Related Functions

[SubscriptionGetTimestamp](#), [SubscriptionGetQuality](#), [SubscriptionGetInfo](#), [SubscriptionGetTag](#)

## Example

```
INT Value = SubscriptionGetValue(hSub);
```

## See Also

[Tag Functions](#)

## SubscriptionRemoveCallback

Removes a function callback from a tag subscription. The subscription handle and callback function needs to match those used when adding the callback.

## Syntax

**SubscriptionRemoveCallback(*iHandle*, *sCallback*)**

*iHandle*

Integer handle of the subscription of the callback.

*sCallback*

String stating the name of the callback function.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TagSubscribe](#), [TagUnsubscribe](#), [SubscriptionAddCallback](#), [SubscriptionGetAttribute](#)

## See Also

[Tag Functions](#)

## TagBrowseClose

The TagBrowseClose function terminates an active data browse session and cleans up resources associated with the session.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**INT TagBrowseClose(LONG *Session*)**

*Session*:

The handle to a browse session previously returned by a [TagBrowseOpen](#) call.

## Return Value

0 if successful -1 if unsuccessful.

## Related Functions

[TagInfoEx](#), [TagInfo](#), [TagBrowseFirst](#), [TagBrowsePrev](#), [TagBrowseNumRecords](#), [TagBrowseOpen](#),  
[TagBrowseNext](#),[TagBrowseGetField](#)

## Example

```
// close
TBResult = TagBrowseClose(TBHandle);
End
```

## See Also

[Tag Functions](#)

## TagBrowseFirst

The TagBrowseFirst function places the data browse cursor at the first record.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

INT **TagBrowseFirst**(LONG *Session*)

*Session*:

The handle to a browse session previously returned by a [TagBrowseOpen](#) call.

## Return Value

0 if successful -1 if unsuccessful.

## Related Functions

[TagInfoEx](#), [TagInfo](#), [TagBrowseClose](#), [TagBrowsePrev](#), [TagBrowseNumRecords](#), [TagBrowseOpen](#),  
[TagBrowseNext](#),[TagBrowseGetField](#)

## Example

```
// first
count = 1;
TBResult = TagBrowseFirst(TBHandle);
ErrLog("First: " + IntToStr(TBResult) + ", Error = " + IntToStr(IsError()));
WHILE (TBResult <> -1) DO
ErrLog("Entry " + IntToStr(count) + ": " +
"Tag: " + TagBrowseGetField(TBHandle , "TAG") + ", " +
"Type: " + TagBrowseGetField(TBHandle , "TYPE") + ", " +
"Addr: " + TagBrowseGetField(TBHandle , "ADDR") + ", " +
"Error = " + IntToStr(IsError()));
```

```
TBResult = TagBrowseNext(TBHandle);
ErrLog("Next: " + IntToStr(TBResult) +
", Error = " + IntToStr(IsError()));
count = count + 1;
END
```

## See Also

[Tag Functions](#)

### TagBrowseGetField

The TagBrowseGetField function retrieves the value of the specified field from the record the data browse cursor is currently referencing.

## Syntax

```
STRING TagBrowseGetField(LONG Session, STRING FieldName)
```

*Session:*

The handle to a browse session previously returned by a TagBrowseOpen call.

*Fieldname:*

The name of the field that references the value to be returned. Supported fields are:

ADDR, ARR\_SIZE, CLUSTER, COMMENT, DEADBAND, ENG\_FULL, ENG\_UNITS, ENG\_ZERO, EQUIPMENT, FORMAT, IODEV, PSI\_TYPE, RAW\_FULL, RAW\_ZERO, SCALED\_TYPE, TAG, ITEM, TYPE

For details on these fields refer to the [Browse Function Field Reference](#).

## Return Value

The value of the specified field as a string if successful. An empty string may or may not be an indication that an error has been detected. The last error should be checked in this instance to determine if an error has actually occurred. -1 if unsuccessful.

## Related Functions

[TagInfoEx](#), [TagInfo](#), [TagBrowseClose](#), [TagBrowseFirst](#), [TagBrowseNumRecords](#), [TagBrowseOpen](#), [TagBrowseNext](#)

## Example

```
// GetField
ErrLog("CLUSTER: " + TagBrowseGetField(TBHandle , "CLUSTER") +
", Error = " + IntToStr(IsError()));
ErrLog("IODEV: " + TagBrowseGetField(TBHandle , "IODEV") +
", Error = " + IntToStr(IsError()));
ErrLog("TAG: " + TagBrowseGetField(TBHandle , "TAG") +
", Error = " + IntToStr(IsError()));
END
```

## See Also

[Tag Functions](#)

### TagBrowseNext

The TagBrowseNext function moves the data browse cursor forward one record.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

INT **TagBrowseNext**(LONG *Session*)

*Session*:

The handle to a browse session previously returned by a [TagBrowseOpen](#) call.

## Return Value

0 if successful -1 if unsuccessful.

## Related Functions

[TagInfoEx](#), [TagInfo](#), [TagBrowseClose](#), [TagBrowseFirst](#), [TagBrowsePrev](#), [TagBrowseNumRecords](#),  
[TagBrowseOpen](#), [TagBrowseGetField](#)

## Example

```
// next without first
TBResult = TagBrowseNext(TBHandle);
ErrLog("Next: " + IntToStr(TBResult) + ", Error = " + IntToStr(IsError()));
END
```

## See Also

[Tag Functions](#)

### TagBrowseNumRecords

The TagBrowseNumRecords function gets the number of records for a given browsing session. This function may not be accurate if the following occurs:

- Project misconfiguration on two separate machines
- Online changes happening on two separate machines.

The count will be a consolidated sum of all browse records per I/O Device as returned by each I/O Server in response to opening a browse session. The count reconciliation is performed on the basis of the "best device

"status", that is records with the "best status" are picked and the others are discarded. "Best device status" is calculated as follows:

- Data Source online state (ONLINE is picked over OFFLINE), then
- Data Source active state (ACTIVE is picked over INACTIVE), then
- Data Source priority (higher priority is picked over a lower one, with highest being 1 – for primary I/O device).

## Syntax

**INT TagBrowseNumRecords(LONG Session)**

*Session:*

The handle to a browse session previously returned by a [TagBrowseOpen](#) call.

## Return Value

Number of records (INT) if successful -1 if unsuccessful.

## Related Functions

[TagInfoEx](#), [TagInfo](#), [TagBrowseClose](#), [TagBrowseFirst](#), [TagBrowsePrev](#), [TagBrowseOpen](#), [TagBrowseNext](#), [TagBrowseGetField](#)

## Example

```
// number of records
TBResult = TagBrowseNumRecords(TBHandle);
ErrLog("Num Records: " + IntToStr(TBResult));
END
```

## See Also

[Tag Functions](#)

## TagBrowseOpen

The TagBrowseOpen function initiates a new browse session and returns a handle to the new session that can be used in subsequent data browse function calls. Tag records are sorted on the server and, arrive at the client in the order specified by the sorting fields parameter, or default sorting order as described below under the Sort parameter.

Tag browsing provides a snapshot of tag configuration data. It is not intended to support live data updates.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

**Note:** In order to conserve memory the following recommendations should be observed, as multiple open tag browsing sessions will use a large amount of memory:

1. Close an opened session at the completion of the browsing session using [TagBrowseClose](#).

---

2. List only the fields that you wish to browse, not all fields.

---

## Syntax

**LONG TagBrowseOpen(STRING Filter, STRING Fields, STRING Sort[, STRING Clusters])**

*Filter:*

Semicolon delimited list of predefined field name filters specifying the records to return during the browsing session. If you do not specify a filter string then all tag records will be displayed.

All string fields can be filtered based on regular expressions. Using an operator other than = will cause strings to not match the filter criteria. The following regular expressions are supported \*expr, expr\*, and \*expr\*.

If any of the filter names are invalid, opening a browsing session will not succeed and will return an invalid handle.

*Field:*

Comma separated list of record fields to be returned during the browsing session. An empty field string will return all possible fields.

Supported fields are:

### Configuration Fields

ADDR, ARR\_SIZE, CLUSTER, COMMENT, CUSTOM1, CUSTOM2, CUSTOM3, CUSTOM4, CUSTOM5, CUSTOM6, CUSTOM7, CUSTOM8, DEADBAND, ENG\_FULL, ENG\_UNITS, ENG\_ZERO, EQUIPMENT, FULLNAME, HISTORIAN, ITEM, RAW\_FULL, RAW\_ZERO, SCALED\_TYPE, TAG, TYPE, WRITE\_ROLES

For full details on these fields refer to the [Browse Function Field Reference](#).

The fields LOG\_UNIT and NET\_UNIT are available when using the Cicode functions and [TagInfoEx](#) are also supported.

### Runtime Fields

Field Value	Description (predefined values)	Possible values
OVR_MODE	Override Mode	Integer (as per override mode element specification).
CTRL_MODE	Control Mode (0-1)	Integer (as per control mode element specification).
NUM_SUBS	Number of current subscriptions to the tag	Integer.
VALUE	Default value	As per value type.
FIELD	Field value	As per value type.
OVERRIDE	Override value	As per value type.
VALID	Last Valid value	As per value type.
STATUS	Last Status value	Integer (as per status element specification).

**Sort:**

Comma delimited list of record fields to be returned in order of sorting preferences (each with an indication of whether the sort is A - ascending or D - descending). For example "TYPE:D". By default tag browsing records are sorted by the tag primary key Cluster.TagName. which is implicitly appended to the list of sorting fields, since all the other fields may end up not being unique.

**Clusters:**

An optional parameter that specifies via a comma delimited string the subset of the clusters to browse. An empty string indicates that all clusters will be browsed.

## Return Value

Session handle (LONG) if successful, -1 if unsuccessful.

## Related Functions

[TagInfoEx](#), [TagInfo](#), [TagBrowseClose](#), [TagBrowseFirst](#), [TagBrowsePrev](#), [TagBrowseNumRecords](#),  
[TagBrowseNext](#), [TagBrowseGetField](#)

## Example 1

```
// open
TBResult = TagBrowseOpen("ADDR=*2; TYPE<=2", "TAG,TYPE,ADDR", "ADDR:D", "");
ErrLog("Open Session ID: " + IntToStr(TBResult) +
", Error = " + IntToStr(IsError()));
TBHandle = TBResult;
END
```

## Example 2 - Filters

The following variable tags have been defined - Tag01, Tag02 and Tag03.

```
// Example Filter
FUNCTION TagBrowseTest1()
    STRING sFilter = "TAG=Tag01|Tag03";
    STRING sField = "TAG";
    STRING sTag = "";
    INT iStatus = -1;
    INT hTagBrowse = TagBrowseOpen(sFilter,sField,sField+":A");
    IF (hTagBrowse <> -1) THEN
        iStatus = TagBrowseFirst(hTagBrowse);
        WHILE iStatus = 0 DO
            sTag = TagBrowseGetField(hTagBrowse,sField);
            Message(sTag,sTag,64); // Tag01, Tag03
            iStatus = TagBrowseNext(hTagBrowse);
        END
        TagBrowseClose(hTagBrowse);
    END
END
```

## Example 3 - Filters

```
// Example Filter
FUNCTION TagBrowseTest2()
    STRING sFilter = "TAG=Tag01 OR TAG=Tag03";
    STRING sField = "TAG";
    STRING sTag = "";
    INT iStatus = -1;
    INT hTagBrowse = TagBrowseOpen(sFilter,sField,sField+":A");
    IF (hTagBrowse <> -1) THEN
        iStatus = TagBrowseFirst(hTagBrowse);
        WHILE iStatus = 0 DO
            sTag = TagBrowseGetField(hTagBrowse,sField);
            Message(sTag,sTag,64); // Tag01, Tag03
            iStatus = TagBrowseNext(hTagBrowse);
        END
        TagBrowseClose(hTagBrowse);
    END
END
```

### Results

Good: STRING sFilter = "TAG=Tag01|Tag03";  
Good: STRING sFilter = "TAG=Tag01 OR TAG=Tag03";  
Fail: STRING sFilter = "TAG=Tag01 OR Tag03";

## See Also

[Tag Functions](#)

### TagBrowsePrev

The TagBrowsePrev function moves the data browse cursor back one record. If you call this function after you have reached the beginning of a browse, error code 412 is returned (Databrowse session EOF).

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

INT **TagBrowsePrev**(LONG *Session*)

*Session*:

The handle to a browse session previously returned by a TagBrowseOpen call.

## Return Value

0 if successful -1 if unsuccessful.

## Related Functions

[TagInfoEx](#), [TagInfo](#), [TagBrowseClose](#), [TagBrowseFirst](#), [TagBrowseNumRecords](#),

[TagBrowseOpen](#), [TagBrowseNext](#), [TagBrowseGetField](#)

## Example

```
// previous without first
TBRResult = TagBrowsePrev(TBHandle);
ErrLog("Prev: " + IntToStr(TBRResult) + ", Error = " + IntToStr(IsError()));
END
```

## See Also

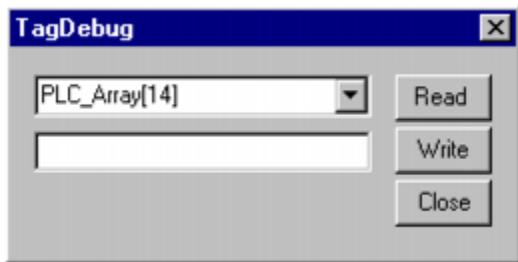

[Tag Functions](#)

## TagDebug

Displays a dialog which allows you to select from a list of the configured variable tags in your system. Once you have selected a tag, you can either press the **Read** button to get the tag's current value; or change the value by entering a new one, and pressing the **Write** button. This function should only be used for debugging or commissioning.

**Note:** An expanded version of the TagDebug dialog is available via the Cicode function [TagDebugForm](#).

To read or change (write) the value of an element in an array variable, type it into the dialog's variable tag field as follows:

## Syntax

`TagDebug()`

## Return Value

The name of the tag entered in the dialog.

## Related Functions

[TagDebugForm](#), [TagInfo](#), [TagReadEx](#), [TagWrite](#)

## Example

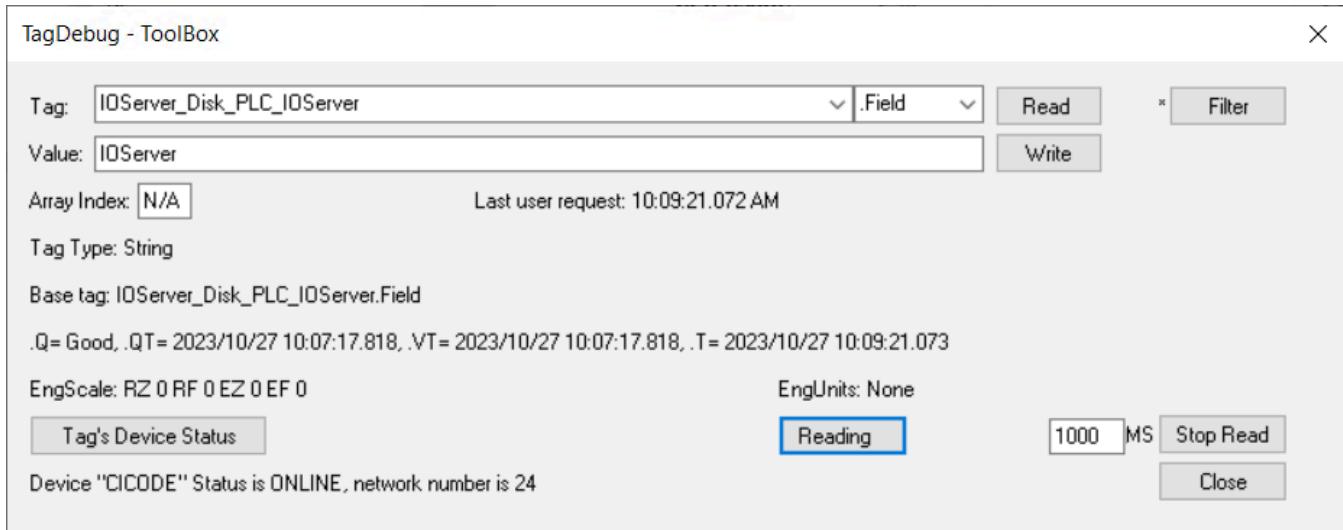

```
TagDebug(); /* Display debug form to allow user to debug */
```

## See Also

[Tag Functions](#)

### TagDebugForm

The TagDebugForm Cicode function displays a dialog that allows you to select a variable tag and perform some basic read/write operations on it. This function is useful for debugging or commissioning a project.

When the TagDebug form appears, you can perform the following tasks:

- **Select a tag**

You can manually enter the name of the tag you would like to debug, or you can select it from the list included in the drop-down menu to the right of the **Tag** field. Be aware that the drop-down list is limited to 500 tags.

**Note:** Local variables will not be included in the **Tag** field drop-down list.

You can use the **Filter** button to help locate specific items from the tags database. A filter allows you to reduce the list of tags included in the tag drop-down menu to only those that match the characters specified in the Tag Filter dialog. To apply a filter, click on the Filter button and enter part of the name of the tag you would like to locate. The text entered can be a common suffix, it does not need to be the start of a tag name.

Click OK to apply the filter, or Clear to remove it.

If a filter is currently implemented, an "F" will appear next to the Filter button. An asterisk (\*) indicates no filter is currently being used.

Once you have a tag selected, you can specify additional properties in the field to the right of the Tag field. The drop-down menu includes a list of available extensions (for example, ".Field", ".Valid", ".Override", etc.). To automatically display these additional properties when a read occurs, you should use the drop-down menu in this field instead of manually adding an extension to a tag name.

- **Read a tag**

The **Read** button will retrieve the value for the tag you have specified, or an error code will be displayed (for example, <Error 424: Tag not found>).

If successful, a read will display the following information about the selected tag:

- Last user request: the time the most recent read occurred.
- Tag Type: the data type.
- Base tag: confirmation of the tag name, including the selected extension.
- .Q (quality), .QT (quality timestamp), .VT (value timestamp), and .T (the object timestamp, which is the most recent of the two timestamps).
- Eng Scale: RZ = raw zero; RF = Raw Full Scale; EZ = engineering zero; EF = engineering full scale.
- Eng Units.

- **Read from a tag array**

You view information for a particular item within a tag array using the **Array Index** field. This field allows you to specify the index number of the required item within the selected tag array.

- **Write to a tag**

To write a value to the selected tag, key in the required value and click on the **Write** button.

When a write has occurred, a log entry similar to the following will be added to the syslog.dat file:

```
<timestamp> TagDebug() Write: User 'Engineer' set tag 'Entry_ScrapWeight' to value ' 23.00' - NO ERROR
```

- **Check the device status**

The **Tag's Device Status** button allows you to confirm if the host device for the selected tag is currently online. In most cases, this will be useful in determining the cause of an error code, for example, <Error 424: Tag not found>. Clicking the button will update the current status of the device.

- **Use the auto-read feature**

The form allows for reads to be automatically repeated at a specified interval, allowing you observe how a tag value is changing over time.

Clicking the **Auto Read** button will start the read cycle; the **Stop Read** button will stop it. To adjust the read period, enter a value (milliseconds) in the field next to the Auto Read button.

## Syntax

`TagDebugForm()`

## Return Value

The name of the tag entered in the dialog.

## Related Functions

[TagDebug](#), [TagInfo](#), [TagReadEx](#), [TagWrite](#)

## Example

```
TagDebug(); /* Display debug form to allow user to debug */
```

## See Also

[Tag Functions](#)

## TagEventFormat

Returns a handle to the format of the data used by the [TagEventQueue\(\)](#).

## Syntax

**TagEventFormat()**

Parameters - None

## Return Value

The format handle.

## Related Functions

[QuePeek](#), [QueRead](#), [TagEventQueue](#)

## See Also

[Tag Functions](#)

## TagEventQueue

Opens the tag update event queue. The I/O server writes events into this queue as they are processed. These events include tag updates from drivers that support time-stamped data.

To read events from this queue, use the [QueRead\(\)](#) or [QuePeek\(\)](#) functions. The data put into the queue contains the following fields:

- Driver (the driver used to communicate with the I/O device)
- Port (the name of the port to which the I/O device is connected)
- Unit (the name of the I/O device)
- Tag (the variable tag name)
- Seconds (a UTC timestamp representing the number of seconds since 1970)
- Milliseconds (number of milliseconds since the last second)
- Value (the tag value)
- Quality (OPC component only equivalent to QualityGetPart, mode 7)

To use this function, you need to enable the tag update event queue with the [\[IOServer\]EnableEventQueue](#) parameter. This parameter will tell the I/O Server to start placing events into the queue. The function [TagEventFormat\(\)](#) returns a handle to the format of the data placed into the string field.

Enabling this formatting feature can increase CPU loading and reduce performance of the I/O Server as every tag update event is formatted and placed in the queue. You should reconsider using this feature if a decrease in performance is noticeable.

The maximum length of each queue is controlled by the [\[Code\]Queue](#) parameter. You may need to adjust this

parameter so as not to miss alarm events. When the queue is full, the I/O Server will discard events.

## Syntax

**TagEventQueue()**

Parameters - None

## Return Value

The queue handle of the Tag Update Event queue.

## Related Functions

[QuePeek](#), [QueRead](#), [TagEventFormat](#)

## Example

```
FUNCTION
ReadEvents()
INT status;
INT queue;
INT format;
INT eventId;
STRING event;
INT sec;
INT ms;
TIMESTAMP time;

queue = TagEventQueue();
format = TagEventFormat();

IF (queue <> -1 AND format <> -1) THEN
WHILE (true) DO
status = QueRead(queue, eventId, event, 1);
IF status = 0 THEN
ErrLog("eventId: " + IntToStr(eventId));
StrToFmt(format, event);
ErrLog(" driver: " + FmtGetField(format, "Driver"));
ErrLog(" port: " + FmtGetField(format, "Port"));
ErrLog(" unit: " + FmtGetField(format, "Unit"));
ErrLog(" tag: " + FmtGetField(format, "Tag"));
sec = FmtGetField(format, "Seconds");
ms = FmtGetField(format, "Milliseconds");
time = TimeIntToTimestamp(sec, ms, 1);
ErrLog(" time: " + TimestampToStr(time,14));
ErrLog(" value: " + FmtGetField(format, "Value"));
ErrLog(" quality: " + FmtGetField(format, "Quality"));
END
END
END
END
```

[Tag Functions](#)

### TagGetProperty

This function reads a property of a variable tag from the data source. This function replaces [TagInfo](#).

## Syntax

```
STRING TagGetProperty(STRING Name, STRING Property [, INT CachedMode] [, STRING ClusterName] )
```

### *Name:*

The name of the tag or the equipment and item name of a variable tag (using equipment.item notation) from which to get information. The tag can be prefixed by the name of the cluster that is "ClusterName.Tag" or "ClusterName.Equipment.Item".

---

**Note:** If the tag name exceeds the length limit of 254 characters the hardware alarm "Tag name exceed length limit" will be raised.

---

### *Property:*

The property to read. Property names are case sensitive. Supported properties are:

Address - Returns the configured address of the tag (as specified in the variable tags form).

ArraySize - Array size of the associated tag. Returns 1 for non-array types.

ClusterName - Name of the cluster the tag resides on.

DataBitWidth - Number of bits used to store the value

Description - Tag description

EngUnitsHigh - Maximum scaled value

EngUnitsLow - Minimum scaled value

Equipment - Name of the equipment associated with the Tag.

Format - Format bit string. The format information is stored in the integer as follows:

- Bits 0-7 - format width
- Bits 8-15 - number of decimal places
- Bits 16 - zero-padded
- Bit 17- left-justified
- Bit 18 - display engineering units
- Bit 20 - exponential (scientific) notation

FormatDecPlaces - Number of decimal places for default format

FormatWidth - Number of characters used in default format

FullName - Full name of the tag in the form cluster.tagname.

Item - Name of the equipment item associated with the Tag. If the tag is not resolved, returns an empty string.

RangeHigh - Maximum unscaled value

RangeLow - Minimum unscaled value

TagName - Name of the tag specified.

Type - General type of tag. Allowed values are:

- 0 - Digital
- 1 - Byte
- 2 - Integer16
- 3 - UInteger16
- 4 - Long
- 5 - Real
- 6 - String
- 7 - ULONG
- 8 - Undefined

Units - Engineering Units for example, %, mm, Volts.

Custom1 ... Custom8 - User-defined strings.

*CachedMode:*

Optional parameter that specifies from where to retrieve the value for the property.

-1 - The mode is determined by the INI parameter [\[Client\]TagReadCachedMode](#).

0 - The property value is retrieved direct from the server in blocking mode and an error code is returned if it is not on the server (or the server is unavailable). For the first call of TagGetProperty to return a proper value for custom fields, mode 0 needs to be specified.

1 - The property value is retrieved from the cache and an error code is returned if the cache is not loaded yet.

2 - The property value is retrieved from the local configuration and an error code is returned if it is not available (this is the traditional behaviour).

3 - The property value is retrieved from the cache, if the cache is loaded, and from the local configuration, if the cache is not loaded yet.

Default value is -1.

*ClusterName:*

Specifies the name of the cluster in which the Tag resides. The argument is enclosed in quotation marks.

---

**Note:** When retrieving bit width ("DataBitWidth" property) or array size ("ArraySize" property) from the local configuration (iCachedMode 2), the value is related to the data structure in the device. For example, MODNET, is a 16 bit device and does not have native LONG and REAL numbers. So when you have a LONG variable, an array of 2 INTEGERS are needed to store it. In the example, the property "DataBitWidth" against the variable will return 16 and property "ArraySize" will return 2. The combination of these two return values will add up to the correct bits.

## Return Value

String representation of the property of the tag. If unsuccessful, an empty string and an error code is set.

## Related Functions

[AssGetProperty](#), [AssGetScale](#), [AssInfo](#), [AssScaleStr](#), [TagGetProperty](#), [TagScaleStr](#), [TagInfo](#)

## Example

```
// Get the engineering full scale value for the variable "PV131"  
EngFullScale = TagGetProperty("PV131", "EngUnitsHigh", 0);  
// Get the cached array size for the array variable "PLC_Array"  
ArrayLength = TagGetProperty("PLC_Array", "ArraySize", 1);
```

## See Also

[Tag Functions](#)

### TagGetScale

Gets the value of a tag at a specified scale from the datasource. The value is returned as a formatted string using the tags format specification and (optionally) the engineering units. Use this function to write generic Cicode that will work with any type of tag. This function replaces [TagScaleStr](#).

## Syntax

**TagGetScale(STRING Name, INT Percent, INT EngUnits [, INT CachedMode] [, STRING ClusterName] )**

*Name:*

The name of the tag, or the equipment and item name of a variable tag (using equipment.item notation). The tag can be prefixed by the name of the cluster that is "ClusterName.Tag".

---

**Note:** If the tag name exceeds the length limit of 254 characters the hardware alarm "Tag name exceed length limit" will be raised.

*Percent:*

The percentage of full scale of the returned value.

*EngUnits:*

Flag to determine if the value is returned with engineering units:

0 - Do not return the value with engineering units

1 - Return the value with engineering units

*CachedMode:*

Optional parameter that specifies from where to retrieve the value for the property.

-1 - The mode is determined by the INI parameter [\[Client\]TagReadCachedMode](#).

0 - The property value is retrieved direct from the server in blocking mode and an error code is returned if it is not on the server (or the server is unavailable).

1 - The property value is retrieved from the cache and an error code is returned if the cache is not loaded yet.

2 - The property value is retrieved from the local configuration and an error code is returned if it is not available (this is the traditional behaviour).

3 - The property value is retrieved from the cache, if the cache is loaded, and from the local configuration, if the cache is not loaded yet.

Default value is -1.

*ClusterName:*

Specifies the name of the cluster in which the Tag resides. The argument is enclosed in quotation marks.

## Return Value

The scale of the tag (as a string).

## Related Functions

[AssGetProperty](#), [AssGetScale](#), [AssInfo](#), [AssScaleStr](#), [TagGetProperty](#), [TagScaleStr](#), [TagInfo](#)

## Example

```
// Display the zero, 50% and full scale of the tag CV_123_PV
DspText(31,0,TagGetScale("CV_123_PV", 0, 1));
DspText(32,0,TagGetScale("CV_123_PV", 50, 1));
DspText(33,0,TagGetScale("CV_123_PV", 100, 1));
```

## See Also

[Tag Functions](#)

## TagGetValue

Reads the value, quality and timestamp of a tag based on the tag subscription.

This function sets up an asynchronous subscription that checks at the specified polling period whether the value of a tag has changed. If the function fails to get a value from the tag initially, subsequent calls at periodic intervals retrieve the tag value. Unused subscriptions initiated by the function automatically expire at the end of the timeout period.

This is a non-blocking function.

## Syntax

**TagGetValue**(*STRING TagName [, INT Item] [, INT Index] [, LONG PollTime] [, INT ScaleMode] [, REAL Deadband] [, INT Lightweight] [, LONG KeepAliveSeconds]*)

### *TagName*

String representing the tag/tag element/ the equipment and item name (using equipment.item notation) associated with that tag, to subscribe to in the form of "cluster\_name.tag\_name.element name" or "cluster\_name.equipment. item.element\_name". If the element name (for example, 'Field') is not specified, it will be resolved at runtime as an unqualified tag reference. . If you need to access a specific tag element item to get timestamp and quality values, use the *nItem* parameter as well (for further information, refer to the [Tag Extensions](#) documentation in the main help).

Cluster name is optional for single-cluster projects.

If the *TagName* represents an array, the entire array is subscribed and will be reused. Note that square brackets for array indexing are unsupported. To retrieve values from individual elements of the array, use the *nIndex* parameter.

---

**Note:** If the tag name exceeds the length limit of 254 characters the hardware alarm "Tag name exceeds length limit" will be raised.

---

*Item*

Optional element number to access tag element values. For more information, refer to the Tag Extensions documentation in the main help.

0: Unqualified tag reference (default) – equivalent to empty element name

1: Value. Equivalent to "v" on Tag Extensions.

2: Value timestamp. Equivalent to "vt" on Tag Extensions.

3: Quality. Equivalent to "q" on Tag Extensions.

4: Quality timestamp. Equivalent to "qt" on Tag Extensions.

5: Timestamp. Equivalent to "t" on Tag Extensions.

*Index:*

Optional index for an array variable. If not specified, it has a default value of 0. Since the *TagName* parameter does not support array indexing, use the *Index* parameter to access an element in an array. Note that the address of the first element in an array is 0 (zero).

*PollTime*

Optional integer representing the Datasource Poll time in milliseconds. Default is 250 milliseconds.

*ScaleMode*

Optional number to specify scaling mode of subscription.

0: Equivalent to "Eng" (default)

1: Equivalent to "Raw"

2: Equivalent to "Percent"

(Deadband, Lightweight, KeepAliveSeconds: Unchanged.)

*Deadband*

Optional real value specifying the percentage of the variable tag's engineering range by which a tag needs to change for an update to be sent through the system. Default is -1.0, indicating the deadband specified by the tag definition is to be used.

*Lightweight*

This optional boolean argument indicates whether or not subscription updates use a "lightweight" version of the tag value that does not include a quality timestamp or a value timestamp.

If not used, this option is set to 1 which means lightweight tag values will be used by default.

To retrieve quality and value timestamps for a tag, you need to set the Lightweight option to 0.

*KeepAliveSeconds*

Optional length of time (in seconds) for which the subscription will remain in memory. The default is 30 seconds. If there are multiple requests to the same tag with different timeout values, only the first timeout value will be taken into account.

---

**Note:** ScaleMode and Deadband are ignored for Digital tags.

---

## Return Value

Returns the value, quality and timestamp of a subscribed tag. The data type of the value returned depends on

the type of the subscribed tag and also the tag extension. The quality and timestamp of the subscribed tag are read and passed with the value returned by the function.

Returns 0 for numerical data types or an empty string for strings if an error occurs. A hardware alarm will be also raised for an error. The tag value may be the last known value (LKV) if the quality of the tag is not good.

When a new subscription is being made and while waiting for its initial value, this function may return 0 or an empty string, which is not regarded as an error.

**Note:** If tag quality is important such that only good quality data values from this function need to be used in your project, you need to monitor the tag quality by calling this function separately with tag extensions. The tag value returned by this function does not reflect the original data quality and it is necessary to specify tag quality item number such as 3 (Quality) on Item argument in order to check the data quality.

## Examples

The following example returns the assigned RealPower item tag value on equipment item "Building.External.Light1".

```
REAL RealPower = TagGetValue("Building.External.Light1.RealPower", 0, 0, 250, 0, -1.0, 1, 30);
```

The following example returns the value of the "BIT\_1" tag.

```
TagGetValue("BIT_1");
```

The following example returns the field timestamp of "BIT\_1" tag.

```
TagGetValue("BIT_1.Field", 5, 0, 250, 0, -1.0, 0, 30);
```

The following example returns the the valid quality timestamp of the StatusEnum item tag value on equipment "Plant.Bottler.Bottle1". Note that lightweight mode is turned off to get quality timestamp values.

```
TagGetValue("Plant.Bottler.Bottle1.StatusEnum.Valid", 4, 0, 250, 0, -1.0, 0, 30);
```

The following example returns the value of the 3rd array element of Plot\_1. Note that array index starts from zero.

```
TagGetValue("Plot_1", 0, 2, 250, 0, -1.0, 0, 30);
```

The following example returns the Quality timestamp of the 1st array element of Plot\_1.

```
TagGetValue("Plot_1", 4, 0, 250, 0, -1.0, 0, 30);
```

[Tag Functions](#)

## TagInfo

Gets information about a variable tag. This function allows you to develop generic Cicode and Super Genies.

## Syntax

```
STRING TagInfo(STRING Name, INT Type [, STRING ClusterName] [, INT CachedMode] )
```

**Name:**

The name of the tag or the equipment and item reference of a variable tag (using equipment.item notation) from which to get information. The tag can be prefixed by the name of the cluster that is "ClusterName.Tag" or "ClusterName.Equipment.Item".

---

**Note:** If the tag name exceeds the length limit of 254 characters the hardware alarm "Tag name exceed length limit" will be raised.

To get information on a particular element in an array, enter the array name here, followed by the number of the element as follows:

"PLC\_Array[9]"

The above example tells the function to get information on the tenth element in PLC\_Array (remember, the address of the first element in an array is 0 (zero)).

**Type:**

The type of information to get:

0 - The Tag name from the variables table. This is the same as sName argument. (Returned to be compatible with the AssInfo() function). An empty string is returned if Type is 0.

1 - Engineering units

2 - Raw zero scale

3 - Raw full scale

4 - Engineering zero scale

5 - Engineering full scale

6 - Width of the format

7 - Number of decimal places of format

8 - The Tag format as a long integer. The format information is stored in the integer as follows:

- Bits 0-7 - format width

- Bits 8-15 - number of decimal places

- Bits 16 - zero-padded

- Bit 17- left-justified

- Bit 18 - display engineering units

- Bit 20 - exponential (scientific) notation

9 - Logical Unit Number - I/O device number (for internal use)

10 - Raw Type - Protocol's raw data type number for this tag. Type numbers are:

- 0 - Digital

- 1 - Integer

- 2 - Real

- 3 - BCD

- 4 - Long

- 5 - Long BCD

- 6 - Long Real

- 7 - String

- 8 - Byte

- 10 - Unsigned integer
  - 11 - Bit Width - Tag's size in bits. For example, an INT is 16 bits
  - 12 - Unit Type - Protocol's unit type number for this tag
  - 13 - Unit Address - Tag's address after the protocol DBF's template is applied.
  - 14 - Unit Count - Array size. For example, if the tag's address is I1[50], the unit count is 50.
  - 15 - Record Number - Tag's record number in variable.DBF - 1. That is, the first tag has a record number of 0.
  - 16 - Comment - As defined in the variable tags list.
  - 17 - ClusterName of the tag. If the tag is not resolved, returns an empty string.
  - 18 - Full name (*cluster.tagname*) of the tag. If the tag is not resolved, returns an empty string.
  - 19 - Reserved for internal operation.
  - 20 - Configured Address of the tag. If the tag is not resolved, returns an empty string.
  - 21 - Network Number - I/O device number (as defined by the Number field of the I/O Devices dialog).
  - 22 - Name of the equipment associated with the Tag. If the tag is not resolved, returns an empty string.
- If the tag is a local variable, mode 9 error code 348 is retrieved when cache mode is 0,1,2,3. Modes 12, 13, 14 and 15 will return an empty string (error 274 is trapped).
- 23 - General Type.
    - 0 - Digital
    - 1 - Byte
    - 2 - Integer16
    - 3 - UInteger 16
    - 4 - Long
    - 5 - Real
    - 6 - String
    - 7 - ULong
    - 8 - Undefined
  - 24 - Reserved for internal use.
  - 25 - Name of the equipment item associated with the Tag. If the tag is not resolved, returns an empty string.
  - 26 - Custom 1 - a user-defined string.
  - 27 - Custom 2 - a user-defined string.
  - 28 - Custom 3 - a user-defined string.
  - 29 - Custom 4 - a user-defined string.
  - 30 - Custom 5 - a user-defined string.
  - 31 - Custom 6 - a user-defined string.
  - 32 - Custom 7 - a user-defined string.
  - 33 - Custom 8 - a user-defined string.

#### *ClusterName*

Specifies the name of the cluster in which the Tag resides. The argument is enclosed in quotation marks.

#### *CachedMode:*

Optional parameter that specifies from where to retrieve the value for the property.

- 1 - The mode is determined by the INI parameter [Client]TagReadCachedMode.
- 0 - The property value is retrieved direct from the server in blocking mode and an error code is returned if it is not on the server (or the server is unavailable).
- 1 - The property value is retrieved from the cache and an error code is returned if the cache is not loaded yet.
- 2 - The property value is retrieved from the local configuration and an error code is returned if it is not available (this is the traditional behaviour).
- 3 - The property value is retrieved from the cache, if the cache is loaded, and from the local configuration, if the cache is not loaded yet.

Default value is -1.

---

**Note:** When retrieving bit width (Type 11) or unit count (Type 14) from local configuration (iCachedMode 2), the value is related to the data structure in the device. For example, MODNET, This is a 16 bit device does not have native LONG and REAL numbers. So when you have a LONG variable, then 2 INTEGERS are needed to store it. In the case, Type 11 against the variable will return 16 and Type 14 will return 2. The combination of these two return values will add up to the correct bits.

---

## Return Value

The value of the information as a string.

## Related Functions

[AssGetProperty](#), [AssGetScale](#), [AssInfo](#), [AssScaleStr](#), [TagGetProperty](#), [TagGetScale](#), [TagInfoEx](#), [TagScaleStr](#)

## Example

```
/* Get the engineering full scale value for the variable "PV131" */  
EngFullScale = TagInfo("PV131", 5);  
/* Get the engineering zero scale value for the array variable "PLC_Array" */  
EngZeroScale = TagInfo("PLC_Array", 4);
```

[Tag Functions](#)

## TagInfoEx

This function replaces TagInfo and is identical in operation. It supports online changes. It is recommended therefore that instances of TagInfo in legacy code are migrated to either TagInfoEx or TagGetProperty. New Cicode should use TagGetProperty.

Gets information about a variable tag. This function allows you to develop generic Cicode and Super Genies. Execution can be blocking or non-blocking depending on the iCached argument.

**Note:** When replacing an instance of TagInfo with TagInfoEx in a loop, you may want to make TagInfoEx blocking using the iCached argument so that you are using the correct value for the Tag in your logic. You should also be aware that TagInfo has different return values if you are using mode 10 for nType

## Syntax

STRING **TagInfoEx**(*STRING Name*, *INT Type* [, *STRING ClusterName*] [, *INT CachedMode*] )

*Name*:

The name of the tag or the equipment and item name of a variable tag (using equipment.item notation) from which to get information. The name of the tag can be prefixed by the name of the cluster that is "ClusterName.Tag" or "ClusterName.Equipment.Item".

If the tag name exceeds the length limit of 254 characters the hardware alarm "Tag name exceed length limit" will be raised.

To get information on a particular element in an array, enter the array name here, followed by the number of the element as follows:

"PLC\_Array[9]"

The above example tells the function to get information on the tenth element in PLC\_Array (remember, the address of the first element in an array is 0 (zero)).

*Type*:

The type of information to get:

*0* - The Tag name from the variables table. This is the same as the *Name* argument. (Returned to be compatible with the [AssInfo](#) function.)

*1* - Engineering units

*2* - Raw zero scale

*3* - Raw full scale

*4* - Engineering zero scale

*5* - Engineering full scale

*6* - Width of the format

*7* - Number of decimal places of format

*8* - The Tag format as a long integer. The format information is stored in the integer as follows:

- Bits 0-7 - format width
- Bits 8-15 - number of decimal places
- Bits 16 - zero-padded
- Bit 17- left-justified
- Bit 18 - display engineering units
- Bit 20 - exponential (scientific) notation

*10* - General Type - Protocol's general data type number for this tag. Type numbers are:

- *0* - Digital
- *1* - Byte
- *2* - Integer16
- *3* - UInteger16
- *4* - Long
- *5* - Real
- *6* - String

- 7 - ULONG

- 8 - Undefined

11 - Bit Width - Tag's size in bits. For example, an INT is 16 bits

Types 12 to 15 are only supported when *iCachedMode* equals to 2 or 3.

12 - Unit Type - Protocol's unit type number for this tag

13 - Unit Address - Tag's address after the protocol DBF's template is applied.

14 - Unit Count - Array size. For example, if the tag's address is I1[50], the unit count is 50.

15 - Record Number - Tag's record number in variable.DBF - 1. That is, the first tag has a record number of 0.

16 - Comment - As defined in the variable tags list.

17 - ClusterName of the tag.

18 - Full name (*cluster.tagname*) of the tag.

19 - Reserved for internal operation.

20 - Configured Address of the tag. If the tag is not resolved, returns an empty string.

21 - Network Number - I/O device number (as defined by the Number field of the I/O Devices dialog).

22 - Name of the equipment associated with the Tag. If the tag is not resolved, returns an empty string.

If the tag is a local variable, mode 9 error code 348 is retrieved when cache mode is 0,1,2,3. Modes 12, 13, 14 and 15 will return an empty string (error 274 is trapped).

23 - Reserved for internal use.

24 - Reserved for internal use.

25 - Name of the equipment item associated with the Tag. If the tag is not resolved, returns an empty string.

26 - Custom 1 - a user-defined string.

27 - Custom 2 - a user-defined string.

28 - Custom 3 - a user-defined string.

29 - Custom 4 - a user-defined string.

30 - Custom 5 - a user-defined string.

31 - Custom 6 - a user-defined string.

32 - Custom 7 - a user-defined string.

33 - Custom 8 - a user-defined string.

#### *ClusterName*

Specifies the name of the cluster in which the Tag resides. The argument is enclosed in quotation marks.

#### *CachedMode*:

Optional parameter that specifies from where to retrieve the value for the property.

-1 - The mode is determined by the INI parameter [Client]TagReadCachedMode.

0 - The property value is retrieved direct from the server in blocking mode and an error code is returned if it is not on the server (or the server is unavailable).

1 - The property value is retrieved from the cache and an error code is returned if the cache is not loaded yet.

2 - The property value is retrieved from the local configuration and an error code is returned if it is not available (this is the traditional behavior).

3 - The property value is retrieved from the cache, if the cache is loaded, and from the local configuration, if the

cache is not loaded yet.

Default value is -1.

**Note:** When retrieving bit width (Type 11) or unit count (Type 14) from local configuration (iCachedMode 2), the value is related to the data structure in the device. For example, MODNET, This is a 16 bit device does not have native LONG and REAL numbers. So when you have a LONG variable, then 2 INTEGERS are needed to store it. In the case, Type 11 against the variable will return 16 and Type 14 will return 2. The combination of these two return values will add up to the correct bits.

## Return Value

The value of the information as a string. If unsuccessful, an empty string is returned. The error code can be obtained by calling the IsError Cicode function.

## Related Functions

[AssGetProperty](#), [AssGetScale](#), [AssInfo](#), [AssScaleStr](#), [TagGetProperty](#), [TagGetScale](#), [TagInfo](#), [TagScaleStr](#)

## Example

```
/* Get the engineering full scale value for the variable "PV131".  
Obtain the value from Cluster1 in blocking mode */  
EngFullScale = TagInfoEx("PV131", 5, "Cluster1", 0);  
/* Get the engineering zero scale value for the array variable  
"PLC_Array" in non-blocking mode*/  
EngZeroScale = TagInfoEx("PLC_Array", 4);
```

## See Also

[Tag Functions](#)

## TagRamp

This function will increment a Tag by the amount defined by *iPercentInc*. It is often used for incrementing a tag while a button is held down.

## Syntax

**TagRamp**(STRING *Tag*, INT *PercentInc*)

*Tag*:

The variable tag name (or alarm property name), as a string. The name of the tag can be prefixed by the name of the cluster that is "ClusterName.Tag".

To read a particular element in an array, you can enter the array name here, followed by an index to the element as follows:

"PLC\_Array[9] "

The above example tells the function to read the 10th element in the array variable PLC\_Array (remember, the

address of the first element in an array is 0 (zero)).

If you enter an array offset using the *nOffset* argument, it will be added to the index value specified here. For example, TagRead("PLC\_Array[9]", 4) will read the 14th element in PLC\_Array (because [9] means the 10th element, and an offset of 4 means 4 elements after the 10th = element 14).

*PercentInc:*

The percentage by which you want to increase the value of the variable. A negative number will decrease the variable. The increment is calculated as a percentage of the full range.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TagInfo](#), [TagReadEx](#), [TagWrite](#)

## Example

Buttons

Text	Ramp Up
Repeat Command	TagRamp("PLC_VAR_1",2);
Comment	Continual increment by 2%

[Tag Functions](#)

## TagRDBReload

Works in conjunction with the TagInfo function. Reloads the variable tag database so when TagInfo is called it picks up all online changes to the tag database.

## Syntax

**TagRDBReload()**

## Return Value

Returns 1 if the tag database was successfully reloaded, and 0 if the tag database fails to load.

**Note:** This function will fail and return 0 if the parameter [\[General\]TagDB](#) has been set to 0.

## Related Functions

[TagInfo](#)

## See Also

[Tag Functions](#)

### TagRead

Reads a variable from an I/O device or a local variable. The variable tag needs to be defined in the Variable Tags database. Because the variable tag is specified as a string (not as a tag), you can ignore the data type of the variable.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

TagRead is useful when the variable tag name is a calculation, such as `sAlarmExt+".Paging"`. For simple assignment of variables use the assignment operator. For example:

```
MyString = MyCluster.MyAlarm.MyProperty
```

---

**Note:** If the Tag property has not been initialized the timestamp value displayed for that tag will be equal to the Unix Epoch, January 1st 1970.

---

If you try to read many variables at the same time, the TagRead() function may be slow. The offset index for array variables is checked against the size of the array.

---

**Note:** TagRead can only return the values of elements for those tags having "Good" quality. If the quality of a tag is not "Good", TagRead returns an empty string. In order to obtain values of tags having not "Good" quality one can use their 'v' item. For example, `TagRead("MyBadQualityTag.v")`. However, the value returned by a TagRead call on a tag with not "Good" quality may be obsolete (due to TagRead asynchronous nature). Use the [IsError](#) Cicode function to control the returned error code when using this function.

## Syntax

**TagRead(STRING Tag [, INT nOffset [, STRING ClusterName]])**

*Tag:*

A string that can be one of the following:

- A tag name — for example, "Fire1"
- An equipment item reference — for example, "Motor1.Fire"
- A tag property — for example, "Fire1.v"
- An equipment item property — for example, "Motor1.Fire.v"
- An alarm property — for example, "AlarmFire1.On"
- An alarm equipment item property — for example, "Motor1.AlarmFire.On"

Currently only the "v" tag extension item is supported by TagRead. References to other extension items will generate an error message. If the element name is not specified, it will be resolved at runtime as an unqualified tag reference.

The name of the tag can be prefixed by the name of the cluster, for example, "ClusterName.Tag" or "ClusterName.Equipment.Item".

If the tag name exceeds the length limit of 254 characters the hardware alarm "Tag name exceed length limit" will be raised.

In the example below, assuming the following variable tag, equipment and item are defined in your project :

Tag: PLC\_Array

Equipment: PLC

Item: Array

Address: 30000[10]

You can refer to the variable tag using the following syntax:

"PLC\_Array"

"PLC.Array"

To read a particular element in an array, you can enter the array name here, followed by an index to the element as follows:

"PLC\_Array[9]"

"PLC.Array[9]"

The above example tells the function to read the 10th element in the array variable PLC\_Array (remember, the address of the first element in an array is 0 (zero)).

If you enter an array offset using the *nOffset* argument, it will be added to the index value specified here. For example, TagRead("PLC\_Array[9]", 4) will read the 14th element in PLC\_Array (because [9] means the 10th element, and an offset of 4 means 4 elements after the 10th = element 14). If you want to read the value of <Valid> element in the above example,

TagRead("PLC\_Array.Valid.V[9]", 4)

*Offset*:

The offset for an array variable. This argument is optional - if not specified, it has a default value of 0.

If you enter an array index as part of the *sTag* argument, it will be added to this offset value. For example, TagRead("PLC\_Array[9]", 4) will read the 14th element in PLC\_Array (because [9] means the 10th element, and an offset of 4 means 4 elements after the 10th = element 14).

*ClusterName*:

Specifies the name of the cluster in which the Tag resides. The argument is enclosed in quotation marks.

## Return Value

The function can return:

- The tag element value (depending on the *sTag* parameter, of the I/O device variable) when the tag has "Good" quality.
- The tag element value (depending on the *sTag* parameter, of the I/O device variable) and the error 257 (can be checked by IsError() built-in function) when the value of the tag is out of the predefined range.
- An empty string and an error code when the tag has not "Good" quality".

## Related Functions

[TagReadEx](#), [TagWrite](#), [IODeviceControl](#), [IODeviceInfo](#)

## Example

```
STRING sStringTagValue;
STRING sStringTagValueField;
INT nIntTagValue;
REAL fRealTagValue;
// Tag1 has a STRING data type.
sStringTagValue = TagRead("Tag1");
sStringTagValueField = TagRead("Tag1.Field");
// Tag2 has an INTEGER data type.
nIntTagValue = TagRead("Tag2");
// Tag3 has a REAL data type.
fRealTagValue = TagRead("Tag3");
```

## See Also

[Tag Reference and TagReadEx Behavior in Cicode Expressions](#)

[Tag Functions](#)

## TagReadEx

Reads the value, quality or timestamp of a particular tag from the I/O device. The variable tag needs to be defined in the Variable Tags database. Because the variable tag is specified as a string (not as a tag), you can ignore the data type of the variable.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

TagReadEx should only be used when the variable tag name is a calculation such as sAlarmExt+.Paging". For simple assignment of variables use the assignment operator. For example, MyString = MyCluster.MyAlarm.MyProperty.

If you try to read many variables at the same time, the TagReadEx() function may be slow. The offset index for array variables is checked against the size of the array.

---

**Note:** TagReadEx can only return the values of elements for those tags having "Good" quality. If the quality of a tag is not "Good", TagReadEx may return an obsolete value (due to TagRead asynchronous nature).

---

## Syntax

**TagReadEx(STRING Tag [, INT Offset [, STRING ClusterName]])**

*Tag:*

A string that can be one of the following:

- A tag name — for example, "Fire1"
- An equipment item reference — for example, "Motor1.Fire"
- A tag property — for example, "Fire1.v"
- An equipment item property — for example, "Motor1.Fire.v"
- An alarm property — for example, "AlarmFire1.On"
- An alarm equipment item property — for example, "Motor1.AlarmFire.On"

Currently only the "v" tag extension item is supported by TagRead. References to other extension items will

generate an error message. If the element name is not specified, it will be resolved at runtime as an unqualified tag reference.

The name of the tag can be prefixed by the name of the cluster, for example, "ClusterName.Tag" or "ClusterName.Equipment.Item".

If the tag name exceeds the length limit of 254 characters the hardware alarm "Tag name exceed length limit" will be raised.

In the example below, assuming the following variable tag, equipment and item are defined in your project:

Tag: PLC\_Array

Equipment: PLC

Item: Array

Address: 30000[10]

You can refer to the variable tag using the following syntax:

"PLC\_Array"

"PLC.Array"

To read a particular element in an array, you can enter the array name here, followed by an index to the element as follows:

"PLC\_Array[9]"

"PLC.Array[9]"

The above example tells the function to read the 10th element in the array variable PLC\_Array (remember, the address of the first element in an array is 0 (zero)).

If you enter an array offset using the *nOffset* argument, it will be added to the index value specified here. For example, TagRead("PLC\_Array[9]", 4) will read the 14th element in PLC\_Array (because [9] means the 10th element, and an offset of 4 means 4 elements after the 10th = element 14). If you want to read the value of <Valid> element in the above example,

TagReadEx("PLC\_Array.Valid.V[9]", 4)

*Offset*:

The offset for an array variable. This argument is optional - if not specified, it has a default value of 0.

If you enter an array offset using the *nOffset* argument, it will be added to the index value specified here. For example, TagReadEx("PLC\_Array[9]", 4) will read the 14th element in PLC\_Array (because [9] means the 10th element, and an offset of 4 means 4 elements after the 10th = element 14).

*ClusterName*:

Specifies the name of the cluster in which the Tag resides. The argument is enclosed in quotation marks.

## Return Value

The function can return:

- The tag element value (depending on the *sTag* parameter, of the I/O device variable) when the tag has "Good" quality.
- The tag element value (depending on the *sTag* parameter, of the I/O device variable) and the error 257 (can be checked by *IsError()* built-in function) when the value of the tag is out of the predefined range.
- A value and an error code when the tag does not have "Good" quality.

## Related Functions

[TagRead](#), [TagWrite](#), [IODeviceControl](#), [IODeviceInfo](#)

## Example

```
STRING sStringTagValue;
STRING sStringTagValueField;
INT nIntTagValue;
REAL fRealTagValue;
// Tag1 has a STRING data type.
sStringTagValue = TagReadEx("Tag1");
sStringTagValueField = TagReadEx("Tag1.Field");
// Tag2 has an INTEGER data type.
nIntTagValue = TagReadEx("Tag2");
// Tag3 has a REAL data type.
fRealTagValue = TagReadEx("Tag3");
TIMESTAMP t1 = TagReadEx("Tag1.T");
TIMESTAMP t2 = TagReadEx("Tag1.VT");
TIMESTAMP t3 = TagReadEx("Tag1.Qt");
QUALITY q1 = TagReadEx("Tag1.Q");
```

## See Also

[Tag Reference /TagReadEx\(\) Behavior in Cicode Expressions](#)

[Tag Functions](#)

## TagResolve

This function can be used to increment a reference count on a tag to keep it resolved, making it readily available to a client.

If a tag is held in a resolved state, it will not be evicted from the client even if it is not being used. This means a client does not need to locate the tag's associated I/O server when a read or write is required.

While this allows faster access to a tag, it should be only utilised for priority tags, as a large number of resolved tags will increase the amount of memory used.

You can use the function [TagUnresolve](#) to decrement the reference count.

## Syntax

**TagResolve(STRING TagName)**

*TagName:*

The name of the tag or the equipment and item name (using equipment.item notation) associated with that tag to resolve (in the format "clusterName.tagName" or "clusterName.equipment.item" if you need to specify a cluster).

**Note:** If the tag name exceeds the length limit of 254 characters the hardware alarm "Tag name exceed length limit" will be raised.

## Return Value

The returned integer is a handle to the tag that has been resolved, or -1 if an error occurred.

The specific error code is accessible by calling [IsError\(\)](#).

## Related Functions

[TagUnresolve](#)

## See Also

[Tag Functions](#)

### TagScaleStr

Gets the value of a tag at a specified scale. The value is returned as a formatted string using the tags format specification and (optionally) the engineering units. Use this function to write generic Cicode that will work with any type of tag.

---

**Note:** This function is being deprecated and is replaced by the [TagGetScale](#) function. If the Tag properties are updated TagScaleStr does not get the updated values whereas TagGetScale does.

---

## Syntax

STRING **TagScaleStr**(STRING *Tag*, INT *Percent* , INT *EngUnits* [,STRING *ClusterName*] [,INT *CachedMode*] )

*Tag*:

The name of the tag, or the equipment and item name of a variable tag (using equipment.item notation).

---

**Note:** If the tag name exceeds the length limit of 254 characters the hardware alarm "Tag name exceed length limit" will be raised.

---

*Percent*:

The percentage of full scale of the returned value.

*EngUnits*:

Determines if the value is returned with engineering units:

0 - Return the value without engineering units

1 - Return the value with engineering units

*ClusterName*:

Name of the cluster

*CachedMode*:

Optional parameter that specifies from where to retrieve the value for the property.

-1 - The mode is determined by the INI parameter [\[Client\]TagReadCachedMode](#).

0 - The property value is retrieved direct from the server in blocking mode and an error code is returned if it is not on the server (or the server is unavailable).

1 - The property value is retrieved from the cache and an error code is returned if the cache is not loaded yet.

2 - The property value is retrieved from the local configuration and an error code is returned if it is not available (this is the traditional behaviour).

3 - The property value is retrieved from the cache, if the cache is loaded, and from the local configuration, if the cache is not loaded yet.

Default value is -1.

## Return Value

The scale of the tag (as a string).

## Related Functions

[AssGetProperty](#), [AssGetScale](#), [AssInfo](#), [AssScaleStr](#), [TagGetProperty](#), [TagGetScale](#), [TagInfo](#)

## Example

```
// Display the zero, 50% and full scale of the tag CV_123_PV
DspText(31,0,TagScaleStr("CV_123_PV", 0, 1));
DspText(32,0,TagScaleStr("CV_123_PV", 50, 1));
DspText(33,0,TagScaleStr("CV_123_PV", 100, 1));
```

[Tag Functions](#)

## TagSetOverrideBad

Sets a quality Override element for a specified tag to Bad Non Specific.

## Syntax

**TagSetOverrideBad**(*STRING Tag* [,*INT Synch* [, *STRING ClusterName*]])

*Tag*:

The variable tag name or the equipment and item name (using equipment.item notation) associated with that tag as a string. The name of the tag can be prefixed by the name of the cluster that is "ClusterName.Tag" or "ClusterName.Equipment.Item".

If the tag name exceeds the length limit of 254 characters the hardware alarm "Tag name exceed length limit" will be raised.

*Synch*:

An optional boolean argument that specifies whether the command is synchronous (blocking) or asynchronous (non-blocking). By default, this parameter is set to "True", synchronous (blocking), and the function will wait until the write has completed and returned from the server before further code execution. If you specify this parameter the other parameters need to be explicitly specified.

*ClusterName*:

Specifies the name of the cluster in which the Tag resides. The argument is enclosed in quotation marks.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TagSetOverrideQuality](#), [TagSetOverrideGood](#), [TagSetOverrideUncertain](#), [QualityIsOverride](#)

## Example

```
TagSetOverrideBad("Tag1");
```

Setting the value of the OverrideMode element to anything other than 3 will overwrite the quality that has been applied to the Override element using this function. See the example below. Also see the topic [Override Mode](#) in Plant SCADA's Scheduler documentation.

```
//The OverrideMode is switched off
Tag1.OverrideMode = 0;
//The quality of Override element is set to Bad
TagSetOverrideUncertain("Tag1");
//The OverrideMode is set to 1 and
//the Field element is copied to the Override element.
//The quality of the Override element is overwritten.
Tag1.OverrideMode = 1;
//The quality is set again to Bad
TagSetOverrideBad("Tag1");
```

## See Also

[Tag Functions](#)

## TagSetOverrideGood

Sets a quality Override element for a specified tag to Good Non Specific.

## Syntax

**TagSetOverrideGood** (STRING *Tag* [,INT *Synch* [, STRING *ClusterName*]])

*Tag*:

The variable tag name or the equipment and item name (using <equipment>.<item> notation) associated with that tag as a string. The name of the tag can be prefixed by the name of the cluster that is "ClusterName.Tag" or "ClusterName.Equipment.Item".

If the tag name exceeds the length limit of 254 characters the hardware alarm "Tag name exceed length limit" will be raised.

*Synch*:

An optional boolean argument that specifies whether the command is synchronous (blocking) or asynchronous (non-blocking). By default, this parameter is set to "True", synchronous (blocking), and the function will wait until the write has completed and returned from the server before further code execution. If you specify this

parameter the other parameters need to be explicitly specified.

*ClusterName:*

Specifies the name of the cluster in which the Tag resides. The argument is enclosed in quotation marks.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TagSetOverrideQuality](#), [TagSetOverrideBad](#), [TagSetOverrideUncertain](#), [TagSetOverrideBad](#), [QualityIsOverride](#)

## Example

```
TagSetOverrideGood("Tag1");
```

Setting the value of the OverrideMode element to anything other than 3 will overwrite the quality that has been applied to the Override element using this function. See the example below. Also see the topic [Override Mode](#) in Plant SCADA's Scheduler documentation.

```
//The OverrideMode is switched off
Tag1.OverrideMode = 0;
//The quality of Override element is set to Good
TagSetOverrideGood("Tag1");
//The OverrideMode is set to 1 and
//the Field element is copied to the Override element.
//The quality of the Override element is overwritten.
Tag1.OverrideMode = 1;
//The quality is set again to Good
TagSetOverrideGood("Tag1");
```

## See Also

[Tag Functions](#)

## TagSetOverrideQuality

Sets a quality of Override element for a specified tag.

## Syntax

**TagSetOverrideQuality**(STRING *Tag*, QUALITY *qualityNew* [,INT *Synch* [, STRING *ClusterName*]])

*Tag*

The variable tag name or the equipment and item name (using equipment.item notation) associated with that tag as a string. The name of the tag can be prefixed by the name of the cluster that is "ClusterName.Tag" or "ClusterName.Equipment.Item".

If the tag name exceeds the length limit of 254 characters the hardware alarm "Tag name exceed length limit" will be raised.

**qualityNew**

The new quality for the tag's Override element.

**Synch**

An optional boolean argument that specifies whether the command is synchronous (blocking) or asynchronous (non-blocking). By default, this parameter is set to "True", synchronous (blocking), and the function will wait until the write has completed and returned from the server before further code execution. If you specify this parameter the other parameters need to be explicitly specified.

**ClusterName**

Specifies the name of the cluster in which the Tag resides. The argument is enclosed in quotation marks.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TagSetOverrideGood](#), [TagSetOverrideBad](#), [QualityIsOverride](#)

## Example

```
QUALITY q1 = QualityCreate(QUAL_UNCR);
TagSetOverrideQuality("Tag1", q1);
```

Setting the value of the OverrideMode element to anything other than 3 will overwrite the quality that has been applied to the Override element using this function. See the example below. Also see the topic [Override Mode](#) in Plant SCADA's Scheduler documentation.

```
//The OverrideMode is switched off
Tag1.OverrideMode = 0;
//The quality of Override element is set to Uncertain
QUALITY q1 = QualityCreate(QUAL_UNCR);
TagSetOverrideQuality("Tag1", q1);
//The OverrideMode is set to 1 and
//the Field element is copied to the Override element.
//The quality of the Override element is overwritten.
Tag1.OverrideMode = 1;
//The quality is set again to Uncertain
QUALITY q1 = QualityCreate(QUAL_UNCR);
TagSetOverrideQuality("Tag1", q1);
```

### TagSetOverrideUncertain

Sets a quality Override element for a specified tag to Uncertain Non Specific.

## Syntax

**TagSetOverrideUncertain(STRING Tag [,INT Synch [, STRING ClusterName]])**

*Tag:*

The variable tag name or the equipment and item name (using equipment.item notation) associated with that tag as a string. The name of the tag can be prefixed by the name of the cluster that is "ClusterName.Tag" or "ClusterName.Equipment.Item".

If the tag name exceeds the length limit of 254 characters the hardware alarm "Tag name exceed length limit" will be raised.

*Synch:*

An optional boolean argument that specifies whether the command is synchronous (blocking) or asynchronous (non-blocking). By default, this parameter is set to "True", synchronous (blocking), and the function will wait until the write has completed and returned from the server before further code execution. If you specify this parameter the other parameters need to be explicitly specified.

*ClusterName:*

Specifies the name of the cluster in which the Tag resides. The argument is enclosed in quotation marks.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TagSetOverrideQuality](#), [TagSetOverrideGood](#), [TagSetOverrideBad](#), [QualityIsOverrride](#)

## Example

```
TagSetOverrideUncertain("Tag1");
```

Setting the value of the OverrideMode element to anything other than 3 will overwrite the quality that has been applied to the Override element using this function. See the example below. Also see the topic [Override Mode](#) in Plant SCADA's Scheduler documentation.

```
//The OverrideMode is switched off
Tag1.OverrideMode = 0;
//The quality of Override element is set to Uncertain
TagSetOverrideUncertain("Tag1");
//The OverrideMode is set to 1 and
//the Field element is copied to the Override element.
//The quality of the Override element is overwritten.
Tag1.OverrideMode = 1;
//The quality is set again to Uncertain
TagSetOverrideUncertain("Tag1");
```

## See Also

[Tag Functions](#)

## TagSubscribe

Subscribes a tag so that Cicode functions can be called when a tag's value changes. The subscription checks each poll period whether the tag has changed value and if it has, the specified callback function is called. This avoids continuously polling a tag value to monitor changes. To add a function callback to the subscription, use the optional parameter in this command or the [SubscriptionAddCallback](#) function.

Multiple subscriptions are possible to the same tag. Each new subscription returns a new subscription handle. Multiple callbacks are possible to the same subscription.

You can use this function to subscribe to a variable that is an array by specifying an array index in the *TagName* argument. For example:

```
TagSubscribe("tag[5]", ...)
```

When the array value changes, a runtime callback will pass the indexed tag value. If an invalid index value is passed, a hardware error will be generated.

- If a negative array index value is used, an "Invalid argument" hardware alarm will be raised.
- If an index value exceeds the maximum value of the array offset, an "Array overrun" hardware alarm will be raised.

To unsubscribe a tag, use the [TagUnsubscribe](#) function.

## Syntax

```
TagSubscribe(STRING TagName [, INT PollTime] [, STRING ScaleMode] [, REAL Deadband] [, STRING Callback] [,  
INT Lightweight] [, INT NoUpdateForDuplicateValues])
```

### TagName

String representing the tag or tag element or the equipment and item name (using equipment.item notation) associated with that tag, to subscribe to in the form of "cluster\_name.tag\_name.element name" or "cluster\_name.equipment.item.element name". If the element name is not specified, it will be resolved at runtime as an unqualified tag reference.

If the tag name exceeds the length limit of 254 characters the hardware alarm "Tag name exceed length limit" will be raised.

### PollTime

Optional integer representing the Datasource Poll time in milliseconds (default 250).

### ScaleMode

Optional string stating the mode to subscribe. Supported modes are: Raw, Eng, Percent. Default is "Eng".

### Deadband

Optional real value specifying the percentage of the variable tag's engineering range that a tag needs to change by for an update to be sent through the system. Default value is -1.0, indicating the deadband specified by the tag definition is to be used.

### Callback

Optional string stating the name of a function to call when the value is updated. If an empty string is specified, no handler is registered. Default value is "" (empty string).

The function should have the structure:

```
FUNCTION evtHandler([INT handle] [, STRING value] [, QUALITY quality] [, TIMESTAMP timestamp])
```

...

END

Where:

*handle* is the subscription that raised the event.

*value* is the tag value.

*quality* is the value quality.

*timestamp* is the value timestamp.

#### *Lightweight*

This optional boolean argument indicates whether or not subscription updates use a "lightweight" version of the tag value that does not include a quality timestamp or a value timestamp.

If not used, this option is set to 1 which means lightweight tag values will be used by default. For a client to retrieve quality and value timestamps for a tag, you should explicitly specify that a full tag value is required by setting this option to 0.

#### *NoUpdateForDuplicateValues*

This optional boolean argument allows you to specify if the subscription accepts duplicated values. Set this value to 1 to indicate that a duplicated update is not required for values that have already successfully written to the device.

---

**Note:** *ScaleMode* and *Deadband* are ignored for digital tags.

---

## Return Value

Integer representing the subscription handle that can be used to read values, hook to events or unsubscribe. If unsuccessful, -1 is returned and an error is set. Even though a subscription handle is returned immediately, it can't be used to get attributes until the subscription has been confirmed as this is an asynchronous Cicode function call. The typical Cicode error is 423 when a subscription handled is used too soon. We recommend the use of a callback function or the direct use of the tag extension, e.g. <tag>.VT

## Related Functions

[TagUnsubscribe](#), [SubscriptionAddCallback](#), [SubscriptionGetAttribute](#), [SubscriptionRemoveCallback](#)

## Example

The following example subscribes the tag "Conveyor1" in order to manually poll for attributes of the tag.

```
...
// Get the last changed value, quality and timestamp for the tag every 1s
...
// LOOP START

SleepMs(1000);

ErrSet(1);
convValue = SubscriptionGetAttribute(subsHandle, "Value");

IF IsError() = 0
convQual = SubscriptionGetAttribute(subsHandle, "ValueQuality");
convTime = SubscriptionGetAttribute(subsHandle, "ValueTimestamp");
```

```
// Format and use data here  
  
END  
  
// LOOP END  
...  
// Unsubscribe the tag TagUnsubscribe(subsHandle);
```

The following example subscribes the "conveyor1" tag as a percentage and polls it every 100ms to check for changes. When the value changes the functions OnValueChanged and ValChanged2 are called. This is the recommended way to do polling of special variables:

```
...  
INT subsHandle = TagSubscribe("Conveyor1", 100, "Percent",  
"OnValueChanged");  
...  
// Later on if no callback was registered initially, a new one can be added.  
SubscriptionAddCallBack(subsHandle, "ValChanged2");  
...  
Function OnValueChanged(INT handle, STRING tagValue, QUALITY valueQuality, TIMESTAMP  
valueTimestamp)  
STRING sTag;  
INT qualityGeneral;  
INT year;  
INT second;  
  
sTag = SubscriptionGetAttribute(handle, "FullName"); // If the name is needed  
qualityGeneral = QualityGetPart(valueQuality, 0); // If General Quality value is needed  
year = TimestampGetPart(valueTimestamp, 0); // if year part is needed  
second = TimestampGetPart(valueTimestamp, 5); // if second part is needed  
...  
END  
...  
Function ValChanged2(INT handle, STRING tagValue, QUALITY valueQuality, TIMESTAMP  
valueTimestamp)  
STRING sTag;  
INT qualityGeneral;  
INT year;  
INT second;  
sTag = SubscriptionGetAttribute(handle, "FullName"); // If the name is needed  
qualityGeneral = QualityGetPart(valueQuality, 0); // if General Quality value is needed  
year = TimestampGetPart(valueTimestamp, 0); // if year part is needed  
second = TimestampGetPart(valueTimestamp, 5); // if second part is needed  
...  
END  
...  
// Remove all callbacks and unsubscribe  
TagUnsubscribe(subsHandle);
```

## See Also

[Tag Functions](#)

## TagUnresolve

This function is used to decrement a reference count implemented on a tag by [TagResolve](#). This will allow the tag to be evicted if the decrement causes its reference count to reach zero (0).

## Syntax

**TagUnresolve(INT *iHandle*)**

*Handle*:

The tag handle returned from a [TagResolve\(\)](#) function call.

## Return Value

The returned integer represents any error that occurs when the unresolve is attempted (0 for no error).

## Related Functions

[TagResolve](#)

## See Also

[Tag Functions](#)

## TagUnsubscribe

Unsubscribes the tag subscription specified by the integer subscription handle that was returned from the [TagSubscribe](#) function. This function also removes any callbacks that are associated with the subscription.

## Syntax

**TagUnsubscribe(INT *Handle*)**

*Handle*

Integer handle of the subscription to unsubscribe.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TagSubscribe](#), [SubscriptionAddCallback](#), [SubscriptionGetAttribute](#), [SubscriptionRemoveCallback](#)

## See Also

[Tag Functions](#)

### TagWrite

Writes to an I/O device variable by specifying the variable tag name or the variable tag name and the name of the requested element having read/write access. The variable tag needs to be defined in the Variable Tags database.

---

**Note:** For this function to be successful a user needs to be logged in.

This function completes asynchronously to the caller. It will be unsuccessful if the tag does not exist or if a write request could not be sent. This function does not test whether the write succeeded. In cases where the write does not succeed, TagWrite does not return a driver error code. You can use the [TagReadEx](#) function to confirm the write operation took place.

TagWrite should only be used when the variable tag name is a calculation such as `sAlarmExt+".Paging"`. For assignment of variables use the assignment operator. For example, `MyCluster.MyAlarm.MyProperty = MyString`.

---

**Note:** When using this function and parameter [Code]ScaleCheck is set to 1, the attempt to write an out-of-range value to a device will not occur. No hardware alarm will be generated. This function checks a value before writing it to a PLC.

## Syntax

**TagWrite**(*STRING Tag, STRING sValue [, INT Offset] [, INT Synch] [, STRING ClusterName]*)

*Tag:*

A string that can be one of the following:

- A tag name — for example, "Fire1"
- An equipment item reference — for example, "Motor1.Fire"
- A tag property — for example, "Fire1.v"
- An equipment item property — for example, "Motor1.Fire.v"
- An alarm property — for example, "AlarmFire1.On"
- An alarm equipment item property — for example, "Motor1.AlarmFire.On"

If the element name is not specified, the writing will be performed to the Field VQT element.

The name of the tag can be prefixed by the name of the cluster, for example, "ClusterName.Tag" or "ClusterName.Equipment.Item".

If the tag name exceeds the length limit of 254 characters the hardware alarm "Tag name exceed length limit" will be raised.

*Value:*

The value to be written to the I/O device variable. The value is specified as a string, however if an integer or real is used the compiler will convert it to a string. The function converts the string into the correct format, and then writes it to the variable.

To write to a particular element in an array, you can enter the array name here, followed by an index to the element as follows:

```
"PLC_Array[9] "
```

The above example tells the function to write to the 10th element in the array variable PLC\_Array (remember, the address of the first element in an array is 0 (zero)).

If you enter an array offset using the *nOffset* argument, it will be added to the index value. See example below.

*Offset:*

Optional offset for an array variable. Default is 0.

If you enter an array index as part of the *sValue* argument, it will be added to this offset value. For example, TagWrite("PLC\_Array[9]", 24, 4) will set the 14th element in PLC\_Array to 24 (because [9] means the 10th element, and an offset of 4 means 4 elements after the 10th = element 14).

*Synch:*

An optional boolean argument that specifies whether the command is synchronous (blocking) or asynchronous (non-blocking). If it is specified as synchronous (blocking) the function will wait until the write has completed and returned from the server before further code execution. This parameter is "False", or asynchronous, by default. If you specify this parameter the rest of the parameters need to be explicitly specified, including *nOffset* which should be set as 0 if the tag is not an array tag.

*ClusterName:*

Specifies the name of the cluster in which the Tag resides. The argument is enclosed in quotation marks.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TagRead](#), [TagReadEx](#), [IODeviceControl](#), [IODeviceInfo](#)

## Example

```
TagWrite("PLC_VAR1", 123);
TagWrite("PLC_VAR1", 123, 0, TRUE); ! Write to PLC variable
! and block until write is successful.
TagWrite("PLC_VAR_STR", "string data to write");
TagWrite("PLC_ARRAY", 42, 3); ! Write to element 4 in array
TagWrite("PLC_Array[9]", 2); ! Write to element 12 in array
TagWrite ("Tag1", "123");
TagWrite("Tag1.Field", "123");
```

## See Also

[Tag Functions](#)

## TagWriteEventQue

Opens the tag write event queue. The TagWriteEventQue is a queue of data containing details of tag value changes initiated by the process. To read events from the queue, use the [QueRead\(\)](#) or [QuePeek\(\)](#) functions. The

queue contains timestamp, tagname and value data for each change event.

This queue is enabled by the corresponding INI parameter [General]TagWriteEventQue. Writes are logged to the queue for all tags whose I/O devices have their Log Write parameter enabled.

## Syntax

*TagWriteEventQue()*

## Return Value

The handle of the tag write event queue, or -1 if the queue cannot be opened.

## Related Functions

[AlarmEventQue](#), [QueRead](#), [QuePeek](#)

## Example

To enable tag logging:

- On the client, set the INI param [General]TagWriteEventQue = 1.
- Enable the IODevices that you want to be logged by setting their Log Write parameters to TRUE. See I/O Devices Properties.

To read the queue you need to create a Cicode function. For example:

```
FUNCTION
checkWrite()
    STRING sTagAndValue = "";
    INT nDateTime = 0;
    INT hQue = TagWriteEventQue();
    IF hQue = -1 THEN
        RETURN;
    END
    WHILE 1 DO
        QueRead(hQue, nDateTime, sTagAndValue, 1);
        Message("Value written", sTagAndValue, 64);
    END
END
```

Where:

- *nDateTime* is the timestamp of the tag write.
- *sTagAndValue* is the tagname and value written to the queue.

When the function is run, successful writes to tags on the IODevice will show as a message "Value written <tagname> <value>".

---

**Note:** The TagWriteEventQue is enabled on each process and will only log the data changes initiated by this process. By combining this data with the current user and machine name Plant SCADA can generate a user activity log with respect to setting data within the control system. This functionality can also be combined with

---

Plant SCADA Reports to augment the detail of the historian data.

---

## See Also

[Tag Functions](#)

### TagWriteIntArray

This function writes an array of integers to a tag. You can write to all elements of an array tag, or write to a subset. Use the Offset parameter to write to the subset (e.g. if you specify a Length of 5 and an Offset of 2, you will write to the 3rd, 4th, 5th, 6th and 7th elements in the tag array).

---

**Note:** For this function to be successful a user needs to be logged in.

---

This function completes asynchronously to the caller. It will be unsuccessful if the tag does not exist or if a write request could not be sent. This function does not test whether the write succeeded. In cases where the write does not succeed, TagWriteIntArray does not return a driver error code. You can use the [TagReadEx](#) function to confirm the write operation took place.

TagWriteIntArray should only be used when the variable tag name is a calculation such as sAlarmExt+".Paging". For assignment of variables use the assignment operator. For example, MyCluster.MyAlarm.MyProperty = MyString.

---

**Note:** When using this function and parameter [\[Code\]ScaleCheck](#) is set to 1, the attempt to write an out-of-range value to a device will not occur. No hardware alarm will be generated. This function checks a value before writing it to a PLC.

---

## Syntax

**TagWriteIntArray**(*STRING Tag, INT Length, VAR LONG Values, INT Offset, INT Sync, STRING ClusterName*)

*Tag:*

The string can refer to either: the variable tag name, the equipment and item name (using equipment.item notation) associated with that tag, the alarm name and the alarm property name, the tag name and the tag element name. If the element name is not specified, the writing will be performed to the Field VQT element. The name of the tag can be prefixed by the name of the cluster that is "ClusterName.Tag" or "ClusterName.Equipment.Item".

If the tag name exceeds the length limit of 254 characters the hardware alarm "Tag name exceed length limit" will be raised.

*Length:*

The number of elements written to the tag.

*Value:*

The element you select in the array to be the first. The array contains the values you are writing to the variable tag. See example below. Must be a Long type variable.

*Offset:*

Optional offset inside the variable tag array where you start writing to. Default is 0.

*Sync:*

An optional boolean argument that specifies whether the command is synchronous (blocking) or asynchronous

(non-blocking). If it is specified as synchronous (blocking) the function will wait until the write has completed and returned from the server before further code execution. This parameter is "False", or asynchronous, by default. If you specify this parameter the rest of the parameters need to be explicitly specified, including *nOffset* which should be set as 0 if the tag is not an array tag.

*ClusterName*:

Specifies the name of the cluster in which the Tag resides. The argument is enclosed in quotation marks.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TagRead](#), [TagReadEx](#), [IODeviceControl](#), [IODeviceInfo](#)

## Example

```
GLOBAL INT ArrayOfInts[64];
FUNCTION ArrayWriteAscendingInts()
    INT i = 0;
    FOR i = 0 TO 63 DO
        ArrayOfInts[i] = i;
    END
    TagWriteIntArray("ModnetIntArray", 64, ArrayOfInts[0]);
END
```

## See Also

[Tag Functions](#)

## TagWriteRealArray

This function writes an array of REAL values to a variable tag. You can write to all elements of an array tag, or write to a subset. Use the Offset parameter to write to the subset (e.g. if you specify a Length of 5 and an Offset of 2, you will write to the 3rd, 4th, 5th, 6th and 7th elements in the tag array).

---

**Note:** For this function to be successful a user needs to be logged in.

This function completes asynchronously to the caller. It will be unsuccessful if the tag does not exist or if a write request could not be sent. This function does not test whether the write succeeded. In cases where the write does not succeed, TagWriteRealArray does not return a driver error code. You can use the [TagReadEx](#) function to confirm the write operation took place.

---

**Note:** When using this function and parameter [Code]ScaleCheck is set to 1, the attempt to write an out-of-range value to a device will not occur. No hardware alarm will be generated. This function checks a value before writing it to a PLC.

## Syntax

**TagWriteRealArray(STRING Tag, INT Length, VAR REAL Value [, INT Offset] [, INT Sync] [, STRING ClusterName])**

*Tag:*

The string can refer to either: the variable tag name, the equipment and item name (using equipment.item notation) associated with that tag, the alarm name and the alarm property name, the tag name and the tag element name. If the element name is not specified, the writing will be performed to the Field VQT element. The name of the tag can be prefixed by the name of the cluster that is "ClusterName.Tag" or "ClusterName.Equipment.Item".

If the tag name exceeds the length limit of 254 characters the hardware alarm "Tag name exceed length limit" will be raised.

*Length:*

The number of elements written to the tag.

*Value:*

The element you select in the array to be the first. The array contains the values you are writing to the variable tag. See example below.

*Offset:*

Optional offset inside the variable tag array where you start writing to. Default is 0.

If you enter an array index as part of the *sValue* argument, it will be added to this offset value. For example, TagWrite("PLC\_Array[9]", 24, 4) will set the 14th element in PLC\_Array to 24 (because [9] means the 10th element, and an offset of 4 means 4 elements after the 10th = element 14).

*Sync:*

An optional boolean argument that specifies whether the command is synchronous (blocking) or asynchronous (non-blocking). If it is specified as synchronous (blocking) the function will wait until the write has completed and returned from the server before further code execution. This parameter is "False", or asynchronous, by default. If you specify this parameter the rest of the parameters need to be explicitly specified, including *nOffset* which should be set as 0 if the tag is not an array tag.

*ClusterName:*

Specifies the name of the cluster in which the Tag resides. The argument is enclosed in quotation marks.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Example

```
GLOBAL REAL ArrayOfInts[64];
FUNCTION ArrayWriteAscendingInts()
    INT i = 0;
    FOR i = 0 TO 63 DO
        ArrayOfInts[i] = i;
    END
    TagWriteIntArray("ModnetIntArray", 64, ArrayOfInts[0]);
END
```

## Task Functions

Task functions support advanced multi-tasking operations in Cicode, handling queues, semaphores, messages, and other process functions. The task functions control the transfer of data between different Cicode tasks and across the network to different computers (by remote procedure calls).

Following are functions relating to tasks:

<a href="#">CodeSetMode</a>	Sets the execution mode of a Cicode task.
<a href="#">EnterCriticalSection</a>	Requests permission for the current thread to have access to a critical shared resource (critical section). If the critical section is already being accessed, the thread will be granted access when it is free.
<a href="#">Halt</a>	Halts the current Cicode task.
<a href="#">LeaveCriticalSection</a>	Relinquishes the current thread's ownership of a critical shared resource (critical section).
<a href="#">MsgBrdcst</a>	Broadcasts a message.
<a href="#">MsgClose</a>	Closes a message.
<a href="#">MsgGetCurr</a>	Gets the handle of the message that called the current report or remote procedure.
<a href="#">MsgOpen</a>	Opens a message session with a Plant SCADA server or client.
<a href="#">MsgRead</a>	Reads a message from a session.
<a href="#">MsgRPC</a>	Calls a remote procedure on another Plant SCADA computer.
<a href="#">MsgState</a>	Verifies the status of a message session.
<a href="#">MsgWrite</a>	Writes a message to a session.
<a href="#">QueClose</a>	Closes a queue.
<a href="#">QueLength</a>	Gets the current length of a queue.

<a href="#">QueOpen</a>	Creates or opens a queue.
<a href="#">QuePeek</a>	Searches a queue for a queue element.
<a href="#">QueRead</a>	Reads elements from a queue.
<a href="#">QueWrite</a>	Writes elements to a queue.
<a href="#">ReRead</a>	ReRead is deprecated in this version.
<a href="#">SemClose</a>	Closes a semaphore.
<a href="#">SemOpen</a>	Creates or opens a semaphore.
<a href="#">SemSignal</a>	Signals a semaphore.
<a href="#">SemWait</a>	Waits on a semaphore.
<a href="#">ServerRPC</a>	Calls a remote procedure on a Plant SCADA server.
<a href="#">Sleep</a>	Suspends the current Cicode task for a specified time.
<a href="#">SleepMS</a>	Suspends the current Cicode task for a specified time (in milliseconds).
<a href="#">TaskCall</a>	Calls a Cicode function by specifying the function name and providing an arguments string.
<a href="#">TaskCluster</a>	Gets the name of the cluster context in which the current task is executing.
<a href="#">TaskGetSignal</a>	Retrieves a value that indicates the stop signal for a specific task.
<a href="#">TaskHnd</a>	Gets the handle of a particular task.
<a href="#">TaskKill</a>	Kills a running task.
<a href="#">TaskNew</a>	Creates a new task.
<a href="#">TaskNew</a>	Creates a new task with a subscription rate.
<a href="#">TaskResume</a>	Resumes a task.
<a href="#">TaskSetSignal</a>	Ends a task by manually triggering its stop signal.
<a href="#">TaskSuspend</a>	Suspends a task.

[Cicode Function Categories](#)

## Using Cicode Functions

### CodeSetMode

Sets various execution modes for Cicode tasks in the current thread. Using this function, you can specify whether to:

- Write to a local image of an I/O device.
- Check if a variable is within range before writing it to the I/O device.
- Echo error messages to the operator.
- Check the case of string data in Cicode.

### Syntax

**CodeSetMode(*nType*, *Value*)**

*nType*:

Type of mode:

0 - Write to a local image of an I/O device. If you set Value to 1, this mode is enabled, and Cicode writes its local memory image of the I/O device whenever you write to the I/O device. (Cicode assumes that most writes to the I/O device will be done immediately).

This local image might produce problems, or you might want to verify that the data was actually written to the I/O device. If you set Value to 0 (zero), this check is disabled, and Cicode does not write to the local memory image.

1 - Check if a variable is within range before writing it to the I/O device. If you set Value to 1, this mode is enabled. When a variable tag is modified, Cicode checks the new value of the variable against the Scales specified in the Variable Tags database. If the value of the variable is out of scale, Cicode generates a hardware error, and does not write to the I/O device.

If you set Value to 0 (zero), this check is disabled. Cicode writes the variable to the I/O device without checking if its value is within range.

2 - Echo error messages to the operator. If you set Value to 1, this mode is enabled. When a simple user error occurs (for example, if the PageDisplay() function is passed a bad page name), Cicode displays an error message at the Error AN, and returns an error code from the function.

If you set Value to 0 (zero), the echo is disabled. Cicode does not display the error message, and the output of the DspError() function is stopped.

3 - Ignore the case of string data in the current thread of Cicode. If you set Value to 1, this mode is enabled, and Plant SCADA will ignore case in string data. For example, Plant SCADA will equate "Hello" to "HELLO".

If you set Value to 0 (zero), Plant SCADA will be case sensitive to string data. Case sensitivity is used when a string comparison operation is performed. For example:

**IF sStr1 = sStr2 THEN**

(You can also make Plant SCADA case sensitive to strings in all of your Cicode, using the [Code]IgnoreCase parameter.)

4 - Calls the Cicode Profiler. If you set Value to 1, the Profiler is enabled. This will only enable\disable the Profiler for the current Cicode task.

*Value*:

The value of the mode:

- 0 - Disable
- 1 - Enable

## Return Value

-1 if there is an error, otherwise the last value of the mode.

## Example

```
! disable local image write
CodeSetMode(0, 0);
```

## See Also

[Task Functions](#)

## EnterCriticalSection

Requests permission for the current thread to have access to a critical section (shared critical resource). If the critical section is already being accessed by another thread (using the [EnterCriticalSection\(\)](#) function), the current thread will be granted access when the other thread relinquishes ownership using the [LeaveCriticalSection\(\)](#) function.

Once a thread has ownership of a critical section, it can access the same section repeatedly (using the [EnterCriticalSection\(\)](#) function each time). Remember, however, that [LeaveCriticalSection\(\)](#) needs to be called once for each [EnterCriticalSection\(\)](#) used.

---

**Note:** This function is process-based, not computer-based, and so is only effective for threads within the same process. Any threads attempting to gain access to this critical section will be blocked until the thread relinquishes ownership. This function will have no effect on threads running within other processes.

### WARNING

#### UNINTENDED EQUIPMENT OPERATION

Do not attempt to access a critical section that is already in use by another thread. This will cause the thread to be blocked until the critical section is relinquished.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

## Syntax

**EnterCriticalSection(*sName*)**

*sName*:

The name of the critical section. The name needs to be entered in quotation marks and follow the rules outlined in the topic **Tag Name Syntax** in the main help..

## Return Value

This function does not return a value.

## Related Functions

[LeaveCriticalSection](#)

## Example

```
/* Request access to critical section, execute code and relinquish
ownership of critical section. */
FUNCTION
MyCriticalSection()
    EnterCriticalSection("MyCriticalSection");
    // critical code is placed here
    LeaveCriticalSection("MyCriticalSection");
END
```

## See Also

[Task Functions](#)

## Halt

Stops the execution of the current Cicode task and returns to Plant SCADA. This function does not affect any other Cicode tasks that are running.

Use this function to stop execution in nested function calls. When Halt() is called, Cicode returns to Plant SCADA and does not execute any return function calls.

## Syntax

**Halt()**

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[Assert](#), [TaskKill](#)

## Example

```
INT
FUNCTION
```

```
MyFunc(INT Arg)
  IF Arg<0 THEN
    Prompt("Invalid Arg");
    Halt();
  END
  ...
END
```

## See Also

[Task Functions](#)

### LeaveCriticalSection

Relinquishes the current thread's ownership of a critical section (shared critical resource). Once ownership is relinquished, access to the critical section is available to the next thread that requests it (using the [EnterCriticalSection\(\)](#) function). If a thread has been waiting for access, it will be granted at this point.

`LeaveCriticalSection()` needs to be called once for each `EnterCriticalSection()` used.

---

**Note:** This function is process-based, not computer-based, and so will only prevent access to a critical section within a single process. This function only works between Cicode tasks within the same process.

---

## Syntax

`LeaveCriticalSection(sName)`

*sName:*

The name of the critical section. The name needs to be entered in quotation marks.

## Return Value

This function does not return a value.

## Related Functions

[EnterCriticalSection](#)

## Example

```
/* Request access to critical section, execute code and relinquish
ownership of critical section. */
FUNCTION
MyCriticalSection()
  EnterCriticalSection("MyCriticalSection");
  // critical code is placed here
  LeaveCriticalSection("MyCriticalSection");
END
```

## See Also

[Task Functions](#)

### MsgBrdcst

Broadcasts a message to all the clients of a server. You should call this function only on a Plant SCADA server. The message is only received by clients that have a current message session (opened with the [MsgOpen\(\)](#) function).

## Syntax

**MsgBrdcst**(*Name*, *Type*, *Str* [, *sClusterName*])

*sName*:

The name of the Plant SCADA server.

*nType*:

The message number.

*Str*:

The message text.

*sClusterName*:

The name of the cluster to which the server being communicated with belongs. This is optional if you have one cluster.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[MsgOpen](#), [MsgClose](#), [MsgRead](#), [MsgWrite](#), [MsgRPC](#)

## Example

```
! Send a message to all alarm clients.  
MsgBrdcst("Alarm",0,"Alarm Occurred");
```

## See Also

[Task Functions](#)

### MsgClose

Closes a message. After the message is closed, the message post function (the callback function specified in the [MsgOpen\(\)](#) function) is not called if a message is received. When the server side is closed, all clients are closed. When the client side is closed, only the specified client is closed.

## Syntax

**MsgClose(*Name*, *hMsg*)**

*sName*:

The name of the Plant SCADA server.

*hMsg*:

The message handle, returned from the **MsgOpen()** function. The message handle identifies the table where all data on the associated message is stored.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[MsgOpen](#), [MsgRead](#), [MsgWrite](#), [MsgRPC](#)

## Example

```
MsgClose("Alarm", hMsg);
```

## See Also

[Task Functions](#)

## MsgGetCurr

Gets the handle of the client message that called the report or remote procedure that is currently running. You can call this function only in a report or a remote procedure call.

If the report was called by a client, this function returns that client message handle. The report can then send a message back to the client. If a function was called remotely by [MsgRPC\(\)](#), this function returns the message handle for the remote client.

## Syntax

**MsgGetCurr()**

## Return Value

The handle for the client message. The message handle identifies the table where all data on the associated message is stored. The function returns -1 if no client called the report or function.

## Related Functions

[MsgOpen](#), [MsgRPC](#)

## Example

```
! Send message back to the client.  
hMsg=MsgGetCurr();  
IF hMsg<>-1 THEN  
    MsgRPC(hMsg,"Prompt","^"Hello Client from Report Server^"",1);  
END
```

## See Also

[Task Functions](#)

## MsgOpen

Opens a message session with a Plant SCADA server. You can specify a message post function - a callback function that is automatically called when a message arrives. In this function you can call [MsgRead\(\)](#) to get the message, and perform other tasks common to your message sessions. You can then call [MsgWrite\(\)](#) to send a message back to the caller, [MsgRPC\(\)](#) to call a procedure on the caller, and so on.

A logged on user is required for this function to be successful.

---

**Note:** This function will only work successfully on a full-control client. It will not work on a view-only client.

---

## Syntax

**MsgOpen(*Name*, *Mode*, *Fn* [, *sClusterName*] )**

You should use [MsgState\(\)](#) to check the return value of [MsgOpen\(\)](#), unless you are using mode 1. The message post function is set effectively only if [MsgState\(\)](#) returns 1, which means the message session is online.

You can open a client-server message session or a session between redundant servers. This function does not create extra network sessions; it uses Plant SCADA's existing sessions, so you create sessions to the alarm server, report server, trend server, or a named I/O server.

*sName*:

The name of the server to open, either:

For Mode 0, 1, or 3: "Alarm", "Report", "Trend", or the name of an I/O server.

For Mode 2: The default computer name, as set in the [\[LAN\]Node](#) parameter.

*Mode*:

The mode of the message session to open:

0 - Open the client side.

1 - Open the server side.

2 - Open a session from a server to the default computer name. Set *Name* to the computer name of the computer, as defined by the [\[LAN\]Node](#) parameter.

3 - Open a message session between redundant servers. (Clients cannot tell which server they are connected to

or if something has changed on the server. Changes should be performed on the redundant server as well.)

4 - Open a message session from the calling process to the client process. The Name and Fn are ignored in this mode. The message session opened in this mode does not need to call MsgClose.

*Fn:*

The message post function, that is a callback function for the message event. Set Fn to 0 if no event callback function is required.

*sClusterName:*

The name of the cluster the server being communicated with belongs to, this is used when mode is 0, 1 or 3. This is not required if the client is connected to only one cluster containing a server of the type set in the name parameter.

## Return Value

The message handle, or -1 if the session cannot be opened. The message handle identifies the table where data on the associated message is stored. The exception to this is mode 1 where the handle 4096 will be returned if the session can be opened.

## Related Functions

[MsgClose](#), [MsgRead](#), [MsgWrite](#), [MsgRPC](#)

## Example

```
INT hClient = -1;
INT hServer = -1;
// Open message session on the client, connecting using the
//existing message session to the current Alarm server
FUNCTION
MsgClientOpen()
    INT nState;
    hClient = MsgOpen("Alarm", 0, MsgPostClient);
    IF hClient <> -1 THEN
        nState = MsgState(hClient);
        SELECT CASE nState
        CASE 1
            Prompt("Client Message session is online!");
        CASE -1
            Prompt("Client Message session handle is invalid!");
        CASE 0
            Prompt("Client Message session is offline!");
        CASE 2
            Prompt("Client Message session is connecting!");
        CASE 3
            Prompt("Client Message session is disconnecting!");
        CASE ELSE
            Prompt("Client Message session has unknown status!");
        END SELECT
    ELSE
        Prompt("Client Message session could not be opened!");
    END
```

```
END
// Open message session on the server
FUNCTION
MsgServerOpen()
    INT nState;
    hServer = MsgOpen("Alarm", 1, MsgPostServer);
    // Opening a server connection will result in returning 4096 (if successfully opened)
    // and should not be checked via MsgState
    IF hServer <> 4096 THEN
        ErrLog("Server Message session could NOT be opened!");
    ELSE
        ErrLog("Server Message session is online!");
    END
END
// This function is called when the server receives a message from
//the client
INT
FUNCTION
MsgPostServer()
    INT Type;
    INT hCurr;
    STRING Str;
    // Record the returned handle from the read to use it for the write
    hCurr = MsgRead(Type,Str);
    ErrLog("Server received Message: Type = "+Type:###+" Str = "+Str);
    MsgServerWrite(hCurr);
    RETURN 0;
END
// This function is called when the client receives a message from
//the server
INT
FUNCTION
MsgPostClient()
    INT Type;
    INT replyHandle;
    STRING Str;
    MsgRead(Type,Str);
    Prompt("Client received message: Type = "+Type:###+" Str = "+Str);
    RETURN 0;
END
// Write a message to the server
FUNCTION
MsgClientWrite()
    Prompt("Client Write");
    MsgWrite(hClient, 1, "MyClientMessage");
END
// Write a message to the client
FUNCTION
MsgServerWrite(INT hCurr)
    MsgWrite(hCurr, 1, "MyServerMessage");
END
```

## See Also

[Task Functions](#)

## MsgRead

Reads a message from a message session. You can call this function only in a message post function (the callback function specified in the [MsgOpen\(\)](#) function), to read the current message.

The *nType* and *Str* variables of this function return the message number and the text of the message. The return value of this function is the message handle (allowing a response to be sent back if required).  
you need to open the message session using the [MsgOpen\(\)](#) function, to enable the callback function.

## Syntax

**MsgRead(*Type*, *Str*)**

*nType*:

The message number. Must be a Long type variable.

*Str*:

The message text. Must be a String type variable.

## Return Value

The message handle of the message being read.

## Related Functions

[MsgOpen](#), [MsgClose](#), [MsgWrite](#), [MsgRPC](#)

## Example

```
/* This function will read a message from the session and if
Type=1, will display the string as a prompt. If Type=2 then the
speaker beeps and an acknowledgment is sent back to the caller. */
INT
FUNCTION
MsgPostClient()
    INT Type;
    STRING Str;
    INT hMsg;
    hMsg=MsgRead(Type,Str);
    IF Type=1 THEN
        Prompt("Message"+Str);
    ELSE
        IF Type=2 THEN
            Beep();
            MsgWrite(hMsg,2,"DONE");
        END
    END
END
```

## See Also

[Task Functions](#)

### MsgRPC

Calls a remote procedure on another Plant SCADA computer. You can call any of the built-in Cicode functions remotely, or your own functions. You pass the *sName* of the function as a string, not as the function tag, and pass all the arguments for that function in *Arg*.

You can call the function in synchronous or asynchronous Mode. In synchronous mode, `MsgRPC()` does not return until the remote function is called and the result is returned. In asynchronous mode, `MsgRPC()` returns before the function is called, and the result cannot be returned.

---

#### Note:

- The **Allow RPC** property for a Role determines if a user or group of users can perform remote `MsgRPC` and `ServerRPC` calls. This functionality now requires a user-specific permission. To allow existing users to use `MsgRPC` and `ServerRPC`, you need to manually change the value of **Allow RPC** to "TRUE" in Plant SCADA Studio's **Security | Roles** view. You also need to set the **Allow RPC** property to "TRUE" for each server process that these functions will access.
  - If you want to use `MsgRPC` to call a procedure on a remote client computer, you will need to set the parameter [\[Client\]AllowRPC=1](#) on the client computer.
- 

## Syntax

**MsgRPC(*hMsg*, *sName*, *Arg*, *Mode*)**

*hMsg*:

The message handle, returned from the `MsgOpen()` function. The message handle identifies the table where all data on the associated message is stored.

*sName*:

The name of the function to call remotely, as a string.

If this function returns an error, you should confirm that the name you have used is not a label instead of the actual function name. Some functions are aliased using a label, for example, the function `_AlarmGetFieldRec` is defined in the labels database as "AlarmGetFieldRec". In this case, only "`_AlarmGetFieldRec`" should be passed to `MsgRPC`.

*Arg*:

The arguments to pass to the function, separated by commas (,). Enclose string arguments in quotes "" and use the string escape character (^) around strings enclosed within a string. If you do not enclose the string in quotes, then the string is only the first tag found.

*Mode*:

The mode of the call:

0 - Blocking mode - synchronous.

1 - Non-blocking mode - asynchronous.

## Return Value

The result of the remote function call (as a string). If the function is called in asynchronous mode the result of the remote function cannot be returned, so an empty string is returned.

**Note:** The error code 513 will be returned if the **Allow RPC** property is not set to TRUE in an associated Role or server process.

## Related Functions

[MsgOpen](#), [MsgClose](#), [MsgRead](#), [MsgWrite](#)

## Example

```
! Call remote procedure, call MyRPC() on server. Wait for result
Str=MsgRPC(hMsg,"MyRPC","Data",0);
! Call remote procedure, pass two strings. Don't wait for call to complete.
! be careful of your string delimiters as shown.
MsgRPC(hMsg,"MyStrFn","^"First string^","Second string^",1);
! Call remote procedure, pass Cicode string. Don't wait for call to complete.
STRING sMessage = "this is a message";
MsgRPC(hMsg,"MyStrFn","^" + sMessage + "^",1);
! These functions could be used to acknowledge an alarm by record
from any Plant SCADA Client on the network.
! The AlmAck() function is initialized by the Control Client
(Don't forget that servers are also Control Clients.)
! The Alarm tag is passed into the function as a string and a
message is sent to the Alarms Server to initialize
! the AlmAckMsg() function.
FUNCTION
AlmAck(String AlmTag)
    INT hAlarm1;
    hAlarm1 = MsgOpen("Alarm", 0, 0);
    MsgRPC(hAlarm1,"AlmAckMsg",AlmTag,1);
    MsgClose("Alarm", hAlarm1);
END
! The AlmAckMsg() function is executed on the Alarms Server that
the client is connected to. This could be
! either the primary or standby Alarms Server. The function
performs the alarm acknowledge.
FUNCTION
AlmAckMsg(String AlmTag)
    AlarmAckRec(AlarmFirstTagRec(AlmTag,"",""));
END
```

## See Also

[Task Functions](#)

## MsgState

Verifies the status of a message session. Use **MsgState()** to check the return value of [MsgOpen\(\)](#). A message post

function is set effectively only if `MsgState()` returns 1, which means the message session is online.

## Syntax

**MsgState(*hMsg*)**

*hMsg*:

The message handle, returned from the `MsgOpen()` function. The message handle identifies the table where all data on the associated message is stored.

## Return Value

This function has the following possible return values:

- -1 if the message session handle is invalid
- 0 if the message session is offline
- 1 if the message session is online
- 2 if the message session is connecting
- 3 if the message session is disconnecting.

## Related Functions

[MsgOpen](#)

## Example

```
INT hClient = -1;
// Open message session on the client, connecting using the
existing
// message session to the current Alarm server
FUNCTION
MsgClientOpen()
    INT nState;
    hClient = MsgOpen("Alarm", 0, MsgPostClient);
    IF hClient <> -1 THEN
        nState = MsgState(hClient);
        SELECT CASE nState
        CASE 1
            Prompt("Message session is online!");
            //Send a message to the server
            MsgWrite(hClient, 1, "MyMessage");
        CASE -1
            Prompt("Message session handle is invalid!");
        CASE 0
            Prompt("Message session is offline!");
        CASE 2
            Prompt("Message session is connecting!");
        CASE 3
            Prompt("Message session is disconnecting!");
        CASE ELSE
```

```
Prompt("Message session has unknown status!");
END SELECT
ELSE
    Prompt("Message session could not be opened!");
END
END
```

## See Also

[Task Functions](#)

## MsgWrite

Writes a message to a message session. The message is sent to the remote computer's callback function and can be read by calling [MsgRead\(\)](#). If the remote computer has not opened the session, this message is disregarded.

This function returns immediately after passing the message to Plant SCADA. Plant SCADA sends the message over the LAN in the background.

You need to first open the message session using the [MsgOpen\(\)](#) function, to obtain the message handle.

## Syntax

**MsgWrite(*hMsg*, *Type*, *Str*)**

*hMsg*:

The message handle, returned from the [MsgOpen\(\)](#) function. The message handle identifies the table where all data on the associated message is stored.

*nType*:

The integer message data, that is the message number.

*Str*:

The message text.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## Related Functions

[MsgRead](#), [MsgOpen](#)

## Example

```
MsgWrite(hMsg,10,"MyMsg");
```

## See Also

[Task Functions](#)

## QueClose

Closes a queue opened with the [QueOpen\(\)](#) function. All data is flushed from the queue.

If a Cicode task is waiting on the [QueRead\(\)](#) function, it returns with a "queue empty" status. You should close all queues when they are no longer required, because they consume memory. At shutdown, Plant SCADA closes all open queues.

## Syntax

**QueClose(*hQue*)**

*hQue*:

The queue handle, returned from the [QueOpen\(\)](#) function. The queue handle identifies the table where all data on the associated queue is stored.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[QueLength](#), [QueOpen](#), [QueRead](#), [QueWrite](#), [QuePeek](#)

## Example

```
hQue=QueOpen("MyQue",1);
...
QueClose(hQue);
```

## See Also

[Task Functions](#)

## QueLength

Gets the current length of the queue.

## Syntax

**QueLength(*hQue*)**

*hQue*:

The queue handle, returned from the [QueOpen\(\)](#) function. The queue handle identifies the table where all data on the associated queue is stored.

## Return Value

The current length of the queue. If the queue is closed then 0 is returned.

## Related Functions

[QueClose](#), [QueOpen](#), [QueRead](#), [QueWrite](#), [QuePeek](#)

## Example

```
Length=QueLength(hQue);
```

## See Also

[Task Functions](#)

## QueOpen

Open a queue for reading and writing data elements. Use this function to create a new queue or open an existing queue. Use queues for sending data from one task to another or for other buffering operations.

## Syntax

**QueOpen(*Name*, *Mode*)**

*sName*:

The name of the queue. You need to use the following syntax:

Names need to begin with either an alpha character (A-Z or a-z) or the underscore character (\_).

Any following characters need to be either alpha characters (A-Z or a-z), digit characters (0 - 9), period characters (.), backslash characters (\), or underscore characters (\_).

The use of any other characters will result in the name being modified.

*Mode*:

The mode of the queue open:

0 - Open existing queue.

1 - Create new queue.

2 - Attempts to open an existing queue. If the queue does not exist, it will create it.

4 - Create a queue that can have multiple blocked readers.

## Return Value

The queue handle, or -1 if the queue cannot be opened. The queue handle identifies the table where all data on the associated queue is stored.

## Related Functions

[QueClose](#), [QueLength](#), [QueRead](#), [QueWrite](#), [QuePeek](#)

## Example

```
! Create a queue.  
hQue=QueOpen("MyQue",1);  
! Write data into the queue.  
QueWrite(hQue,1,"Quetext");  
QueWrite(hQue,1,"Moretext");  
! Read back data from the queue.  
QueRead(hQue,Type,Str,0);
```

## See Also

[Task Functions](#)

## QuePeek

Searches a queue for a queue element. You can search for the element by specifying a string, an integer, or both. You can remove the element from the queue by adding 8 to the *Mode*.

---

**Note:** This function may modify the arguments *Type* and *Str* depending on the Mode. Therefore, these arguments need to be variables. You should consider that they may be impacted by the setting for Mode when calling the function.

---

## Syntax

**QuePeek(*hQue*, *Type*, *Str*, *Mode*)**

*hQue*:

The queue handle, returned from the [QueOpen\(\)](#) function. The queue handle identifies the table where all data on the associated queue is stored.

*nType*:

The number to search for (if using the search mode for a matching number). If you are using a matching string mode, the number found is returned in *Type*. Must be a Long type variable.

*Str*:

The string to search for (if using the search mode for a matching string). If you are using a matching number mode, the string found is returned in *Str*. Must be a String type variable.

*Mode*:

The mode of the search:

- 1 - Search for a matching string.
- 2 - Search for a matching number.
- 4 - Search for a matching string and use a case-sensitive search.
- 8 - If the element is found, remove it from the queue.

16 Search the queue, in order, for the element at the offset specified by Type.

Use mode 16 when you know the location of the element you want. For example if you set Type = 0, QuePeek will return the first element in the queue, type = 2, will return the 3rd element in the queue, etc. If you specify an offset which is greater than the length of the queue, the "queue empty" error (296) is returned.

You can extend the search by adding modes. For example, set Mode to 3 to search for a matching string and matching number, or set Mode to 11 to also remove the string and number from the queue.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[QueClose](#), [QueLength](#), [QueOpen](#), [QueRead](#), [QueWrite](#)

## Example

```
STRING Str;
INT Type;
! search for 'mystring' in queue, don't remove if found
Str = "mystring";
status=QuePeek(hQue,Type,Str,1);
IF Status = 0 THEN
    ! Now use found Type
...
END
```

## See Also

[Task Functions](#)

## QueRead

Reads data from a queue, starting from the head of the queue. Data is returned in the same order as it was written onto the queue and is removed from the queue when read. If the *Mode* is 0 (non-blocking) and the queue is empty, the function returns with an error. If the *Mode* is 1 (blocking) the function does not return until another Cicode task writes data onto the queue.

This function is a blocking function. It will block the calling Cicode task until the operation is complete.

## Syntax

**QueRead(*hQue*, *Type*, *Str*, *Mode*)**

*hQue*:

The queue handle, returned from the QueOpen() function. The queue handle identifies the table where all data on the associated queue is stored.

*nType*:

The integer to read from the queue (written to the queue as Type by the QueWrite() function). Must be an Integer type variable.

*Str:*

The string to read from the queue (written to the queue as Str by the QueWrite() function). Must be a String type variable.

*Mode:*

The mode of the read:

0 - Non-blocking.

1 - Wait for element.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[QueClose](#), [QueLength](#), [QueOpen](#), [QueWrite](#), [QuePeek](#)

## Example

```
Status=QueRead(hQue,Type,Str,0);
IF Status = 0 THEN
    ! Now use Type and Str.
    ...
END
```

## See Also

[Task Functions](#)

## QueWrite

Writes an integer and string onto the end of a queue. The integer and string have no meaning to the queue system, they are just passed from QueWrite() to QueRead(). Queue data is written to the end of the queue. When the data is later read from the queue, it is returned on a first-in-first-out basis.

This function is a blocking function. It will block the calling Cicode task until the operation is complete.

## Syntax

**QueWrite(*hQue, Type, Str*)**

*hQue:*

The queue handle, returned from the QueOpen() function. The queue handle identifies the table where all data on the associated queue is stored.

*nType:*

The integer to put into the queue.

*Str:*

The string to put into the queue.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[QueClose](#), [QueLength](#), [QueOpen](#), [QueRead](#), [QuePeek](#)

## Example

```
QueWrite(hQue,2,"Hello there");
QueWrite(hQue,4,"Help");
```

## See Also

[Task Functions](#)

## ReRead

ReRead is deprecated in this version of Plant SCADA.

Tags are now subscribed at the start of a function and updated tag values are sent to the subscribing function. Tag subscriptions are made at the update rate of:

- the graphics page if called from a page
- the default subscription rate as determined by [\[Code\]TimeData](#) if called from Cicode (default 250ms)
- the update rate requested of a task created using [TaskNewEx](#)
- the update rate requested of a subscription created using [TagSubscribe](#).

You will want to verify that the subscription update rate matches the requirements of your system.

After removing ReRead from looping code you may need to extend the period of the [Sleep](#) function. This is to replace the pause ReRead created while it read all the tag values.

## Syntax

**ReRead(*Mode*)**

*Mode:*

The mode of the read:

0 - Read only if data is stale.

1 - Read anyway.

## Return Value

No value (void).

## See Also

[Task Functions](#)

## SemClose

Closes a semaphore opened with [SemOpen\(\)](#). You should close all semaphores when they are no longer required, because they consume memory. If any Cicode tasks are waiting on this semaphore, the tasks are released with an error.

---

**Note:** This function is process-based, not computer-based, and so will only prevent access to an important section within a single process. This function only works between Cicode tasks within the same process.

---

## Syntax

**SemClose(*hSem*)**

*hSem*:

The semaphore handle, returned from the [SemOpen\(\)](#) function. The semaphore handle identifies the table where all data on the associated semaphore is stored.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[SemOpen](#), [SemSignal](#), [SemWait](#)

## Example

```
SemClose(hSem);
```

## See Also

[Task Functions](#)

## SemOpen

Opens a semaphore for access control. When the semaphore is opened, it is initially signaled. Use a semaphore for controlling access to a restricted device, for example, to stop another Cicode task accessing a device while it is in use. You might require semaphores for some Cicode operations, because they can access a device that is critical. (Cicode is a multi-tasking system.)

---

**Note:** This function is process-based, not computer-based, and so will only prevent access to a critical section within a single process. This function only works between Cicode tasks within the same process.

---

## Syntax

**SemOpen(*Name*, *Mode*)**

*sName*:

The name of the semaphore. Follow the naming convention outlined in the topic **Tag Name Syntax** in the main help.

*Mode*:

The mode of the open:

0 - Open existing semaphore.

1 - Create new semaphore.

2 - Attempts to open an existing semaphore. If the semaphore does not exist, it will create it.

## Return Value

The semaphore handle, or -1 if the semaphore was not opened successfully. The semaphore handle identifies the table where all data on the associated semaphore is stored.

## Related Functions

[SemClose](#), [SemSignal](#), [SemWait](#)

## Example

```
hSem=SemOpen("MySem",1);
```

## See Also

[Task Functions](#)

## SemSignal

Signals a semaphore. If several Cicode tasks are waiting on this semaphore, the first task is released. This function is a blocking function. It will block the calling Cicode task until the operation is complete.

---

**Note:** This function is process-based, not computer-based, and so will only prevent access to a critical section within a single process. This function only works between Cicode tasks within the same process.

---

## Syntax

**SemSignal(*hSem*)**

*hSem*:

The semaphore handle, returned from the SemOpen() function. The semaphore handle identifies the table where all data on the associated semaphore is stored.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[SemClose](#), [SemOpen](#), [SemWait](#)

## Example

```
SemSignal(hSem);
```

## See Also

[Task Functions](#)

## SemWait

Waits on a semaphore to be signaled. This function is a blocking function. It will block the calling Cicode task until the operation is complete.

**Note:** This function is process-based, not computer-based, and so will only prevent access to a critical section within a single process. This function only works between Cicode tasks within the same process.

## Syntax

**SemWait(*hSem, Timeout*)**

*hSem*:

The semaphore handle, returned from the SemOpen() function. The semaphore handle identifies the table where all data on the associated semaphore is stored.

*Timeout*:

Semaphore time-out time:

-1 - Wait until semaphore is clear (regardless of how long).

0 - Do not wait - return immediately. (This timeout can be used to check the state.)

> 0 - The number of seconds to wait if semaphore is not signalling, then return.

## Return Value

0 (zero) if the semaphore has been gained, otherwise an error code is returned.

## Related Functions

[SemClose](#), [SemOpen](#), [SemSignal](#)

## Example

```
Status=SemWait(hSem,10);
IF Status=0 THEN
    ...
ELSE
    Prompt("Could not get semaphore");
END
```

## See Also

[Task Functions](#)

## ServerRPC

Calls a remote procedure on the Plant SCADA server specified by the *ServerName* argument. You can call any of the built-in Cicode functions remotely, or your own functions. You pass the Name of the function as a string and pass the arguments for that function in Arg.

You can call the function in synchronous or asynchronous mode. In synchronous mode, ServerRPC() does not return until the function call has completed on the server and the result is returned. In asynchronous mode, ServerRPC() returns before the function is called, an empty string is returned as the result cannot be returned.

This means this function is a blocking function if *iMode* is set to zero (0). A logged on user is required for this function to be successful.

**Note:** The **Allow RPC** property for a Role determines if a user or group of users can perform remote MsgRPC and ServerRPC calls. This functionality now requires a user-specific permission. To allow existing users to use MsgRPC and ServerRPC, you need to manually change the value of **Allow RPC** to "TRUE" in Plant SCADA Studio's **Security | Roles** view. You also need to set the **Allow RPC** property to "TRUE" for each server process that these functions will access.

## Syntax

**ServerRPC(*sServerName*, *sName*, *sArg*, *iMode* [, *sClusterName*])**

*sServerName*:

Plant SCADA server name where the Cicode function needs to be executed. You can optionally specify this name in <ClusterName>.<ServerName> syntax.

*sName*:

The name of the Cicode function to call remotely as string.

*sArg*:

The arguments to pass to the function, separated by commas (,). Enclose string arguments in quotes "" and use the string escape character (^) around strings enclosed within a string. If you forget to enclose the string in quotes, then the string is only the first tag found.

***iMode:***

The mode of the call:

0 - Blocking mode - synchronous

1 - Non-blocking mode - asynchronous

***sClusterName:***

The name of the cluster that the server resides in. This argument is optional, as in several situations it may not be required. In single cluster systems, it is not required, or if the current Cicode task already has the correct cluster context for the server you may omit this argument.

## Return Value

The result of the remote function call (as a string). If the function is called in asynchronous mode the result of the remote function cannot be returned, so an empty string is returned. If the function cannot work due to an error, empty string is also returned and the error can be obtained by calling the IsError function. If current user has view-only access on client side, the function will return an error code.

**Note:** The error code 513 will be returned if the **Allow RPC** property is not set to TRUE in an associated Role or server process.

---

## Related Functions

[TaskNew](#), [TaskNewEx](#)

## See Also

[Task Functions](#)

## Sleep

Suspends the current Cicode task for a specified number of seconds. After the time delay, the Cicode task wakes and continues execution. If the sleep time is 0, the Cicode task is pre-empted for 1 time slice only.

This function does not affect any other Cicode tasks - only the task calling Sleep() is suspended. If you have Cicode that runs continuously in a loop, you should call the Sleep() function somewhere within the loop, to pause the loop and allow other tasks to run.

This function is a blocking function. It will block the calling Cicode task until the operation is complete.

## Syntax

**Sleep(Seconds)**

***Seconds:***

The number of seconds. Set to 0 to pre-empt the task for one time-slice.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TaskNew](#), [ReRead](#), [SleepMS](#)

## Example

Buttons

Text	Step
Command	PLCBit=1;Sleep(2);PLCBit=0;
Comment	Switch Bit ON and then OFF 2 seconds later

```
! Display "Hello" 10 times at 60 second intervals.  
WHILE I < 10 DO  
    Sleep(60);  
    Prompt("Hello");  
    I = I + 1;  
END  
! Sleep a while in polling loops  
WHILE < waiting for event or time> DO  
    ! do what ever here  
    ...  
    Sleep(10); ! sleep a while to give other tasks a go.  
    ! the longer the sleep the better for other tasks.  
END
```

## See Also

[Task Functions](#)

## SleepMS

Suspends the current Cicode task for a specified number of milliseconds. After the time delay, the Cicode task wakes and continues execution. This function is similar to the [Sleep](#) function but with greater resolution.

Although a value of 0 milliseconds is accepted, it is not recommended. Try to use at least a value of 1.

This function does not affect any other Cicode tasks; only the task calling SleepMS() is suspended. If you have Cicode that runs continuously in a loop, you should call the SleepMS() or Sleep() function somewhere within the loop, to pause the loop and allow other tasks to run.

This function is a blocking function. It will block the calling Cicode task until the operation is complete.

## Syntax

**SleepMS(*Milliseconds*)**

*Milliseconds*:

The number of milliseconds (1000 milliseconds per second). Set to 0 to pre-empt the task for one time-slice. Be careful not to use a value that is too small. Setting the value to 0 would generally have no desirable effect.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TaskNew](#), [ReRead](#), [Sleep](#)

## Example

Buttons

Text	Step
Command	PLCBit=1;SleepMS(500);PLCBit=0;
Comment	Switch Bit ON and then OFF 500 milliseconds later.

```
! Increment a memory variable by ten, 120 times over one minute
(twice a second).
I = 0;
WHILE I < 180 DO
    SleepMS(500);
    iRamp = iRamp + 10;
    I = I + 1;
END
! sleep a while in polling loops
WHILE < waiting for event or time> DO
    ! do what ever here
    ...
    SleepMS(200); ! sleep a while to give other tasks a go.
    ! the longer the sleep the better for other tasks.
END
```

## See Also

[Task Functions](#)

## TaskCall

Calls a Cicode function by specifying the function name and providing an arguments string.

The function will be executed in a new Cicode task with the same cluster context as the current task. The current task will be blocked until the new task completes and a value can be returned.

This function cannot be called from page foreground animation code. If this is attempted, a hardware alarm will be raised and IsError() will return 282 (foreground Cicode cannot block).

You can use this function to call a private function, but only from within the file in which the private function is declared. See [Function Scope](#).

TaskCall allows the function to be called and the arguments provided to be specified dynamically by the Cicode logic. This may be useful in some cases where the function needed is not known until runtime.

Plant SCADA requests the required I/O device data and waits for the data to be returned before starting the function.

## Syntax

**TaskCall(*sName*, *sArgs*)**

*sName*:

The name of the function to call, as a string.

*sArgs*;

The arguments to pass to the function, separated by commas (,). Enclose string arguments in quotes "" and use the string escape character (^) around strings enclosed within a string.

## Return Value

The result of the function call (as a string). If a void function is called, an empty string is returned. To see if an error occurred (such as an invalid function name or invalid arguments) call [IsError\(\)](#).

## Related Functions

[TaskNew](#), [TaskNewEx](#)

## Example

```
STRING result;
result = TaskCall("StrFill", "^"abc^",10");
// result will be set to "abcabcabca"
```

## See Also

[Task Functions](#)

## TaskCluster

Gets the name of the cluster context in which the current task is executing.

## Syntax

**TaskCluster()**

## Return Value

The cluster name of the current context or an empty string if the task is executing without a cluster context.

## Related Functions

[ClusterActivate](#), [ClusterDeactivate](#), [ClusterFirst](#), [ClusterGetName](#), [ClusterIsActive](#), [ClusterNext](#),  
[ClusterServerTypes](#), [ClusterSetName](#), [ClusterStatus](#), [ClusterSwapActive](#), [TaskNew](#), [TaskNewEx](#)

## Example

```
! Get the cluster context of the current task
sCluster = TaskCluster();
```

## See Also

[Task Functions](#)

[Cluster Functions](#)

[Clusters](#)

## TaskGetSignal

Retrieves a value that indicates the signal that is currently set for a specific task. This function can be used to check the value of the current signal before using [TaskSetSignal](#) to apply a new signal.

## Syntax

**TaskGetSignal(*Hnd*)**

*Hnd*:

The task's handle. To retrieve this use the function [TaskHnd\(\)](#).

## Return Value

The value of the current signal. (0 (zero) represents normal operation, 1 indicates the task is stopped).

## Related Functions

[TaskSetSignal](#), [TaskHnd](#), [TaskKill](#), [TaskNew](#), [TaskResume](#)

## See Also

[Task Functions](#)

## TaskHnd

Gets the task handle of a specific task. You can then use the task handle with other task functions to control the task. If you do not specify a thread name, it will default to that of the current task.

## Syntax

**TaskHnd( [sName] )**

*sName:*

The thread name of the task. The thread name is the name of the function that was passed to the [TaskNew\(\)](#) function. For example, if . . .

TaskNew("MyTask", "", 0);

then:

hTask=TaskHnd("MyTask");

will return the handle of this task.

If you do not specify a thread name, it will default to that of the current task.

## Return Value

The task handle, identifying the table where all data on the task is stored.

## Related Functions

[TaskKill](#), [TaskNew](#), [TaskResume](#), [TaskSuspend](#)

## Example

```
! Get the task handle of the current task and then kill it.  
hTask=TaskHnd();  
TaskKill(hTask);  
! Get the task handle of MyTask and then kill it.  
hTask=TaskHnd("MyTask");  
TaskKill(hTask);
```

## See Also

[Task Functions](#)

## TaskKill

Kills a task. The Cicode task will be stopped and will not run again.

## Syntax

**TaskKill(*hTask*)**

*hTask:*

The task handle, returned from the [TaskNew\(\)](#) or [TaskHnd\(\)](#) function. The task handle identifies the table where all data on the associated task is stored.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

**Note:** TaskKill is an abrupt way to stop a Cicode task. It can cause system errors and may have unintended consequences. Whenever possible, use [TaskGetSignal](#) and [TaskSetSignal](#) to stop Cicode tasks. Use TaskKill as a last resort and after observing the following:

### UNINTENDED EQUIPMENT OPERATION

- Do not use TaskKill to stop Cicode tasks until you have attempted the alternative methods stated above.
- Place the processes and devices controlled by Plant SCADA into a state preventing unintended operation before using TaskKill to stop a Cicode task.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

## Related Functions

[TaskGetSignal](#), [TaskSetSignal](#), [TaskHnd](#), [TaskNew](#), [TaskResume](#), [TaskSuspend](#)

## Example

```
! Create a task, run it for 10 seconds and then kill it.  
hTask=TaskNew("MyFunc","",0);  
Sleep(10);  
TaskKill(hTask);  
FUNCTION  
MyFunc()  
    INT Count;  
    WHILE 1 DO  
        Prompt("Hello "+Count:###);  
        Count=Count+1;  
    END  
END
```

## See Also

[Task Functions](#)

## TaskNew

Creates a new Cicode task and returns the task handle. You pass the *sName* of the function (that creates the task) as a string, not as the function tag, and pass the arguments for that function in *Arg*. After the task is created, it runs in parallel to the calling task. The new task will run forever unless it returns from the function or is killed by another task.

By default, Plant SCADA requests necessary I/O device data and waits for the data to be returned before starting

the task - the task is provided with the correct data, but there will be a delay in starting the task. If you add 16 to the Mode, Plant SCADA starts the task immediately, without waiting for any data from the I/O devices - any I/O device variable that you use will either contain 0 (zero) or the last value read.

## **WARNING**

### **UNINTENDED EQUIPMENT OPERATION**

When mode 16 is used, ensure either appropriate delays are applied before processing references to tags or check qualities of tags. Otherwise, the execution system may process invalid data and returns incorrect results.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

You can specify that if the task is already running, the function will exit without launching a new task and an error will display. This is useful when you want only a single instance of the function running at any point in time.

It is also possible to run the task within the context of a particular cluster in a multi cluster system by setting the *ClusterName* parameter. If a cluster is not specified, the task will use the cluster context of the caller, be it a page or Cicode task. Please be aware that the cluster context cannot be changed once the code is running.

Any animation output for the new task is displayed in the window where it was created. If you want to send output to other windows, use the [WinSelect\(\)](#) function.

**Note:** You can use this function to call a private function, but only from within the file in which the private function is declared. See [Function Scope](#).

## Syntax

**TaskNew(*sName*, *sArg*, *Mode* [, *sClusterName*] )**

*sName*:

The name of the function to create the task, as a string.

*sArg*:

The set of arguments to be passed to the function. Individual arguments need to be separated by commas (,). Enclose string arguments in quotes "" and use the string escape character (^) around strings enclosed within a string. If the string in quotes is not enclosed, then the string is only the first tag found. The entire set of arguments need to be enclosed in quotes ("").

*Mode*:

The mode of the task:

0 - Task runs forever.

1 - Task runs until the current page is changed.

2 - Task runs until the current window is freed.

4 - This mode is deprecated and not active. Currently, by default, task requests I/O device data before starting.

8 - If the task already exists, the function will exit without launching the new task.

16- Task doesn't wait for necessary I/O device data and starts immediately.

You can select any one of modes 0, 1 or 2 and may add mode 4 and/or mode 8 and/or mode 16. For example, set Mode to 6 to request I/O device data before starting the task, and to run the task until the current window is freed.

*sClusterName*:

The name of the cluster context to be applied to the new Cicode task. This is optional if you have one cluster or are resolving the task via the current cluster context. The argument is enclosed in quotation marks "". You may pass "-" as the *ClusterName* argument to run the requested Cicode task without a cluster context.

## Return Value

The task handle, or -1 if the task cannot be successfully created. The task handle identifies the table where data on the associated task is stored.

## Related Functions

## Example

```
! Create a task that displays a message for 10 seconds.  
hTask=TaskNew("MyFunc","Data",0);  
! Continue to run while task runs.  
FUNCTION  
MyFunc(STRING Msg)  
    FOR I=0 TO 10 DO  
        Prompt(Msg);  
        Sleep(1);  
    END  
END  
...  
! Call a function which expects more complex argument  
hTask=TaskNew("ArgFunc","^"string one^","^"string two^",1,2",0);  
hTask=TaskNew("ArgFunc","^""+sOne+"^",^""+sTwo+"^","+iOne:##+", "+  
iTwo:##,0);  
FUNCTION  
ArgFunc(STRING sOne, STRING sTwo, INT iOne, INT iTwo)  
    ...  
END
```

## See Also

[Task Functions](#)

## TaskNewEx

Creates a new Cicode task with an individual subscription rate and returns the task handle. You pass the *sName* of the function (that creates the task) as a string, not as the function tag, and pass the arguments for that function in *Arg*. After the task is created, it runs in parallel to the calling task. The new task will run forever with tags updated at the specified time interval unless it returns from the function or is killed by another task.

By default, Plant SCADA requests necessary I/O device data and waits for the data to be returned before starting the task - the task is provided with the correct data, but there will be a delay in starting the task. If you add 16 to the Mode, Plant SCADA starts the task immediately, without waiting for any data from the I/O devices - any I/O device variable that you use will either contain 0 (zero) or the last value read. Use Mode 16 when the task has to

start immediately.

## WARNING

### UNINTENDED EQUIPMENT OPERATION

When mode 16 is used, ensure either appropriate delays are applied before processing references to tags or check qualities of tags. Otherwise, the execution system may process invalid data and return incorrect results.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

You can specify that if the task is already running, the function will exit without launching the new task and an error will display. This is useful when you want only a single instance of the function running at any point in time.

It is also possible to run the task within the context of a particular cluster in a multi cluster system by setting the *ClusterName* parameter. If a cluster is not specified, the task will use the cluster context of the caller, be it a page or Cicode task. Please be aware that the cluster context cannot be changed once the code is running.

Any animation output for the new task is displayed in the window where it was created. If you want to send output to other windows, use the [WinSelect\(\)](#) function.

**Note:** You can use this function to call a private function, but only from within the file in which the private function is declared. See [Function Scope](#).

## Syntax

**TaskNewEx(*sName*, *sArg*, *Mode*, *SubscriptionRate* [, *sClusterName*] )**

*sName*:

The name of the function to create the task, as a string.

*sArg*:

The set of arguments to be passed to the function. Individual arguments need to be separated by commas (,). Enclose string arguments in quotes "" and use the string escape character (^) around strings enclosed within a string. If you do not enclose the string in quotes, then the string is only the first tag found. The entire set of arguments need to be enclosed in quotes ("").

*Mode*:

The mode of the task:

0 - Task runs forever.

1 - Task runs until the current page is changed.

2 - Task runs until the current window is freed.

4 -This mode is deprecated and not active. Currently, by default, task requests all I/O device data before starting.

8 - If the task already exists, the function will exit without launching the new task.

16- Task doesn't wait for necessary I/O device data and starts immediately.

You can select any one of modes 0, 1 or 2 and may add mode 4 and/or mode 8, and/or mode 16. For example, set Mode to 6 to request I/O device data before starting the task, and to run the task until the current window is freed.

*SubscriptionRate*

The subscription rate for the task, between 0 and 60000 milliseconds, which determines the frequency at which the I / O Server reads I/O device data in order to provide tags with up-to-date Cicode variables. A value of -1 may

be passed which will use the current task's subscription rate or the default value as set by the existing parameter [\[Code\]TimeData](#) which defaults to 250.

*sClusterName*:

The name of the cluster context to be applied to the new Cicode task. This is optional if you have one cluster or are resolving the task via the current cluster context. The argument is enclosed in quotation marks "". You may pass "-" as the *ClusterName* argument to run the requested Cicode task without a cluster context.

## Return Value

The task handle, or -1 if the task cannot be successfully created. The task handle identifies the table where data on the associated task is stored.

## Related Functions

[TaskHnd](#), [TaskKill](#), [TaskNew](#), [TaskResume](#), [TaskSuspend](#), [ReRead](#), [WinSelect](#)

## Example

```
! Create a task that calls a function every half second.  
hTask=TaskNewEx("MyFunc","Data",0,500);
```

## See Also

[Task Functions](#)

## TaskResume

Resumes a task that was suspended by the [TaskSuspend\(\)](#) function. After a task is resumed, it runs on the next time-slice.

## Syntax

**TaskResume(*hTask*)**

*hTask*:

The task handle, returned from the [TaskNew\(\)](#) or [TaskHnd\(\)](#) function. The task handle identifies the table where all data on the associated task is stored.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TaskHnd](#), [TaskKill](#), [TaskSuspend](#), [TaskNew](#)

## Example

```
TaskResume(hTask);
```

[Task Functions](#)

### TaskSetSignal

Manually applies a signal to a specified task.

## Syntax

**TaskSetSignal(Hnd, nSignal)**

*Hnd:*

The task's handle. To retrieve this use the function TaskHnd().

*nSignal:*

Allows you to signal a specified task. Set to 0 (zero) for normal operation, 1 to stop the task or any other number that represents a defined signal.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TaskGetSignal](#), [TaskHnd](#), [TaskKill](#), [TaskSuspend](#), [TaskNew](#), [TaskResume](#)

## See Also

[Task Functions](#)

### TaskSuspend

Suspends a task. The task will stop running and will start again only when [TaskResume\(\)](#) is called.

## Syntax

**TaskSuspend(hTask)**

*hTask:*

The task handle, returned from the TaskNew() or TaskHnd() function. The task handle identifies the table where all data on the associated task is stored.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TaskHnd](#), [TaskKill](#), [TaskNew](#), [TaskResume](#)

## Example

```
TaskSuspend(hTask);
...
TaskResume(hTask);
```

## Time and Date Functions

Time/date functions manipulate time and date variables. Plant SCADA stores time/date-related variables as a single integer. This integer represents the number of seconds since 01/01/1970. It is in GMT, but it has an offset that updates it to local time (determined by the timezone the application is in). The Time/date functions convert this integer into time and date variables.

---

**Note:** The Time/date functions can only be used with dates between 1980 and 2035.

---

Following are functions relating to Time and Date:

<a href="#">Date</a>	Gets the current system date in string format.
<a href="#">DateAdd</a>	Adds time to a date.
<a href="#">DateDay</a>	Gets the day from a date.
<a href="#">DateInfo</a>	Returns the date format currently in effect on the Plant SCADA Server.
<a href="#">DateMonth</a>	Gets the month from a date.
<a href="#">DateSub</a>	Subtracts two dates.
<a href="#">DateWeekDay</a>	Gets the day of week from a date.
<a href="#">DateYear</a>	Gets the year from a date.
<a href="#">OLEDateToTime</a>	Converts an OLE DATE value to a Plant SCADA time/date value.
<a href="#">SysTime</a>	Marks the start of an event.

<a href="#">SysTimeDelta</a>	Calculates the time-span of an event.
<a href="#">Time</a>	Gets the current system time in string format.
<a href="#">TimeCurrent</a>	Gets the current time/date value.
<a href="#">TimeHour</a>	Gets hours from a time.
<a href="#">TimeInfo</a>	Returns the time format currently in effect on the Plant SCADA Server.
<a href="#">TimeMidNight</a>	Converts a time variable into the time at midnight.
<a href="#">TimeMin</a>	Gets minutes from a time.
<a href="#">TimeSec</a>	Gets seconds from a time.
<a href="#">TimeSet</a>	Sets the new system time.
<a href="#">TimeToOLEDate</a>	Converts a time/date value to an OLE DATE value.
<a href="#">TimeToStr</a>	Converts a time/date variable into a string.
<a href="#">TimeUTCOffset</a>	Determines the local time bias from UTC at a specified time.

## See Also

[Cicode Function Categories](#)

[Using Cicode Functions](#)

## Date

Gets the current date in string format.

**Note:** Time/Date functions can only be used with dates between 1980 and 2035. You should check that the date you are using is valid with Cicode similar to the following:

```
IF StrToDate(Arg1)>0 THEN
  ...
ELSE
  ...
END
```

## Syntax

**Date( [Format] )**

*Format:*

Format of the string:

0 - Short time format, hh:mm AM/PM.

1 - Long time format, hh:mm:ss AM/PM.  
2 - Short date format, dd/mm/yy.  
3 - Long date format, day month year.  
4 - Time and date, weekday month day year hh:mm:ss AM/PM.  
5 - Long time period, hh:mm:ss. Time needs to be in seconds.  
6 - Millisecond time period, hh:mm:ss.xxx ("xxx" represents milliseconds). Time needs to be in milliseconds.  
7 - Short time period, hh:mm. Time needs to be in seconds.  
8 - Long time period, "xxxxx Days hh Hours mm min ss sec where xxxx = number of days since 1/1/1970". Time needs to be in seconds.  
9 - Extended date format, dd/mm/yyyy.  
10 - Local TimeDate format, yyyy-mm-dd hh:mm:ss  
11 - Time of Day, hh:mm:ss tt format with no date  
*UTC:*  
Coordinated Universal Time (optional)  
0 - Display the string as a local date/time (default).  
1 - Display the string as a UTC date/time (valid for formats 0-4 and 9).  
If omitted, the default Format is 2. These formats follow the Regional Settings found in the Windows Control Panel.

## Return Value

The current date (in string format).

## Related Functions

[Time](#), [TimeToStr](#), [TimeCurrent](#)

## Example

```
/* If the current system date is 3rd November 1991 and the Windows
date format is dd/mm/yy; */
str = Date();
! Sets str to "3/11/91".
str = Date(2);
! Sets str to "3/11/91".
str = Date(3);
! Sets str to "3rd November 1991".
```

## See Also

[Time and Date Functions](#)

## DateAdd

Adds time (in seconds) to a time/date value. The return value is in time/date variable format. Use this function for time and date calculations.

## Syntax

**DateAdd**(*Time*, *AddTime*)

*Time*:

The time/date to which the *AddTime* will be added.

*AddTime*:

The time to add, in seconds.

## Return Value

The date as a time/date variable.

## Related Functions

[TimeToStr](#), [DateSub](#)

## Example

```
DateVariable=DateAdd(StrToDate("3/11/91"),86400);
! Adds 24 hours to 3/11/91.
NewDate=TimeToStr(DateVariable);
! Sets NewDate to 4/11/91.
```

## See Also

[Time and Date Functions](#)

## DateDay

Gets the day of the month from a time/date variable.

**Note:** Time/Date functions can only be used with dates between 1980 and 2035. You should check that the date you are using is valid with Cicode similar to the following:

```
IF StrToDate(Arg1)>0 THEN
...
ELSE
...
END
```

## Syntax

**DateDay(*Time*)**

*Time*:

The time/date variable.

## Return Value

The day of the month as an integer.

## Related Functions

[Date](#)

## Example

```
! If the current system date is 3rd November 1991;  
Variable=DateDay(TimeCurrent());  
! Sets Variable to 3.
```

## See Also

[Time and Date Functions](#)

## DateInfo

Returns the date format currently used on the Plant SCADA Server.

## Syntax

**DateInfo(*nInfo*, *nExtra*)**

*nInfo*:

Determines the contents of the string returned by the DateInfo() function. Valid values and resulting strings are:

1 - The current date order:

- "0" - MMDDYY
- "1" - DDMMYY
- "2" - YYMMDD.

2 - The current date delimiter.

3 - The current short date format.

4 - The current long date format.

5 - The current extended date format.

6 - The short weekday string. The particular weekday returned is determined by the *nExtra* argument.

7 - The long weekday string. The particular weekday returned is determined by the *nExtra* argument.

8 - The short month string. The particular month returned is determined by the *nExtra* argument.

9 - The long month string. The particular month returned is determined by the *nExtra* argument.

*nExtra*:

When an *nInfo* argument of 6 or 7 is specified, the *nExtra* argument determines which weekday (1-7) is returned by the DateInfo() function.

When an *nInfo* argument of 8 or 9 is specified, the *nExtra* argument determines which month (1-12) is returned by the DateInfo() function.

The *nExtra* argument is ignored if any other *nInfo* value is passed to the function.

## Return Value

A string containing one of the following:

- Current date order ("0" for MMDDYY, "1" for DDMMYY, "2" for YYMMDD);
- Current date delimiter;
- Current short date format;
- Current long date format;
- Current extended date format;
- Short weekday string;
- Long weekday string;
- Short month string;
- Long month string;

This depends on the *nInfo* and *nExtra* arguments passed to the function.

## Related Functions

[TimeInfo](#)

## Example

```
! If the current system date is the fourth of December 2002;  
TwelfthMonth=DateInfo(9,12);  
! Sets TwelfthMonth to "December".
```

## See Also

[Time and Date Functions](#)

## DateMonth

Gets the month from a time/date variable.

**Note:** Time/Date functions can only be used with dates between 1980 and 2035. You should check that the date

---

you are using is valid with Cicode similar to the following:

```
IF StrToDate(Arg1)>0 THEN
...
ELSE
...
END
```

---

## Syntax

**DateMonth(*Time*)**

*Time*:

The time/date variable.

## Return Value

The month of the year as an integer.

## Related Functions

[Date](#)

## Example

```
! If the current system date is 3rd November 1991;
Variable=DateMonth(TimeCurrent());
! Sets Variable to 11.
```

## See Also

[Time and Date Functions](#)

## DateSub

Subtracts time (in seconds) from a time/date value. The return value is in time/date variable format. Use this function for time and date calculations.

## Syntax

**DateSub(*Time*, *SubTime*)**

*Time*:

The time/date from which the SubTime will be subtracted.

*SubTime*:

The time to subtract, in seconds.

## Return Value

The time difference (in seconds) as an integer.

## Related Functions

[Date](#), [DateAdd](#)

## Example

```
Variable=DateSub(StrToDate("05/11/91"),StrToDate("03/11/91"));
! Sets Variable to number of seconds between 2 date/times.
Str=TimeToStr(Variable,5);
! Sets Str to "48:00:00".
```

## See Also

[Time and Date Functions](#)

## DateWeekDay

Gets the day of the week from a time/date variable.

**Note:** Time/Date functions can only be used with dates between 1980 and 2035. You should check that the date you are using is valid with Cicode similar to the following:

```
IF StrToDate(Arg1)>0 THEN
...
ELSE
...
END
```

## Syntax

**DateWeekDay(*Time*)**

*Time:*

The time/date variable.

## Return Value

An integer representing the day of the week as follows:

- 1 - Sunday
- 2 - Monday
- 3 - Tuesday
- 4 - Wednesday
- 5 - Thursday

6 - Friday  
7 - Saturday

## Related Functions

[Date](#), [TimeCurrent](#)

## Example

```
! If the current system date is Sunday, 3rd November 1991;  
Variable=DateWeekDay(TimeCurrent());  
! Sets Variable to 1.
```

## See Also

[Time and Date Functions](#)

## DateYear

Gets the year from a time/date variable.

**Note:** Time/Date functions can only be used with dates between 1980 and 2035. You should check that the date you are using is valid with Cicode similar to the following:

```
IF StrToDate(Arg1)>0 THEN  
...  
ELSE  
...  
END
```

## Syntax

**DateYear**(*Time* [, *Mode*] )

*Time*:

The time/date variable.

*Mode*:

The format required:

0 - Short year, yy. If you use this mode during the year 2000, 0 (zero) will be returned.

1 - Long year, yyyy

If omitted, the default Mode is 0.

## Return Value

The year as an integer.

**Note:** In the year 2000, this function will return 0 (zero) if mode 0 (zero) is used.

## Related Functions

[Date](#)

## Example

```
! If the current system date is 3rd November 1991;  
Variable=DateYear(TimeCurrent(),0);  
! Sets Variable to 91.  
! If the current system date is 18th October 2000;  
Variable=DateYear(TimeCurrent(),0);  
! Sets Variable to 0.  
Variable=DateYear(TimeCurrent(),1);  
! Sets Variable to 1991.
```

## See Also

[Time and Date Functions](#)

## OLEDateToTime

Converts an OLE DATE value (stored in a REAL) to a Plant SCADA time/date value.

**Note:** An OLE DATE representing a local time in the daylight savings(DST) to standard time(Std) transition period will be converted to the DST value internally. For example, if the DST transition is 30/3/2003 2:00:00 Std, the local time will behave in the following manner: 2:00:00 DST -> 2:59:59 DST -> 2:00:00 Std. Because of this, a value representing the period between 2:00:00 and 2:59:59 on that date will be interpreted as 2:00:00 DST, not Std.

## Syntax

**OLEDateToTime(OLEDate, Local)**

*OLEDate:*

The OLE DATE value to convert (stored as a REAL).

*Local:*

*0* - OleDate represents a UTC time.

*1* - OleDate represents a Local time.

## Return Value

Returns a Plant SCADA time/date value.

## Related Functions

[TimeCurrent](#), [TimeToOLEDate](#)

## Example

```
Real = TimeToOLEDate(TimeCurrent(), 1);
! Sets Real to the local date/time value
TimeVariable = OLEDateToTime(Real, 1);
! Sets TimeVariable to the value of Real when interpreted as Local
time.
```

## See Also

[Time and Date Functions](#)

## SysTime

Gets the Plant SCADA internal system millisecond counter. The counter is not based on time, but counts from 0 up to the maximum unsigned integer value and then back to 0.

As Cicode integer handling is signed, values above 24 days will appear negative. For users needing the full 49 day range, please use the [Timestamp Functions](#).

---

**Note:** The delta time between two timestamps will be correct and positive provided the difference between the two is less than 49 days. If the gap exceeds this, the timestamp functions should be used.

You can use this function to time events down to the millisecond level, either by subtracting the current SysTime from the SysTime at the start of the event, or by using the SysTimeDelta() function (which will give the same result).

The SysTime() function does not return the time of day. Use the Time() or TimeCurrent() function to obtain the time of day.

---

**Note:** Time/Date functions can only be used with dates between 1980 and 2035. You should check that the date you are using is valid with Cicode similar to the following:

```
IF StrToDate(Arg1)>0 THEN
...
ELSE
...
END
```

---

## Syntax

**SysTime()**

## Return Value

The Plant SCADA internal system millisecond counter (as an integer).

## Related Functions

[SysTimeDelta](#), [Time](#), [TimeCurrent](#)

## Example

```
Start=SysTime();
! Gets the current time.
...
Delay=SysTime()-Start;
! Sets Delay to the time difference, in milliseconds.
```

## See Also

[Time and Date Functions](#)

## SysTimeDelta

Calculates the time difference between a start time and the current time, and updates the start time to the current time. You can time continuous events in a single operation. See the SysTime() function for information on its use.

**Note:** Time/Date functions can only be used with dates between 1980 and 2035. You should check that the date you are using is valid with Cicode similar to the following:

```
IF StrToDate(Arg1)>0 THEN
...
ELSE
...
END
```

## Syntax

**SysTimeDelta(Start)**

*Start:*

The start time returned from the SysTime() function. Must be a Long type variable.

## Return Value

The time difference from a start time and the current time.

## Related Functions

[SysTime](#)

## Example

```
Start=SysTime();
! Gets the current time.
...
Delay1=SystimeDelta(Start);
! Sets Delay1 to the time difference from Start.
...
```

```
Delay2=SysTimeDelta(Start);
! Sets Delay2 to the time difference from the last SysTimeDelta()
call.
```

## See Also

[Time and Date Functions](#)

### Time

Gets the current time in string format.

**Note:** Time/Date functions can only be used with dates between 1980 and 2035. You should check that the date you are using is valid with Cicode similar to the following:

```
IF StrToDate(Arg1)>0 THEN
...
ELSE
...
END
```

## Syntax

**Time( [Format] )**

*Format:*

The format of the time:

0 - Short time format, hh:mm AM/PM

1 - Long time format., hh:mm:ss AM/PM

If omitted, the default *Format* is 0.

## Return Value

The current time (as a string).

## Related Functions

[Date](#), [TimeToStr](#)

## Example

```
! If the current time is 10:45:30;
Variable=Time();
! Sets Variable to "10:45".
Variable=Time(0);
! Sets Variable to "10:45 AM".
Variable=Time(1);
! Sets Variable to "10:45:30 AM".
```

## See Also

[Time and Date Functions](#)

## TimeCurrent

Gets the current system time/date in time/date variable format. Please be aware that Plant SCADA stores time as the number of seconds since 01/01/1970. You can convert this value into usable date and time variables by using the various Date and Time functions.

**Note:** Time/Date functions can only be used with dates between 1980 and 2035. You should check that the date you are using is valid with Cicode similar to the following:

```
IF StrToDate(Arg1)>0 THEN
...
ELSE
...
END
```

## Syntax

**TimeCurrent()**

## Return Value

A time/date variable.

## Related Functions

[StrToDate](#), [StrToTime](#)

## Example

```
! If the current system time is 11:43:10 a.m.;
TimeVariable=TimeToStr(TimeCurrent(),0);
! Sets TimeVariable to "11:43".
```

## See Also

[Time and Date Functions](#)

## TimeHour

Gets the hour value from a time/date variable.

**Note:** Time/Date functions can only be used with dates between 1980 and 2035. You should check that the date you are using is valid with Cicode similar to the following:

```
IF StrToDate(Arg1)>0 THEN
```

---

```
...
ELSE
...
END
```

---

## Syntax

**TimeHour(*Time*)**

*Time*:

The time/date variable.

## Return Value

The hour (as an integer).

## Related Functions

[TimeCurrent](#)

## Example

```
! If the current system time is 11:43:10 a.m.;
HoursVariable=TimeHour(TimeCurrent());
! Sets HoursVariable to 11.
```

## See Also

[Time and Date Functions](#)

## TimeInfo

Returns the time format currently used on the Plant SCADA Server.

## Syntax

**TimeInfo(*nInfo*)**

*nInfo*:

Determines the contents of the string returned by the TimeInfo() function. Valid values and resulting strings are:

1- The current time hour format:

- "0" - 12 hour
- "1" - 24 hour

2- The current time delimiter.

3- The current morning time extension.

4- The current evening time extension.

## Return Value

Depending on the *nInfo* argument passed to the function, a string containing:

- Current time hour format ("0" for 12 hour, "1" for 24 hour)
- Current time delimiter
- Current morning time extension
- Current evening time extension

## Related Functions

[DateInfo](#)

## Example

```
! If the current system time is 15:43:10.;  
ClockType=TimeInfo(1);  
! Sets ClockType to "1".
```

## See Also

[Time and Date Functions](#)

## TimeMidNight

Returns the number of seconds between midnight on January 1, 1970, and the midnight immediately prior to the specified time/date. This function is useful for performing calculations with the time and date.

**Note:** Time/Date functions can only be used with dates between 1980 and 2035. You should check that the date you are using is valid with Cicode similar to the following:

```
IF StrToDate(Arg1)>0 THEN  
...  
ELSE  
...  
END
```

## Syntax

**TimeMidNight(*Time*)**

*Time*:

The time/date variable.

## Return Value

A time/date variable.

## Related Functions

[TimeCurrent](#)

## Example

```
timeNow = TimeCurrent();
! get the time variable at 7am today
time7am = TimeMidNight(timeNow) + 7*60*60;
IF timeNow > time7am AND timeNow < time7am + 10 THEN
    Beep();
    Prompt("Wake Up!");
END
```

## See Also

[Time and Date Functions](#)

## TimeMin

Gets the minutes value from a time/date variable.

---

**Note:** Time/Date functions can only be used with dates between 1980 and 2035. You should check that the date you are using is valid with Cicode similar to the following:

```
IF StrToDate(Arg1)>0 THEN
    ...
ELSE
    ...
END
```

---

## Syntax

**TimeMin(*Time*)**

*Time*:

The time/date variable.

## Return Value

The minute (as an integer).

## Related Functions

[TimeCurrent](#)

## Example

```
! If the current system time is 11:43:10 a.m.
```

```
MinutesVariable=TimeMin(TimeCurrent());  
! Sets MinutesVariable to 43.
```

## See Also

[Time and Date Functions](#)

## TimeSec

Gets the seconds value from a time/date variable.

**Note:** Time/Date functions can only be used with dates between 1980 and 2035. You should check that the date you are using is valid with Cicode similar to the following:

```
IF StrToDate(Arg1)>0 THEN  
...  
ELSE  
...  
END
```

## Syntax

**TimeSec(*Time*)**

*Time*:

The time/date variable.

## Return Value

The second (as an integer).

## Example

```
! If the current system time is 11:43:10 a.m.;  
SecondsVariable=TimeSec(TimeCurrent());  
! Sets SecondsVariable to 10.
```

## See Also

[Time and Date Functions](#)

## TimeSet

Sets the new system time. You can set the time only on the computer which this function is called.

Time/date functions can only be used with dates from 1980 to 2035.

If you call TimeSet without the required privileges to change the system time you will receive a hardware alarm indicating this.

## Syntax

**TimeSet(*Time*)**

*Time*:

The time/date variable to which the new time is set. Sets the time on this computer only.

## Return Value

The error status of the set

## Related Functions

[DateInfo](#)

## Example

```
! set the time to 11:43 on June 23 1993
time = StrToTime("11:43:00") + StrToDate("23/6/93");
TimeSet(time);.
```

## See Also

[Time and Date Functions](#)

## TimeToOLEDate

Converts a Plant SCADA time/date value to an OLE DATE value (this should be stored in a REAL).

## Syntax

**TimeToOLEDate(*Time, Local*)**

*Time*:

Time/date variable.

*Local*:

0 - The return value is output as UTC time.

1 - The return value is output as Local time.

## Return Value

Returns an OLE date value.

## Related Functions

[TimeCurrent, OLEDATETIME](#)

## Example

```
Real = TimeToOLEDate(TimeCurrent(), 1);
! Sets Real to the local date/time value
```

## See Also

[Time and Date Functions](#)

### TimeToStr

Converts a time/date variable into a string. Use this function for calculating time differences or run times, and so on. Set *Format* to 6 to convert time periods that are in milliseconds, such as the times that are returned from the *SysTime()* and *SysTimeDelta()* functions.

**Note:** Once a date/time is retrieved as UTC, the string cannot be used by the Cicode functions [StrToDate](#) and [StrToTime](#) to synthesize a date/time value as these functions support local time only.

Time/date functions can only be used with dates from 1980 to 2035. You should check that the date you are using is valid with Cicode similar to the following:

```
IF StrToDate(Arg1)>0 THEN
...
ELSE
...
END
```

## Syntax

**TimeToStr**(*Time*, *Format* [, *UTC*] )

*Time*:

The time/date variable.

*Format*:

Format of the string:

0 - Short time format, hh:mm AM/PM.

1 - Long time format, hh:mm:ss AM/PM.

2 - Short date format, based on the system locale setting. For example, dd/mm/yy for English (Australia); mm/dd/yy for English (United States); or dd.mm.yy for German (Germany).

3 - Long date format, day month year.

4 - Time and date, weekday month day year hh:mm:ss AM/PM.

5 - Long time period, hh:mm:ss. Time needs to be in seconds.

6 - Millisecond time period, hh:mm:ss.xxx ("xxx" represents milliseconds). Time needs to be in milliseconds.

7 - Short time period, hh:mm. Time needs to be in seconds.

8 - Long time period, "xxxxx Days hh Hours mm min ss sec". Time needs to be in seconds.

9 - Extended date format, based on the system locale setting. For example, dd/mm/yyyy for English (Australia); mm/dd/yyyy for English (United States); or dd.mm.yyyy for German (Germany).

10 - Local TimeDate format, yyyy-mm-dd hh:mm:ss

11 - Time of Day, hh:mm:ss tt format with no date

*UTC:*

Coordinated Universal Time (optional)

0 - Display the string as a local date/time (default).

1 - Display the string as a UTC date/time (valid for formats 0-4 and 9).

## Return Value

A string containing the converted time/date or period variable, or an empty string if invalid.

## Related Functions

[Time](#), [TimeCurrent](#), [Date](#)

## Example

```
! If the current system time is 11:50:00 a.m.  
String=TimeToStr(TimeCurrent(),0);  
! Sets String to "11:50 AM".  
String=TimeToStr(125 + TimeCurrent(),5);  
! Sets String to "11:52:05" (the current time + 2 minutes and 5  
seconds).
```

## See Also

[Time and Date Functions](#)

## TimeUTCOffset

Determines the local time bias from UTC that was in force at a specified time. For example, US Pacific Standard Time is -8 hrs from UTC, so -28800 would be returned (-8 hours x 60 minutes x 60 seconds). However, if the specified time occurred during daylight saving, the returned value would be -7 hours (or -25200 seconds).

## Syntax

**TimeUTCOffset(*Time*)**

*Time:*

The time/date variable.

## Return Value

The local time bias in seconds.

## Related Functions

[TimeCurrent](#)

## See Also

## Timestamp Functions

The Timestamp functions enable you to programmatically read and write the Timestamp values of tag elements and access the timestamp information associated with a tag value.

No function taking either Timestamp or Quality as an argument can be called from the Cicode Kernel Window or through a CtCicode CtAPI function.

The following functions are used to interface with the TIMESTAMP data type.

<a href="#">StrToTimestamp</a>	Converts timestamp in a STRING format into a TIMESTAMP format.
<a href="#">TimestampAdd</a>	Adds time (in part of) to a TIMESTAMP variable.
<a href="#">TimestampCreate</a>	Returns a timestamp variable created from the parts.
<a href="#">TimestampToStr</a>	Converts a TIMESTAMP variable into a string.
<a href="#">TimestampDifference</a>	Returns a difference between two TIMESTAMP variables as a number of milliseconds.
<a href="#">TimestampCurrent</a>	Returns the current system date and time as a TIMESTAMP variable.
<a href="#">TimestampFormat</a>	Format a TIMESTAMP variable into a string.
<a href="#">TimestampGetPart</a>	Returns one part (year, month, day, etc) of the timestamp variable.
<a href="#">TimeIntToTimestamp</a>	Converts a time INTEGER which is represented as a number of seconds since 01/01/1970 to a TIMESTAMP.
<a href="#">TimestampSub</a>	Subtracts time (in part of) from a TIMESTAMP variable.
<a href="#">TimestampToInt</a>	Converts a TIMESTAMP variable into a time INTEGER which is represented as a number of seconds since 01/01/1970.
<a href="#">VariableTimestamp</a>	Extracts the timestamp from a given variable.

## See Also

[Using Cicode Functions](#)

### StrToTimestamp

This function converts timestamp in a STRING format into a TIMESTAMP format. This function can be used in browsing functions to convert timestamp fields returned as a string.

## Syntax

`TIMESTAMP StrToTimestamp(STRING String [, INT Format [, INT UTC]])`

*String:*

The date and time as a STRING or TIMESTAMP

*Format:*

The format of the string. Should be 15. Other types reserved for future use.

*UTC:*

If 1, the date is considered to be in UTC. Otherwise, local time is used. This field is only applicable for format STRING formats (i.e. format is not equal 15).

## Return Value

This function returns a date in TIMESTAMP format if successful, otherwise returns TIMESTAMP of January 1, 1601, 00:00:00 (UTC). If the function is unsuccessful you can call the IsError() function to get the actual error code.

### TimeIntToTimestamp

Converts a time INTEGER which is represented as a number of seconds since 01/01/1970 to a TIMESTAMP.

## Syntax

**TimeIntToTimestamp(INT TimeInt [, INT Millisecond [, INT UTC]])**

*TimeInt*:

The number of seconds since 01/01/1970.

*Millisecond*:

The number of milliseconds since last second (optional).

*UTC*:

Coordinated Universal Time (optional):

0 – The given time INTEGER is a local date/time.

1 – The given time INTEGER is a UTC date/time (default).

## Return Value

A TIMESTAMP variable or INVALID\_TIMESTAMP if invalid.

## Related Functions

[TimestampCurrent](#), [TimestampDifference](#), [TimestampSub](#), [TimestampToStr](#), [TimestampAdd](#), [TimestampCreate](#), [TimestampFormat](#), [TimestampGetPart](#), [TimestampToInt](#)

## Example

```
INT TimeInt = TimeCurrent();
TIMESTAMP t1 = TimeIntToTimestamp(TimeInt);
STRING sTimestamp = TimestampToStr(t1, 0, 0);
// sTimestamp equals current time in the short time format
// i.e. 'HH:MM AM/PM'
```

## See Also

[Timestamp Functions](#)

## TimestampAdd

Adds an offset to a TIMESTAMP variable.

## Syntax

**TimestampAdd(TIMESTAMP *Timestamp*, INT *Offset* [, INT *Part*])**

*Timestamp*:

The timestamp to which Offset will be added

*Offset*:

The offset to add, expressed in units of the part parameter

*Part:*

Indicates which part to add:

- 0 – Offset is in years.
- 1 – Offset is in months.
- 2 – Offset is in days.
- 3 - Offset is in hours.
- 4 - Offset is in minutes.
- 5 - Offset is in seconds (default)
- 6 - Offset is in milliseconds

## Return Value

The TIMESTAMP variable, or INVALID\_TIMESTAMP if invalid.

## Related Functions

[TimestampCurrent](#), [TimestampDifference](#), [TimestampSub](#), [TimestampToStr](#), [TimeIntToTimestamp](#),  
[TimestampCreate](#), [TimestampFormat](#), [TimestampGetPart](#), [TimestampToTimeInt](#)

## Example

```
TIMESTAMP t1 = TimestampAdd(Tag1.T, 100); // 100 seconds
TIMESTAMP t2 = TimestampAdd(Tag1.T, 1, 0); // 1 year
```

## See Also

[Timestamp Functions](#)

## TimestampCurrent

Return the current system date and time as a TIMESTAMP variable.

## Syntax

**TimestampCurrent()**

## Return Value

A TIMESTAMP variable containing the current system date and time.

## Related Functions

[TimestampAdd](#), [TimestampDifference](#), [TimestampSub](#), [TimestampToStr](#), [TimestampCreate](#), [TimestampFormat](#),  
[TimestampGetPart](#), [TimestampToInt](#), [TimeIntToTimestamp](#)

## Example

```
TIMESTAMP t1 = TimestampCurrent();
```

## See Also

[Timestamp Functions](#)

## TimestampCreate

Returns a TIMESTAMP variable created from the parts.

## Syntax

**TimestampCreate(INT Year, INT Month, INT Day, INT Hour, INT Minute, INT Second, INT Millisecond [, INT bUtc])**

*Timestamp:*

The timestamp from which the part will be extracted.

*Year:*

The year part.

*Month:*

The month part.

*Day:*

The day part.

*Hour:*

The hour part.

*Minute:*

The minute part.

*Second:*

The second part.

*Millisecond:*

The millisecond part.

*UTC:*

Coordinated Universal Time (optional):

0 – The given time INTEGER is a local date/time.

1 – The given time INTEGER is a UTC date/time (default).

## Return Value

The composed TIMESTAMP variable, or INVALID\_TIMESTAMP if invalid

## Related Functions

[TimestampAdd](#), [TimestampCurrent](#), [TimestampDifference](#), [TimestampSub](#), [TimestampToStr](#), [TimestampFormat](#),  
[TimestampGetPart](#), [TimestampToInt](#), [TimeIntToTimestamp](#)

## Example

```
TIMESTAMP timestamp = TimestampCreate(2009, 6, 29, 11, 2, 10, 468);
STRING sTimestamp = TimestampFormat(t1, "dd/MM/yyyy hh:mm:ss.fff");
// sTimestamp equals '29/06/2009 11:02:10.468'
```

## See Also

[Timestamp Functions](#)

## TimestampDifference

Returns the difference between two TIMESTAMP variables as a number of milliseconds.

## Syntax

**TimestampDifference**(TIMESTAMP *Timestamp1*, TIMESTAMP *Timestamp2* [, INT *Part* [, INT *bCumulative*]])

*Timestamp 1:*

The TIMESTAMP variable 1.

*Timestamp 2:*

The TIMESTAMP variable 2.

*Part:*

The type of time units being used for the result:

0 – Result is in years.

1 – Result is in months.

2 – Result is in days.

3 - Result is in hours

4 - Result is in minutes.

5 - Result is in seconds (default).

6 - Result is in milliseconds.

*bCumulative:*

Defines how to pass results which values are greater than their time units (see example below).

0 – Non-cumulative

1 – Cumulative mode (default).

## Return Value

The time period between Timestamp1 and Timestamp2. The value is equal or greater than zero. If error, returns 0 with an error code.

## Related Functions

[TimestampAdd](#), [TimestampCurrent](#), [TimestampSub](#), [TimestampToStr](#), [TimestampCreate](#), [TimestampFormat](#),  
[TimestampGetPart](#), [TimestampToInt](#), [TimeIntToTimestamp](#)

## Example

```
TIMESTAMP t1 = TimestampCreate(2008, 11, 28, 09, 01, 30);
TIMESTAMP t2 = TimestampCreate(2008, 11, 28, 09, 00, 00);
INT nTimespanCumulative = TimestampDifference(t1, t2, 5, 1);
// nTimespanCumulative is equal 90 (seconds)
INT nTimespanNonCumulative = TimestampDifference(t1, t2, 5, 0);
// nTimespanNonCumulative is equal 30 (seconds)
```

## See Also

[Timestamp Functions](#)

## TimestampFormat

Format a TIMESTAMP variable into a string.

## Syntax

**TimestampFormat**(TIMESTAMP *Timestamp*, STRING *Format* [, INT *UTC*])

*Timestamp*:

The timestamp variable.

*Format*:

The format of the string is the same as .NET Framework DateTime format. Specifically be reminded that the format is case sensitive. For example 'MM' is the zero padded month number, whereas 'mm' is the zero padded current minute within the hour. Therefore no Year, Day or Seconds will be displayed if they are specified in uppercase as: YYYY, DD, SS. The correct display will only occur when they are specified in lowercase as: yyyy, dd, ss.

A short list of formats are included below extracted from the "Custom Date and Time Format Strings" in the Microsoft .NET Framework Developer's Guide from the MSDN Library. It is recommended that you confirm its currency by consulting the source information periodically.

Use the following single-character format strings by themselves to choose predefined standard date and time formats:

- d Short date pattern. Ex. "6/15/2009"
- D Long date pattern. Ex. "Monday, June 15, 2009"
- f Full date/time pattern (short time). Ex. "Monday, June 15, 2009 1:45 PM"
- F Full date/time pattern (long time). Ex. "Monday, June 15, 2009 1:45:30 PM"
- g General date/time pattern (short time). Ex. "6/15/2009 1:45 PM"
- G General date/time pattern (long time). Ex. "6/15/2009 1:45:30 PM"•
- M or m Month/day pattern. "June 15"
- O or o Round-trip date/time pattern. Ex. "2009-06-15T13:45:30.0900000"
- R or r RFC1123 pattern. Ex. "Mon, 15 Jun 2009 20:45:30 GMT"
- s Sortable date/time pattern. Ex. "2009-06-15T13:45:30"
- t Short time pattern. Ex. "1:45 PM"
- T Long time pattern. Ex. "1:45:30 PM"
- u Universal sortable date/time pattern. Ex. "2009-06-15 20:45:30Z"
- U Universal full date/time pattern. Ex. "Monday, June 15, 2009 8:45:30 PM"
- Y or y Year month pattern. Ex. "June, 2009"

For all the examples above, the input time/date is assumed to be 6/15/2009 1:45:30 PM with Windows set to the en-US locale. Many of the formats will change according to the current Windows locale.

You may combine the following format specifiers to make up custom format specifications:

- d The day of the month, from 1 through 31.
- dd The day of the month, from 01 through 31.
- ddd The abbreviated name of the day of the week.
- dddd The full name of the day of the week.
- f Fraction of a second. Returns one decimal place for each 'f', up to 'fffffff'
- F Fraction of a second, if non-zero. Returns one decimal place for each 'f', up to 'fffffff'
- g, gg The period or era.
- h The hour, using a 12-hour clock from 1 to 12.
- hh The hour, using a 12-hour clock from 01 to 12.
- H The hour, using a 24-hour clock from 0 to 23.
- HH The hour, using a 24-hour clock from 00 to 23.
- K Time zone information.
- m The minute, from 0 through 59.
- mm The minute, from 00 through 59.
- M The month, from 1 through 12.
- MM The month, from 01 through 12.
- MMM The abbreviated name of the month.
- MMMM The full name of the month.
- s The second, from 0 through 59.
- ss The second, from 00 through 59.
- t The first character of the AM/PM designator.

- tt The AM/PM designator.
- y The year, from 0 to 99.
- yy The year, from 00 to 99.
- yyy The year, with a minimum of three digits.
- yyyy The year as a four-digit number.
- yyyy The year as a five-digit number.
- z Hours offset from UTC, with no leading zeros.
- zz Hours offset from UTC, with a leading zero for a single-digit value.
- zzz Hours and minutes offset from UTC.
- : The time separator.
- / The date separator.
- "string" or 'string' Literal string delimiter.
- % Defines the following character as a custom format specifier.
- \ The escape character.
- Any other character The character is copied to the result string unchanged.

*UTC:*

Coordinated Universal Time (optional):

0 - Returns the time as a local date/time (default).

1 - Returns the time as a UTC date/time.

## Return Value

A string containing the converted time/date, or an empty string if invalid.

## Related Functions

[TimestampAdd](#), [TimestampCurrent](#), [TimestampDifference](#), [TimestampSub](#), [TimestampToStr](#), [TimestampCreate](#),  
[TimestampGetPart](#), [TimestampToInt](#), [TimeIntToTimestamp](#)

## Example

```
TIMESTAMP t1 = TimestampCreate(2009,07,11,09,27,34,123);
STRING sTimestamp = TimestampFormat(t1, "dd/MM/yyyy hh:mm:ss.ffff");
// sTimestamp equals "11/07/2009 09:27:34.123"
```

## See Also

[Timestamp Functions](#)

## TimestampGetPart

Returns one part (year, month, day, etc) of the TIMESTAMP variable.

## Syntax

**TimestampGetPart**(TIMESTAMP *Timestamp*, INT *Part* [, INT *bUtc*])

*Timestamp*:

The timestamp from which the part will be extracted.

*Part*:

Indicates which part to extract:

0 – The year part

1 – The month part.

2 – The day part.

3 – The hour part.

4 – The minute part.

5 – The second part.

6 – The millisecond part.

7 - The number of milliseconds since midnight last occurred.

*bUtc*:

Coordinated Universal Time (optional):

0 – The given time INTEGER is a local date/time.(default).

1 – The given time INTEGER is a UTC date/time.

## Return Value

The required part of the TIMESTAMP variable.

## Related Functions

[TimestampAdd](#), [TimestampCurrent](#), [TimestampDifference](#), [TimestampSub](#), [TimestampToStr](#), [TimestampCreate](#),  
[TimestampFormat](#), [TimestampToInt](#), [TimeIntToTimestamp](#)

## Example

```
TIMESTAMP t1;  
    // insert code here  
INT year = TimestampGetPart(t1, 0);  
INT second = TimestampGetPart(t1, 5);
```

## See Also

[Timestamp Functions](#)

## TimestampSub

Subtracts an offset from a TIMESTAMP variable.

## Syntax

**TimestampSub**(TIMESTAMP *Timestamp*, INT *Offset* [, INT *Part*])

*Timestamp*:

The timestamp to which Offset will be subtracted

*Offset*:

The offset to subtract, expressed in units of the part parameter

*Part*:

Indicates which part to subtract:

0 – Offset is in years.

1 – Offset is in months.

2 – Offset is in days.

3 - Offset is in hours.

4 - Offset is in minutes.

5 - Offset is in seconds (default)

6 - Offset is in milliseconds

## Return Value

The TIMESTAMP variable, or INVALID\_TIMESTAMP if invalid.

## Related Functions

[TimestampFormat](#), [TimestampGetPart](#), [TimestampToInt](#), [TimeIntToTimestamp](#)

## Example

```
TIMESTAMP t1 = TimestampSub(Tag1.T, 1, 0); // 1 year;
```

## See Also

[Timestamp Functions](#)

## TimestampToStr

Converts a TIMESTAMP variable into a string.

## Syntax

**TimestampToStr**(*Timestamp*, INT *Format* [, INT *UTC*])

*Timestamp*:

Specifies the TIMESTAMP variable.

*Format:*

The format number determines which of date/time patterns are used for formatting returned string. Date/time patterns are defined in regional settings on a particular computer and can vary depend on national or individual preferences. The possible format numbers together with examples based on en-US regional settings are listed below:

- 0 – Short time format, hh:mm.
- 1 – Long time format, hh:mm:ss.
- 2 – Short date format, dd/MM/yyyy.
- 3 – Long date format, dddd, dd MMMM yyyy.
- 4 – Short date & short time format, dd/MM/yyyy hh:mm.
- 5 – Short date & long time format, dd/MM/yyyy hh:mm:ss.
- 6 – Long date & short time format, dddd, dd MMMM yyyy hh:mm.
- 7 – Long date & long time format, dddd, dd MMMM yyyy hh:mm:ss.
- 8 – Month day format, dd MMMM.
- 9 – Year month format, MMMM yyyy.
- 10 – RFC1123 format, ddd, dd MMM yyyy hh:mm:ss GMT
- 11 – Sortable date time format, yyyy-MM-ddThh:mm:ss
- 12 – Short universal format, yyyy-MM-dd hh:mm:ssZ
- 13 – Long universal format, dddd, dd MMMM yyyy hh:mm:ss
- 14 – Long Time & millisecond, hh:mm:ss.fff
- 15 - Date and time as a 64-bit value specified by the number of 100-nanosecond intervals since January 1, 1601 .

*UTC (optional)*

Determines if Universal Time Coordinate is used..

- 0 - Display the string as a local date/time (default).
- 1 - Display the string as a UTC date/time.

## Return Value

A string containing the converted time/date or period variable, or an empty string if invalid.

## Related Functions

[TimestampAdd](#), [TimestampCurrent](#), [TimestampDifference](#), [TimestampCreate](#), [TimestampFormat](#),  
[TimestampGetPart](#), [TimestampToStr](#), [TimeIntToTimestamp](#)

## Example

```
TIMESTAMP t1 = TimestampCreate(2009,07,11,09,27,34,123);
STRING sTimestamp = TimestampToStr(t1, 0, 0);
// sTimestamp equals '9:27 AM'
```

## See Also

[Timestamp Functions](#)

### TimestampToInt

Converts a TIMESTAMP variable into a time INTEGER which is represented as a number of seconds since 01/01/1970.

## Syntax

**TimestampToInt(TIMESTAMP *Timestamp* [, INT *UTC*])**

*Timestamp*:

The timestamp variable.

*UTC*:

Coordinated Universal Time (optional):

0 – Returns the time as a local date/time.

1 – Returns the time as a UTC date/time (default)

## Return Value

Time as a number of seconds since 01/01/1970 in UTC or local time depending on the last input parameter,-1 if invalid.

## Related Functions

[TimestampAdd](#), [TimestampCurrent](#), [TimestampDifference](#), [TimestampSub](#), [TimestampToStr](#), [TimestampCreate](#), [TimestampFormat](#), [TimestampGetPart](#), [TimeIntToTimestamp](#)

## Example

```
TIMESTAMP t1 = TimestampCreate(2009,07,11,09,27,34,123);
INT TimeInt = TimestampToInt(t1);
STRING sTimestamp = TimeToStr(t1, 0, 0);
// sTimestamp equals '9:27 AM'
```

## See Also

[Timestamp Functions](#)

### VariableTimestamp

Extracts the timestamp from a given variable.

**Note:** This function is designed to be used within Cicode; using it on graphical pages may result in displaying an

---

error message instead of an expected timestamp message when either its argument has not good quality or an execution error is set.

---

## Syntax

**VariableTimestamp(Variable, INT Type)**

*Variable*:

The variable from which the timestamp will be extracted.

*nType*:

The type of timestamp:

- 0 – The element's date/time (default)
- 1 – The element's quality date/time
- 2 – The element's value date/time

## Return Value

A TIMESTAMP of the given variable depending on the type. If Variable is NULL, returns INVALID\_TIMESTAMP.

Timestamps of uninitialized stack variables, uninitialized code variables and constants are equal to 0 - invalid timestamp, while their qualities are GOOD.

## Related Functions

[TimestampAdd](#), [TimestampCurrent](#), [TimestampDifference](#), [TimestampSub](#), [TimestampToStr](#), [TimestampCreate](#),  
[TimestampFormat](#), [TimestampGetPart](#), [TimeIntToTimestamp](#)

## Example

```
INT codeVariable = 1;
INT
FUNCTION
MyFunction(REAL arg1)
STRING str = "My string";
TIMESTAMP ts;
ts = VariableTimestamp(codeVariable, 0); //code variable
ts = VariableTimestamp(arg1, 0); //function argument
ts = VariableTimestamp(str, 0); //stack variable
ts = VariableTimestamp(Tag1, 0); //any tag/local variable
RETURN 1;
END
```

## Trend Functions

You can control a trend's operation by using the trend functions. Plant SCADA has standard trend pages, so you would not normally use these low-level functions unless you want to define your own trend displays. You can control the movement of the trend cursor, trend scaling, and the definition of trend attributes (such as the trend starting time and sampling period). You can also create, and subsequently delete trends.

Following are functions relating to Trends:

<a href="#">TrnAddHistory</a>	Restores an old history file to the trend system.
<a href="#">TrnBrowseClose</a>	Closes a trend browse session.
<a href="#">TrnBrowseFirst</a>	Gets the oldest trend entry.
<a href="#">TrnBrowseGetField</a>	Gets the field indicated by the cursor position in the browse session.
<a href="#">TrnBrowseNext</a>	Gets the next trend entry in the browse session.
<a href="#">TrnBrowseNumRecords</a>	Returns the number of records in the current browse session.
<a href="#">TrnBrowseOpen</a>	Opens a trend browse session.
<a href="#">TrnBrowsePrev</a>	Gets the previous trend entry in the browse session.
<a href="#">TrnClientInfo</a>	Gets information about the trend that is being displayed at the AN point.
<a href="#">TrnComparePlot</a>	Prints two trends (one overlaid on the other), each with up to four trend tags.
<a href="#">TrnDelete</a>	Deletes a trend created by the TrnNew() function.
<a href="#">TrnDelHistory</a>	Deletes an old history file from the trend system.
<a href="#">TrnEcho</a>	Enables and disables the echo on the trend display.
<a href="#">TrnEventGetTable</a>	Stores event trend data and the associated time stamp in an event table and time table, for a specified trend tag.
<a href="#">TrnEventGetTableMS</a>	Stores event trend data and time data (including milliseconds) for a specified trend tag.
<a href="#">TrnEventSetTable</a>	Sets trend data from a table, for a specified trend tag.
<a href="#">TrnEventSetTableMS</a>	Sets event trend data and time data (including milliseconds) for a specified trend tag.
<a href="#">TrnExportClip</a>	Exports trend data to the clipboard.

TrnExportCSV	Exports trend data to a file in CSV (comma separated values) format.
TrnExportDBF	Exports trend data to a file in dBASE III format.
TrnExportDDE	Exports trend data to applications via DDE.
TrnFlush	Flushes the trend to disk.
TrnGetBufEvent	Gets the event number of a trend at an offset for a pen.
TrnGetBufTime	Gets the trend time at an offset for a pen.
TrnGetBufValue	Gets the trend value at an offset for a pen.
TrnGetCluster	Gets the name of the cluster the trend graph is associated with.
TrnGetCursorEvent	Gets the event number of a trend at the trend cursor.
TrnGetCursorMSTime	Gets the time (in milliseconds from the previous midnight) at a trend cursor for a specified pen.
TrnGetCursorPos	Gets the position of the trend cursor.
TrnGetCursorTime	Gets the time/date at the trend cursor.
TrnGetCursorValue	Gets the current trend cursor value of a pen.
TrnGetCursorValueStr	Gets the current trend cursor value of a pen as a formatted string.
TrnGetDefScale	Gets the default engineering zero and full scales of a trend tag.
TrnGetDisplayMode	Gets the display mode of a trend.
TrnGetEvent	Gets the event number of a trend at a percentage along the trend.
TrnGetFormat	Gets the format of a pen.
TrnGetGatedValue	Returns the internally stored value for <GATED>.
TrnGetInvalidValue	Returns the internally stored value for <TRN_NO_VALUES>.
TrnGetMode	Gets the display mode of trends (historical or real-time).
TrnGetMSTime	Gets the time (in milliseconds from the previous

	midnight) of the trend (plotted by a specified pen) at a percentage along the trend, using the time and date of the latest sample displayed.
TrnGetPen	Gets the trend tag of a pen.
TrnGetPenComment	Gets the comment of a trend pen.
TrnGetPenFocus	Gets the number of the pen currently in focus.
TrnGetPenNo	Gets the pen number of a pen name.
TrnGetPeriod	Gets the display period of a trend.
TrnGetScale	Gets the scale of a pen.
TrnGetScaleStr	Gets the scale of a pen as a formatted string.
TrnGetSpan	Gets the span time of a trend.
TrnGetTable	Stores trend data in an array.
TrnGetTime	Gets the time/date of a pen.
TrnGetUnits	Gets the data units of a trend pen.
TrnInfo	Gets the configured values of a trend tag.
TrnIsValidValue	Determines whether a logged trend value is <VALID>, <GATED>, or invalid <TRN_NO_VALUES>.
TrnNew	Creates a new trend at run time.
TrnPlot	Prints a plot of one or more trend tags.
TrnPrint	Prints a trend that is displayed on the screen.
TrnSamplesConfigured	Gets the number of samples configured for the currently displayed trend.
TrnScroll	Scrolls a trend pen.
TrnSelect	Sets up a page for a trend.
TrnSetCursor	Moves the trend cursor a specified number of samples.
TrnSetCursorPos	Moves the trend cursor to the given x-axis position.
TrnSetDisplayMode	Specifies how trend samples will be displayed on the screen.
TrnSetEvent	Sets the start event of a trend pen.

<a href="#">TrnSetPen</a>	Sets a trend pen to a new trend tag.
<a href="#">TrnSetPenFocus</a>	Sets the pen focus.
<a href="#">TrnSetPeriod</a>	Sets the display period (time base) of a trend.
<a href="#">TrnSetScale</a>	Re-scales a pen.
<a href="#">TrnSetSpan</a>	Sets the span time of a trend.
<a href="#">TrnSetTable</a>	Sets trend data from an array.
<a href="#">TrnSetTime</a>	Sets the starting time/date of a pen.

The following trend functions are used on standard trend templates. Use these functions only if you create your own trend templates.

(These functions are written in Cicode and can be found in the include project.)

<a href="#">TrendDspCursorComment</a>	Displays the Trend Comment for the currently selected pen.
<a href="#">TrendDspCursorScale</a>	Displays a scale value for the current pen.
<a href="#">TrendDspCursorTag</a>	Displays the tag name of the current pen.
<a href="#">TrendDspCursorTime</a>	Displays the cursor time of the current pen.
<a href="#">TrendDspCursorValue</a>	Displays the cursor value of the current pen.
<a href="#">TrendGetAn</a>	Gets the AN number of the trend under the mouse position.
<a href="#">TrendPopUp</a>	Displays a pop-up trend with the specified trend pens.
<a href="#">TrendRun</a>	Initializes the cursor and rubber-band features on a trend page.
<a href="#">TrendSetDate</a>	Sets the starting date for the pens on a trend.
<a href="#">TrendSetScale</a>	Sets the scale of one or more pens on a trend.
<a href="#">TrendSetSpan</a>	Sets the span time of a trend.
<a href="#">TrendSetTime</a>	Sets the starting time for the pens on a trend.
<a href="#">TrendSetTimebase</a>	Sets a new sampling period for a trend.
<a href="#">TrendWin</a>	Displays a trend page (in a new window) with the specified trend pens.
<a href="#">TrendZoom</a>	Zooms a trend in either one or both axes.

### TrendDspCursorComment

Displays the Trend Comment for the currently selected pen on the displayed trend graph.

## Syntax

**TrendDspCursorComment(*nAN*)**

*nAN*:

The AN of the trend.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

### TrendDspCursorScale

Displays a scale value for the current pen in the current pen font.

## Syntax

**TrendDspCursorScale(*nAN, Percent*)**

*nAN*:

The AN of the trend.

*Percent*:

The percentage of full scale to display for the current pen, as an integer.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TrendDspCursorComment](#), [TrendDspCursorTag](#), [TrendDspCursorTime](#), [TrendDspCursorValue](#), [TrendGetAn](#),  
[TrendRun](#), [TrendSetDate](#), [TrendSetScale](#), [TrendSetSpan](#), [TrendSetTime](#), [TrendSetTimebase](#), [TrendZoom](#)

## Example

See built-in trend templates.

[Trend Functions](#)

## TrendDspCursorTag

Displays the trend tag name of the current pen in the pen font.

## Syntax

**TrendDspCursorTag(AN [, Mode] )**

*AN:*

The AN of the trend.

*Mode:*

An optional argument used to specify whether the trend tag name is displayed with a cluster prefix. Set:

0 display tag without cluster prefix (default)

1 display tag with cluster prefix.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TrendDspCursorComment](#), [TrendDspCursorScale](#), [TrendDspCursorTime](#), [TrendDspCursorValue](#), [TrendGetAn](#),  
[TrendRun](#), [TrendSetDate](#), [TrendSetScale](#), [TrendSetSpan](#), [TrendSetTime](#), [TrendSetTimebase](#), [TrendZoom](#)

## Example

See built-in trend templates.

## See Also

[Trend Functions](#)

### TrendDspCursorTime

Displays the cursor time of the current pen in the current pen font.

## Syntax

**TrendDspCursorTime(*nAN*, *Format*)**

*nAN*:

The AN number of the trend.

*Format*:

Format of the string:

0 - Short time format, hh:mm AM/PM.

1 - Long time format, hh:mm:ss AM/PM.

2 - Short date format, dd/mm/yy.

3 - Long date format, day month year.

4 - Time and date, weekday month day year hh:mm:ss AM/PM.

5 - Long time period, hh:mm:ss. Time needs to be in seconds.

6 - Millisecond time period, hh:mm:ss:xxx ("xxx" represents milliseconds). Time needs to be in milliseconds.

7 - Short time period, hh:mm. Time needs to be in seconds.

8 - Long time period, days:hh:mm:sec. Time needs to be in seconds.

9 - Extended date format, dd/mm/yyyy.

---

**Note:** If *Format* is set to 1, 2, or 3, the mode will be ignored when the sampling period of the trend changes to less than 1 second. Instead, the time is displayed as hh:min:ss.xxx, that is, displayed as mode 6.

---

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## TrendPopUp

Displays a pop-up trend with the specified trend pens. You need to create the trend page with the graphic builder and set the pen names to blank.

## Syntax

**TrendPopUp(*sPage*, *sTag1* [, *sTag2..sTag8*] )**

*sPage*:

The name of the trend page (drawn with the Graphics Builder).

*sTag1*:

The First trend tag to display on the page.

*sTag2..sTag8*:

The trend tags to display on the page.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[PageTrend](#), [TrendWin](#), [WinNewAt](#)

## Example

Buttons

Text	Popup Trend
Command	TrendPopUp("MyPop", "PV1", "PV2", "PV3")

Comment	Display a popup trend with three trend pens
---------	---

## See Also

[Trend Functions](#)

## TrendRun

Initializes the cursor and rubber-band features on a trend page. This function is included as a Cicode Object on all new trend pages. Only use this function when configuring a trend template that requires this functionality.

## Syntax

**TrendRun(*iPageType*)**

*iPageType*:

The type of the page:

0 - Normal trend page template

1 - Compare trend page template

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TrendDspCursorComment](#), [TrendDspCursorScale](#), [TrendDspCursorTag](#), [TrendDspCursorTime](#),  
[TrendDspCursorValue](#), [TrendGetAn](#), [TrendSetDate](#), [TrendSetScale](#), [TrendSetSpan](#), [TrendSetTime](#),  
[TrendSetTimebase](#), [TrendZoom](#)

## Example

See built-in trend templates.

## See Also

[Trend Functions](#)

## TrendSetDate

Sets the end date for all pens on a trend. Samples taken after this date will not be displayed. You can enter the date in the *Value* argument, or leave the *Value* blank - a form is then displayed in run time for the operator to enter an end date.

## Syntax

**TrendSetDate(*nAN*, *Value*)**

*nAN*:

The AN of the trend.

*Value*:

The new date, as a string. Samples taken after date will not be displayed. This argument is optional.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TrendDspCursorComment](#), [TrendDspCursorScale](#), [TrendDspCursorTag](#), [TrendDspCursorTime](#),  
[TrendDspCursorValue](#), [TrendGetAn](#), [TrendRun](#), [TrendSetScale](#), [TrendSetSpan](#), [TrendSetTime](#), [TrendSetTimebase](#),  
[TrendZoom](#)

## Example

See built-in trend templates.

## See Also

[Trend Functions](#)

## TrendSetScale

Sets the scale of the current pen or of all pens on a trend. You can enter a scale in the *Value* argument, or leave the *Value* blank. A form is then displayed in run time for the operator to enter a value for the scale.

## Syntax

**TrendSetScale(*nAN*, *Percent* [, *Value*] )**

*nAN*:

The AN of the trend.

*Percent*:

The scale to be set:

0 - Zero scale

100 - Full scale

*Value*:

An optional value for the scale, as a string.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TrendDspCursorComment](#), [TrendDspCursorScale](#), [TrendDspCursorTag](#), [TrendDspCursorTime](#),  
[TrendDspCursorValue](#), [TrendGetAn](#), [TrendRun](#), [TrendSetDate](#), [TrendSetSpan](#), [TrendSetTime](#), [TrendSetTimebase](#),  
[TrendZoom](#)

## Example

## See Also

[Trend Functions](#)

## TrendSetSpan

Sets the span time of the trend. The span time is the time period covered in the trend window. You can enter a span time in the *Value* argument, or leave the *Value* blank - a form is then displayed in run time for the operator to enter a value for the span time.

## Syntax

**TrendSetSpan(AN [, Value] )**

*nAN*:

The AN of the trend.

*Value*:

An optional value for the span time, as a string.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

## See Also

[Trend Functions](#)

### TrendSetTimebase

Sets a new sampling period for a trend. You can enter a sampling period in the *Value* argument, or leave the *Value* blank. A form is then displayed in run time for the operator to enter a value for the sampling period.

## Syntax

**TrendSetTimebase(AN [, Value] )**

*nAN:*

The AN of the trend.

*Value:*

An optional value for the sampling period, as a string.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TrendDspCursorComment](#), [TrendDspCursorScale](#), [TrendDspCursorTag](#), [TrendDspCursorTime](#),  
[TrendDspCursorValue](#), [TrendGetAn](#), [TrendRun](#), [TrendSetDate](#), [TrendSetScale](#), [TrendSetSpan](#), [TrendSetTime](#),  
[TrendZoom](#)

## Example

See built-in trend templates.

## See Also

[Trend Functions](#)

## TrendWin

Displays a trend page (in a new window) with the specified trend pens. You need to create the trend page with the graphic builder and set the pen names to blank. You then display that page by calling this function and pass the required trend tags. The function will create a new window with the specified window mode.

## Syntax

**TrendWin(sPage, X, Y, Mode, sTag1 [, sTag2..sTag8] )**

*sPage:*

The name of the trend page (drawn with the Graphics Builder).

*X:*

The x pixel coordinate of the top left corner of the window.

*Y:*

The y pixel coordinate of the top left corner of the window.

*Mode:*

The mode of the window:

- 0 - Normal page.
- 1 - Page child window. The window is closed when a new page is displayed, for example, when the [PageDisplay\(\)](#) or [PageGoto\(\)](#) function is called. The parent is the current active window.
- 2 - Window child window. The window is closed automatically when the parent window is freed with the [WinFree\(\)](#) function. The parent is the current active window.
- 4 - No re-size. The window is displayed with thin borders and no maximize/minimize icons. The window cannot be re-sized.
- 8 - No icons. The window is displayed with thin borders and no maximize/minimize or system menu icons. The window cannot be re-sized.
- 16 - No caption. The window is displayed with thin borders, no caption, and no maximize/minimize or system menu icons. The window cannot be re-sized.
- 32 - Echo enabled. When enabled, keyboard echo, prompts, and error messages are displayed on the parent window. This mode should only be used with child windows (for example, Mode 1 and 2).
- 64 - Always on top.
- 128 - Open a unique window. This mode helps prevent this window from being opened more than once.
- 256 - Display the entire window. This mode commands that no parts of the window will appear off the screen
- 512 - Open a unique Super Genie. This mode helps prevent a Super Genie from being opened more than once (at the same time). However, the same Super Genie with different associations can be opened.
- 1024 - Disables dynamic resizing of new window, overriding the setting of the [\[Page\]DynamicSizing](#) parameter.

You can select multiple modes by adding modes together (for example, set Mode to 9 to open a page child window without maximize, minimize, or system menu icons).

*sTag1:*

The first trend tag to display on the page.

*sTag2..sTag8:*

The trend tags to display on the page.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[PageTrend](#), [TrendPopUp](#), [WinNew](#)

## Example

Buttons

Text	Trend Window
Command	<code>TrendWin("MyTrend", 0, 0, 4, "PV1", "PV2", "PV3")</code>
Comment	Display a trend page in a new window with no maximize and minimize icons

## See Also

[Trend Functions](#)

### TrendZoom

"Zooms" a specified trend in either one or both axes. Set the zoom values (*TimeZoom* and/or *ScaleZoom*) to greater than one to "zoom in" or to less than one to "zoom out".

If you specify a destination AN, you can zoom one trend (at *SourceAn*) onto another (at *DestAn*), in the same way as on the standard zoom trend page.

## Syntax

**TrendZoom(*SourceAN*, *TimeZoom*, *ScaleZoom* [, *DestAn*] )**

*SourceAN*:

The AN on which the source trend is located.

*TimeZoom*:

The scale by which the Time axis will be changed (as a real number).

*ScaleZoom*:

The scale by which the Scale axis will be changed (as a real number).

*DestAn*:

The AN on which the destination or target trend is located. If you do not enter a DestAn, it is set to the same AN as SourceAn.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TrendDspCursorComment](#), [TrendDspCursorScale](#), [TrendDspCursorTag](#), [TrendDspCursorTime](#),  
[TrendDspCursorValue](#), [TrendGetAn](#), [TrendRun](#), [TrendSetDate](#), [TrendSetScale](#), [TrendSetSpan](#), [TrendSetTime](#),  
[TrendSetTimebase](#)

## Example

```
TrendZoom(30, 2.0, 2.0);
/* Zoom in by a factor of 2 on both the time and scale axes. */
TrendZoom(30, 0.5, 0.5);
/* Zoom out by a factor of 2 on both the time and scale axes. */
```

## See Also

[Trend Functions](#)

## TrnAddHistory

Adds an old (backed up) trend history file to the trend system so that its data can be used. When you back-up a trend file, change its extension so that it indicates the age of the file's trend data (for example, the month and year).

An archived trend file does not need to reside in the same directory as existing active trends. Plant SCADA retrieves the trend name from the header of the specified file and adds its data to the trend history. Please be aware that only a reference to the archived file, and not the file itself, is kept in the trend history. Therefore, care needs to be taken if using this function to access archived files residing on removable storage media. When you remove the media, the archived data is no longer available for display.

This function can only be used if the Trend Server is on the current machine. When the Trend Server is not in the calling process, this function will become blocking and cannot be called from a foreground task. In this case, the return value will be undefined and a Cicode hardware alarm will be raised.

## Syntax

**TrnAddHistory(FileName [, sClusterName] )**

*FileName:*

The file name and directory path of an old history file. The old file does not need to reside in the same directory as existing active trends to be restored.

*sClusterName:*

Specifies the name of the cluster in which the Trend Server resides. This is optional if you have one cluster or are resolving the trend server via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TrnDelHistory](#), [MsgRPC](#)

## Example

```
TrnAddHistory("C:\Plant SCADAx\DATA\TR1.MAY91");
! Adds the file TR1.MAY91 to the trend system.
```

## See Also

[Trend Functions](#)

## TrnBrowseClose

The TrnBrowseClose function terminates an active data browse session and cleans up all resources associated with the session.

This function is a non-blocking function. It does not block the calling Cicode task.

#### **TrnBrowseClose(*iSession*)**

*iSession*

The handle to a browse session previously returned by a [TrnBrowseOpen](#) call.

### **Return Value**

0 (zero) if the trend browse session exists, otherwise an error code is returned.

### **Related Functions**

[TrnBrowseFirst](#), [TrnBrowseGetField](#), [TrnBrowseNext](#), [TrnBrowseNumRecords](#), [TrnBrowsePrev](#)

### **See Also**

[Trend Functions](#)

#### **TrnBrowseFirst**

The TrnBrowseFirst function places the data browse cursor at the first record.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

### **Syntax**

#### **TrnBrowseFirst(*iSession*)**

*iSession*

The handle to a browse session previously returned by a [TrnBrowseOpen](#) call.

### **Return Value**

0 (zero) if the trend browse session exists, otherwise an error code is returned.

### **Related Functions**

[TrnBrowseClose](#), [TrnBrowseGetField](#), [TrnBrowseNext](#), [TrnBrowseNumRecords](#), [TrnBrowseOpen](#), [TrnBrowsePrev](#)

### **See Also**

[Trend Functions](#)

#### **TrnBrowseGetField**

The TrnBrowseGetField function retrieves the value of the specified field from the record the data browse cursor is currently referencing.

This function is a non-blocking function. It does not block the calling Cicode task.

## Syntax

```
STRING TrnBrowseGetField(INT Session, STRING FieldName)
```

*Session*

The handle to a browse session previously returned by a [TrnBrowseOpen](#) call.

*FieldName*

The name of the field that references the value to be returned. Supported fields are:

ACQERROR, AREA, EQUIPMENT, EXPRESSION, FILENAME, FILES, ITEM, LSL, PRIV, RANGE, SDEVIATION, SPCFLAG, STORMETHOD, SUBGRPSIZE, TIME, TRIGGER, USL, XDOUBLEBAR.

See [Browse Function Field Reference](#) for information about fields.

## Return Value

The value of the specified field as a string. An empty string may or may not be an indication that an error has been detected. This should be checked in this instance to determine if an error has actually occurred.

## Related Functions

[TrnBrowseClose](#), [TrnBrowseFirst](#), [TrnBrowseNext](#), [TrnBrowseNumRecords](#), [TrnBrowseOpen](#), [TrnBrowsePrev](#)

## Example

```
STRING fieldValue = "";
STRING fieldName = "TYPE";
INT errorCode = 0;
...
fieldValue = TrnBrowseGetField(iSession, sFieldName);
IF fieldValue <> "" THEN
    // Successful case
ELSE
    // Function did not succeed
END
...
```

## See Also

[Trend Functions](#)

## TrnBrowseNext

The TrnBrowseNext function moves the data browse cursor forward one record. If you call this function after you have reached the end of the records, error 412 is returned (Databrowse session EOF).

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**TrnBrowseNext(*iSession*)**

*iSession*

The handle to a browse session previously returned by a [TrnBrowseOpen](#) call.

## Return Value

0 (zero) if the trend browse session exists, otherwise an error code is returned.

## Related Functions

[TrnBrowseClose](#), [TrnBrowseFirst](#), [TrnBrowseGetField](#), [TrnBrowseNumRecords](#), [TrnBrowseOpen](#), [TrnBrowsePrev](#)

## See Also

[Trend Functions](#)

## TrnBrowseNumRecords

The TrnBrowseNumRecords function returns the number of records that match the filter criteria.

This function is a non-blocking function. It does not block the calling Cicode task.

## Syntax

**TrnBrowseNumRecords(*iSession*)**

*iSession*

The handle to a browse session previously returned by a [TrnBrowseOpen](#) call.

## Return Value

The number of records that have matched the filter criteria. A value of 0 denotes that no records have matched. A value of -1 denotes that the browse session is unable to provide a fixed number. This may be the case if the data being browsed changed during the browse session.

## Related Functions

[TrnBrowseClose](#), [TrnBrowseFirst](#), [TrnBrowseGetField](#), [TrnBrowseNext](#), [TrnBrowseOpen](#), [TrnBrowsePrev](#)

## Example

```
INT numRecords = 0;  
...  
numRecords = TrnBrowseNumRecords(iSession);
```

```
IF numRecords <> 0 THEN
    // Have records
ELSE
    // No records
END
...
```

## See Also

[Trend Functions](#)

## TrnBrowseOpen

The TrnBrowseOpen function initiates a new browse session and returns a handle to the new session that can be used in subsequent data browse function calls.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**INT TrnBrowseOpen( STRING *Filter*, STRING *Fields* [, STRING *Clusters*] )**

### *Filter*

A filter expression specifying the records to return during the browse. An empty string indicates that all records will be returned. Where a fieldname is not specified in the filter, it is assumed to be tagname. For example, the filter "AAA" is equivalent to "name=AAA".

The following regular expressions are supported: \*expr, expr\*, and \*expr\*. To specify an exclusion filtering condition, use the NOT keyword after the = operator.

### *Fields*

Specifies via a comma delimited string the columns to be returned during the browse. An empty string indicates that the server will return all available columns. Supported fields are:

ACQERROR, CLUSTER, COMMENT, DEADBAND, ENG\_UNITS, EQUIPMENT, EXPRESSION, FILENAME, FILES, FORMAT, HISTORIAN, ITEM, LSL, NAME, PRIV, SAMPLEPER, SDEVIATION, SPCFLAG, STORMETHOD, SUBGRPSIZE, TAGGENLINK, TIME, TRIGGER, TYPE, USL, XDOUBLEBAR.

See [Browse Function Field Reference](#) for information about fields.

### *Clusters*

An optional parameter that specifies via a comma delimited string the subset of the clusters to browse. An empty string indicates that the connected clusters will be browsed.

## Return Value

Returns an integer handle to the browse session. Returns -1 if unsuccessful.

The returned entries will be ordered alphabetically by name.

## Related Functions

[TrnBrowseClose](#), [TrnBrowseFirst](#), [TrnBrowseGetField](#), [TrnBrowseNext](#), [TrnBrowseNumRecords](#), [TrnBrowsePrev](#)

## Example 1

```
INT iSession;  
...  
iSession = TrnBrowseOpen("NAME=ABC*", "NAME,TYPE",  
"ClusterA,ClusterB");  
IF iSession <> -1 THEN  
    // Successful case  
ELSE  
    // Function did not succeed  
END  
...
```

## Example 2 - Filters

The following trend tags have been defined: Trend01, Trend02 and Trend03.

```
// Example Filter  
FUNCTION TrnBrowseTest()  
    STRING sFilter = "TAG=Trend01 OR Trend03";  
    STRING sField = "TAG";  
    STRING sTag = "";  
    INT iStatus = -1;  
    INT hTagBrowse = TrnBrowseOpen(sFilter,sField);  
    IF (hTagBrowse <> -1) THEN  
        iStatus = TrnBrowseFirst(hTagBrowse);  
        WHILE iStatus = 0 DO  
            sTag = TrnBrowseGetField(hTagBrowse,sField);  
            Message(sTag,sTag,64); // Trend01, Trend03  
            iStatus = TrnBrowseNext(hTagBrowse);  
    END  
    TrnBrowseClose(hTagBrowse);  
END  
END
```

### Results

Good: STRING sFilter = "TAG=Trend01 OR Trend03";  
Good: STRING sFilter = "TAG=Trend01|Trend03";  
Fail: STRING sFilter = "TAG=Trend01 OR TAG=Trend03";

### TrnBrowsePrev

The TrnBrowsePrev function moves the data browse cursor back one record. If you call this function after you have reached the beginning of the records, error 412 is returned (Databrowse session EOF).

This function is a non-blocking function. It does not block the calling Cicode task.

## Syntax

**TrnBrowsePrev(*iSession*)**

*iSession*

The handle to a browse session previously returned by a [TrnBrowseOpen](#) call.

## Return Value

0 (zero) if the trend browse session exists, otherwise an error code is returned.

## Related Functions

[TrnBrowseClose](#), [TrnBrowseFirst](#), [TrnBrowseGetField](#), [TrnBrowseNext](#), [TrnBrowseNumRecords](#), [TrnBrowseOpen](#)

## See Also

[Trend Functions](#)

## TrnClientInfo

Gets information about the trend that is being displayed at the AN point.

## Syntax

**TrnClientInfo(*nAN, Pen, Type, Data, Error*)**

*nAN*:

The AN point number at which the trend is displayed.

*Pen*:

The trend pen number:

0 - The pen currently in focus

1...8 - Pen1 . . . Pen8

*nType*:

The type of information you would like returned.

1 - The number of samples configured for the trend. If you select Type 1, the *Data* argument is ignored.

*Data*:

For future enhancements; is currently ignored.

*Error*:

Output Parameter: If the function is successful, the error is set to 0 (zero). If unsuccessful, an error value is set, and a hardware alarm is triggered. Must be a Long type variable.

## Return Value

The requested information (as a string) if successful, otherwise a hardware alarm is generated.

## Related Functions

[TrnInfo](#)

## Example

```
INT nError;
INT nSamples;
INT nTime;
!Gets the number of samples configured for the current pen of the
trend displayed at AN 30.
nSamples = TrnClientInfo(30, 0, 1, "", nError);
IF nError = 0 THEN
    nTime = nSamples * 50;
ELSE
    nTime = 0;
END
```

## See Also

[Trend Functions](#)

## TrnComparePlot

Prints two trends, one overlaid on the other. Each trend can have up to four tags configured on it. The significance of this type of plot is that the two trends show different times and display periods. It is possible to compare a trend tag or tags over different time slots. Each trend line is drawn with a different pen style and marker as appropriate. The trend plot includes a comment and a legend, and you can specify the vertical high and low scales.

For more advanced trend plotting, you can use the low-level plot functions.

## Syntax

**TrnComparePlot(*sPort*, *sTitle*, *sComment*, *AN*, *iMode*, *nSamples*, *iTime1*, *rPeriod1*, *iTime2*, *rPeriod2*,  
*Tag1.....Tag8*, *rLoScale1*, *rHiScale1*,.....*rLoScale8*, *rHiScale8*)**

***sPort*:**

The name of the printer port to which the plot will be printed. This name needs to be enclosed within quotation marks. For example LPT1:, to print to the local printer, or \\Pserver\canon1 using UNC to print to a network printer.

***sTitle*:**

The title of the trend plot.

***sComment*:**

The comment that is to display beneath the title of the trend plot. You do not have to enter a comment.

*nAN:*

Sets the display mode. A value of 0 causes the default display mode to be used. Otherwise, the display mode of the specified AN is set.

*iMode:*

The color mode of the printer.

0 - black and white (default)

1 - Color

*nSamples:*

The number of data points on the plot.

*iTime1:*

The end point in time (the most recent point) for the first trend.

*rPeriod1:*

The period (in seconds) of the first trend. This can differ from the actual trend period. If you do not enter a period, it defaults to the sample period of Tag1.

*iTime2:*

The end point in time (the most recent point) for the second trend.

*rPeriod2:*

The period (in seconds) of the second trend. This can differ from the actual trend period. If you do not enter a period, it defaults to the sample period of Tag5.

*Tag1 . . . Tag8:*

The trend tags for the plot. Tags 1 to 4 needs to be for the first trend, and tags 5 to 8 needs to be for the second.

*rLoScale1, HiScale1,...,LoScale8, HiScale8*

The minimum and maximum on the vertical scale for the trend line of each of the tags (Tag1 . . . Tag8)

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TrnPlot](#), [TrnPrint](#), [PlotOpen](#), [SPCPlot](#)

## Example

```
/* Prints two black and white trends (one overlaid on the other)
to LPT1, comparing the trend lines of one trend tag (Feed_Flow) at
different times. The first trend line has a starting time of
12 noon, on 11/12/96, and the second has a starting time of 9am, on
11/10/96. Both contain 200 sample points, and have a period of 2
seconds. Both trend lines will be on a vertical scale of 10-100.
*/
INT Time;
```

```
INT RefTime;
Time = StrToDate("11/12/96") + StrToTime("12:00:00");
RefTime = StrToDate("11/10/96") + StrToTime("09:00:00");
TrnComparePlot("LPT1:","Citect Flow Comparison Plot","Comparison
with Reference",0,
0,200,Time,2,RefTime,2,"Feed_Flow","","","","Feed_Flow","","","","",
10,100,0,0,0,0,0,0,10,100);
```

[Trend Functions](#)

### TrnDelete

Deletes a trend that is displayed on a current page. This trend may have been created by the [TrnNew\(\)](#) function or by a trend object.

## Syntax

**TrnDelete(*nAN*)**

*nAN*:

The AN where the trend is located.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TrnNew](#)

## Example

```
TrnDelete(20);
! Deletes the trend at AN20.
```

## See Also

[Trend Functions](#)

### TrnDelHistory

Removes a trend history file that has been added to the trend system by the [TrnAddHistory\(\)](#) function. This function does not delete the file completely, it only disconnects it from the historical trend system.

This function can only be used if the Trend Server is on the current machine. When the Trend Server is not in the calling process, this function will become blocking and cannot be called from a foreground task. In this case, the

return value will be undefined and a Cicode hardware alarm will be raised.

## Syntax

**TrnDelHistory(FileName [, sClusterName] )**

*FileName*:

The trend history file to disconnect from the historical trend system.

*sClusterName*:

Specifies the name of the cluster in which the Trend Server resides. This is optional if you have one cluster or are resolving the trend server via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TrnAddHistory](#), [MsgRPC](#)

## Example

```
TrnDelHistory("C:\Plant SCADA\DATA\TR1_91.MAY");
! Disconnects the file from the trend system.
```

## See Also

[Trend Functions](#)

## TrnEcho

Enables and disables the echo of the trend display. Use this function when you need to make many changes to a trend display, so that the display updates only once. You should first disable the trend echo, do all the trend changes, and then enable the echo to show the changes.

## Syntax

**TrnEcho(*nAN*, *nMode*)**

*nAN*:

The animation number of the trend.

*nMode*:

The mode of the echo:

0 - Disable echo of the trend display.

1 - Enable echo of the trend display, to show changes.

## Return Value

The current echo mode, otherwise 0 (zero) is returned, and an error code is set. You can call the `IsError()` function to get the actual error code.

## Related Functions

[TrnSetScale](#), [TrnSetPeriod](#)

## Example

```
! Disable echo of trend display at AN40
TrnEcho(40,0);
! Change the scales on pens 1 and 2
TrnSetScale(40,1,0,-1000);
TrnSetScale(40,1,100,-1000);
TrnSetScale(40,2,0,-1000);
TrnSetScale(40,2,100,-1000);
! Enable echo to show changes to the display
TrnEcho(40,1);
```

## See Also

[Trend Functions](#)

## TrnEventGetTable

Stores event trend data in an event table and the associated time stamp in a time table, for a specified trend tag. Data is stored at the specified *Period*, working backwards from the starting point specified by *EventNo*. If *Period* differs from the trend period configured in the Trend Tags database, the values to be stored are calculated from the trend data. Values are either averaged or interpolated.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**TrnEventGetTable**(*Tag*, *EventNo*, *Period*, *Length*, *Table*, *TimeTable*, *Mode* [, *sClusterName*] )

*Tag*:

The trend tag enclosed in quotation marks "" (can be prefixed by the name of the cluster that is ClusterName.Tag).

*EventNo*:

The starting event number for entries in the trend table.

*Period*:

The time difference between tabulated trend values (in seconds). For example, if you set this period to 30 seconds, Plant SCADA will get the last trend value (sampled at the end of the trend section), then get the trend value that was sampled 30 seconds before that, and so on until it reaches the start time of the trend section.

If this period is different to the trend's sampling period, the trend values will be averaged or interpolated. Set to

0 (zero) to default to the actual trend period.

*Length:*

The number of trend values to store in the trend table, from 1 to the maximum number of items in the table.

*Table:*

The Cicode array in which the trend data is stored. You can enter the name of an array here (see the example). Must be a Real type variable.

*TimeTable:*

The table of integer values in which the time stamp is stored. Must be a Long type variable.

*Mode:*

The Display Mode parameters allow you to enter a single integer to specify the display options for a trend (for a maximum of eight trends).

To calculate the integer that you should enter for a particular trend, select the options you want from the list below, adding their associated numbers together. The resulting integer is the DisplayMode parameter for that trend.

**Invalid/Gated trend options:**

0 - Convert invalid/gated trend samples to zero.

1 - Leave invalid/gated trend samples as they are.

**Ordering trend sample options:**

0 - Order returned trend samples from oldest to newest.

2 - Order returned trend samples from newest to oldest.

**Condense method options:**

0 - Set the condense method to use the mean of the samples.

4 - Set the condense method to use the minimum of the samples.

8 - Set the condense method to use the maximum of the samples.

**Stretch method options:**

0 - Set the stretch method to step.

128 - Set the stretch method to use a ratio.

256 - Set the stretch method to use raw samples.

**Gap Fill Constant option:**

*n* - the number of missed samples that the user wants to gap fill) x 4096.

The options listed in each group are mutually exclusive. The default value for each Display Mode is 258 (0 + 2 + 256).

*sClusterName:*

The name of the cluster in which the trend tag resides. This is optional if you have one cluster or are resolving the trend via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

The actual number of samples read. The return value is 0 if an error is detected. You can call the IsError() function to get the actual error code. If EventNo is 0 (zero) then the EventNo will be set to the current event number.

---

**Note:** A maximum of 32,000 samples can be retrieved in a single call to TrnEventGetTable.

---

### TrnEventGetTableMS

Stores event trend data and time data (including milliseconds) for a specified trend tag. The event trend data is stored in an event table, and the time stamp in time tables. Data is stored at the specified *Period*, working backwards from the starting point specified by *EventNo*. If *Period* differs from the trend period configured in the Trend Tags database, the values to be stored are calculated from the trend data. Values are either averaged or interpolated.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**TrnEventGetTableMS(*Tag*, *EventNo*, *Period*, *Length*, *Table*, *TimeTable*, *Mode*, *MSTimeTable* [, *sClusterName* ] )**

*Tag*:

The trend tag enclosed in quotation marks "" (can be prefixed by the name of the cluster that is ClusterName.Tag).

*EventNo*:

The starting event number for entries in the trend table.

*Period*:

The time difference between tabulated trend values (in seconds). For example, if you set this period to 30 seconds, Plant SCADA will get the last trend value (sampled at the end of the trend section), then get the trend value that was sampled 30 seconds before that, and so on until it reaches the start time of the trend section.

If this period is different to the trend's sampling period, the trend values will be averaged or interpolated. Set to 0 (zero) to default to the actual trend period.

*Length*:

The number of trend values to store in the trend table, from 1 to the maximum number of items in the table.

*Table*:

The Cicode array in which the trend data is stored. You can enter the name of an array here (see the example). Must be a Real type variable.

*TimeTable*:

The table of integer values in which the time stamp is stored. Must be a Long type variable.

*Mode*:

The Display Mode parameters allow you to enter a single integer to specify the display options for a trend (for a maximum of eight trends).

To calculate the integer that you should enter for a particular trend, select the options you wish to use from those listed below, adding their associated numbers together. The resulting integer is the DisplayMode parameter for that trend.

**Invalid/Gated trend options:**

- 0 - Convert invalid/gated trend samples to zero.
- 1 - Leave invalid/gated trend samples as they are.

**Ordering trend sample options:**

- 0 - Order returned trend samples from oldest to newest.
- 2 - Order returned trend samples from newest to oldest.

**Condense method options:**

- 0 - Set the condense method to use the mean of the samples.
- 4 - Set the condense method to use the minimum of the samples.
- 8 - Set the condense method to use the maximum of the samples.

**Stretch method options:**

- 0 - Set the stretch method to step.
- 128 - Set the stretch method to use a ratio.
- 256 - Set the stretch method to use raw samples.

**Gap Fill Constant option:**

*n* - the number of missed samples that the user wants to gap fill) x 4096.

Options listed in each group are mutually exclusive. The default value for each Display Mode is 258 (0 + 2 + 256).

**MSTimeTable:**

The table of integer values in which the millisecond component of the time stamp is stored. Must be a Long type variable.

**sClusterName:**

The name of the cluster in which the trend tag resides. This is optional if you have one cluster or are resolving the trend via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

The actual number of samples read. The return value is 0 if an error is detected. You can call the IsError() function to get the actual error code.

## Related Functions

[TrnEventSetTableMS](#), [TrnGetEvent](#), [TrnEventGetTable](#)

## See Also

[Trend Functions](#)

## TrnEventSetTable

Sets event trend data and time data for a specified trend tag. The event trend data is set in an event table, and the time stamp in time tables. Data is set at the period specified, working backwards from the starting point specified by *EventNo*.

If the period of setting data differs from the trend period (defined in the Trend Tags database), the values to be set are calculated from the trend data, either averaged or interpolated. The user needs to have the correct privilege (as specified in the Trend Tag settings), otherwise the data is not written.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**TrnEventSetTable**(*Tag*, *EventNo*, *Period*, *Length*, *Table*, *TimeTable* [, *sClusterName*] )

*Tag*:

The trend tag enclosed in quotation marks "" (can be prefixed by the name of the cluster that is ClusterName.Tag).

*EventNo*:

Event Number:

When adding new events to a trend, set *EventNo* to 0.

When overwriting existing values, set *EventNo* to the last event number to be overwritten. For example, if overwriting events 100 to 110, set *EventNo* to 110.

*Period*:

This will be the interval (in seconds) between trend values when they are set (that is, it will be the perceived sampling period for the trend). This period can differ from the actual trend period. Set to 0 (zero) to default to the actual trend period.

*Length*:

The number of trend values in the trend table.

*Table*:

The table of floating-point values in which the trend data is stored. You can enter the name of an array here (see the example). Must be a Real type variable.

*TimeTable*:

The table of integer values in which the time stamp is stored. If you would like events to stay in correct time-stamp order, sort the values in this table in ascending order. When *EventNo* is non-zero the values in this table may be zero. This will result in the values of the requested events being overwritten but the time-stamps staying the same. Must be a Long type variable.

*sClusterName*:

The name of the cluster in which the trend tag resides. This is optional if you have one cluster or are resolving the trend via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

The actual number of samples written. The return value is 0 if an error is detected. You can call the [IsError\(\)](#) function to get the actual error code.

## Related Functions

[TrnEventGetTable](#)

## Example

```
REAL TrendTable1[100];
INT TimeTable[100];
/* Defines an array of a maximum of 100 entries. Assume that
TrendTable1 has been storing data from a source. */
TrnEventSetTable("OP1",nEventNo, 1,10,TrendTable1[0],
TimeTable[0], "ClusterXYZ");
/* A set of 10 trend data values are set for the OP1 trend tag. */
```

## TrnEventSetTableMS

Sets event trend data and time data (including milliseconds) for a specified trend tag. The event trend data is set in an event table, and the time stamp in time tables. Data is set at the period specified, working backwards from the starting point specified by *EventNo*.

If the period of setting data differs from the trend period (defined in the Trend Tags database), the values to be set are calculated from the trend data, either averaged or interpolated. The user needs to have the correct privilege (as specified in the Trend Tags settings), otherwise the data is not written.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**TrnEventSetTableMS(*Tag*, *EventNo*, *Period*, *Length*, *Table*, *TimeTable*, *MSTimeTable* [, *sClusterName*] )**

*Tag*:

The trend tag enclosed in quotation marks "" (can be prefixed by the name of the cluster that is ClusterName.Tag).

*EventNo*:

Event Number:

When adding new events to a trend, set EventNo to 0.

When overwriting existing values, set EventNo to the last event number to be overwritten. For example, if overwriting events 100 to 110, set EventNo to 110.

*Period*:

This will be the interval (in seconds) between trend values when they are set (that is it will be the perceived sampling period for the trend). This period can differ from the actual trend period. Set to 0 (zero) to default to the actual trend period.

*Length*:

Number of trend values in the trend table.

**Table:**

Table of floating-point values in which the trend data is stored. You can enter the name of an array here (see example). Must be a Real type variable.

**TimeTable:**

Table of integer values in which the time stamp is stored. If you would like events to stay in correct time-stamp order, sort the values in this table in ascending order. When *EventNo* is non-zero the values in this table may be zero. This will result in the values of the requested events being overwritten but the timestamps staying the same. Must be a Long type variable.

**MSTimeTable:**

The table of integer values in which the millisecond component of the time stamp is stored. Must be a Long type variable.

**sClusterName:**

The name of the cluster in which the trend tag resides. This is optional if you have one cluster or are resolving the trend via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

The actual number of samples written. The return value is 0 if an error is detected. You can call the IsError() function to get the actual error code.

## Related Functions

    nSamplesWritten = TrnEventSetTableMS
(sTagName, 0, 0, 1, garSingleValue[0], ganSingleTime[0], ganSingleMS[0], "ClusterXYZ");
    RETURN nSamplesWritten;
END
```

## See Also

[Trend Functions](#)

## TrnExportClip

Exports trend data to the Windows Clipboard. The data is set at the specified *Time* and *Period*, and listed from earliest to latest. Any gated or invalid data is written as 0.0.

Data is stored as a grid, with each row time-stamped. The first column/field is the date, followed by the time, followed by the tags 1 to 8.

You can use the *ClipMode* argument to make the output more useful. For example, to paste the data into Excel, use *ClipMode* 2 for CSV format. If you use *ClipMode* 1 or 3, the default paste menu option causes data to be pasted into the user's spreadsheet as text. If you use *ClipMode* 3, use the Paste Special option to paste the required format. Please be aware that not all packages support multiple clipboard formats in this way.

## Syntax

**TrnExportClip**(*Time*, *Period*, *Length*, *Mode*, *ClipMode*, *sTag1* ... *sTag8*, *iDisplayMode1* ... *iDisplayMode 8*)

*Time*:

The starting time for the data being exported.

*Period*:

The period (in seconds) of the entries being exported. (This period can differ from the actual trend period.)

*Length*:

The length of the data table, that is The number of rows of samples to be exported. for example if you put the length as 12, and you declare two tags to be exported, you get a grid with 12 rows of samples. Each row has values for each of the two tags making a total of 24 samples.

*Mode*:

The format mode to be used:

### Periodic trends

- 1 - Export the Date and Time, followed by the tags.
- 2 - Export the Time only, followed by the tags.
- 4 - Ignore any invalid or gated values. (Only supported for periodic trends.)
- 8 - The time returned will have millisecond accuracy.

### Event trends

- 1 - Export the Time, Date and Event Number, followed by the tags.
- 2 - Export the Time and Event Number, followed by the tags.
- 8 - The time returned will have millisecond accuracy.

*ClipMode*:

The format for the data being exported.

- 1 - Text
- 2 - CSV

You can add these modes for a combination of formats.

*sTag1* ... *sTag8*:

The trend tag names for the data being exported.

*iDisplayMode1* ... *iDisplayMode8*:

The Display Mode parameters allow you to enter a single integer to specify the display options for a trend (for a maximum of eight trends).

To calculate the integer that you should enter for a particular trend, select the options you wish to use from those listed below, adding their associated numbers together. The resulting integer is the `DisplayMode` parameter for that trend.

By default, this argument is set to 3 (see the details for options 1 and 2 below).

**Invalid/Gated trend options:**

0 - Convert invalid/gated trend samples to zero.

1 - Leave invalid/gated trend samples as they are.

Invalid and gated samples that are not converted to zero will appear in the destination file as the string "na" (for invalid) or "gated".

**Ordering trend sample options:**

0 - Order returned trend samples from newest to oldest.

2 - Order returned trend samples from oldest to newest.

**Condense method options:**

0 - Set the condense method to use the mean of the samples.

4 - Set the condense method to use the minimum of the samples.

8 - Set the condense method to use the maximum of the samples.

12 - Set the condense method to use the newest of the samples.

**Stretch method options:**

0 - Set the stretch method to step.

128 - Set the stretch method to use a ratio.

256 - Set the stretch method to use raw samples.

**Gap Fill Constant option:**

*n* - the number of missed samples that the user wants to gap fill) x 4096.

**Display as Periodic options:**

0 - Display according to trend type.

1048576 - Display as periodic regardless of trend type.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

---

**Note:** If using this function to export trends by using event numbers, you need to specify a valid event number in the `Time` argument, rather than a time.

## Related Functions

### TrnExportCSV

Exports trend data to a file in CSV (Comma Separated Variable) format. The data is set at the specified *Time* and *Period*, and listed from earliest to latest. Any gated or invalid data is written as 0.0.

Data is stored as a grid, with each row time-stamped. The first column/field is the date, followed by the time, followed by the tags 1 to 8.

You can view the CSV file with a text editor, and import the file directly into other packages such as Excel for data analysis and presentation.

If you are using this function to export trends by using event numbers, you need to specify a valid event number in the Time argument, rather than a time.

## Syntax

**TrnExportCSV(Filename, Time, Period, Length, Mode, sTag1 ... sTag8, iDisplayMode1 ... iDisplayMode 8)**

*Filename:*

The name of the destination path and file.

*Time:*

The starting time for the data being exported.

*Period:*

The period (in seconds) of the entries being exported. (This period can differ from the actual trend period.)

*Length:*

The length of the data table, that is, The number of rows of samples to be exported. for example if you put the length as 12, and you declare two tags to be exported, you get a grid with 12 rows of samples. Each row has values for each of the two tags making a total of 24 samples.

*Mode:*

The format mode to be used:

#### Periodic trends

1 - Export the Date and Time, followed by the tags.

2 - Export the Time only, followed by the tags.

4 - Ignore any invalid or gated values. (This mode is only supported for periodic trends.)

8 - The time returned will have millisecond accuracy.

#### Event trends

1 - Export the Time, Date and Event Number, followed by the tags.

2 - Export the Time and Event Number, followed by the tags.

8 - The time returned will have millisecond accuracy.

*sTag1 ... sTag8:*

The trend tag names for the data being exported.

*iDisplayMode1 ... iDisplayMode8:*

The Display Mode parameters allow you to enter a single integer to specify the display options for a trend (for a maximum of eight trends).

To calculate the integer that you should enter for a particular trend, select the options you wish to use from those listed below, adding their associated numbers together. The resulting integer is the DisplayMode parameter for that trend. By default, this argument is set to 3 (see the details for options 1 and 2 below).

#### **Invalid/Gated trend options:**

0 - Convert invalid/gated trend samples to zero.

1 - Leave invalid/gated trend samples as they are.

Invalid and gated samples that are not converted to zero will appear in the destination file as the string "na" (for invalid) or "gated".

#### **Ordering trend sample options:**

0 - Order returned trend samples from newest to oldest.

2 - Order returned trend samples from oldest to newest.

#### **Condense method options:**

0 - Set the condense method to use the mean of the samples.

4 - Set the condense method to use the minimum of the samples.

8 - Set the condense method to use the maximum of the samples.

12 - Set the condense method to use the newest of the samples.

#### **Stretch method options:**

0 - Set the stretch method to step.

128 - Set the stretch method to use a ratio.

256 - Set the stretch method to use raw samples.

#### **Gap Fill Constant option:**

n - the number of missed samples that the user wants to gap fill) x 4096.

Options listed in each group are mutually exclusive.

## **Return Value**

0 (zero) if successful, otherwise an error code is returned.

## **Related Functions**

[TrnExportDBF](#), [TrnPrint](#)

## Example

```
TrnExportCSV("c:\TrnData.CSV", TimeCurrent(), 2, 60 * 60/2, 2,  
"Feed", "Weight");  
/* Export the last hour of data from the trend tags Feed and  
Weight.  
The 60 * 60/2 is a decomposed way of writing 1800, which is the  
number of 2 second samples in 1 hour. */
```

[Trend Functions](#)

### TrnExportDBF

Exports trend data to a file in dBASE III format. The data is set at the specified *Time* and *Period*, and listed from earliest to latest. Any gated or invalid data is written as 0.0.

Data is stored as a grid, with each row time-stamped. The first column/field is the date, followed by the time, followed by the tags 1 to 8.

You can import the DBF file directly into other packages such as Excel, for data analysis and presentation.

## Syntax

**TrnExportDBF(*Filename*, *Time*, *Period*, *Length*, *Mode*, *sTag1* ... *sTag8*, *iDisplayMode1* ... *iDisplayMode 8*)**

*Filename*:

The name of the destination path and file.

*Time*:

The starting time for the data being exported.

*Period*:

The period (in seconds) of the entries being exported. (This period can differ from the actual trend period.)

*Length*:

The length of the data table, that is The number of rows of samples to be exported. for example if you put the length as 12, and you declare two tags to be exported, you get a grid with 12 rows of samples. Each row has values for each of the two tags making a total of 24 samples.

*Mode*:

The format mode to be used:

#### Periodic trends

1 - Export the Date and Time, followed by the tags.

2 - Export the Time only, followed by the tags.

4 - Ignore any invalid or gated values. (This mode is only supported for periodic trends.)

8 - The time returned will have millisecond accuracy.

#### Event trends

1 - Export the Time, Date and Event Number, followed by the tags.

2 - Export the Time and Event Number, followed by the tags.

8 - The time returned will have millisecond accuracy.

*sTag1 ... sTag8:*

The trend tag names for the data being exported. Tag names longer than 10 characters will be truncated, as the standard DBF field format is 10 characters.

*iDisplayMode1 ... iDisplayMode8:*

The Display Mode parameters allow you to enter a single integer to specify the display options for a trend (for a maximum of eight trends).

To calculate the integer that you should enter for a particular trend, select the options you wish to use from those listed below, adding their associated numbers together. The resulting integer is the DisplayMode parameter for that trend. By default, this argument is set to 3 (see the details for options 1 and 2 below).

**Invalid/Gated trend options:**

0 - Convert invalid/gated trend samples to zero.

1 - Leave invalid/gated trend samples as they are.

Invalid and gated samples that are not converted to zero will appear in the destination file as the string "na" (for invalid) or "gated".

**Ordering trend sample options:**

0 - Order returned trend samples from newest to oldest.

2 - Order returned trend samples from oldest to newest.

**Condense method options:**

0 - Set the condense method to use the mean of the samples.

4 - Set the condense method to use the minimum of the samples.

8 - Set the condense method to use the maximum of the samples.

12 - Set the condense method to use the newest of the samples.

**Stretch method options:**

0 - Set the stretch method to step.

128 - Set the stretch method to use a ratio.

256 - Set the stretch method to use raw samples.

**Gap Fill Constant option:**

n - the number of missed samples that the user wants to gap fill) x 4096.

Options listed in each group are mutually exclusive.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TrnExportCSV](#), [TrnPrint](#)

## Example

```
TrnExportDBF("c:\TrnData.DBF", TimeCurrent(), 2, 60 * 60/2, 2,  
"Feed", "Weight");  
/* Export the last hour of data from the trend tags Feed and  
Weight. Be aware that the 60 * 60/2 is a decomposed way of writing  
1800, which is the number of 2 second samples in 1 hour. */
```

## See Also

[Trend Functions](#)

### TrnExportDDE

Exports trend data via DDE. The data is set at the specified Time and Period, and listed from earliest to latest. Any gated or invalid data is written as 0.0. Data is stored as a grid, with each row time-stamped. The first column/field is the date, followed by the time, followed by the tags 1 to 8.

You can use the DDEMMode argument to make the output more useful. For example; to paste the data into Excel, use DDEMMode 2 for CSV format. If you use DDEMMode 1, data will be put into the user's spreadsheet as text.

**Note:** If you are using this function to export trends by using event numbers, you need to specify a valid event number in the Time argument, rather than a time.

## Syntax

**TrnExportDDE**(*sApplication*, *sDocument*, *sTopic*, *Time*, *Period*, *Length*, *Mode*, *DDEMMode*, *sTag1* ... *sTag8*,  
*iDisplayMode1* ... *iDisplayMode8*)

*sApplication*:

The application name to export the data.

*sDocument*:

The document in the application to export the data.

*sTopic*:

The topic in the application to export the data. Be aware you may have to use a special topic format to make the data export correctly. See your application documentation for details; For example with Excel you need to specify the matrix of rows and columns as "R1C1:R8C50" depending on the size of the data.

*Filename*:

The name of the destination path and file.

*Time*:

The starting time for the data being exported.

*Period*:

The period (in seconds) of the entries being exported. (This period can differ from the actual trend period.)

*Length*:

The length of the data table, that is The number of rows of samples to be exported. for example if you put the length as 12, and you declare two tags to be exported, you get a grid with 12 rows of samples. Each row has values for each of the two tags making a total of 24 samples.

**Mode:**

The format mode to be used:

**Periodic trends**

- 1 - Export the Date and Time, followed by the tags.
- 2 - Export the Time only, followed by the tags.
- 4 - Ignore any invalid or gated values. (This mode is only supported for periodic trends.)
- 8 - The time returned will have millisecond accuracy.

**Event trends**

- 1 - Export the Time, Date and Event Number, followed by the tags.
- 2 - Export the Time and Event Number, followed by the tags.
- 8 - The time returned will have millisecond accuracy.

**DDEMode:**

The format for the data being exported. CSV format allows the application to separate the data into each individual element, however not every application will support this mode. See your applications documentation for details.

- 1 - Text (default)
- 2 - CSV

**sTag1 ... sTag8:**

The trend tag names for the data being exported. Tag names longer than 10 characters will be truncated, as the standard DBF field format is 10 characters.

**iDisplayMode1 ... iDisplayMode8:**

The Display Mode parameters allow you to enter a single integer to specify the display options for a trend (for a maximum of eight trends).

To calculate the integer that you should enter for a particular trend, select the options you wish to use from those listed below, adding their associated numbers together. The resulting integer is the DisplayMode parameter for that trend.

By default, this argument is set to 3 (see the details for options 1 and 2 below).

**Invalid/Gated trend options:**

- 0 - Convert invalid/gated trend samples to zero.
- 1 - Leave invalid/gated trend samples as they are.

Invalid and gated samples that are not converted to zero will appear in the destination file as the string "na" (for invalid) or "gated".

**Ordering trend sample options:**

- 0 - Order returned trend samples from newest to oldest.
- 2 - Order returned trend samples from oldest to newest.

**Condense method options:**

- 0 - Set the condense method to use the mean of the samples.
- 4 - Set the condense method to use the minimum of the samples.
- 8 - Set the condense method to use the maximum of the samples.
- 12 - Set the condense method to use the newest of the samples.

**Stretch method options:**

- 0 - Set the stretch method to step.
- 128 - Set the stretch method to use a ratio.
- 256 - Set the stretch method to use raw samples.

**Gap Fill Constant option:**

- $n$  - the number of missed samples that the user wants to gap fill)  $\times 4096$ .
- Options listed in each group are mutually exclusive.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TrnExportCSV](#), [TrnExportClip](#), [TrnExportDBF](#)

## Example

```
TrnExportDDE("Excel", "data.xls", "R1C1:R61C4", TimeCurrent(), 1,  
60, 2, 2, "Feed", "Weight");  
/* Export the last 60 seconds of data from the trend tags Feed and  
Weight into Excel at R1C1:R61C4 in CSV formats */
```

[Trend Functions](#)

## TrnFlush

Writes acquired trend data to disk without waiting for the trend buffer to be filled. Plant SCADA normally buffers the trend data in memory and only writes to disk when required, to give optimum performance. Because this function reduces the performance of the Trends Server, use it only when necessary.

## Syntax

**TrnFlush(*sName* [, *sClusterName*] )**

*sName*:

The name of the logging tag (can be prefixed by the name of the cluster that is ClusterName.Tag). Set to "\*" to flush all trend data.

*sClusterName*:

The name of the cluster in which the trend tag resides. This is optional if you have one cluster or are resolving the trend via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TrnSetTable](#)

## Example

```
TrnFlush("Trend1", "ClusterXYZ");
! Forces the Trend1 data to be written to disk.
```

## See Also

[Trend Functions](#)

## TrnGetBufEvent

Gets the event number of a trend at an offset for a specified pen. This function only operates on an event-based trend.

## Syntax

**TrnGetBufEvent(*nAN*, *Pen*, *Offset*)**

*nAN*:

The AN where the trend is located.

*Pen*:

The trend pen number:

0 - The pen currently in focus

1...8 - Pen1...Pen8

*Offset*:

The trend buffer offset, in samples. The number of samples can range from 0 to the maximum number of samples that can display on the trend - 1.

## Return Value

The event number. If *Offset* is not within boundaries, 0 (zero) is returned. If *AN* or *Pen* is invalid, 0 (zero) is returned and an error code is set.

## Related Functions

[TrnGetEvent](#), [TrnSetEvent](#), [TrnGetCursorEvent](#)

## Example

```
! For the trend at AN20
DspText(31,0,TrnGetBufEvent(20,0,10));
/* Displays the trend event at offset 10 for the pen currently in
focus. The event will display at AN31. */
```

## See Also

[Trend Functions](#)

### TrnGetBufTime

Gets the time and date of a trend at an offset for a specified pen. The *Offset* should be a value between 0 (zero) and the number of samples displayed on the trend.

## Syntax

**TrnGetBufTime(*nAN*, *Pen*, *Offset*)**

*nAN*:

The AN where the trend is located.

*Pen*:

The trend pen number:

0 - The pen currently in focus

1...8 - Pen1...Pen8

*Offset*:

The trend buffer offset, in samples. The number of samples can range from 0 to the maximum number of samples that can display on the trend - 1.

## Return Value

A time/date variable. If *Offset* is not within boundaries, 0 (zero) is returned. If *nAN* or *Pen* is invalid, 0(zero) is returned and an error code is set.

## Related Functions

[TrnGetCursorTime](#)

## Example

```
! For the trend at AN20
INT time;
time = TrnGetBufTime(20,0,10);
IF time <> 0 THEN
    DspText(31,0,TimeToStr(time,2));
```

```
END
/* Displays the trend date at offset 10 for the pen currently in
focus. The time will display at AN31. */
```

## See Also

[Trend Functions](#)

### TrnGetBufValue

Gets the value of a trend at an offset for a specified pen. The offset should be a value between -1 and the number of samples displayed on the trend.

## Syntax

**TrnGetBufValue(*nAN*, *Pen*, *Offset*)**

*nAN*:

The AN where the trend is located.

*Pen*:

The trend pen number:

0 - The pen currently in focus

1...8 - Pen1...Pen8

*Offset*:

The trend buffer offset, in samples. The number of samples can range from -1 to the maximum number of samples that can display on the trend minus 1.

-1 means get the last valid value in the display (provided it is less than 1.5 sample periods old).

If there is no invalid or gated sample within the last 1.5 sample periods, it is assumed that a sample has been missed and an invalid trend value is returned. See the [TrnIsHeaderValue](#) function.

## Return Value

The trend value. If the actual value is gated or invalid, the standard invalid or gated values are returned (no error is set). You can check this return value using [TrnIsHeaderValue\(\)](#).

## Related Functions

[TrnGetCursorValue](#), [TrnIsHeaderValue](#)

## Example

```
! For the trend at AN20
DspText(31,0,TrnGetBufValue(20,0,10):###.#);
/* Displays the trend value at offset 10 for the pen currently in
focus. */
```

## See Also

[Trend Functions](#)

### TrnGetCluster

Gets the cluster name of a trend graph on a page.

## Syntax

**TrnGetCluster(*nAN*)**

*nAN*:

The AN of the chosen trend graph.

## Return Value

The name of the cluster the trend graph is associated with.

## See Also

[Trend Functions](#)

### TrnGetCursorEvent

Gets the event number of a trend, at the trend cursor position for a specified pen. This function only operates on an event-based trend.

## Syntax

**TrnGetCursorEvent(*nAN*, *Pen*)**

*nAN*:

The AN where the trend is located.

*Pen*:

The trend pen number:

0 - The pen currently in focus

1...8 - Pen1...Pen8

## Return Value

The event number, or 0 (zero) if the trend cursor is disabled.

## Related Functions

[TrnSetEvent](#), [TrnGetCluster](#), [TrnGetEvent](#)

## Example

```
! For the trend at AN20
DspText(31,0,TrnGetCursorEvent(20,0));
/* Displays the trend event at the cursor for the pen currently in
focus. The event will display at AN31. */
```

## See Also

[Trend Functions](#)

## TrnGetCursorMSTime

Gets the time (in milliseconds from the previous midnight) at a trend cursor for a specified pen.

## Syntax

**TrnGetCursorMSTime(*nAN*, *Pen*)**

*nAN*:

The AN where the trend is located.

*Pen*:

The trend pen number:

0 - The pen currently in focus

1...8 - Pen1..Pen8

## Return Value

The number of milliseconds since the previous midnight. If the trend cursor is disabled, 0 (zero) is returned. If *nAN* or *Pen* is invalid, 0 (zero) is returned and an error code is set.

## Related Functions

[TrnGetCursorTime](#)

## Example

```
! For the trend at AN20
STRING timeStr;
STRING msecStr;
timeStr = TimeToString(TrnGetCursorTime(20,1),2) + " ";
msecStr = TimeToString(TrnGetCursorMSTime(20,1),6);
```

```
DspText(31,0,timeStr + msecStr);
! Returns "23/02/01 10:53:22.717"
```

## See Also

[Trend Functions](#)

### TrnGetCursorPos

Gets the offset of a trend cursor from its origin, in samples.

## Syntax

**TrnGetCursorPos(*nAN*)**

*nAN*:

The AN where the trend is located.

## Return Value

The offset of a trend cursor from its origin, in samples, or -1 if the trend cursor is disabled.

## Related Functions

[TrnSetCursorPos](#)

## Example

```
! For the trend at AN20
! If the trend cursor is disabled
Offset=TrnGetCursorPos(20);
! Sets Offset to -1.
! If the trend cursor is 50 samples from the origin
Offset=TrnGetCursorPos(20);
! Sets Offset to 50.
```

## See Also

[Trend Functions](#)

### TrnGetCursorTime

Gets the time and date at a trend cursor for a specified pen.

## Syntax

**TrnGetCursorTime(*nAN, Pen*)**

*nAN:*

The AN where the trend is located.

*Pen:*

The trend pen number:

0 - The pen currently in focus

1...8 - Pen1 . . . Pen8

## Return Value

A time/date variable. If the trend cursor is disabled, 0 (zero) is returned. If *nAN* or *Pen* is invalid, 0 (zero) is returned and an error code is set.

## Related Functions

[TrnGetBufTime](#)

## Example

```
! For the trend at AN20
INT time;
time = TrnGetCursorTime(20,1);
DspText(31,0,TimeToStr(time,2));
! Displays the trend cursor date for Pen1.
DspText(32,0,TimeToStr(time,1));
! Displays the trend cursor time for Pen1.
```

## See Also

[Trend Functions](#)

## TrnGetCursorValue

Gets the value at a trend cursor for a specified pen.

## Syntax

**TrnGetCursorValue(*nAN*, *Pen*)**

*nAN:*

The AN where the trend is located.

*Pen:*

The trend pen number:

0 - The pen currently in focus

1...8 - Pen1 . . . Pen8

## Return Value

The trend value. If the actual value is gated or invalid, the standard invalid or gated values are returned (no error is set). You can check this return value using [TrnIsValidValue\(\)](#).

## Related Functions

[TrnGetBufValue](#)

## Example

```
! For the trend at AN20
DspText(31,0,TrnGetCursorValue(20,0));
! Displays the value at the trend cursor for the focus pen.
```

## See Also

[Trend Functions](#)

## TrnGetCursorValueStr

Gets the value at a trend cursor for a specified pen. The value is returned as a formatted string using the pen's format specification and (optionally) the engineering units.

## Syntax

**TrnGetCursorValueStr(*nAN*, *Pen*, *EngUnits*)**

*nAN*:

The AN where the trend is located.

*Pen*:

The trend pen number:

0 - The pen currently in focus

1...8 - Pen1...Pen8

*EngUnits*:

Engineering units mode:

0 - Do not include the engineering units at the end of the formatted string.

1 - Include the engineering units at the end of the formatted string.

## Return Value

The trend value (as a string). If trend data is invalid, or an argument passed to the function is invalid "<na>" is returned. If the actual value is gated (not triggered) "<gated>" is returned. If the trend cursor is disabled, an empty string is returned.

## Related Functions

[TrnGetCursorValue](#)

## Example

```
! For the trend at AN20
DspText(31,0,TrnGetCursorValueStr(20,0,1));
/* Displays the value at the trend cursor for the focus pen. The
value will display as a formatted string (including the
engineering units).*/
```

## See Also

[Trend Functions](#)

## TrnGetDefScale

Gets the default engineering zero and full scales of a trend tag.

This function is a blocking function. It will block the calling Cicode task until the operation is complete.

## Syntax

**TrnGetDefScale(*Tag*, *LoScale*, *HiScale* [, *sClusterName*] )**

*Tag*:

The trend tag enclosed in quotation marks "" (can be prefixed by the name of the cluster that is "ClusterName.Tag").

*LoScale*:

The engineering zero scale. Must be a Real type variable.

*HiScale*:

The engineering full scale. Must be a Real type variable.

*sClusterName*:

The name of the cluster in which the trend tag resides. This is optional if you have one cluster or are resolving the trend via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TrnGetScale](#), [TrnInfo](#)

## Example

```
REAL LoScale;  
REAL HiScale;  
TrnGetDefScale("PV1",LoScale,HiScale,"ClusterXYZ");  
/* Returns engineering zero and full scales of the trend tag  
"PV1". */
```

## See Also

[Trend Functions](#)

### TrnGetDisplayMode

Returns the display mode of the selected trend pen. The display mode is set using [TrnSetDisplayMode](#).

## Syntax

**TrnGetDisplayMode(*nAN*, *PenNumber*)**

*nAN*:

The AN of the chosen trend.

*PenNumber*:

The trend pen number:

0 - The pen currently in focus.

1...8 - Pen1...Pen8.

## Return Value

An integer representing the trend's display mode:

**Invalid/Gated trend options:**

0 - Convert invalid/gated trend samples to zero.

1 - Leave invalid/gated trend samples as they are.

**Ordering trend sample options:**

0 - Order returned trend samples from oldest to newest.

2 - Order returned trend samples from newest to oldest.

**Condense method options:**

0 - Set the condense method to use the mean of the samples.

4 - Set the condense method to use the minimum of the samples.

8 - Set the condense method to use the maximum of the samples.

12 - Set the condense method to use the newest of the samples.

**Stretch method options:**

0 - Set the stretch method to step.

128 - Set the stretch method to use a ratio.

256 - Set the stretch method to use raw samples.

**Gap Fill Constant option:**

*n* - the number of missed samples that the user wants to gap fill) x 4096.

**Display as Periodic options:**

0 - Display according to trend type.

1048576 - display as periodic regardless of trend type.

## Related Functions

[TrnSetDisplayMode](#)

## Example

```
int DisplayMode = TrnGetDisplayMode (10, 7)
/* Returns The Display Mode of pen 7 for the trend at AN 10.*/
```

## See Also

[Trend Functions](#)

## TrnGetEvent

Gets the event number of the trend at a percentage along the trend, using the current event as the base point. This function only operates on an event-based trend. The first recorded event (the start event) would be event number 1 and the highest number would be the latest event. The event number is stored in a LONG and would eventually wrap around if you have enough events.

## Syntax

**TrnGetEvent(*nAN*, *Pen*, *Percent*)**

*nAN*:

The AN of the chosen trend.

*Pen*:

The trend pen number:

0 - The pen currently in focus

1...8 - Pen1..Pen8

*Percent*:

The percentage of the trend from the starting event, from 0 (the start event) to 100 (the end event).

## Return Value

The event number.

## Related Functions

[TrnSetEvent](#), [TrnGetCluster](#), [TrnGetCursorEvent](#)

## Example

```
/* Display the start event for the current pen of the trend at
AN20. */
DspText(31,0,TrnGetEvent(20,0,0));
```

## See Also

[Trend Functions](#)

## TrnGetFormat

Gets the format of a trend tag being plotted by a specified pen.

## Syntax

**TrnGetFormat**(*nAN*, *Pen*, *Width*, *DecPlaces*)

*nAN*:

The AN of the chosen trend.

*Pen*:

The trend pen number:

0 - The pen currently in focus

1...8 - Pen1...Pen8

*Width*:

Variable denoting the width of the format.

*DecPlaces*:

Variable denoting the number of decimal places in the format.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TrnGetScale](#), [TrnGetUnits](#)

## Example

```
/* If the trend tag being plotted by Pen1 of the trend at AN20 has
a format of "###.#" */
```

```
TrnGetFormat(20,1,Width,DecPlaces);
! Sets Width to 5 and DecPlaces to 1.
```

## TrnGetMode

Gets the mode (real-time or historical trending) of the trend pen.

## Syntax

```
TrnGetMode(nAN, Pen)
```

*nAN*:

The AN of the chosen trend.

*Pen:*

The trend pen number:

0 - The pen currently in focus

1...8 - Pen1...Pen8

## Return Value

The current mode, 0 for real-time or 1 for historical.

## Related Functions

[TrnScroll](#)

## Example

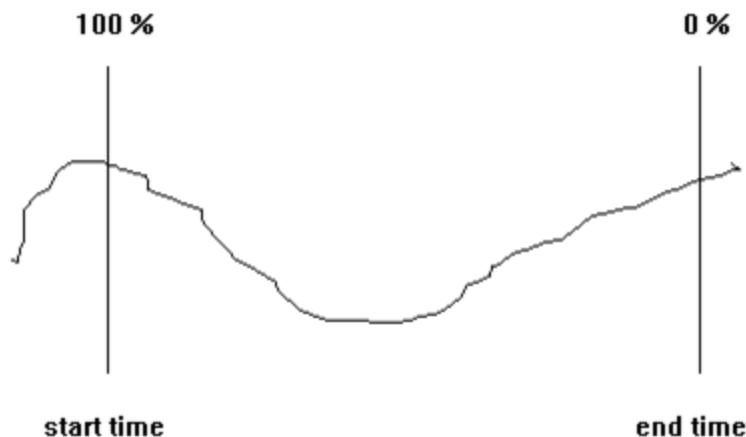

```
! For the trend at AN20
INT Mode;
Mode=TrnGetMode(20,0);
! Gets the current mode of the pen in focus.
IF Mode=0 THEN
    DspText(31,0,"Real Time Trending");
ELSE
    DspText(31,0,"Historical Trending");
END
```

## See Also

[Trend Functions](#)

## TrnGetMSTime

Gets the time (in milliseconds from the previous midnight) of the trend (plotted by a specified pen) at a percentage along the trend, using the time and date of the right-most sample displayed. The time associated with the right-most sample displayed is known as the end time. The start time is the time of the left-most sample displayed. Percent 0 (zero) will correspond to the end time, and Percent 100 will correspond to the start time

## Syntax

**TrnGetMSTime(*nAN*, *Pen*, *Percent*)**

*nAN*:

The AN of the chosen trend.

*Pen*:

The trend pen number:

0 - The pen currently in focus

1...8 - Pen1...Pen8

*Percent*:

The percentage of the trend from the time and date of the right-most sample displayed (end time), from 0 to 100.

## Return Value

The number of milliseconds since the previous midnight. Zero (0) is returned if an error is detected.

## Related Functions

[TrnGetTime](#)

## Example

```
! For Pen 1 at AN20
STRING timeStr;
STRING msecStr;
timeStr = TimeToString(TrnGetTime(20,1,100),2) + " ";
msecStr = TimeToString(TrnGetMSTime(20,1,100),6);
DspText(31,0,timeStr + msecStr);
```

Returns:

```
"23/02/01 10:53:22.717"
```

## See Also

[Trend Functions](#)

### TrnGetPen

Gets the trend tag being plotted by a specified pen.

## Syntax

**TrnGetPen(*nAN*, *Pen* [, *Mode*] )**

*nAN*:

The AN of the chosen trend.

*Pen*:

The trend pen number:

0 - The pen currently in focus

1...8 - Pen1 . . . Pen8

*Mode*:

An optional argument used to specify whether the trend tag name is returned with a cluster prefix. Set:

0 return tag without cluster prefix (default)

1 return tag with cluster prefix.

## Return Value

The trend tag (as a string) being plotted by *Pen*. If *nAN* or *Pen* is invalid, an empty string is returned, and an error code is set. You can call the *IsError()* function to get the actual error code.

## Related Functions

[TrnSetPen](#)

## Example

```
! For the trend at AN20
DspText(31,0,TrnGetPen(20,0,1));
! Displays the trend tag with cluster prefix of the focus pen.
```

## See Also

[Trend Functions](#)

## TrnGetPenComment

Retrieves the comment of a pen.

### Syntax

**TrnGetPenComment(*nAN*, *Pen*)**

*AN*

The AN of the chosen trend.

*Pen*:

The trend pen number:

0 - The pen currently in focus

1...8 - Pen1...Pen8

### Return Value

The comment of the pen as a string.

### Related Functions

[TrnGetPen](#)

### Example

```
! For the trend at AN18
DspText(31,0,TrnGetPenComment(18,0));
! Displays the trend comment of the focus pen.
```

### See Also

[Trend Functions](#)

## TrnGetPenFocus

Gets the number of the pen currently in focus.

### Syntax

**TrnGetPenFocus(*nAN*)**

*nAN*:

The AN of the chosen trend.

## Return Value

The pen currently in focus (between 1 and 8). If *nAN* is invalid, -1 is returned and an error code is set.

## Related Functions

[TrnSetPenFocus](#)

## Example

```
! For the trend at AN20
DspText(31,0,TrnGetPenFocus(20));
! Displays the pen currently in focus.
```

## See Also

[Trend Functions](#)

## TrnGetPenNo

Gets the pen number of a pen name. The pens on a trend are either defined in the Page Trends database or set by the [TrnSetPen\(\)](#) function.

## Syntax

**TrnGetPenNo(*nAN*, *Tag*)**

*AN*:

The AN of the chosen trend.

*Tag*:

The trend tag.

## Return Value

The pen number, or 0 (zero) if an error is detected.

## Related Functions

[TrnSetPen](#)

## Example

```
/* Assume that 8 trend fonts, Pen1TrendFont ... Pen8TrendFont are
defined in the Fonts database. The following code will display the
trend tag using the matching font for that pen. */
! For the trend at AN20
```

```
STRING sFont;
INT iPen;
iPen = TrnGetPenNo(20,"PV1");
IF 0 < iPen AND iPen < 9 THEN
    sFont = "Pen" + IntToStr(iPen) + "TrendFont";
    DspStr(31,sFont,"PV1");
END
```

## See Also

[Trend Functions](#)

### TrnGetPeriod

Gets the current display period of a trend. (To obtain the sampling period, use the [TrnInfo](#) function.)

## Syntax

**TrnGetPeriod(*nAN*)**

*nAN*:

The AN of the chosen trend.

## Return Value

The current display period of a trend (in seconds), or 0 (zero) if an error code is detected.

## Related Functions

[TrnSetPeriod](#), [TrnInfo](#)

## Example

```
/* For the trend at AN20, get and display the current display
period. */
! If the period is 10 seconds
INT Period;
STRING Str;
Period=TrnGetPeriod(20);
Str=TimeToStr(Period,5);
DspStr(31,"",Str);
```

## See Also

[Trend Functions](#)

## TrnGetScale

Gets the display scale of the trend tag being plotted by a specified pen.

## Syntax

**TrnGetScale(*nAN*, *Pen*, *Percent*)**

*AN*:

The AN of the chosen trend.

*Pen*:

The trend pen number:

0 - The pen currently in focus

1...8 - Pen1 . . . Pen8

*Percent*:

The percentage of the full scale, from 0 to 100.

## Return Value

The scale of the trend tag being plotted by *Pen*. If *nAN* or *Pen* is invalid, 0 (zero) is returned and an error code is set.

## Related Functions

[TrnSetScale](#), [TrnGetDefScale](#)

## Example

```
! For the trend at AN20
DspText(31,0,TrnGetScale(20,0,0));
! Displays the zero scale of the focus pen.
DspText(32,0,TrnGetScale(20,0,50));
! Displays the 50% scale of the focus pen.
DspText(33,0,TrnGetScale(20,0,100));
! Displays the full scale of the focus pen.
```

## See Also

[Trend Functions](#)

## TrnGetScaleStr

Gets the scale of the trend tag being plotted by a specified pen. The value is returned as a formatted string using the pen's format specification and (optionally) the engineering units.

## Syntax

**TrnGetScaleStr(*nAN*, *Pen*, *Percent*, *EngUnits*)**

*AN*:

The AN of the chosen trend.

*Pen*:

The trend pen number:

0 - The pen currently in focus

1...8 - Pen1..Pen8

*Percent*:

The percentage of the full scale, from 0 to 100.

*EngUnits*:

Engineering units mode:

0 - Do not include the engineering units at the end of the formatted string.

1 - Include the engineering units at the end of the formatted string.

## Return Value

The scale of the trend tag being plotted by *Pen* (as a string). If *nAN* or *Pen* is invalid, <na> is returned and an error code is set.

## Related Functions

[TrnGetScale](#)

## Example

```
! For the trend at AN20
DspText(31,0,TrnGetScaleStr(20,0,0,1));
/* Displays the zero scale of the focus pen. The scale displays as
a formatted string (including the engineering units). */
DspText(32,0,TrnGetScaleStr(20,2,50,1));
/* Displays the 50% scale of Pen2. The scale displays as a
formatted string (including the engineering units). */
DspText(33,0,TrnGetScaleStr(20,0,100,0));
/* Displays the full scale of the trend tag being plotted by the
focus pen. The scale displays as a formatted string (excluding the
engineering units). */
```

## See Also

[Trend Functions](#)

## TrnGetSpan

Gets the span time of a trend (if the span was set by the [TrnSetSpan\(\)](#) function). The span time is the total time displayed in the trend window.

**Note:** If you call the [TrnSetPeriod\(\)](#) function after the [TrnSetSpan\(\)](#) function, the span is automatically set to 0 (zero).

## Syntax

**TrnGetSpan(*nAN*)**

*nAN*:

The AN of the chosen trend.

## Return Value

The span time, in seconds. 0(zero) is returned if the AN is invalid or if the span was not set by the [TrnSetSpan\(\)](#) function.

## Related Functions

[TrnSetSpan](#), [TrnGetPeriod](#), [TrnSetPeriod](#)

## Example

```
// Use a keyboard command or button to set a span of 2 hours.  
TrnSetSpan(40,StrToTime("2:00:00"));  
// Then use TrnGetSpan function to display the span  
Time = TrnGetSpan(40)  
DspText(31,0,TimeToStr(Time,5));
```

## See Also

[Trend Functions](#)

## TrnGetTable

This function allows you to tabulate values from a specific section of trend. The values in the table (possibly an array variable) are arranged by time.

If the period (*Period*) is different to the trend's sampling period (configured in the Trend Tags database), the returned values are determined by *DisplayMode*.

This function is a blocking function. It will block the calling Cicode task until the operation is complete.

## Syntax

**TrnGetTable(*Tag, Time, Period, Length, Table, DisplayMode [, Milliseconds] [, sClusterName]*)**

**Tag:**

The trend tag enclosed in quotation marks "" (can be prefixed by the name of the cluster that is ClusterName.Tag).

**Time:**

The end time and date (long integer) of the desired trend section. Once you have entered the end time and date (Time), period (Period), and number of trend tag values collected (Length), the start time and date will be calculated automatically. For example, if Time = StrToDate("21/07/20") + StrToTime("09:00"), Period = 30, and Length = 60, the start time would be 08:30. In other words, the trend values for the period between 8.30am and 9am (on July 21, 2020) would be tabulated.

If this argument is set to 0 (zero), the time used will be the current time.

**Period:**

The time difference between tabulated trend values (in seconds). For example, if you set this period to 30 seconds, Plant SCADA will get the last trend value (sampled at the end of the trend section), then get the trend value that was sampled 30 seconds before that, and so on until it reaches the start time of the trend section.

If this period is different to the trend's sampling period, the trend values will be averaged or interpolated. Set to 0 (zero) to default to the actual trend period.

**Length:**

The number of trend values to store in the trend table, from 1 to the maximum number of items in the table. This argument has a max of 4000 (in v6). Specifying a length of greater than 4000 results in a return value of 0 and IsError()=274 (INVALID\_ARGUMENT). This limit can be configured using the citect.ini parameter [Trend]MaxRequestLength.

**Table:**

Variable containing the Cicode array in which the trend data is stored. You can enter the name of an array here (see the example).

**DisplayMode:**

The Display Mode parameters allow you to enter a single integer to specify the display options for a trend (for a maximum of eight trends).

To calculate the integer that you should enter for a particular trend, select the options you want to use from those listed below, adding their associated numbers together. The resulting integer is the DisplayMode parameter for that trend.

**Invalid/Gated trend options:**

0 - Convert invalid/gated trend samples to zero.

1 - Leave invalid/gated trend samples as they are.

**Ordering trend sample options:**

0 - Order returned trend samples from newest to oldest.

2 - Order returned trend samples from oldest to newest.

**Condense method options:**

0 - Set the condense method to use the mean of the samples.

4 - Set the condense method to use the minimum of the samples.

8 - Set the condense method to use the maximum of the samples.

12 - Set the condense method to use the newest of the samples.

**Stretch method options:**

- 0 - Set the stretch method to step.
- 128 - Set the stretch method to use a ratio.
- 256 - Set the stretch method to use raw samples.

**Gap Fill Constant option:**

*n* - the number of missed samples that the user wants to gap fill) x 4096.

**Synchronize to Display Period options:**

- 0 - Synchronize the returned samples to the nearest display period.
- 16777216 - Do not synchronize samples to the nearest display period.

Options listed in each group are mutually exclusive. The default value for each Display Mode is 258 (0 + 2 + 256).

**Milliseconds:**

This argument allows you to set your sample request time with millisecond precision. After defining the time and date in seconds with the Time argument, you can then use this argument to define the milliseconds component of the time.

For example, if you wanted to request data from the 21/07/20, at 9am, 13 seconds, and 250 milliseconds you could set the Time and Milliseconds arguments as follows:

```
Time = StrToDate("21/07/20") + StrToTime("09:00:13")
Milliseconds = 250
```

If you don't enter a Milliseconds value, it defaults to 0 (zero). There is no range constraint, but as there are only 1000 milliseconds in a second, you should keep your entry between 0 (zero) and 999.

**sClusterName:**

Name of the cluster in which the trend tag resides. This is optional if you have one cluster or are resolving the trend via the current cluster context. The argument is enclosed in quotation marks "".

---

**Note:** If you are putting a value for "sClusterName" in the TrnGetTable(...), then you have to provide a value for "Milliseconds" parameter.

---

## Return Value

The actual number of samples read. 0(zero) is returned if an error occurs. You can call the IsError() function to get the actual error code.

## Related Functions

[TrnSetTable](#), [TrnGetDisplayMode](#)

## Example

```
REAL TrendTable1[100];
/* Defines an array of a maximum of 100 entries in which the trend
data is stored. */
TrnGetTable("OP1",StrToDate("17/07/20")
+StrToTime("09:00"),2,10,TrendTable1[0],0,0,"ClusterXYZ");
/* Stores the values of trend tag "OP1" in Table TrendTable1. Data
is stored at the following times:
17/07/20 09:00:00 TrendTable1[0]
```

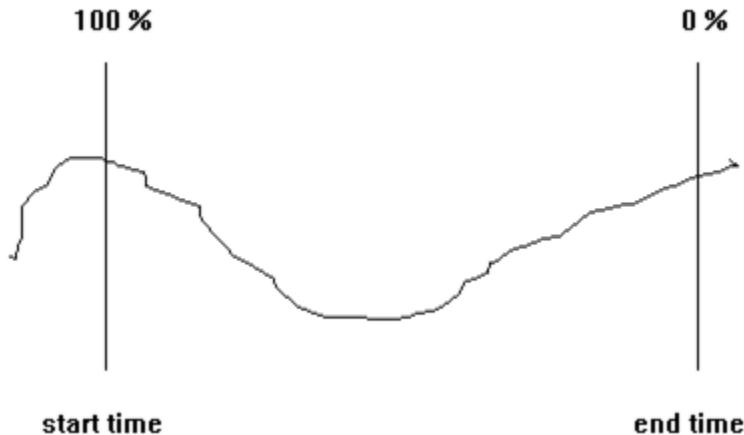

```
08:59:58 TrendTable1[1]
08:59:56 TrendTable1[2]
...
17/07/20 08:59:42 TrendTable1[9] */
Average=TableMath(TrendTable1[0],100,2);
/* Gets the average of the trend data. */
```

### TrnGetTime

Gets the time and date of the trend (plotted by a specified pen) at a percentage along the trend, using the time and date of the right-most sample displayed. The time associated with the rightmost sample displayed is known as the end time. The start time is the time of the left-most sample displayed. Percent 0 (zero) will correspond to the end time, and Percent 100 will correspond to the start time.

## Syntax

**TrnGetTime(*nAN*, *Pen*, *Percent*)**

*AN*:

The AN of the chosen trend.

*Pen*:

The trend pen number:

0 - The pen currently in focus

1..8 - Pen1..Pen8

*Percent*:

The percentage of the trend from the time and date of the right-most sample displayed (end time), from 0 to 100.

## Return Value

A time/date variable. 0 (zero) is returned if an error is detected.

## Related Functions

[TrnSetTime](#)

## Example

```
! For the trend at AN20
DspText(31,0,TimeToStr(TrnGetTime(20,0,0),2));
! Displays the trend current date for the focus pen.
DspText(32,0,TimeToStr(TrnGetTime(20,0,0),1));
! Displays the trend current time for the focus pen.
DspText(33,0,TimeToStr(TrnGetTime(20,0,50),1));
! Displays the time 50% along the trend for the focus pen.
```

## See Also

[Trend Functions](#)

## TrnGetUnits

Gets the data units for the trend tag plotted by a specified *Pen*.

## Syntax

**TrnGetUnits(*nAN*, *Pen*)**

*AN*:

The AN of the chosen trend.

*Pen*:

The trend pen number:

0 - The pen currently in focus

1...8 - Pen1...Pen8

## Return Value

The data units for the trend tag plotted by *Pen*, otherwise an empty string is returned, and an error code is set.  
You can call the [IsError\(\)](#) function to get the actual error code.

## Related Functions

[TrnGetFormat](#), [TrnGetScale](#)

## Example

```
! For the trend at AN20
DspText(31,0,TrnGetUnits(20,0));
! Displays the data units for the focus pen.
```

## See Also

[Trend Functions](#)

### TrnInfo

Gets the configured values of a trend tag.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**TrnInfo(*Tag*, *Type* [, *sClusterName*] )**

*Tag*:

The name of the trend tag enclosed in quotation marks "" (can be prefixed by the name of the cluster that is ClusterName.Tag).

*nType*:

The type of information required:

1 - Trend Type

2 - Sample Period (to obtain the Display Period, use the TrnGetPeriod function)

3 - Trend File Name (without file extension)

4 - Area

5 - Privilege

6 - Current Event Number. Valid only for event type trends

7 - Engineering Units

8 - The storage method used for the tag. A returned value of 2 represents two byte storage (scaled), 8 represents eight byte storage (floating point).

9 - The file period of the tag in seconds. If the file period is set to monthly or yearly, a file period cannot be calculated as months and years vary in length. Therefore, a file period of 0 will be returned for trends with such file periods.

*sClusterName*:

The name of the cluster in which the trend tag resides. This is optional if you have one cluster or are resolving the trend via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

The value (as a string), otherwise an empty string is returned, and an error code is set. You can call the [IsError\(\)](#) function to get the actual error code.

## Example

```
! Get the file name of trend tag LT131
sFileName = TrnInfo("LT131", 3, "ClusterXYZ");
```

## See Also

[Trend Functions](#)

### TrnIsValidValue

Determines whether a logged trend value is:

- <VALID> - an actual trend value;
- <GATED> - if a periodic trend has a trigger condition, and that condition is FALSE, a standard substitute (or GATED) value is logged instead of the actual value; or
- <INVALID> - for some reason, no value was logged.

## Syntax

**TrnIsValidValue(*TrendValue*)**

*TrendValue*:

A trend value (of type REAL).

## Return Value

0 for <VALID>  
1 for <GATED>  
2 for <INVALID>

## Related Functions

[TrnGetGatedValue](#), [TrnGetInvalidValue](#)

## Example

```
INT
FUNCTION
DoubleArray()
    INT i;
    FOR i = 0 TO 99 DO
        IF TrnIsValidValue(oldArray[i]) = 1 OR trigger = 0 THEN
            newArray[i] = TrnGetGatedValue();
            Prompt ("This value is <GATED>");
        ELSE
            IF i >= 90 OR TrnIsValidValue(oldArray[i]) = 2 THEN
```

```
        newArray[i] = TrnGetInvalidValue();
ELSE
    newArray[i] = oldArray[i] * 2;
    Prompt ("This value is <TRN_NO_VALUES>");
END
END
END
RETURN i;
END
```

## See Also

[Trend Functions](#)

## TrnNew

Creates a new trend at run time. This function performs the same operation as an entry in the Page Trends database. After the trend is created by the TrnNew() function, all the other trend functions can access and control the trend.

## Syntax

**TrnNew(*nAN*, *Trend* [, *Tag1* ... *Tag8*] [, *sClusterName*] )**

*AN*:

The AN where the bottom right-hand corner of the trend is located.

*Trend*:

The trend definition number (as a STRING).

*Tag1* ... *Tag8*:

The trend tags. (These tags cannot be prefixed with cluster name, cluster should be specified with the ClusterName argument).

*sClusterName*:

The name of the cluster in which all the trend tags reside. This is optional if you have one cluster or are resolving the trends via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TrnDelete](#)

## Example

```
TrnNew(20, "trn002", "PV1", "OP1", "ClusterXYZ");
/* Creates a new trend at AN20 using trend definition 2, plotting
```

```
"PV1" on Pen1 and "OP1" on Pen2. */
```

## See Also

[Trend Functions](#)

### TrnPlot

Prints the trend line of one or more trend tags. Each trend line is drawn with a different pen style and marker as appropriate. The trend plot includes a comment and a legend, and you can specify the vertical high and low scales. The *Mode* defines the color mode of the printer. The default mode is black and white.

---

**Note:** The TrnPlot() function is used only for sending trends to a printer, and cannot be used for embedding a trend plot in a report.

---

For more advanced trend plotting, you can use the low-level plot functions.

## Syntax

```
TrnPlot(sPort, nSamples, iTime, rPeriod, sTitle, AN, Tag1.....Tag8, iMode, sComment, rLoScale1, rHiScale1,  
.....rLoScale8, rHiScale8)
```

*sPort*:

The name of the printer port to which the plot will be printed. This name needs to be enclosed within quotation marks. For example LPT1:, to print to the local printer, or \\Pserver\canon1 using UNC to print to a network printer.

*nSamples*:

The number of data points on the plot.

*iTime*:

For periodic trend or event trends displayed as periodic:

The end point in time (the latest point) for the trend plot.

For event trend type:

The event sample number (e.g. using [TrnGetEvent](#))

*rPeriod*:

The period (in seconds) of the trend plot. This can differ from the actual trend period.

If you omit the period, it defaults to the sample period of Tag1.

*sTitle*:

The title of the trend plot.

*Tag1..Tag8*:

The trend tags.

*AN*:

The AN of the chosen trend. If you enter 0 (zero), the display mode will default to 258. (This is the display mode that is passed into [TrnGetTable](#)() when it is called internally by TrnPlot().) If you call TrnPlot() from a report, you need to enter 0 (zero) here.

*iMode*:

The color mode of the printer.

0 - Black and White

1 - Color

*sComment:*

The comment that is to display beneath the title of the trend plot. You may pass an empty string if no comment is required.

*rLoScale1, HiScale1,.....LoScale8, HiScale8:*

The minimum and maximum on the vertical scale for the trend line of each of the tags (Tag1... Tag8).

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TrnComparePlot](#), [TrnPrint](#), [PlotOpen](#), [SPCPlot](#)

## Example

```
/* Prints a black and white plot to LPT1, containing the trend
lines of two variable tags (PV1 & PV2). The trend lines have a
starting time of 9am, on 11/10/96, 200 sample points, and a period
of 2 seconds. The trend line of PV1 will be on a vertical scale of
0-200, and PV2 will be on a vertical scale of 0-400. */
INT time;
Time = StrToDate("11/10/96") + StrToTime("09:00:00");
TrnPlot("LPT1:",200,Time,2,"Citect Trend
Plot","PV1","PV2","","","","","","",0,"Process variable operation
at shutdown",0,200,0,400);
```

## See Also

[Trend Functions](#)

## TrnPrint

Prints the trend that is displayed on the screen (at *nAN*) using the current display mode for each trend. You can specify the trend title, the target printer, whether to print in color or black and white, and whether to display the Plot Setup form when the function is called.

## Syntax

**TrnPrint(*sPort*, *sTitle*, *AN*, *iModeColor*, *iDisplayForm*)**

*sPort:*

The name of the printer port to which the plot will be printed. This name needs to be enclosed within quotation marks "". For example "LPT1:", to print to the local printer, or "\\\Pserver\canon1" using UNC to print to a

network printer.

It is not necessary to enter a printer port. The first time the printer port is omitted, you will be prompted to select one at the Printer Setup form. The selection you make will then be used as the default.

*sTitle:*

The title to print at the top of the trend plot. If you omit the title in *sTitle*, the page title will be used.

*AN:*

The AN where the trend plot is located.

*iModeColor:*

The color mode of the printer.

-1 - Color to be decided (Default). Plant SCADA refers to the [General]PrinterColourMode parameter to determine print color. If there is no setting for this parameter, it will default to black and white.

0 - Black and White

1 - Color

*DisplayForm:*

Defines whether or not the Plot Setup form will display when the function is called. This form allows you to enter the color mode of the printer, and define the printer setup etc. (See Printing Trend Data for more information on this form.)

-1 - Plant SCADA refers to the [General]DisablePlotSetupForm parameter to determine if the form will display.

0 - Do not display form

1 - Display form

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TrnPlot](#), [TrnComparePlot](#), [WinPrint](#), [SPCPlot](#)

## Example

```
TrnPrint("LPT1:","Test Print",40,0,0);
/* Prints the trend plot displayed at AN40, without prompting for setup details.*/
```

## See Also

[Trend Functions](#)

## TrnSamplesConfigured

Gets the number of samples configured for the currently displayed trend.

## Syntax

**TrnSamplesConfigured(*nAN*)**

*AN*:

The AN where the trend is located.

## Return Value

The number of samples configured for the trend, or 0 (zero) if an error is detected. You can call the [IsError\(\)](#) function to get the actual error code.

## Example

```
/* For the trend at AN20, get and display the number of samples */  
INT nSamples;  
nSamples=TrnSamplesConfigured(20);  
DspStr(31,"",IntToStr(nSamples));
```

## See Also

[Trend Functions](#)

## TrnScroll

Scrolls the trend pen by a specified percentage (of span), or number of samples.

## Syntax

**TrnScroll(*nAN, Pen, nScroll [, nMode]* )**

*AN*:

The AN where the trend is located. Set to -1 for all trends on the current page.

*Pen*:

The trend pen number. Set to -1 for all pens.

*nScroll*:

The amount by which the trend will be scrolled. Use *nMode* to specify whether the trend will be scrolled by percentage or by number of samples.

Because the resolution of Client requests is 1 second, requests of millisecond accuracy are rounded to 1 second. For example, if requested to scroll 2 samples of 400 milliseconds (a total of 0.8 seconds), the trend will actually scroll 1 second.

*nMode*

The type of scrolling to be performed.

1 - The trend will be scrolled by a percentage of span. Default.

2 - The trend will be scrolled by a number of samples. This mode is not available if the user puts the trend into the 'trend span' mode by setting the span. In this case no scrolling would take place; the user needs to use

*nMode* 1.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TrnSetTime](#)

## Example

```
! Scroll all pens (of the trend at an20) 100% forwards.  
TrnScroll(20,-1,100); or TrnScroll(20,-1,100,1);  
! Scrolls all pens (of all trends on the current trend page) 300% backwards.  
TrnScroll(-1, -1, -300); or TrnScroll(20,-1,-300,1);  
!Scrolls all pens (of all trends on the current trend page) 3 samples forwards.  
TrnScroll(20,-1,3,2);  
!Scrolls all pens (of all trends on the current trend page) 1 sample backwards.  
TrnScroll(20,-1,-1,2);
```

## See Also

[Trend Functions](#)

## TrnSelect

Sets up a page for a trend. This function allows you to set up a trend before the trend page is displayed. You can therefore use a single trend page to display any trend in the project by selecting the trend first, and then displaying the trend page. The [PageTrend\(\)](#) function uses this function to display the standard trend pages.

Call this function and a set of [TrnSetPen\(\)](#) functions before you display a trend page. When the trend page is displayed, all pens set by the TrnSetPen() functions are displayed. You can use the TrnSelect() function to configure different set of pens to be displayed on one generic trend page. The pen settings in the Page Trend database are overridden.

---

**Note:** Trend functions used after the TrnSelect() function needs to use the special value -2 as their AN. (See the example below).

---

## Syntax

**TrnSelect(*Window*, *Page*, *AN* [, *sClusterName*] )**

*Window*:

The window number (returned from the WinNumber function).

-3 - for the current window.

-2 - for the next window displayed.

*Page*:

The name of the page that displays the trend.

*AN:*

The AN where the trend displays, or -3 for the first trend on the page.

*sClusterName:*

The name of the cluster that is associated with any trend tag for this trend graph. This is optional if you have one cluster or are resolving the trend via the current cluster context. The argument is enclosed in quotation marks "".

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TrnSetPen](#), [PageTrend](#), [WinNumber](#)

## Example

```
TrnSelect(WinNumber(), "TrendPage", 40, "ClusterXYZ");
TrnSetPen(-2,1,"PV1");
TrnSetPen(-2,2,"PV2");
TrnSetPen(-2,3,"PV3");
TrnSetPen(-2,4,"PV4");
PageDisplay("TrendPage");
```

## See Also

[Trend Functions](#)

## TrnSetCursor

Moves the trend cursor by a specified number of samples. If the trend cursor is disabled, this function enables it. If the cursor is enabled and the number of samples is 0 (zero), the cursor is disabled. If the cursor is moved off the current trend frame, the trend scrolls.

## Syntax

**TrnSetCursor(*nAN, Samples*)**

*AN:*

The AN where the trend is located. Set to -1 for all trends on the current page.

*Samples:*

The number of samples to move the cursor.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TrnGetCursorTime](#), [TrnGetCursorValue](#), [TrnGetCursorValueStr](#), [TrnSetCursorPos](#)

## Example

```
! For the trend at AN20
TrnSetCursor(20,1);
! Moves the trend cursor forwards 1 sample.
TrnSetCursor(-1,-40);
! Moves the trend cursor (of all trends on the current trend page)
backwards 40 samples.
```

## See Also

[Trend Functions](#)

## TrnSetCursorPos

Moves the trend cursor to a specified x-axis point, offset from the trend cursor origin. If the trend cursor is disabled, this function enables it. If the position is outside of the trend frame, it sets the trend cursor to half of the frame.

## Syntax

**TrnSetCursorPos(*nAN*, *Position*)**

*AN*:

The AN where the trend is located. Set to -1 for all trends on the current page.

*Position*:

The x-axis point at which to position the trend cursor, offset from the trend cursor origin.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TrnGetCursorPos](#), [TrnSetCursor](#)

## Example

```
! For the trend at AN20, if the trend frame is 400 points
TrnSetCursorPos(20,0);
! Moves the trend cursor to its origin.
TrnSetCursorPos(20,200);
! Moves the trend cursor to half of its frame size (200 points).
```

## See Also

[Trend Functions](#)

### TrnSetDisplayMode

Specifies how raw trend samples are displayed on the screen.

## Syntax

**TrnSetDisplayMode(*nAN*, *PenNumber*, *DisplayMode*)**

*AN*:

The animation number of the chosen trend.

*PenNumber*:

The pen number of the chosen trend. Specify:

0 - The current pen

1-8 - Pens 1 through 8

-1 - All pens

*DisplayMode*:

The Display Mode parameters allow you to enter a single integer to specify the display options for a trend (for a maximum of eight trends).

To calculate the integer you should enter, select the options you want to use from the list below, adding their associated numbers together. The resulting integer is the *DisplayMode* parameter for that trend.

**Invalid/Gated trend options:**

0 - Convert invalid/gated trend samples to zero.

1 - Leave invalid/gated trend samples as they are.

**Ordering trend sample options:**

0 - Order returned trend samples from oldest to newest.

2 - Order returned trend samples from newest to oldest.

**Condense method options:**

0 - Set the condense method to use the mean of the samples.

4 - Set the condense method to use the minimum of the samples.

8 - Set the condense method to use the maximum of the samples.

12 - Set the condense method to use the newest of the samples.

**Stretch method options:**

0 - Set the stretch method to step.

128 - Set the stretch method to use a ratio.

256 - Set the stretch method to use raw samples.

**Gap Fill Constant option:**

*n* - the number of missed samples that the user wants to gap fill) x 4096.

**Display as Periodic options:**

0 - Display according to trend type.

1048576 - display as periodic regardless of trend type.

Since the Display as Periodic options are read-only, they cannot be set using TrnSetDisplayMode. They can be retrieved using [TrnGetDisplayMode\(\)](#) and also used with the TrnExport group of functions.

**Synchronize to Display Period options:**

0 - Synchronize the returned samples to the nearest display period.

16777216 - Do not synchronize samples to the nearest display period.

**Note:** Options listed in each group are mutually exclusive. The default value for each Display Mode is 258 (0 + 2 + 256).

---

**Return Value**

0 (zero) if successful, otherwise an error code is returned.

**Related Functions**

[TrnGetDisplayMode](#), [TrnGetTable](#)

**See Also**

[Trend Functions](#)

**TrnSetEvent**

Sets the start event of a trend pen. This function only operates on an event-based trend.

**Syntax**

**TrnSetEvent(*nAN*, *Pen*, *Event*)**

*AN*:

The AN of the chosen trend.

*Pen*:

The trend pen number:

0 - The pen currently in focus

1...8 - Pen1 . . . Pen8

*Event*:

The number of the start event.

**Return Value**

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TrnGetEvent](#), [TrnGetCluster](#), [TrnGetCursorEvent](#)

## Example

```
! Sets pen1 to event number 123456
TrnSetEvent(20,1,123456);
! Scrolls pen1 back by 100 events
TrnSetEvent(20,1,TrnGetBufEvent(20,1,0)-100);
```

## See Also

[Trend Functions](#)

### TrnSetPen

Sets the trend tag of a trend pen. The trend pen changes to the specified tag and the trend is refreshed. The trend pen needs to be in the operator's area to be displayed. If outside of the operator's area, data is not displayed. You cannot mix periodic trends and event trends in the same trend window.

This function may sometimes return before the pen is actually set when called on a PC which is not the trend server. This may create difficulties for following functions such as [TrnSetScale](#). A wrapper function can be used to confirm the pen is set before returning. See example 2 below.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

## Syntax

**TrnSetPen(*nAN*, *Pen*, *Tag*)**

*AN*:

The AN where the trend is located.

-1 - All trends on the current trend page.

-2 - The function being called is using the special AN setup by the TrnSelect() function.

*Pen*:

The pen for which the trend tag will be changed.

-2 - The first available pen (This value is automatically changed to 0 for SPC trends because they have only one pen per trend.)

-1 - All pens on the trend. (Not allowed for SPC trends.)

0 - The pen currently in focus.

1...8 - Pen1....Pen8

*Tag*:

The trend tag. If Tag = ! the pen is deleted.

## Return Value

0 (zero) if successful, otherwise an error code is returned. Be aware that if a mixture of periodic and event trends is detected, the return value is 0 (zero), but the hardware alarm #329 is set.

## Related Functions

[TrnGetPen](#), [TrnSelect](#)

### Example 1

```
! For the trend at AN20
TrnSetPen(20,1,"PV1");
! Sets the trend tag of Pen1 to "PV1".
```

### Example 2

```
INT
FUNCTION
BlockedTrnSetPen(INT hAN, INT nPen, STRING sTrend)
    INT timeout = 5000
    INT sleepTime = 10
    INT error = -1
    INT elapsed = 0
    INT currentTime
    STRING sPenName
    error = TrnSetPen(hAN, nPen, sTrend)
    IF error = 0 THEN
        error = -1
        currentTime = SysTime()
        WHILE error <> 0 AND elapsed < timeout DO
            sPenName = TrnGetPen(hAN, nPen)
            IF sPenName = sTrend THEN
                error = 0
            ELSE
                SleepMS(sleepTime)
                elapsed = elapsed + SysTimeDelta(currentTime)
            END
        END
    END
    RETURN error
END
```

## See Also

[Trend Functions](#)

### TrnSetPenFocus

Sets the focus to a specified pen. After the focus is set, the focus pen is used with other trend functions.

## Syntax

**TrnSetPenFocus(*nAN*, *Pen*)**

*AN*:

The AN of the chosen trend.

*Pen*:

The trend pen:

- 4 - Make the next pen the focus pen; without skipping blank pens.
- 3 - Make the previous pen the focus pen; without skipping blank pens.
- 2 - Make the next pen the focus pen; skip blank pens.
- 1 - Make the previous pen the focus pen; skip blank pens.
- 0 - Keep the current focus.
- 1...8 - Change Pen1. . .8 to be the focus pen.

## Return Value

The old pen focus number, or -1 if an error is detected. You can call the [IsError\(\)](#) function to get the actual error code.

## Related Functions

[TrnGetPenFocus](#)

## Example

System Keyboard

Key Sequence	NextPen
Command	<code>TrnSetPenFocus(20, -2)</code>
Comment	For the trend at AN20, make the next pen the focus pen

## See Also

[Trend Functions](#)

## TrnSetPeriod

Sets the display period (time base) of a trend. When the period is changed, Plant SCADA reads the historical data to reconstruct the trend data, and refreshes the trend. Every pen has the same display period.

This function clears the span set by the [TrnSetSpan\(\)](#) function.

## Syntax

**TrnSetPeriod(*nAN*, *Period*)**

*AN*:

The AN where the trend is located. Set to -1 for every trend on the current page.

*Period*:

The new sampling period (in seconds) of the trend. To set the display period to the sampling period, set this argument to 0 (zero),

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TrnGetPeriod](#), [TrnEcho](#), [TrendSetTimebase](#), [TrendSetSpan](#)

## Example

System Keyboard

Key Sequence	## Enter
Command	TrnSetPeriod(20, Arg1)
Comment	Set a new sampling period for the trend at AN20

## See Also

[Trend Functions](#)

## TrnSetScale

Sets a new scale for a trend pen. In the automatic scaling mode, the zero and full scales are automatically generated.

## Syntax

**TrnSetScale(*nAN*, *Pen*, *Percent*, *Scale*)**

*AN*:

The AN where the trend is located. Set to -1 for all trends on the current page.

*Pen*:

The trend pen number:

-1 - All pens

0 - The pen currently in focus

1...8 - Pen1...Pen8

*Percent:*

The scale mode:

-2 - Set both zero and full scales to the default scales.

-1 - Place the trend into automatic scale mode.

0 - Set the zero scale.

100 - Set the full scale.

*Scale:*

The new value of the scale. Scale is ignored if Percent is -2.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TrnGetScale](#), [TrnEcho](#), [TrnSetScale](#)

## Example

```
! For the trend at AN20
TrnSetScale(20,-1,100,5000.0);
! Sets the full scale of all pens to 5000.0
```

## See Also

[Trend Functions](#)

## TrnSetSpan

Sets the span time of a trend. The span time is the total time displayed in the trend window. You can set the period to contain fractions of a second. For example, if you set a trend with 240 samples to a span of 10 minutes, then each sample would be 2.5 seconds. Choose a span long enough to provide a sufficient sample rate to capture accurate real time data.

## Syntax

**TrnSetSpan(*nAN*, *Span*)**

*AN:*

The AN of the chosen trend.

*Span:*

The span time (in seconds).

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TrnSetPeriod](#), [TrnGetSpan](#), [TrnSetSpan](#)

## Example

```
// Set a span of 2 hours.  
TrnSetSpan(40,StrToTime("2:00:00"));  
// Then use TrnGetSpan function to display the span  
Time = TrnGetSpan(40);  
DspText(31,0,TimeToStr(Time,5));
```

## See Also

[Trend Functions](#)

## TrnSetTable

Writes trend tag data from a table to the trend logging system (starting at the top of the table, and continuing to the bottom). Each value is written with a time and date, as specified by *Period*. If *Period* differs from the trend sampling period (defined in the Trend Tags database), the trend's sample values will be calculated (averaged or interpolated) from the tabulated trend data.

The user needs to have the correct privilege (as specified in the database), otherwise the data is not written.

This function is a blocking function. It will block the calling Cicode task until the operation is complete.

## Syntax

**TrnSetTable**(*Tag*, *Time*, *Period*, *Length*, *Table* [, *Milliseconds*] [, *sClusterName*] )

*Tag*:

The trend tag enclosed in quotation marks "" (can be prefixed by the name of the cluster that is ClusterName.Tag).

*Time*:

The time and date (long integer) to be associated with the first value in the table when it is set. Once you have entered the end time and date (Time), set period (Period), and number of trend tag values to be set (Length), the start time and date will be calculated automatically. For example, if Time = StrToDate("22/07/20") + StrToTime("09:00"), Period = 30, and Length = 60, the start time would be 08:30. In other words, the first value from the table would be set with time 9am, and the last would be set with time 8.30am (on July 22, 2020).

If this argument is set to 0 (zero), the time used will be the current time.

*Period*:

This will be the interval (in seconds) between trend values when they are set (that is it will be the perceived sampling period for the trend). This period can differ from the actual trend period. Set to 0 (zero) to default to

the actual trend period.

*Length:*

The number of trend values in the trend table.

*Table:*

Variable containing the table of floating-point values in which the trend data is stored. You can enter the name of an array here (see the example). Must be a Real type variable.

*Milliseconds:*

This argument allows you to set the time of the first sample in the table with millisecond precision. After defining the time and date in seconds with the Time argument, you can then use this argument to define the milliseconds component of the time.

For example, if you wanted to set data from the 22/07/20, at 9am, 13 seconds, and 250 milliseconds you could set the Time and Milliseconds arguments as follows:

```
Time = StrToDate("22/07/20") + StrToTime("09:00:13")
Milliseconds = 250
```

If you don't enter a milliseconds value, it defaults to 0 (zero). There is no range constraint, but as there are only 1000 milliseconds in a second, you should keep your entry between 0 (zero) and 999.

*sClusterName:*

The name of the cluster in which the trend tag resides. This is optional if you have one cluster or are resolving the trend via the current cluster context. The argument is enclosed in quotation marks "".

---

**Note:** If you are putting a value for "sClusterName" in the TrnSetTable(...), then you have to provide a value for "Milliseconds" parameter.

---

## Return Value

The actual number of samples written. The return value is 0 if an error is detected. You can call the IsError() function to get the actual error code.

## Related Functions

[TrnGetTable](#)

## Example

```
REAL TrendTable1[100];
/* Defines an array of a maximum of 100 entries. Assume that
TrendTable1 has been storing data from a source. */
TrnSetTable("OP1",StrToDate("22/07/20")
+StrToTime("09:00"),2,10,TrendTable1,0,"ClusterXYZ");
/* A set of 10 trend data values are set for the OP1 trend tag. */
```

## See Also

[Trend Functions](#)

## TrnSetTime

Sets the end time and date of a trend pen.

If you set a time less than the current time, the trend display is set to historical mode and samples taken after this time and date will not be displayed.

If you set the time to the current time, for example by using the [TimeCurrent](#) or [TrendZoom](#) Cicode functions, the trend is displayed in real-time mode and samples after this date and time will display.

**Note:** The end time specified for a trend object may automatically align with the display period that is used. To stop this occurring, you can use the [TrnSetDisplayMode](#) function by setting the *DisplayMode* parameter to 16777216 (samples will no longer synchronize to the nearest display period). You can set this as a default for a page by configuring the function as an **On page shown** event in the Page Properties (see [Page Properties - Events](#)).

## Syntax

**TrnSetTime(***nAN, Pen, Time***)**

*AN*:

The AN where the trend is located, or:

-1 - All trends on the current page

0 - The trend where the cursor is positioned

*Pen*:

The trend pen number:

-1 - All pens

0 - The pen currently in focus

1...8 - Pen1...Pen8

*Time*:

The end time and date of the trend. Samples taken after this time and date will not be displayed. Set to 0 (zero) to set the trend to the current time (real-time mode).

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[TrnGetTime](#)

## Example

```
TrnSetTime(20,1,TimeCurrent()-60*30);
/* Sets Pen1 to 30 minutes before the current time (30 minutes ago). */
TrnSetTime(20,1,0);
/* Sets the trend to real-time mode. */
```

## Window Functions

Window functions control the display of windows. You can open, move, size, activate, and de-activate windows. You can also specify titles for your windows.

Following are functions relating to Windows:

<a href="#">GetWinTitle</a>	Returns the name of the active window as a string.
<a href="#">HtmlHelp</a>	Display a specific topic from an HTML Help file (.chm).
<a href="#">MultiMonitorStart</a>	Displays a Plant SCADA window on each of the configured monitors when a display client starts up.
<a href="#">WinCopy</a>	Copies the active window to the Windows clipboard.
<a href="#">WinFile</a>	Writes the active window to a file.
<a href="#">WinFree</a>	Removes a display window.
<a href="#">WinGetClicked</a>	Gets the number of the Plant SCADA window that has most recently been clicked on using the left mouse button.
<a href="#">WinGetFirstChild</a>	Gets the window number of the first child of a parent window.
<a href="#">WinGetFocus</a>	Gets the number of the Plant SCADA window that has the keyboard focus.
<a href="#">WinGetName</a>	Gets the name previously associated with a particular window number using WinSetName.
<a href="#">WinGetNextChild</a>	Gets the window number of the next child in a child link.
<a href="#">WinGetParent</a>	Retrieves the Window Number of the specified window's parent or root window.
<a href="#">WinGetWndHnd</a>	Gets the window handle for the current window.
<a href="#">WinGoto</a>	Changes the active window.
<a href="#">WinMode</a>	Sets the display mode of the active window.
<a href="#">WinMove</a>	Moves the active window.
<a href="#">WinNew</a>	Opens a display window.

<a href="#">WinNewAt</a>	Opens a display window at specified coordinates.
<a href="#">WinNewPinAt</a>	Opens a new display window at a specified location, relative to the current active window, with a selected page displayed.
<a href="#">WinNext</a>	Makes the next window active.
<a href="#">WinNumber</a>	Gets the window number of the active Plant SCADA window.
<a href="#">WinPos</a>	Positions a window on the screen.
<a href="#">WinPrev</a>	Makes the previous window active.
<a href="#">WinPrint</a>	Prints the active window.
<a href="#">WinPrintFile</a>	Prints a file to the printer.
<a href="#">WinSelect</a>	Selects a window for Cicode output.
<a href="#">WinSetName</a>	Associates a name with a particular window by its window number.
<a href="#">WinSize</a>	Sizes a window.
<a href="#">WinStyle</a>	Switches on and off scrolling and scroll bar features for existing windows.
<a href="#">WinTitle</a>	Sets the title of the active window.
<a href="#">WndFind</a>	Gets the Windows number of any window in any application.
<a href="#">WndGetFileProfile</a>	Gets a profile string from any .INI file.
<a href="#">WndGetProfile</a>	This function is now obsolete.
<a href="#">WndHelp</a>	This function is obsolete.
<a href="#">WndInfo</a>	Gets the Windows system metrics information.
<a href="#">WndMonitorInfo</a>	Returns information about a particular monitor.
<a href="#">WndMonitorInfoEx</a>	Returns information about a particular monitor using the screen name.
<a href="#">WndPutFileProfile</a>	Puts a profile string into any .INI file.
<a href="#">WndPutProfile</a>	This function is now obsolete.
<a href="#">WndShow</a>	Sets the display mode of any window of any

	application.
WndViewer	This function is obsolete.

## See Also

[Cicode Function Categories](#)

[Using Cicode Functions](#)

[WndPutFileProfile](#)

## GetWinTitle

Returns the name of the active window as a string.

**Note:** This function does not work with pinned windows.

## Syntax

`GetWinTitle()`

## Return Value

The title of the active window as a string if successful; otherwise, an error is returned.

## Related Functions

[WinTitle](#)

## See Also

[Window Functions](#)

## HtmlHelp

Invokes the Microsoft HTML Help application (hh.exe) to display a specific topic from an HTML help file (.chm).

## Syntax

`HtmlHelp(sHelpFile, nCommand, sData)`

*sHelpFile*:

The help file to display. For example, "C:\Program Files (x86)\AVEVA Plant SCADA\Bin\ProcessAnalyst.chm".

This argument supports path substitutions. For example, "[BIN]:ProcessAnalyst.chm".

*nCommand*:

The type of help:

0 - Display a topic identified by an internal file name in the *sData* field. This is the name of the file within the .chm file. For example: "1126187.htm".

1 - Display a topic identified by the Mapped Topic ID in the *sData* field. For example: "1000".

2 - Terminate the help application.

3 - Display the index.

*sData*:

Optional data, depending on the value of *nCommand*.

## Return Value

0 (zero) if successful, otherwise an error is returned.

## See Also

[Window Functions](#)

## MultiMonitorStart

Displays a Plant SCADA window on each of the configured monitors when a display client starts up. It sets up the windows according to the Multi-Monitor Parameters [\[MultiMonitors\]Monitors](#) and [\[MultiMonitors\]StartupPage<n>](#).

## Syntax

**MultiMonitorStart()**

## Return Value

None.

## See Also

[Window Functions](#)

## WinCopy

Copies the graphics image of the active window to the Windows Clipboard. You can paste this Clipboard image into other applications.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

---

### Note:

- This function might not work as expected if called directly from the Kernel; instead, this function should be called from a graphics page.
  - This function is not supported in the server process in a multiprocessor environment. Calling this function from the server process results in a hardware alarm being raised.
-

## Syntax

**WinCopy( [xScale] [, yScale] [, bSwapBlackWhite] [, sMap] )**

*xScale*:

The x scaling factor for the item being copied. This argument is optional, as a default setting of 1 is used to maintain the current horizontal scaling of the image. The outcome is proportional to 1; for example, 0.5 halves the width of the image.

*yScale*:

The y scaling factor for the item being copied. This argument is optional, as a default setting of 1 is used to maintain the current vertical scaling of the image. The outcome is proportional to 1; for example, 0.5 halves the height of the image.

*bSwapBlackWhite*:

Swaps the colors black and white for the purpose of printing pages with a lot of black content. Use the default value of 1 to swap black and white (optional).

*sMap*:

The file name or path of a text based map file used to specify colors to swap when printing. By default Plant SCADA will look in the bin directory for the map file. The format for the map file is:

RRR GGG BBB RRR GGG BBB [HHH] [SSS] [LLL]//  
RRR GGG BBB RRR GGG BBB [HHH] [SSS] [LLL]//

Where:

*RRR* is a decimal red intensity value between 000 and 255.

*GGG* is a decimal green intensity value between 000 to 255.

*BBB* is a decimal blue intensity value between 000 to 255.

*HHH*, *SSS* and *LLL* are optional tolerance values to enable swapping a range of colors. Default values are shown below.

*HHH* is a decimal value representing the Hue tolerance. Valid range is 0 to 360. Default = 0.

*SSS* is a decimal value representing the Saturation tolerance. Valid range is 0 to 255. Default = 2 \* Hue tolerance.

*LLL* is a decimal value representing the Luminance tolerance. Valid range is 0 to 255. Default = 2 \* Hue tolerance.

Leading zeros are not required, however they aid readability.

The first three RGB values specify the FROM color, and the second three RGB values specify the TO color. The tolerance values are applied to the FROM color when replacing individual pixels in the image.

Comments may be placed at the end of each line, or on individual lines, and needs to be proceeded with // or !.

## Example

```
043 043 255 155 205 255 025 000 025
//Change dark blue to light blue using Hue and Luminance tolerance of 25.
000 000 000 255 255 255 //Swap black to white with no tolerance
```

**Note:** If swap color ranges overlap, the behavior is undefined (i.e. a color that falls in both ranges may end up as either color)

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[WinPrint](#)

## Example

```
WinCopy();  
! Copies the active window to the Windows Clipboard.  
WinCopy(0.5,0.5);  
! Copies the active window to the Windows Clipboard at half the  
current size.
```

## See Also

[Window Functions](#)

## WinFile

Writes the graphics image of the active window to a file. The file is saved in the Plant SCADA compressed .bmp format.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

---

**Note:**

- This function might not work as expected if called directly from the Kernel; instead, this function should be called from a graphics page.
  - This function is not supported in the server process in a multiprocessor environment. Calling this function from the server process results in a hardware alarm being raised.
- 

## Syntax

**WinFile(*sFile* [, *xScale*] [, *yScale*] [, *bSwapBlackWhite*] [, *sMap*] )**

*sFile*:

The name of the file to be created. If no path information is specified, the function will try to create the file in the bin directory (the current directory of the runtime process). Write permission is required.

Path operators such as [data] and [run] are also supported. For example to save the file in the [data] directory, you can specify:

[data]:screendump.bmp

The specified path needs to point to a writable folder.

*xScale*:

The x scaling factor for the item being printed. This argument is optional, as a default setting of 1 is used to maintain the horizontal scaling of the image. The outcome is proportional to 1; for example, 0.5 halves the width of the image .

**yScale:**

The y scaling factor for the item being printed. This argument is optional, as a default setting of 1 is used to maintain the current vertical scaling of the image. The outcome is proportional to 1; for example, 0.5 halves the height of the image.

**bSwapBlackWhite:**

Swaps the colors black and white for the purpose of printing pages with a lot of black content. Use the default value of 1 to swap black and white (optional).

**sMap:**

The file name or path of a text based map file used to specify colors to swap when printing. By default Plant SCADAWill look in the bin directory for the map file. The format for the map file is:

```
RRR GGG BBB RRR GGG BBB [HHH] [SSS] [LLL]//  
RRR GGG BBB RRR GGG BBB [HHH] [SSS] [LLL]//
```

Where:

*RRR* is a decimal red intensity value between 000 and 255.

*GGG* is a decimal green intensity value between 000 to 255.

*BBB* is a decimal blue intensity value between 000 to 255.

*HHH*, *SSS* and *LLL* are optional tolerance values to enable swapping a range of colors. Default values are shown below.

*HHH* is a decimal value representing the Hue tolerance. Valid range is 0 to 360. Default = 0.

*SSS* is a decimal value representing the Saturation tolerance. Valid range is 0 to 255. Default = 2 \* Hue tolerance.

*LLL* is a decimal value representing the Luminance tolerance. Valid range is 0 to 255. Default = 2 \* Hue tolerance.

Leading zeros are not required, however they aid readability.

The first three RGB values specify the FROM color, and the second three RGB values specify the TO color. The tolerance values are applied to the FROM color when replacing individual pixels in the image.

Comments may be placed at the end of each line, or on individual lines, and needs to be proceeded with // or !.

Example map file:

```
043 043 255 155 205 255 025 000 025  
//Change dark blue to light blue using Hue and Luminance tolerance of 25.  
000 000 000 255 255 255 //Swap black to white with no tolerance
```

**Note:** If swap color ranges overlap, the behavior is undefined. This means a color that falls in both ranges may end up as either color.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

### WinGetFirstChild

Gets the window number of the first child of a parent window. This number can be used with other functions to control the window.

## Syntax

**WinGetFirstChild(*Window*)**

*Window*:

The window number of the parent window.

## Return Value

The window number associated with the first child of the specified parent window. If a child window does not exist, -1 is returned.

## Related Functions

[WinGetNextChild](#), [WinNew](#), [WinNewAt](#), [WinNumber](#)

## Example

```
...
// Get the active window number
iParentWindowNum = WinNumber();
iFirstChild = WinGetFirstChild(iParentWindowNum);
iSecondChild = WinGetNextChild(iFirstChild);
iThirdChild = WinGetNextChild(iSecondChild);
...
```

## See Also

[Window Functions](#)

### WinFree

Removes the active display window. Be aware that the last window (and any child windows owned by the last window) cannot be removed. You cannot call this function as an exit command or from a Cicode Object.

**Note:** This function is not supported in the server process in a multiprocessor environment. Calling this function

---

from the server process results in a hardware alarm being raised.

---

## Syntax

**WinFree()**

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[WinNew](#), [WinNewAt](#)

## Example

```
WinFree();  
! Removes the active display window.
```

## See Also

[Window Functions](#)

## WinFreeEx

Removes the active display window and allows you to pass a Windows handle to the function for closing the window. Note that the last window (and any child windows owned by the last window) cannot be removed. You cannot call this function as an exit command or from a Cicode Object.

## Syntax

**WinFreeEx(*Window*)**

*Window*:

The window number (returned from the [WinNumber\(\)](#) function). Note that this is not the same as the window handle, returned from the [WndFind\(\)](#) function.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[WinFree](#), [WinNew](#), [WinNewAt](#)

## Example

```

[Window Functions](#)

## WinGetName

Gets the name previously associated with a particular window number using [WinSetName](#). An association with a window is removed when the window is free-ed.

## Syntax

**WinGetName([*iWinNum*])**

*iWinNum*

An optional parameter which specifies the window number to lookup for the associated Name. If no number is specified, the name returned is the one associated with the currently selected window number.

## Return Value

String name associated with window number *iWinNum*, otherwise an empty string is returned.

## Related Functions

[WinSetName](#), [WinNumber](#)

## See Also

[Window Functions](#)

### WinGetNextChild

Gets the window number of the next child in a child link. This number can be used with other functions to control the window.

## Syntax

**WinGetNextChild(*Window*)**

*Window*:

The window number of the previous child in the child link.

## Return Value

The window number associated with the next child in the child link. If a window does not exist, -1 is returned.

## Related Functions

[WinGetFirstChild](#), [WinNew](#), [WinNewAt](#), [WinNumber](#)

## Example

```
...
// Get the active window number
iParentWindowNum = WinNumber();
iFirstChild = WinGetFirstChild(iParentWindowNum);
iSecondChild = WinGetNextChild(iFirstChild);
iTThirdChild = WinGetNextChild(iSecondChild);
...
```

## See Also

[Window Functions](#)

### WinGetParent

Retrieves the window number of the specified window's parent or root window.

## Syntax

**WinGetParent([*WinNum*], [*GetRoot*])**

*WinNum*

An optional parameter which specifies the window number of the child window. If no number is specified, it retrieves the window number of the currently selected window's parent or root window.

#### *GetRoot*

An optional parameter which determines whether to get the parent or root window. If false, it will retrieve the immediate parent window number (default). If true, it retrieves the root window number by walking the chain of parent windows.

### Return Value

The window number of the parent or root window.

### Related Functions

[WinGetName](#), [WinGetFocus](#)

### Examples

```
nParentWin=WinGetParent();
! Gets the number of the parent window for the currently selected Plant SCADA window

nRootWin=WinGetParent(WinGetFocus(), TRUE);
! Gets the number of the root window for the window that has keyboard focus
```

### See Also

[Window Functions](#)

### WinGetWndHnd

Gets the window handle for the current window. The window handle may be used by 'C' programs and Plant SCADA Wnd... functions. You may pass the windows handle to a 'C' program by using the DLL functions.

### Syntax

**WinGetWndHnd()**

### Return Value

The window handle if successful, otherwise 0 (zero) is returned. Be aware that this is not the same as a Plant SCADA window number returned from the [WinNumber\(\)](#) function.

### Related Functions

[DLLCall](#), [WinNew](#), [WndFind](#), [WndShow](#)

## Example

```
INT hWnd;
hWnd = WinGetWndHnd();
WinShow(hWnd,6); //iconize the window
```

## WinGoto

Changes the active window. The specified window is placed in front of all other windows and all keyboard commands will apply to this window. You cannot call this function as an exit command or from a Cicode Object.

**Note:** This function is not supported in the server process in a multiprocessor environment. Calling this function from the server process results in a hardware alarm being raised.

## Syntax

**WinGoto(*Window*)**

*Window*:

The window number (returned from the [WinNumber\(\)](#) function). Be aware that this is not the same as the window handle, returned from the [WndFind\(\)](#) function.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[WinNew](#)

## Example

```
! If two windows are displayed;
WinGoto(1);
! Changes the active window to Window 1.
WinGoto(0);
! Changes the active window to Window 0.
```

## See Also

[Window Functions](#)

## WinMode

Sets the display mode of the active Plant SCADA window.

**Note:**

- This function does not work with pinned windows.
- This function is not supported in the server process in a multiprocessor environment. Calling this function from the server process results in a hardware alarm being raised.

## Syntax

**WinMode(*Mode*)**

*Mode*:

The mode:

- 0 - Hide the window.
- 2 - Activate the window in an iconized state.
- 3 - Activate the window in a maximized state.
- 4 - Display the window in its previous state without activating it.
- 5 - Activate the window in its current state.
- 6 - Iconize the window.
- 7 - Display the window in an iconized state without activating it.
- 8 - Display the window in its current state without activating it.
- 9 - Activate the window in its previous state.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[WinNew](#)

## Example

```
! Iconize the active Plant SCADA window.  
WinMode(7);
```

## See Also

[Window Functions](#)

## WinMove

Moves the active window to a new location and sizes the window in a single operation. This is the same as calling

the WinPos() and the WinSize() functions. You use PageInfo to get the current window position.

**Note:** This function is not supported in the server process in a multiprocessor environment. Calling this function from the server process results in a hardware alarm being raised.

## Syntax

**WinMove(*X*, *Y*, *Width*, *Height*)**

*X*, *Y*:

The new x and y pixel coordinates for the top-left corner of the active window.

If the window is a pinned window, the new coordinates will specify a location for the window that is based on the unscaled version of the page that hosts it.

*Width*:

The width of the window, in pixels.

If the target is a pinned window, the new width will be measured against the original window size as it is on the unscaled version of the page that hosts it.

*Height*:

The height of the window, in pixels.

If the target is a pinned window, the new height will be measured against the original window size as it is on the unscaled version of the page that hosts it.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[WinSize](#), [WinPos](#), [PageInfo](#)

## Example

```
WinMove(100,50,500,300);
/* Moves the top-left corner of the active window to the pixel
coordinate 100,50 and size the window to 500 x 300 pixels. */
```

## See Also

[Window Functions](#)

## WinNew

Opens a new display window, with a specified page displayed. The window can later be destroyed with the [WinFree\(\)](#) function.

You can also specify if the displayed page operates within the context of a particular cluster in a multiple cluster project. When the page is displayed during runtime, the *ClusterName* argument is used to resolve any tags that

do not have a cluster explicitly defined.

**Note:** This function is not supported in the server process in a multiprocessor environment. Calling this function from the server process results in a hardware alarm being raised.

## Syntax

**WinNew(*Page*, *ClusterName*)**

*Page*:

The name or page number of the page to display (in quotation marks ""). Can be prefixed by the name of a host cluster, that is "ClusterName.Page". This will take precedence over the use of the *ClusterName* parameter if the two differ.

*sClusterName*:

The name of the cluster that will accommodate the page at runtime. This is optional if you have one cluster or are resolving the page via the current cluster context. The argument is enclosed in quotation marks "". If the *Page* parameter is prefixed with the name of a cluster, this parameter will not be used.

## Return Value

The window number of the window, or -1 if the window cannot be opened. Be aware that this is not the same as the window handle returned from the WndFind() function.

## Related Functions

[WinFree](#), [WinNewAt](#)

## Example

```
! If the display window being opened is window number 2:  
Window=WinNew("Alarm");  
! Displays the Alarm page and sets Window to 2.
```

## See Also

[Window Functions](#)

## WinNewAt

Opens a new display window at a specified location, with a selected page displayed. The window can later be removed with the [WinFree\(\)](#) function.

You can also specify if the displayed page operates within the context of a particular cluster in a multiple cluster project. When the page is displayed during runtime, the *ClusterName* argument is used to resolve any tags that have a cluster omitted.

**Note:** This function is not supported in the server process in a multiprocessor environment. Calling this function from the server process results in a hardware alarm being raised.

## Syntax

**WinNewAt(*Page*, *X*, *Y*, *Mode*[, *sClusterName*])**

*Page*:

The name or page number of the page to display (in quotation marks ""). Can be prefixed by the name of a host cluster, that is "ClusterName.Page". This will take precedence over the use of the *sClusterName* parameter if the two differ.

*X*:

The x pixel coordinate of the top left corner of the window.

*Y*:

The y pixel coordinate of the top left corner of the window.

*Mode*:

The mode of the window:

0 - Normal page.

1 - Page child window. The window is closed when a new page is displayed, for example, when the [PageDisplay\(\)](#) or [PageGoto\(\)](#) function is called. The parent is the current active window.

2 - Window child window. The window is closed automatically when the parent window is freed with the [WinFree\(\)](#) function. The parent is the current active window.

4 - No re-size. The window is displayed with thin borders and no maximize/minimize icons. The window cannot be re-sized.

8 - No icons. The window is displayed with thin borders and no maximize/minimize or system menu icons. The window cannot be re-sized.

16 - No caption. The window is displayed with thin borders, no caption, and no maximize/minimize or system menu icons. The window cannot be re-sized.

32 - Echo enabled. When enabled, keyboard echo, prompts, and error messages are displayed on the parent window. This mode should only be used with child windows (for example, Mode 1 and 2).

64 - Always on top.

128 - Open a unique window. This mode helps to prevent this window from being opened more than once.

256 - Display the entire window. This mode commands that no parts of the window will appear off the screen

512 - Open a unique Super Genie. This mode helps to prevent a Super Genie from being opened more than once (at the same time). However, the same Super Genie with different associations can be opened.

1024 - Disables dynamic resizing of the new window, overriding the setting of the [\[Page\]DynamicSizing](#) parameter.

4096 - Allows the window to be resized without maintaining the current aspect ratio. The aspect ratio defines the relationship between the width and the height of the window, which means this setting allows you to stretch or compress the window to any proportions. This option overrides the setting of the [\[Page\]MaintainAspectRatio](#) parameter.

8192 - Text on a page will be resized in proportion with the maximum scale change for a resized window. For example, consider a page that is resized to three times the original width, and half the original height. If this mode is set, the font size of the text on the page will be tripled (in proportion with the maximum scale). This option overrides the setting of the [\[Page\]ScaleTextToMax](#) parameter.

16384 - Hide the horizontal scroll bar.

32768 - Hide the vertical scroll bar.

65536 - Disable horizontal scrolling.

131072 - Disable vertical scrolling.

You can select multiple modes by adding modes together (for example, set Mode to 9 to open a page child window without maximize, minimize, or system menu icons).

*sClusterName*:

The name of the cluster that will accommodate the page at runtime. This is optional if you have one cluster or are resolving the page via the current cluster context. The argument is enclosed in quotation marks "". If the Page parameter is prefixed with the name of a cluster, this parameter will not be used.

## Return Value

The window number of the window, or -1 if the window cannot be opened. Be aware that this is not the same as the window handle returned from the WndFind() function.

## Related Functions

Command	WinNewAt(Arg1, 100, 200, 4)
Comment	Display a specified popup page in a new window with no maximize and minimize icons

**See Also**

[Window Functions](#)

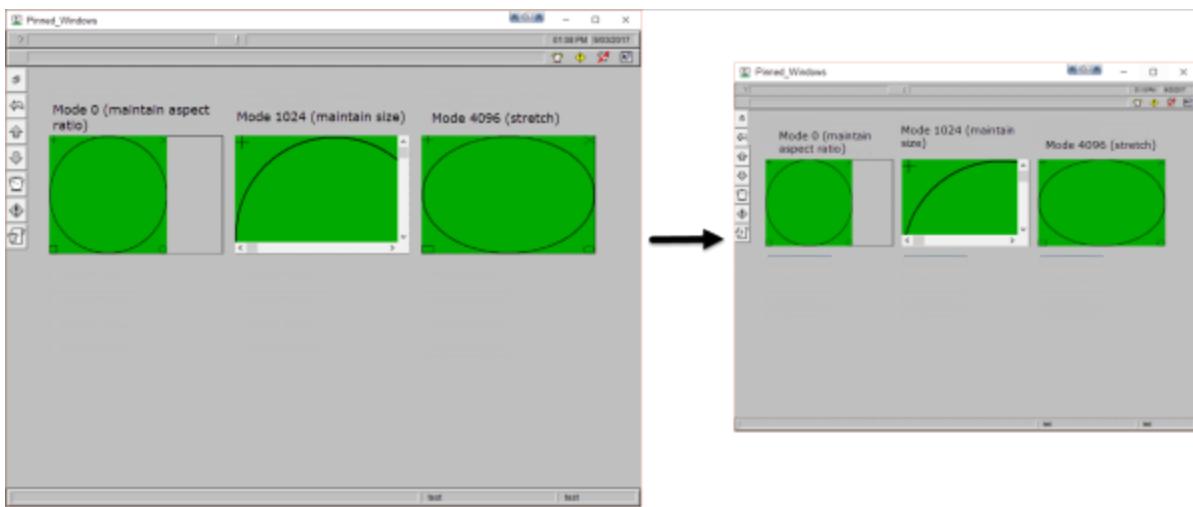

**WinNewPinAt**

Allows for windows to be "pinned" at specified locations within a main window or within other pinned windows. This function opens a new display window at a specified location, relative to the current active window, with a selected page displayed. The window can later be removed with the WinFree() function.

The pinned windows become child windows of the parent window, and maintain their size and position relative to the parent window.

Pinned windows do not have a border, title bar or title. They cannot be maximized or minimized. Pinned windows are automatically closed when the main window is closed. They can be created in one of the following modes (as detailed in the Syntax section below).

- As the window is sized, the page inside maintains its original aspect ratio. The aspect ratio defines the relationship between the width and the height of the window. In this mode, the page is aligned to the top left. Blank areas are filled in using the background color of the main window.
- As the window is sized, the page inside maintains its original size. Scroll bars are displayed to allow the user to navigate the window if the content cannot be accommodated in the window. The scroll bars can be disabled using the Cicode function WinStyle OR by passing in various modes into the winnewpinat mode parameter.
- the page is stretched to fit in the window. For example, consider a page that is resized to three times the original width, and half the original height. If this mode is set, the font size of the text on the page will be tripled (in proportion with the maximum scale).

**Note:** Pinned windows cannot overlap. If you use this function to create a pinned window that overlaps an existing one, the window will not appear and the "Pinned window overlaps" hardware alarm will be generated.

The content of pinned windows can be manipulated using most Windows Cicode functions **except** the following:

- GetWindowTitle()
- WinMode()
- WinTitle()
- WndShow()

**Note:** This function is not supported in the server process in a multiprocessor environment. Calling this function from the server process results in a hardware alarm being raised.

You can also specify if the displayed page operates within the context of a particular cluster in a multiple cluster project. When the page is displayed during runtime, the *ClusterName* argument is used to resolve any tags that have a cluster omitted.

**Note:** When executing a keyboard command while the focus is in a pinned window, the keyboard command will first be matched against the list of keyboard commands associated with the graphics object that has current focus, and then the list of keyboard commands associated with the pinned window page itself. The keyboard command will then be matched against the list of keyboard commands associated with the parent of the pinned window, and so on. Command execution will stop at the first object or page that matches the keyboard command sequence.

## Syntax

**WinNewPinAt(*Page*, *X*, *Y*[, *Mode*][, *Width*][, *Height*][, *sClusterName*])**

*Page*:

The name or page number of the page to display (in quotation marks ""). Can be prefixed by the name of a host cluster, that is "ClusterName.Page". This will take precedence over the use of the ClusterName parameter if the two differ.

*X*:

The x pixel coordinate of the top left corner of the window.

*Y:*

The y pixel coordinate of the top left corner of the window.

*Mode:*

The mode of the window:

0 - Set by default. Normal page, maintain aspect ratio when resized. The aspect ratio defines the relationship between the width and the height of the window.

1024 - Disables dynamic resizing of the new window.

4096 - Allows the window to be resized without maintaining the current aspect ratio. The aspect ratio defines the relationship between the width and the height of the window, which means this setting allows you to stretch or compress the window to any proportions.

8192 - Text on a page will be resized in proportion with the maximum scale change for a resized window. This option overrides the setting of the [\[Page\]ScaleTextToMax](#) parameter.

You can select multiple modes by adding modes together.

*Width:*

The pixel width of the window, scaled relative to the current active window.

Default value - The width of the page associated with argument 'Page'.

*Height:*

The pixel height of the window, scaled relative to the current active window.

Default value - The height of the page associated with argument 'Page'.

*sClusterName:*

The name of the cluster that will accommodate the page at runtime. This is optional if you have one cluster or are resolving the page via the current cluster context. The argument is enclosed in quotation marks "". If the Page parameter is prefixed with the name of a cluster, this parameter will not be used.

## Return Value

The window number of the window, or -1 if the window cannot be opened. Be aware that this is not the same as the window handle returned from the WndFind() function.

---

**Note:** A common cause of the window not being created is because you have reached the maximum allowable windows, which can be changed via the parameter [\[Page\]Windows](#). Also, a window will not be created if it overlaps with an existing one. Check for the "Pinned window overlaps" hardware alarm.

---

## Related Functions

[WinFree](#), [WinNew](#), [WinNewAt](#)

## Example

Here is a Cicode example that creates three pinned windows using the current window as the parent:

- window 1 : coordinates - 0,0, size - 100, 100, resize mode - maintain aspect ratio
- window 2 : coordinates - 100,0, size - 100, 100, resize mode - stretch content to fit window bounds
- window 3 : coordinates - 0,100, size - 200, 100, resize mode - maintain content size

```
INT windowPin1 = -1;
INT windowPin2 = -1;
INT windowPin3 = -1;
INT windowParent = -1;
FUNCTION MyPinnedLayout()
    IF windowParent = -1 THEN
        windowParent = WinNumber();
    END
    IF windowParent <> -1 THEN
        WinGoto(windowParent);
        windowPin1 = WinNewPinAt("page1", 0, 0, 0, 100, 100);
        IF -1 = windowPin1 THEN
            Prompt("WinNewPinAt failed with error: " + ErrMsg(IsError()));
        END
        WinGoto(windowParent);
        windowPin2 = WinNewPinAt("page2", 100, 0, 4096, 100, 100);
        IF -1 = windowPin2 THEN
            Prompt("WinNewPinAt failed with error: " + ErrMsg(IsError()));
        END
        WinGoto(windowParent);
        windowPin3 = WinNewPinAt("page3", 0, 100, 1024, 200, 100);
        IF -1 = windowPin3 THEN
            Prompt("WinNewPinAt failed with error: " + ErrMsg(IsError()));
        END
        WinGoto(windowParent);
    END
END
```

## See Also

[Window Functions](#)

## WinNext

Makes the next window (in order of creation) active.

## Syntax

**WinNext()**

## Return Value

The window number of the window, or -1 if there is no next window. Be aware that this is not the same as the window handle returned from the WndFind() function.

## Related Functions

[WinNew](#), [WinPrev](#)

## Example

```
! If the display window being made active is window number 2:  
Window=WinNext();  
! Makes the next window active and sets Window to 2.
```

[Window Functions](#)

### WinNumber

Gets the window number of the active Plant SCADA window. This number can be used with other functions to control the window.

## Syntax

**WinNumber([*sName*])**

*sName*:

String name previously associated with a window number using WinSetName().

## Return Value

Window Number associated with the Name provided. If no Name is specified then the active window number is returned. If there isn't a valid window number associated with the name provided then -1 is returned.

## Related Functions

[WinNew](#), [WinGoto](#), [WinSetName](#)

## Example

```
! Create a new window, but keep the active window the same:  
Window=WinNumber();  
WinNew("Alarm");  
WinGoto(Window);
```

## See Also

[Window Functions](#)

### WinPos

Moves the active window to a new location. You use [PageInfo\(\)](#) to get the current window position.

**Note:** This function is not supported in the server process in a multiprocessor environment. Calling this function

---

from the server process results in a hardware alarm being raised.

---

## Syntax

**WinPos(*X*, *Y*)**

*X*, *Y*:

The new x and y pixel coordinates of the top-left corner of the active window.

If the window is a pinned window, the new coordinates will specify a location for the window that is based on the unscaled version of the page that hosts it.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[WinSize](#), [WinMove](#), [PageInfo](#)

## Example

```
WinPos(100,50);
/* Moves the top-left corner of the active window to the pixel coordinate 100,50. */
```

## See Also

[Window Functions](#)

## WinPrev

Makes the previous window (in order of creation) active.

## Syntax

**WinPrev()**

## Return Value

The window number of the window, or -1 if there is no next window. Be aware that this is not the same as the window handle returned from the WndFind() function.

## Related Functions

[WinNext](#)

## Example

```
! If the display window being made active is window number 2:  
Window=WinPrev();  
! Makes the previous window active and sets Window to 2.
```

## See Also

[Window Functions](#)

## WinPrint

Sends the graphics image of the active window to a printer.

This function is a blocking function. It blocks the calling Cicode task until the operation is complete.

### Note:

- This function might not work as expected if called directly from the Kernel; instead, this function should be called from a graphics page.
- This function is not supported in the server process in a multiprocessor environment. Calling this function from the server process results in a hardware alarm being raised.

## Syntax

**WinPrint(*sPort* [, *xScale*] [, *yScale*] [, *bSwapBlackWhite*] [, *sMap*] )**

*sPort*:

The name of the printer port to which the window will be printed. This name needs to be enclosed within quotation marks "". For example "LPT1:", to print to the local printer, or "\\Pserver\canon1" using UNC to print to a network printer. *sPort* may not contain spaces.

*xScale*:

The x scaling factor for the print. The default value of 0 (zero) automatically scales the print to fit the page. A value of 1 is used to maintain the current horizontal scaling of the image. The outcome is proportional to 1; for example, 0.5 halves the width of the image (optional).

*yScale*:

The y scaling factor for the print. The default value of 0 (zero) automatically scales the print to fit the page. A value of 1 is used to maintain the current horizontal scaling of the image. The outcome is proportional to 1; for example, 0.5 halves the width of the image (optional).

*bSwapBlackWhite*:

Swaps the colors black and white for the purpose of printing pages with a lot of black content. Use the default value of 1 to swap black and white (optional).

*sMap*:

The file name or path of a text based map file used to specify colors to swap when printing. By default Plant SCADA will look in the bin directory for the map file. The format for the map file is:

RRR GGG BBB RRR GGG BBB [HHH] [SSS] [LLL]//  
RRR GGG BBB RRR GGG BBB [HHH] [SSS] [LLL]//

Where:

*RRR* is a decimal red intensity value between 000 and 255.

*GGG* is a decimal green intensity value between 000 to 255.

*BBB* is a decimal blue intensity value between 000 to 255.

*HHH*, *SSS* and *LLL* are optional tolerance values to enable swapping a range of colors. Default values are shown below.

*HHH* is a decimal value representing the Hue tolerance. Valid range is 0 to 360. Default = 0.

*SSS* is a decimal value representing the Saturation tolerance. Valid range is 0 to 255. Default = 2 \* Hue tolerance.

*LLL* is a decimal value representing the Luminance tolerance. Valid range is 0 to 255. Default = 2 \* Hue tolerance.

Leading zeros are not required, however they aid readability.

The first three RGB values specify the FROM color, and the second three RGB values specify the TO color. The tolerance values are applied to the FROM color when replacing individual pixels in the image.

Comments may be placed at the end of each line, or on individual lines, and needs to be proceeded with // or !.

Example map file:

```
043 043 255 155 205 255 025 000 025
//Change dark blue to light blue using Hue and Luminance tolerance of 25.
000 000 000 255 255 255 //Swap black to white with no tolerance
```

**Note:** If swap color ranges overlap, the behavior is undefined (i.e. a color that falls in both ranges may end up as either color).

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[WinPrintFile](#)

## Example

```
WinPrint("LPT3:",0,0,0);
! Prints the active window on printer "LPT3". The print will be
scaled to fit the largest possible page area and will retain the
orientation of the printer, aspect ratio and colors that are
displayed on screen.
WinPrint("LPT3:");
!Prints the page as in the first example, but swaps black and
white on the printout.
```

[Window Functions](#)

## WinPrintFile

Prints a file to the system printer. The file needs to be saved with the WinFile() function.

---

**Note:** This function might not work as expected if called directly from the Kernel; if the WinFile function does not succeed, WinPrintFile either doesn't print anything or prints a previously saved page. This function should be called from a graphics page.

---

## Syntax

**WinPrintFile(*sFile*, *sPort* [, *xScale*] [, *yScale*] [, *bSwapBlackWhite*] [, *fromColor*] [, *toColor*] )**

*sFile*:

The file name.

*sPort*:

The name of the printer port to which the window will be printed. This name needs to be enclosed within quotation marks "". For example "LPT1:", to print to the local printer, or "\\Pserver\canon1" using UNC to print to a network printer. *sPort* may not contain spaces

*xScale*:

The x scaling factor for the print. The default value of 0 (zero) automatically scales the print to fit the page. A value of 1 is used to maintain the current horizontal scaling of the image. The outcome is proportional to 1; for example, 0.5 halves the width of the image (optional).

*yScale*:

The y scaling factor for the print. The default value 0 (zero) automatically scales the print to fit the page. A value of 1 is used to maintain the current horizontal scaling of the image. The outcome is proportional to 1; for example, 0.5 halves the width of the image (optional).

*bSwapBlackWhite*:

Swaps the colors black and white for the purpose of printing pages with a lot of black content. Use the default value of 1 to swap black and white (optional).

*fromColor*

The hex RGB color value (0xRRGGBB) to change into *toColor*. The default value of -1 results in no color change (optional).

*toColor*

The hex RGB color value (0xRRGGBB) into which *fromColor* is changed. The default value of -1 results in no color change (optional).

---

**Note:** To change a color, a value needs to be specified for both *fromColor* and *toColor*.

---

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[WinPrint](#)

## Example

```
! Save image to disk then print.
```

```
WinFile("temp");
WinPrintFile("temp", "LPT3:",0,0,0);
! Prints the file "temp" on printer "LPT3". The print will be
scaled to fit the largest possible page area and will retain the
orientation of the printer, aspect ratio and colors that are
displayed on screen.
WinPrintFile("temp","LPT3:");
! Prints the page as in the first example, but swaps black and
white on the printout.
WinPrintFile("temp","LPT3:",0,0,0,0x00FF00,0xFF0000);
! Changes green to red.
WinPrintFile("temp","LPT3:",0,0,1,0x00FF00,0xFF0000);
! Changes green to red and black to white.
```

[Window Functions](#)

### WinSelect

Selects a window to make active. This function only affects the output of Cicode functions. It does not change the screen focus of the windows, or move a background window to the foreground.

Always re-select the original window if it is called from a Page database (Page Numbers, Page Symbols, and so on), because other Cicode tasks will assume it is the correct window. This function only changes the active window for the Cicode task that called it.

---

**Note:** This function is not supported in the server process in a multiprocessor environment. Calling this function from the server process results in a hardware alarm being raised.

---

## Syntax

**WinSelect(*Window*)**

*Window*:

The window number to select. Be aware that this is not the same as the window handle returned from the WndFind() function.

## Return Value

The old window number.

## Related Functions

[WinGoto](#), [WinNumber](#)

## Example

```
OldWindow=WinSelect(1);
! Selects window number 1.
```

```
Prompt("Message to Window 1");
! Sends message to window number 1.
WinSelect(2);
! Selects window number 2.
Prompt("Message to Window 2");
! Sends message to window number 2.
WinSelect(OldWindow);
! Selects original window.
```

### WinSetName

Associates a name with a particular window by its window number. An association with a window is removed when the window is free.

## Syntax

**WinSetName**(*sName* [, *iWinNum*] )

*sName*:

String name to associate with window number *iWinNum*.

*iWinNum*:

An optional parameter which specifies the window number with which to associate Name. If no number is specified the name is associated with the currently selected window number.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[WinNumber](#)

## See Also

[Window Functions](#)

### WinSize

Sizes the active window. The origin of the window does not move.

**Note:** This function is not supported in the server process in a multiprocessor environment. Calling this function from the server process results in a hardware alarm being raised.

## Syntax

**WinSize(Width, Height, Mode)**

*Width, Height:*

The new width and height of the window, in pixels.

If the target is a pinned window, the new width and height will be measured against the original window size as it is on the unscaled version of the page that hosts it.

*Mode:*

Specifies if the size refers to the viewable area or the total window.

0 - the size to refer to the viewable area.

1 - the size to refer to the total window size.

Default - 1

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[WinMove](#), [WinPos](#)

## Example

```
WinSize(200,100);
! Sizes the active window to 200 pixels wide x 100 pixels high.
```

## See Also

[Window Functions](#)

## WinStyle

Switches on and off scrolling and scrollbar features for existing windows.

## Syntax

**WinStyle(Style, Mode)**

*Style:*

One of the following:

- 1 - Hide horizontal scroll bars.
- 2 - Hide vertical scroll bars.
- 3 - Disable horizontal scrolling.
- 4 - Disable vertical scrolling.

**Mode:**

The mode of the option:

0 - Turn option off.

1 - Turn option on.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[WinNewAt](#)

## Example

To turn horizontal and vertical scroll bars off for the current window:

```
WinStyle(1, 1);  
WinStyle(2, 1);
```

[Window Functions](#)

## WinTitle

Sets the title of the active window.

If a window title has been set with the [\[Page\]WinTitle](#) parameter, Plant SCADA uses this title when it refreshes the page (overriding the window title set with the WinTitle() function). To minimize the likelihood of Plant SCADA from overriding the title, set the parameter [\[Page\]WinTitle](#) to \*.
