---

**Note:** This function does not work with pinned windows.

---

## Syntax

**WinTitle(*sTitle*)**

*sTitle*:

The new title for the window.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[WinNew](#), [GetWinTitle](#)

## Example

```
WinTitle(Time()+" "+Date());  
! Places the current time and date into the window title.
```

## See Also

[Window Functions](#)

## WndFind

Gets the Windows handle of any window of any application, so that the window can be manipulated. The window handle is not the same as the Plant SCADA window number and cannot be used with functions that expect the Plant SCADA window number (the *Win...* functions).

The window title (caption) needs to be an exact match of the window name (including any blank spaces) for this function to find the window. You should therefore check that the other application does not change the title of the window during execution.

Be aware that if the title banner of a Plant SCADA window is set with the Plant SCADA parameter [\[Page\]WinTitle](#), you should not specify justification (for example, use {TITLE,32,N}). If justification is not disabled (that is the N is omitted), you need to pass the full title of the window (including leading and trailing blanks) to this function.

## Syntax

**WndFind(*sTitle*)**

*sTitle*

The title (caption) of the window.

## Return Value

The window handle. Be aware that this is not the same as a Plant SCADA window number returned from the WinNumber() function.

## Related Functions

[WinNew](#)

## Example

```
hWndExcel=WndFind("Microsoft Excel - Book1");  
! Gets the Windows number of the window titled "Microsoft Excel -  
Book1"
```

## See Also

[Window Functions](#)

## WndGetFileProfile

Gets a profile string from any .ini file.

## Syntax

**WndGetFileProfile(*sGroup*, *sName*, *sDefault*, *sFile*)**

*sGroup*:

The name of the [group].

*sName*:

The name of the variable.

*sDefault*:

The default value.

*sFile*:

The .ini file name.

## Return Value

The profile string from *sFile*.

## Related Functions

[WndPutFileProfile](#)

## Example

```
! get this user startup page from USER.INI File
sStartup =
WndGetFileProfile(Name(), "Startup", "menu", "[Run]:\USER.INI");
PageDisplay(sStartup);
```

## See Also

[Window Functions](#)

## WndInfo

Gets information on the window system (such as the width and height of the various elements displayed by Windows). WndInfo() can also return flags that indicate whether the current version of the Windows operating system is a debugging version, whether a mouse is present, or whether the functions of the left and right mouse buttons have been exchanged.

## Syntax

**WndInfo(*iType*)**

*iType*:

The system measurement to be retrieved. Measurements are in pixels. The system measurement needs to be one of the following values:

0 - Width of the screen.

1 - Height of the screen.

2 - Width of the arrow bitmap on a vertical scroll bar.

3 - Height of the arrow bitmap on a horizontal scroll bar.

4 - Height of the window title. This is the title height plus the height of the window frame that cannot be sized (SM\_CYBORDER).

5 - Width of the window frame that cannot be sized.

6 - Height of the window frame that cannot be sized.

7 - Width of the frame when the window has the WS\_DLFRAME style.

8 - Height of the frame when the window has the WS\_DLFRAME style.

9 - Height of the scroll box on vertical scroll bar.

10 - Width of the scroll box (thumb) on horizontal scroll bar.

12 - Height of the icon.

13 - Width of the cursor.

14 - Height of the cursor.

15 - Height of a single-line menu bar. This is the menu height minus the height of the window frame that cannot be sized (SM\_CYBORDER).

16 - Width of the window client area for a fullscreen window.

17 - Height of the window client area for a fullscreen window (equivalent to the height of the screen minus the height of the window title).

18 - Height of a Kanji window.

19 - Non-zero if the mouse hardware is installed.

20 - Height of arrow bitmap on a vertical scroll bar.

21 - Width of arrow bitmap on a horizontal scroll bar.

22 - Non-zero if the Windows version is a debugging version.

23 - Non-zero if the left and right mouse buttons are swapped.

24-27 - Not Used

28 - Minimum width of the window.

29 - Minimum height of the window.

30 - Width of bitmaps contained in the title bar.

31 - Height of bitmaps contained in the title bar.

32 - Width of the window frame that can be sized.

33 - Height of the window frame that can be sized.

34 - Minimum tracking width of the window.

- 35 - Minimum tracking height of the window.
- 76 - x co-ordinate of upper left corner of virtual screen
- 77 - y co-ordinate of upper left corner of virtual screen
- 78 - width of virtual screen
- 79 - height of virtual screen
- 80 - number of monitors available

## Return Value

The system metric information.

## Example

```
width = WndInfo(0); ! get width of screen
height = WndInfo(1); ! get height of screen
WinPos(width/2, height/2); ! move window to centre of screen
monitors = WndInfo(80); ! get number of monitors available
```

## See Also

[Window Functions](#)

## WndMonitorInfo

Returns information about a particular monitor.

## Syntax

**WndMonitorInfo(*iMonitor*, *iType*)**

*iMonitor*:

Monitor Number 1 to n, where n is the number of monitors returned from WndInfo(80). Using 0 will return the value for the virtual screen. Using an unsupported monitor number (0 or n) will return -1 for all values.

*iType*:

Type The monitor measurement to be retrieved:

0 - x co-ordinate of upper left corner of monitor.

1 - y co-ordinate of upper left corner of monitor.

2 - width of monitor.

3 - height of monitor.

4 - x co-ordinate of upper left corner of monitor working area.

5 - y co-ordinate of upper left corner of monitor working area.

6 - width of monitor working area.

7 - height of monitor working area.

## Return Value

Requested information about the selected monitor.

## See Also

[Window Functions](#)

### WndMonitorInfoEx

Returns information about a particular monitor using the screen name of the screen profile.

## Syntax

**WndMonitorInfoEx(*sMonitor*, *iType*)**

*sMonitor*:

Screen profile's screen name.

*iType*:

Type The monitor measurement to be retrieved:

0 - x co-ordinate of upper left corner of monitor.

1 - y co-ordinate of upper left corner of monitor.

2 - width of monitor.

3 - height of monitor.

4 - x co-ordinate of upper left corner of monitor working area.

5 - y co-ordinate of upper left corner of monitor working area.

6 - width of monitor working area.

7 - height of monitor working area.

## Return Value

Requested information about the selected monitor.

## See Also

[Window Functions](#)

### WndPutFileProfile

Puts a profile string into any .INI file.

## Syntax

**WndPutFileProfile(*sGroup*, *sName*, *sData*, *sFile*)**

*sGroup*:

The name of the [group].

*sName*:

The name of the variable.

*sData*:

The variable data.

*sFile*:

The .INI file name.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[WndGetFileProfile](#)

## Example

```
WndPutFileProfile(Name(), "What", "100", "USER.INI");
```

## See Also

[Window Functions](#)

## WndShow

Sets the display mode of any window of any application.

---

**Note:** This function does not work with pinned windows.

---

## Syntax

**WndShow(*hWnd*, *nMode*)**

*hWnd*:

The Windows handle of the window (returned from the WndFind() function). Be aware that this is not the same as a Plant SCADA window number returned from the WinNumber() function.

*nMode*:

The window mode:

0 - Hide the window.

- 1 - Activate the window in normal mode.
- 2 - Activate the window in an iconized state.
- 3 - Activate the window in a maximized state.
- 4 - Display the window in its previous state without activating it.
- 5 - Activate the window in its current state.
- 6 - Iconize the window.
- 7 - Display the window in an iconized state without activating it.
- 8 - Display the window in its current state without activating it.
- 9 - Activate the window in its previous state.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[WndFind](#)

## Example

```
WndShow(WndFind("Microsoft Excel"), 0);
! Hides the "Microsoft Excel" window.
```

## XML Functions

Following are functions related to XML:

<a href="#">XMLClose</a>	Deletes an XML document in memory.
<a href="#">XMLCreate</a>	Creates a new XML document in memory.
<a href="#">XMLGetAttribute</a>	Retrieves the attribute value of the node from an XML document in memory.
<a href="#">XMLGetAttributeCount</a>	Retrieves the number of attributes (properties of a node. Each attribute has a name and a value) within an XML document in memory.
<a href="#">XMLGetAttributeName</a>	Retrieves the name of an attribute (property of a node. Each attribute has a name and a value) within an XML document in memory.

<a href="#">XMLGetAttributeValue</a>	Retrieves the value of an attribute (property of a node. Each attribute has a name and a value) within an XML document in memory.
<a href="#">XMLGetChild</a>	Retrieves the child node for the specified parent node in XML document in memory.
<a href="#">XMLGetChildCount</a>	Retrieves the total number of child nodes for the specified parent node in an XML document in memory.
<a href="#">XMLGetParent</a>	Retrieves the parent node within the contents of an XML document in memory.
<a href="#">XMLGetRoot</a>	Retrieves the root node of an XML document in memory
<a href="#">XMLNodeAddChild</a>	Creates an element node with the specified Name and Namespace and appends the node to the end of the list of child nodes of specified parent node in the XML document.
<a href="#">XMLNodeFind</a>	Selects a single node from the contents of an XML document in memory.
<a href="#">XMLNodeGetName</a>	Retrieves the name of the specified node.
<a href="#">XMLNodeGetValue</a>	Retrieves the value of a node from the contents of an XML document in memory.
<a href="#">XMLNodeRemove</a>	Removes specified XML node from its parent and XML document.
<a href="#">XMLNodeSetValue</a>	Sets the value of the specified node.
<a href="#">XMLOpen</a>	Loads an XML file from disk.
<a href="#">XMLSave</a>	Saves an XML file to disk.
<a href="#">XMLSetAttribute</a>	Sets the value of specified attribute of the node in the XML document. If the attribute does not exist, it will be created.

## See Also

[Cicode Function Categories](#)[Using Cicode Functions](#)

## XMLClose

Use this function to delete an XML document in memory.

## Syntax

```
INT XMLClose(INT hDoc)
```

*hDoc*

Handle of the XML document. Returned by [XMLCreate](#) or [XMLOpen](#).

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[XMLCreate](#), [XMLGetAttribute](#), [XMLGetAttributeCount](#), [XMLGetAttributeName](#), [XMLGetAttributeValue](#),  
[XMLGetChild](#), [XMLGetChildCount](#), [XMLGetParent](#), [XMLGetRoot](#), [XMLNodeAddChild](#), [XMLNodeFind](#),  
[XMLNodeGetName](#), [XMLNodeGetValue](#), [XMLNodeRemove](#), [XMLNodeSetValue](#), [XMLOpen](#), [XMLSave](#),  
[XMLSetAttribute](#)

## Example

Following example creates an empty XML document and sets root element to shapes and namespace of root element to "http://mycompany.com/shapes/v1", then destroys the XML document.

```
INT hDoc=XMLCreate("shapes","http://mycompany.com/shapes/v1");  
XMLClose(hDoc);
```

## See Also

[XML Functions](#)

## XMLCreate

Use this function to create a new XML document in memory.

## Syntax

```
INT XMLCreate(STRING sRootElement, STRING sNamespace = "")
```

*sRootElement*:

Root element of the XML document.

*sNamespace*:

Optional. Namespace URI of root element.

## Return Value

Handle of XML document, or returns -1 on error

## Related Functions

[XMLClose](#), [XMLGetAttribute](#), [XMLGetAttributeCount](#), [XMLGetAttributeName](#), [XMLGetAttributeValue](#),  
[XMLGetChild](#), [XMLGetChildCount](#), [XMLGetParent](#), [XMLGetRoot](#), [XMLNodeAddChild](#), [XMLNodeFind](#),  
[XMLNodeGetName](#), [XMLNodeGetValue](#), [XMLNodeRemove](#), [XMLNodeSetValue](#), [XMLOpen](#), [XMLSave](#),  
[XMLSetAttribute](#)

## Example

Following example creates an empty XML document and sets root element to shapes and namespace of root element to "http://mycompany.com/shapes/v1".

```
INT hDoc=XMLCreate("shapes","http://mycompany.com/shapes/v1");
```

## See Also

[XML Functions](#)

## XMLGetAttribute

Retrieves the attribute value of the node from an XML document in memory.

## Syntax

```
INT XMLGetAttribute(INT hDoc, INT hNode, STRING sAttributeName)
```

*hDoc*

Handle of the XML document. Returned by [XMLCreate](#) or [XMLOpen](#).

*hNode*

Handle of the node. Returned by [XMLGetRoot](#), [XMLGetChild](#), [XMLGetParent](#) or [XMLNodeFind](#).

*sAttributeName*

Name of attribute.

## Return Value

Value of specified node's attribute

## Related Functions

[XMLClose](#), [XMLCreate](#), [XMLGetAttributeCount](#), [XMLGetAttributeName](#), [XMLGetAttributeValue](#), [XMLGetChild](#),  
[XMLGetChildCount](#), [XMLGetParent](#), [XMLGetRoot](#), [XMLNodeAddChild](#), [XMLNodeFind](#), [XMLNodeGetName](#),  
[XMLNodeGetValue](#), [XMLNodeRemove](#), [XMLNodeSetValue](#), [XMLOpen](#), [XMLSave](#), [XMLSetAttribute](#)

## Example

Following example creates an XML document from local file "H:\Data\books.xml", then selects the first node that matches XPath expression "/bookstore/book/", then gets value of the node's attribute "Language".

```
INT hDoc, hNode;
STRING sValue;
hDoc=XMLOpen("H:\Data\books.xml");
IF hDoc <> -1 THEN
    hNode = XMLNodeFind(hDoc, "/bookstore/book/");
    IF hDoc <> -1 THEN
        sValue=XMLGetAttribute(hDoc,hNode,"Language");
    End
End
```

## See Also

[XML Functions](#)

### XMLGetAttributeCount

Gets number of attribute of specified XML node.

## Syntax

INT **XMLGetAttributeCount**(INT *hDoc*, INT *hNode*)

*hDoc*

Handle of the XML document. Returned by or [XMLOpen](#).

*hNode*

Handle of the node. Returned by [XMLGetRoot](#), [XMLGetChild](#), [XMLGetParent](#) or [XMLNodeFind](#).

## Return Value

Number of attribute of specified node.

## Related Functions

[XMLClose](#), [XMLCreate](#), [XMLGetAttribute](#), [XMLGetAttributeName](#), [XMLGetAttributeValue](#), [XMLGetChild](#),  
[XMLGetChildCount](#), [XMLGetParent](#), [XMLGetRoot](#), [XMLNodeAddChild](#), [XMLNodeFind](#), [XMLNodeGetName](#),  
[XMLNodeGetValue](#), [XMLNodeRemove](#), [XMLNodeSetValue](#), [XMLOpen](#), [XMLSave](#), [XMLSetAttribute](#)

## Example

Following example creates an XML document from local file "H:\Data\books.xml", then selects the first node that matches XPath expression "/bookstore/book/", then gets number of attribute of the node.

```
INT hDoc, hNode;
INT nCount;
```

```
hDoc=XMLOpen("H:\Data\books.xml");
IF hDoc <> -1 THEN
    hNode = XMLNodeFind(hDoc, "/bookstore/book/");
    IF hDoc <> -1 THEN
        nCount=XMLGetAttributeCount(hDoc, hNode);
    End
End
```

## See Also

[XML Functions](#)

### XMLGetAttributeName

Gets name of specified XML Node's attribute by using attribute index.

## Syntax

STRING **XMLGetAttributeName**(INT *hDoc*, INT *hNode*, INT *iAttribute*)

*hDoc*

Handle of the XML document. Returned by [XMLCreate](#) or [XMLOpen](#).

*hNode*

Handle of the node. Returned by [XMLGetRoot](#), [XMLGetChild](#), [XMLGetParent](#) or [XMLNodeFind](#).

*iAttribute*

The attribute index.

## Return Value

Name of specified node's attribute

## Related Functions

[XMLClose](#), [XMLCreate](#), [XMLGetAttribute](#), [XMLGetAttributeCount](#), [XMLGetAttributeValue](#), [XMLGetChild](#),  
[XMLGetChildCount](#), [XMLGetParent](#), [XMLGetRoot](#), [XMLNodeAddChild](#), [XMLNodeFind](#), [XMLNodeGetName](#),  
[XMLNodeGetValue](#), [XMLNodeRemove](#), [XMLNodeSetValue](#), [XMLOpen](#), [XMLSave](#), [XMLSetAttribute](#)

## Example

Following example creates an XML document from local file "H:\Data\books.xml", then selects the first node that matches XPath expression "/bookstore/book/", then gets name of the first attribute of the node.

```
INT hDoc, hNode;
STRING sName;
hDoc=XMLOpen("H:\Data\books.xml");
IF hDoc <> -1 THEN
    hNode = XMLNodeFind(hDoc, "/bookstore/book/");
    IF hNode <> -1 THEN
```

```
sName=XMLGetAttributeName(hDoc,hNode,0);
End
End
```

## See Also

[XML Functions](#)

### XMLGetAttributeValue

Gets the value of the specified XML node's attribute by using attribute index.

## Syntax

```
STRING XMLGetAttributeValue(INT hDoc, INT hNode, INT iAttribute)
```

*hDoc*

Handle of the XML document. Returned by [XMLCreate](#) or [XMLOpen](#).

*hNode*

Handle of the node. Returned by [XMLGetRoot](#), [XMLGetChild](#), [XMLGetParent](#) or [XMLNodeFind](#).

*iAttribute*

The attribute index.

## Return Value

Value of specified node's attribute.

## Related Functions

[XMLClose](#), [XMLCreate](#), [XMLGetAttribute](#), [XMLGetAttributeCount](#), [XMLGetAttributeName](#), [XMLGetChild](#),  
[XMLGetChildCount](#), [XMLGetParent](#), [XMLGetRoot](#), [XMLNodeAddChild](#), [XMLNodeFind](#), [XMLNodeGetName](#),  
[XMLNodeGetValue](#), [XMLNodeRemove](#), [XMLNodeSetValue](#), [XMLOpen](#), [XMLSave](#), [XMLSetAttribute](#)

## Example

Following example creates an XML document from local file "H:\Data\books.xml", then selects the first node that matches XPath expression "/bookstore/book/", then gets value of the first attribute of the node.

```
INT hDoc, hNode;
STRING sValue;
hDoc=XMLOpen("H:\Data\books.xml");
IF hDoc <> -1 THEN
    hNode = XMLNodeFind(hDoc,"/bookstore/book/");
    IF hNode <> -1 THEN
        sValue=XMLGetAttributeValue(hDoc,hNode,0);
    End
End
```

## See Also

[XML Functions](#)

### XMLGetChild

Retrieves the child node for the specified parent node in XML document in memory.

## Syntax

`INT XMLGetChild(INT hDoc, INT hNode, INT iChild)`

*hDoc*

Handle of the XML document the parent node belongs to. Returned by [XMLCreate](#) or [XMLOpen](#).

*hNode*

Handle of the parent node. Returned by [XMLGetRoot](#), [XMLGetChild](#), [XMLGetParent](#) or [XMLNodeFind](#).

*iChild*

The child index.

## Return Value

Handle of child node, or -1 on error

## Related Functions

[XMLClose](#), [XMLCreate](#), [XMLGetAttribute](#), [XMLGetAttributeCount](#), [XMLGetAttributeName](#), [XMLGetAttributeValue](#),  
[XMLGetChildCount](#), [XMLGetParent](#), [XMLGetRoot](#), [XMLNodeAddChild](#), [XMLNodeFind](#), [XMLNodeGetName](#),  
[XMLNodeGetValue](#), [XMLNodeRemove](#), [XMLNodeSetValue](#), [XMLOpen](#), [XMLSave](#), [XMLSetAttribute](#)

## Example

Following example creates an XML document from local file "H:\Data\books.xml", then gets the root node, then gets the first child node of the root node.

```
INT hDoc, hRoot, hChild;  
hDoc = XMLOpen("H:\Data\books.xml");  
IF hDoc <> -1 THEN  
    hRoot = XMLGetRoot(hDoc);  
    IF hRoot <> -1 THEN  
        hChild = XMLGetChild(hDoc,hRoot,0);  
    End  
End
```

## See Also

[XML Functions](#)

## XMLGetChildCount

Retrieves the total number of child nodes for the specified parent node in an XML document in memory.

## Syntax

```
INT XMLGetChildCount(INT hDoc, INT hNode)
```

*hDoc*

Handle of the XML document the parent node belongs to. Returned by [XMLCreate](#) or [XMLOpen](#).

*hNode*

Handle of the parent node. Returned by [XMLGetRoot](#), [XMLGetChild](#), [XMLGetParent](#) or [XMLNodeFind](#).

## Return Value

Number of child nodes, or -1 on error

## Related Functions

[XMLClose](#), [XMLCreate](#), [XMLGetAttribute](#), [XMLGetAttributeCount](#), [XMLGetAttributeName](#), [XMLGetAttributeValue](#),  
[XMLGetChild](#), [XMLGetParent](#), [XMLGetRoot](#), [XMLNodeAddChild](#), [XMLNodeFind](#), [XMLNodeGetName](#),  
[XMLNodeGetValue](#), [XMLNodeRemove](#), [XMLNodeSetValue](#), [XMLOpen](#), [XMLSave](#), [XMLSetAttribute](#)

## Example

Following example creates an XML document from local file "H:\Data\books.xml", then selects the first node that matches XPath expression "/bookstore/book/", then gets the number of children of the node.

```
INT hDoc, hNode;
INT nCount;
hDoc=XMLOpen("H:\Data\books.xml");
IF hDoc <> -1 THEN
    hNode = XMLNodeFind(hDoc, "/bookstore/book/");
    IF hDoc <> -1 THEN
        nCount=XMLGetChildCount(hDoc,hNode);
    End
End
```

## See Also

[XML Functions](#)

## XMLGetParent

Gets the parent of specified node. If specified node is the root node in the tree, the parent is the document node.

## Syntax

```
INT XMLGetParent(INT hDoc, INT hNode)
```

*hDoc*

Handle of the XML document. Returned by [XMLCreate](#) or [XMLOpen](#).

*hNode*

Handle of the node. Returned by [XMLGetRoot](#), [XMLGetChild](#), [XMLGetParent](#) or [XMLNodeFind](#).

## Return Value

Handle of parent node, or error will be returned.

## Related Functions

[XMLClose](#), [XMLCreate](#), [XMLGetAttribute](#), [XMLGetAttributeCount](#), [XMLGetAttributeName](#), [XMLGetAttributeValue](#),  
[XMLGetChild](#), [XMLGetChildCount](#), [XMLGetRoot](#), [XMLNodeAddChild](#), [XMLNodeFind](#), [XMLNodeGetName](#),  
[XMLNodeGetValue](#), [XMLNodeRemove](#), [XMLNodeSetValue](#), [XMLOpen](#), [XMLSave](#), [XMLSetAttribute](#)

## Example

Following example creates an XML document from local file "H:\Data\books.xml", then selects the first node that matches XPath expression "/bookstore/book/", then gets the parent of the node.

```
INT hDoc, hNode, hParent;  
hDoc=XMLOpen("H:\Data\books.xml");  
If hDoc <> -1 THEN  
    hNode=XMLNodeFind(hDoc, "/bookstore/book/");  
    IF hNode <> -1 THEN  
        hParent=XMLGetParent(hDoc, hNode);  
    End  
End
```

## See Also

[XML Functions](#)

## [XMLGetRoot](#)

Gets the root element of the specified XML document.

## Syntax

```
INT XMLGetRoot(INT hDoc)
```

*hDoc*

Handle of the XML document. Returned by [XMLCreate](#) or [XMLOpen](#).

## Return Value

Handle of root element, or -1 on error.

## Related Functions

[XMLClose](#), [XMLCreate](#), [XMLGetAttribute](#), [XMLGetAttributeCount](#), [XMLGetAttributeName](#), [XMLGetAttributeValue](#),  
[XMLGetChild](#), [XMLGetChildCount](#), [XMLGetParent](#), [XMLNodeAddChild](#), [XMLNodeFind](#), [XMLNodeGetName](#),  
[XMLNodeGetValue](#), [XMLNodeRemove](#), [XMLNodeSetValue](#), [XMLOpen](#), [XMLSave](#), [XMLSetAttribute](#)

## Example

Following example creates an XML document from local file "H:\Data\books.xml", then gets the root element.

```
INT hDoc, hRoot;  
hDoc=XMLOpen( "H:\Data\books.xml" );  
If hDoc <> -1 THEN  
    hRoot=XMLGetRoot(hDoc);  
End
```

## See Also

[XML Functions](#)

### XMLNodeAddChild

Creates an element node with the specified Name and Namespace and appends the node to the end of the list of child nodes of specified parent node in the XML document.

## Syntax

INT **XMLNodeAddChild**(INT *hDoc*, INT *hNode*, STRING *sName*[, STRING *sNamespace* = "" ])

*hDoc*

Handle of the XML document the parent node belongs to. Returned by [XMLCreate](#) or [XMLOpen](#).

*hNode*

Handle of the parent node.e.g. <shapes>, <polygons>, <polygon>. Returned by [XMLGetRoot](#), [XMLGetChild](#), [XMLGetParent](#) or [XMLNodeFind](#).

*sName*

The qualified name of the new element node.

*sNamespace*

Optional parameter. The namespace URI of the new node. For example, <shapes xmlns="http://mycompany.com/shapes/v1">.

## Return Value

Handle of the newly created node, or -1 on error.

## Related Functions

[XMLClose](#), [XMLCreate](#), [XMLGetAttribute](#), [XMLGetAttributeCount](#), [XMLGetAttributeName](#), [XMLGetAttributeValue](#),  
[XMLGetChild](#), [XMLGetChildCount](#), [XMLGetParent](#), [XMLGetRoot](#), [XMLNodeFind](#), [XMLNodeGetName](#),  
[XMLNodeGetValue](#), [XMLNodeRemove](#), [XMLNodeSetValue](#), [XMLOpen](#), [XMLSave](#), [XMLSetAttribute](#)

## Example

The example adds a new element node to the root of XML document and then adds two new element nodes to the first created node.

```
INT hDoc, hRoot, hNode;
hDoc = XMLCreate("shapes", "http://mycompany.com/shapes/v1");
IF hDoc <> -1 THEN
    hRoot = XMLGetRoot(hDoc);
    IF hRoot <> -1 THEN
        hNode = XMLNodeAddChild(hDoc, hRoot, "polygons");
        IF hNode <> -1 THEN
            XMLNodeAddChild(hDoc, hNode, "polygon");
            XMLNodeAddChild(hDoc, hNode, "polygon");
        END
    END
END
```

The xml document created by the code above:

```
<?xml version="1.0" encoding="utf-8" ?>
<shapes xmlns="http://mycompany.com/shapes/v1">
<polygons>
<polygon/>
<polygon/>
</polygons>
</shapes>
```

## See Also

[XML Functions](#)

## XMLNodeFind

Use this function to select the first XML node that matches the XPath expression.

## Syntax

**INT XMLNodeFind(INT *hDoc*, STRING *sQuery*)**

*hDoc*

Handle of the XML document. Returned by [XMLCreate](#) or [XMLOpen](#).

*sQuery*

XPath Expression

## Return Value

Handle of the first XML node that matches the XPath expression, or BAD HANDLE on error.

## Related Functions

[XMLClose](#), [XMLCreate](#), [XMLGetAttribute](#), [XMLGetAttributeCount](#), [XMLGetAttributeName](#), [XMLGetAttributeValue](#),  
[XMLGetChild](#), [XMLGetChildCount](#), [XMLGetParent](#), [XMLGetRoot](#), [XMLNodeAddChild](#), [XMLNodeGetName](#),  
[XMLNodeGetValue](#), [XMLNodeRemove](#), [XMLNodeSetValue](#), [XMLOpen](#), [XMLSave](#), [XMLSetAttribute](#)

## Example

Following example creates an XML document from local file "H:\Data\books.xml", then selects the first node that matches XPath expression "/bookstore/book/"

```
INT hDoc, hNode;  
hDoc=XMLOpen("H:\data\books.xml");  
IF hDoc <> -1 THEN  
    hNode=XMLNodeFind(hDoc,"/bookstore/book/");  
End
```

## See Also

[XML Functions](#)

## XMLNodeGetName

Gets the name of the specified node.

## Syntax

STRING **XMLNodeGetName**(INT *hDoc*, INT *hNode*)

*hDoc*

Handle of the XML document. Returned by [XMLCreate](#) or [XMLOpen](#).

*hNode*

Handle of the node. Returned by [XMLGetRoot](#), [XMLGetChild](#), [XMLGetParent](#) or [XMLNodeFind](#).

## Return Value

Name of specified node.

## Related Functions

[XMLClose](#), [XMLCreate](#), [XMLGetAttribute](#), [XMLGetAttributeCount](#), [XMLGetAttributeName](#), [XMLGetAttributeValue](#),  
[XMLGetChild](#), [XMLGetChildCount](#), [XMLGetParent](#), [XMLGetRoot](#), [XMLNodeAddChild](#), [XMLNodeFind](#),  
[XMLNodeGetValue](#), [XMLNodeRemove](#), [XMLNodeSetValue](#), [XMLOpen](#), [XMLSave](#), [XMLSetAttribute](#)

## Example

Following example creates an XML document from local file "H:\Data\books.xml", then selects the first node that matches XPath expression "/bookstore/book/", then gets the name of the node.

```
INT hDoc, hNode;
STRING sName;
hDoc=XMLOpen("H:\Data\books.xml");
IF hDoc <> -1 THEN
    hNode = XMLNodeFind(hDoc, "/bookstore/book/");
    IF hDoc <> -1 THEN
        sName=XMLNodeGetName(hDoc, hNode);
    End
End
```

## See Also

[XML Functions](#)

### XMLNodeGetValue

Gets the value of the specified node.

## Syntax

STRING **XMLNodeGetValue**(INT *hDoc*, INT *hNode*)

*hDoc*

Handle of the XML document. Returned by [XMLCreate](#) or [XMLOpen](#).

*hNode*

Handle of the node. Returned by [XMLGetRoot](#), [XMLGetChild](#), [XMLGetParent](#) or [XMLNodeFind](#).

## Return Value

Value of specified node

## Related Functions

[XMLGetChild](#), [XMLGetChildCount](#), [XMLGetParent](#), [XMLGetRoot](#), [XMLNodeAddChild](#), [XMLNodeFind](#),  
[XMLNodeGetName](#), [XMLNodeRemove](#), [XMLNodeSetValue](#), [XMLOpen](#), [XMLSave](#), [XMLSetAttribute](#)

## Example

Following example creates an XML document from local file "H:\Data\books.xml", then selects the first node that matches XPath expression "/bookstore/book/", then gets the value of the node.

```
INT hDoc, hNode;
STRING sValue;
hDoc=XMLOpen("H:\Data\books.xml");
IF hDoc <> -1 THEN
    hNode = XMLNodeFind(hDoc, "/bookstore/book/");
    IF hDoc <> -1 THEN
        sValue=XMLNodeGetValue(hDoc,hNode);
    End
End
```

## See Also

[XML Functions](#)

### XMLNodeRemove

Removes the specified XML node from its parent and XML document.

## Syntax

INT **XMLNodeRemove**(INT *hDoc*, INT *hNode*)

*hDoc*

Handle of the XML document. Returned by [XMLCreate](#) or [XMLOpen](#).

*hNode*

Handle of the node. Returned by [XMLGetRoot](#), [XMLGetChild](#), [XMLGetParent](#) or [XMLNodeFind](#).

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[XMLClose](#), [XMLCreate](#), [XMLGetAttribute](#), [XMLGetAttributeCount](#), [XMLGetAttributeName](#), [XMLGetAttributeValue](#),  
[XMLGetChild](#), [XMLGetChildCount](#), [XMLGetParent](#), [XMLGetRoot](#), [XMLNodeAddChild](#), [XMLNodeFind](#),  
[XMLNodeGetName](#), [XMLNodeGetValue](#), [XMLNodeSetValue](#), [XMLOpen](#), [XMLSave](#), [XMLSetAttribute](#)

## Example

```
INT hDoc, hNode;
hDoc=XMLOpen("H:\Data\books.xml");
IF hDoc <> -1 THEN
    hNode = XMLNodeFind(hDoc, "/bookstore/book/");
    IF hDoc <> -1 THEN
```

```
    XMLNodeRemove(hDoc, hNode);
End
End
```

## See Also

[XML Functions](#)

### XMLNodeSetValue

Sets the value of the specified node.

## Syntax

```
INT XMLNodeSetValue(INT hDoc, INT hNode, STRING sValue)
```

*hDoc*

Handle of the XML document the parent node belongs to. Returned by [XMLCreate](#) or [XMLOpen](#).

*hNode*

Handle of the node. Returned by [XMLGetRoot](#), [XMLGetChild](#), [XMLGetParent](#), [XMLNodeFind](#).

*sValue*

Value of the element node.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[XMLClose](#), [XMLCreate](#), [XMLGetAttribute](#), [XMLGetAttributeCount](#), [XMLGetAttributeName](#), [XMLGetAttributeValue](#),  
[XMLGetChild](#), [XMLGetChildCount](#), [XMLGetParent](#), [XMLGetRoot](#), [XMLNodeAddChild](#), [XMLNodeFind](#),  
[XMLNodeGetName](#), [XMLNodeGetValue](#), [XMLNodeRemove](#), [XMLOpen](#), [XMLSave](#), [XMLSetAttribute](#)

## Example

The following example creates an XML document from local file "H:\Data\books.xml", then selects the first node that matches XPath expression "/bookstore/book/title" and sets the node's value to "Harry Potter".

```
INT hDoc, hNode;
hDoc = XMLOpen("H:\Data\books.xml");
IF hDoc <> -1 THEN
    hNode=XMLNodeFind(hDoc,"/bookstore/book/title");
    IF hNode <>-1 THEN
        XMLNodeSetValue(hDoc,hNode,"Harry Potter");
    End
End
```

## See Also

[XML Functions](#)

### XMLOpen

Reads an XML file from disk to create XML document.

## Syntax

**INT XMLOpen(STRING *sFilePath*)**

*sFilePath*

Absolute path of XML file

## Return Value

Handle of the XML document, or -1 on error.

## Related Functions

[XMLClose](#), [XMLCreate](#), [XMLGetAttribute](#), [XMLGetAttributeCount](#), [XMLGetAttributeName](#), [XMLGetAttributeValue](#),  
[XMLGetChild](#), [XMLGetChildCount](#), [XMLGetParent](#), [XMLGetRoot](#), [XMLNodeAddChild](#), [XMLNodeFind](#),  
[XMLNodeGetName](#), [XMLNodeGetValue](#), [XMLNodeRemove](#), [XMLNodeSetValue](#), [XMLSave](#), [XMLSetAttribute](#)

## Example

Following example reads disk file "H:\Data\books.xml" to create XML document.

```
INT hDoc, hNode;  
hDoc=XMLOpen("H:\Data\books.xml");
```

## See Also

[XML Functions](#)

### XMLSave

Use this function to save XML document on disk.

## Syntax

**INT XMLSave(INT *hDoc*, STRING *sFilePath*)**

*hDoc*

Handle of the XML document. Returned by XMLCreate or XMLOpen.

*sQuery*

Absolute path of the disk file that XML document is written to.

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[XMLClose](#), [XMLCreate](#), [XMLGetAttribute](#), [XMLGetAttributeCount](#), [XMLGetAttributeName](#), [XMLGetAttributeValue](#),  
[XMLGetChild](#), [XMLGetChildCount](#), [XMLGetParent](#), [XMLGetRoot](#), [XMLNodeAddChild](#), [XMLNodeFind](#),  
[XMLNodeGetName](#), [XMLNodeGetValue](#), [XMLNodeRemove](#), [XMLNodeSetValue](#), [XMLOpen](#), [XMLSetAttribute](#)

## Example

```
INT hDoc, hNode;
hdoc=XMLOpen("H:\Data_Backup\books.xml");
IF hDoc <> -1 THEN
    XMLSave(hDoc, "H:\Data_Backup\books.xml");
END
```

## See Also

[XML Functions](#)

## XMLSetAttribute

Use this function to set the value of specified attribute of the node in the XML document. If the attribute does not exist, it will be created.

## Syntax

INT **XMLSetAttribute**(INT *hDoc*, INT *hNode*, STRING *sName*, STRING *sValue*)

*hDoc*

Handle of the XML document. Returned by [XMLCreate](#) or [XMLOpen](#).

*hNode*

Handle of the node. Returned by [XMLGetRoot](#), [XMLGetChild](#), [XMLGetParent](#) or [XMLNodeFind](#).

*sName*

The name of the attribute.

*sValue*

The value of the attribute

## Return Value

0 (zero) if successful, otherwise an error code is returned.

## Related Functions

[XMLClose](#), [XMLCreate](#), [XMLGetAttribute](#), [XMLGetAttributeCount](#), [XMLGetAttributeName](#), [XMLGetAttributeValue](#),  
[XMLGetChild](#), [XMLGetChildCount](#), [XMLGetParent](#), [XMLGetRoot](#), [XMLNodeAddChild](#), [XMLNodeFind](#),  
[XMLNodeGetName](#), [XMLNodeGetValue](#), [XMLNodeRemove](#), [XMLNodeSetValue](#), [XMLOpen](#), [XMLSave](#)

## Example

Following example creates an XML document from local file "H:\Data\books.xml", then selects the first node that matches XPath expression "/bookstore/book/" and sets the value of the node's attribute "Language" to "English".

```
INT hDoc, hNode;
hDoc = XMLOpen("H:\Data\books.xml");
IF hDoc less -1 THEN
    hNode = XMLNodeFind(hDoc, "/bookstore/book/");
    IF hNode less -1 THEN
        XMLSetAttribute(hDoc, hNode, "Language", "English");
    END
END
```

## AccumBrowseOpen Fields

The fields in the following table can be used with the [AccumBrowseOpen](#) Cicode function.

Field Name	Description	Length	Values
AREA	Alarm area.	16	Numeric value (integer) indicating the security area configured for the accumulator.
CLUSTER	Cluster name.	32	The name of the cluster that runs the accumulator.
EQUIPMENT	Equipment name.	254	The name of the equipment associated with the accumulator.
ITEM	Name of an equipment item.	63	The name of the equipment item with which the accumulator is associated.
NAME	Accumulator name.	80	The name configured for the accumulator.
PRIV	Operator privilege.	16	Numeric value (integer) representing the privilege needed by an operator to perform operations on the accumulator (by using accumulator functions).

Field Name	Description	Length	Values
RUNNING	Running time in seconds.	16	Numeric value (real).
STARTS	Number of starts.	16	Numeric value (real) indicating the number of times the trigger has changed from FALSE to TRUE.
TOTALISER	Running total of value.	16	Numeric value (real).
TRIGGER (accumulator fields)	Last trigger value, used to check for rising edge of the trigger code.	5	0 or 1.
VALUE (accumulator fields)	The value to be added to the totalizer while trigger is true.	16	Numeric value (real).

### AlmBrowseGetField Fields

The fields in the following table can be used with the [AlmBrowseGetField](#) Cicode function.

Field Name	Description	Length	Values
ACKDATE	Event acknowledgement date (short format).	12	<p>Short date format (based on the system locale settings). For example, "dd-mm-yy". This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p> <p><b>Note:</b> An extended date format is used by default. The short date format only applies when <a href="#">[Alarm]ExtendedDate</a> is set to 0 in the Citect.ini file.</p>
ACKDATEEXT	Event acknowledgement date (extended format).	12	The date format used when

Field Name	Description	Length	Values
			<p>[Alarm]ExtendedDate is set to 1 in the Citect.ini file.</p> <p>For non-hardware alarms, extended date format (based on the system locale settings).</p> <p>For example, "dd-mm-yyyy".</p> <p>This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p>
ACKMILLI	Millisecond precision for the event acknowledgement time.	6	<p>For high resolution time stamped digital and time stamped analog alarms, this value represents the milliseconds part of the acknowledgement time.</p>
ACKTIME	Event acknowledgement time.	12	<p>This can be in 12 hour format (for example, h:mm:ss tt), or 24 hour format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.</p> <p><b>Note:</b> This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p>
ACKUTC	Event acknowledgment time in UTC format.	12	<p>Integer that represents a time value based on the number of seconds since Jan 1, 1970 (in UTC format).</p>
ACQDESC	Acquisition error description.	254	Textual representation of an alarm acquisition error.
ACQERROR	Acquisition error.	6	Numeric value (integer).
ALARMTYPE	Alarm type.	16	Text describing the

Field Name	Description	Length	Values
			following alarm types: "Digital", "Analog", "Advanced", "Multi-Digital", "Time Stamped", "Time Stamped Digital", "Time Stamped Analog".
ALMCOMMENT	Alarm comment.	254	A text-based comment added to an alarm during configuration.
AREA	Alarm area.	16	Numeric value (integer) representing area.
ARR_SIZE	Array size.	16	Integer (1 means it is not an array).
CATEGORY	Alarm category.	16	Numeric value (integer) representing the alarm category.
CAUSE1	The first cause defined for the alarm.	254	Up to eight causes can be defined for an alarm to help operators determine the most appropriate course of action.  See <a href="#">Add Cause and Response Information to Alarms</a> .
CAUSE2	The second cause defined for the alarm.	254	
CAUSE3	The third cause defined for the alarm.	254	
CAUSE4	The fourth cause defined for the alarm.	254	
CAUSE5	The fifth cause defined for the alarm.	254	
CAUSE6	The sixth cause defined for the alarm.	254	
CAUSE7	The seventh cause defined for the alarm.	254	
CAUSE8	The eighth cause defined for the alarm.	254	
CLASSIFICATION	The class of the event.	32	The classification applied to an event. For example: Action - The event was

Field Name	Description	Length	Values
			logged due to an action being performed.  Comment - The event was logged due to a comment being created.  Configuration - The event was logged due to configuration changes being made.  System - The event has been logged due to an occurrence that affects the entire system, such as the server being stopped and restarted.  Alarm type - Type of alarm (for example, digital, multi-digital, etc.).
CLUSTER	The cluster to which the tag belongs.	32	The cluster name.
COMMENT	Comment.	64	If hardware alarm = "". Or a configured event description or trend comment.
CONSEQUENCE1	The first consequence defined for an alarm.	254	Up to eight consequences can be defined for an alarm to help operators determine the most appropriate course of action.  See <a href="#">Add Cause and Response Information to Alarms</a> .
CONSEQUENCE2	The second consequence defined for an alarm.	254	
CONSEQUENCE3	The third consequence defined for an alarm.	254	
CONSEQUENCE4	The fourth consequence defined for an alarm.	254	
CONSEQUENCE5	The fifth consequence defined for an alarm.	254	
CONSEQUENCE6	The sixth consequence defined for an alarm.	254	
CONSEQUENCE7	The seventh consequence defined for an alarm.	254	

Field Name	Description	Length	Values
CONSEQUENCE8	The eighth consequence defined for an alarm.	254	
CUSTOM1	Alarm custom field #1	64	A user-defined string.
CUSTOM2	Alarm custom field #2	64	A user-defined string.
CUSTOM3	Alarm custom field #3	64	A user-defined string.
CUSTOM4	Alarm custom field #4	64	A user-defined string.
CUSTOM5	Alarm custom field #5	64	A user-defined string.
CUSTOM6	Alarm custom field #6	64	A user-defined string.
CUSTOM7	Alarm custom field #7	64	A user-defined string.
CUSTOM8	Alarm custom field #8	64	A user-defined string.
DATE	Alarm date in short format.	12	<p>Short date format (based on the system locale settings).  For example, "dd-mm-yy".  This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p> <p><b>Note:</b> An extended date format is used by default. The short date format only applies when <a href="#">[Alarm]ExtendedDate</a> is set to 0 in the Citect.ini file.</p>
DATEEXT	Alarm date in extended format.	12	<p>The date format used when <a href="#">[Alarm]ExtendedDate</a> is set to 1 in the Citect.ini file.  For non-hardware alarms, extended date format (based on the system locale settings).  For example, "dd-mm-yyyy".  This works between UTC</p>

Field Name	Description	Length	Values
			time January 1 1970 - January 18 2038, otherwise "".
DEADBAND	Alarm deadband.	12	For analog, and timestamped analog alarms, a numeric value (real).
DELAY	The delay configured for the alarm.	12	The delay period in the following format: hh:mm:ss The value will be between 0 seconds (00:00:00) and 24 hours (24:00:00).
DELTAMILLI	Millisecond precision for the delta time.	6	For high resolution time stamped digital and time stamped analog alarms, it is the milliseconds part of the delta time.
DELTATIME	The time difference between OnDate/OnTime and OffDate/OffTime.	12	The delta time in the following format: hh:mm:ss
DESC	Alarm description.	254	For analog alarms: "DEVIATION", "RATE OF CHANGE", "LOW", "HIGH", "LOW LOW", "HIGH HIGH". For other alarm types: Configured descriptions.
DEVDELAY	Deviation delay.	16	Delay value (in seconds) for analog alarms and time stamped analog alarms.
DEVIATION	Alarm deviation.	12	For analog and time stamped analog alarms: Numeric value (real).
DISABLECOMMENT	A comment added by a user when an alarm is shelved.	254	A user defined text string.

Field Name	Description	Length	Values
DISABLEDDATE	The date an alarm was disabled.	12	<p>The date format is based on the system locale settings.</p> <p>Extended date format: (for example, dd-mm-yyyy).</p> <p>Short date format: (for example, dd-mm-yy).</p> <p>This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p> <p><b>Note:</b> Extended date format is used by default. The short date format only applies when <a href="#">[Alarm]ExtendedDate</a> is set to 0 in the Citect.ini file.</p>
DISABLEDTIME	The time an alarm was disabled.	12	<p>A time string that indicates when an alarm was disabled.</p> <p>This can be in 12 hour format (for example, h:mm:ss tt), or 24 hour format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.</p>
DISABLEENDDATE	The disable end date for a shelved alarm (short format).	12	<p>Short date format (based on the system locale settings).</p> <p>For example, "dd-mm-yy".</p> <p>This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p> <p><b>Note:</b> An extended date format is used by default. The short date format only applies when</p>

Field Name	Description	Length	Values
			[Alarm]ExtendedDate is set to 0 in the Citect.ini file.
DISABLEENDDATEEXT	The disable end date for a shelved alarm (extended format).	12	<p>The date format used when [Alarm]ExtendedDate is set to 1 in the Citect.ini file.</p> <p>For non-hardware alarms, extended date format (based on the system locale settings).</p> <p>For example, "dd-mm-yyyy".</p> <p>This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p>
DISABLEENDTIME	The disable end time for a shelved alarm.	12	<p>A time string that indicates when a shelved alarm will no longer be disabled.</p> <p>This can be in 12 hour format (for example, h:mm:ss tt), or 24 hour format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.</p>
ENG_ZERO	The engineering zero scale for this value.	11	Numeric value (real).
EQUIPMENT	The name of the equipment associated with the alarm.	254	This can be a name that represents a single piece of equipment, or a name that also reflects the location of the equipment within the equipment hierarchy (where a period (.) is used to indicate levels in the hierarchy).

Field Name	Description	Length	Values
FORMAT	Alarm format.	12	For analog, and time stamped analog alarms, a numeric value (real).
FULLNAME	Event user full name.	20	For non-hardware alarms, the configured full name of the event user if exists. Otherwise "System".
GROUP	Alarm group.	16	For multi-digital alarms, a numeric value
HDELAY	High delay.	16	Delay value (in seconds) for analog alarms and time stamped analog alarms.
HELP	Alarm help.	254	The name of the help page.
HHDELAY	High high delay.	16	Delay value (in seconds) for analog alarms and time stamped analog alarms.
HIGH	Alarm high	12	For analog and time stamped analog alarms, a numeric value (real).
HIGHHIGH	Alarm high high	12	For analog and time stamped analog alarms, a numeric value (real).
HISTORIAN	Determines if the alarm will be included in an automated configuration process within the Historian environment.	6	True or False (blank).
ITEM	Name of equipment item.	63	The name configured in the alarm's <b>Item Name</b> field.
LDELAY	Low delay.	16	Delay value (in seconds) for analog alarms and time stamped analog alarms.
LLDELAY	Low low delay.	16	Delay value (in seconds)

Field Name	Description	Length	Values
			for analog alarms and time stamped analog alarms.
LOCALTIMEDATE	Alarm date and time.	24	yyyy-mm-dd hh:mm:ss[.ttt]. This works between: UTC time January 1 1970 - January 18 2038, otherwise "".
LOGSTATE	Log state text.	13	"ACTIVE", "INACTIVE", "DISABLED", "ENABLED", "ACKNOWLEDGED", "LOW", "HIGH", "LOW LOW", "HIGH HIGH", "RATE", "DEVIATION", "Cleared", "UNACKNOWLEDGED".
LOW	Alarm low.	12	For analog and time stamped analog alarms, a numeric value (real).
LOWLOW	Alarm low low.	12	For analog and time stamped analog alarms, a numeric value (real).
MESSAGE	The event message.	254	Text entered in the <b>Alarm Desc</b> field of digital, advanced and time-stamped alarms.
MILLISEC	Alarm milliseconds.	6	Numeric value (integer).
NAME	Alarm name.	80	A meaningful description of the alarm defined in the <b>Alarm Name</b> property.
NATIVE_COMMENT	Event comment.	64	A text-based comment added to an event on the SOE page at runtime.
NATIVE_DESC	Alarm description.	80	For analog alarms, the alarm state text. Otherwise, the configured alarm description.

Field Name	Description	Length	Values
NATIVE_NAME	Alarm name.	80	Configured alarm name.
NATIVE_SUMDESC	Event description text.	80	For non-hardware analog alarms: the event state string. For non-hardware other alarms: the event [or if it does not exist] the alarm description.
OFFDATE	Event off date (short format).	12	Short date format (based on the system locale settings). For example, "dd-mm-yy". This works between UTC time January 1 1970 - January 18 2038, otherwise "". <b>Note:</b> An extended date format is used by default. The short date format only applies when <a href="#">[Alarm]ExtendedDate</a> is set to 0 in the Citect.ini file.
OFFDATEEXT	Extended event off date.	12	The date format used when <a href="#">[Alarm]ExtendedDate</a> is set to 1 in the Citect.ini file. For non-hardware alarms, extended date format (based on the system locale settings). For example, "dd-mm-yyyy". This works between UTC time January 1 1970 - January 18 2038, otherwise "".
OFFMILLI	Millisecond precision for the off time.	6	For high resolution timestamped digital and timestamped analog

Field Name	Description	Length	Values
			alarms, it is the milliseconds part of the off time.
OFFTIME	Event off time.	12	<p>This can be in 12 hour format (for example, h:mm:ss tt), or 24 hour format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.</p> <p><b>Note:</b> This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p>
OFFTIMEDATE	Special SQL formatted date and time.	28	<p>For non-hardware alarms: HH:MI:SS.</p> <p><b>Note:</b> The format can be configured in the citect.ini file using the <a href="#">[Alarm]TimeDate</a> parameter.</p>
OFFUTC	Alarm off time in UTC format.	12	Integer that represents a "time" value based on the number of seconds since Jan 1, 1970 (in UTC format not Local).
OLD_DESC	Multi digital old state description.	8	"Invalid", "OFF", "ON", "ON State 2", "ON State 3", "ON State 4", "ON State 5", "ON State 6", "ON State 7".
ONDATE	Event on date (short format).	12	<p>Short date format (based on the system locale settings).</p> <p>For example, "dd-mm-yy".</p> <p>This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p> <p><b>Note:</b> An extended date</p>

Field Name	Description	Length	Values
			format is used by default. The short date format only applies when [Alarm]ExtendedDate is set to 0 in the Citect.ini file.
ONDATEEXT	Event on date (extended format).	12	<p>The date format used when [Alarm]ExtendedDate is set to 1 in the Citect.ini file.</p> <p>For non-hardware alarms, extended date format (based on the system locale settings).</p> <p>For example, "dd-mm-yyyy".</p> <p>This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p>
ONMILLI	Millisecond precision for the on time.	6	<p>For high resolution timestamped digital and timestamped analog alarms, it is the milliseconds part of the on time.</p>
ONTIME	Event on time.	12	<p>This can be in 12 hour format (for example, h:mm:ss tt), or 24 hour format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.</p> <p><b>Note:</b> This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p>
ONTIMEDATE	Special SQL formatted date and time.	28	<p>For non-hardware alarms: HH:MI:SS.</p> <p><b>Note:</b> The format can be</p>

Field Name	Description	Length	Values
			configured in the citect.ini file using the <a href="#">[Alarm]TimeDate</a> parameter.
ONUTC	Alarm on time in UTC format.	12	Integer that represents a "time" value based on the number of seconds since Jan 1, 1970 (in UTC format not Local).
PAGING	Alarm paged flag.	8	A flag to indicate that the alarm is going to be paged. Values are 1 (TRUE) or 0 (FALSE).
PAGINGGROUP	Paging group for alarm.	80	A freeform text field indicating the sequence of people to notify in the event the alarm occurred.
PRIORITY	Alarm category priority.	4	Numeric value (integer).
PRIV	Alarm privilege.	16	Numeric value (integer) that represents the level of privilege an operator requires to acknowledge or disable the alarm.
RATE	Alarm rate.	12	For analog and time stamped analog alarms, a numeric value (real).
RECEIPTLOCALTIMEDATE	The alarm's occurrence time.	28	Displays the alarm's occurrence time (if known), otherwise it displays the receipt time of the alarm.
RECEIPTDATE	The date the master station received the event (short format).  For example, the date the RTU received the event.	12	Short date format (based on the system locale settings).  For example, "dd-mm-yy".  This works between UTC time January 1 1970 - January 18 2038, otherwise "".

Field Name	Description	Length	Values
			<b>Note:</b> An extended date format is used by default. The short date format only applies when [Alarm]ExtendedDate is set to 0 in the Citect.ini file.
RECEIPTDATEEXT	The date the master station received the event (extended format).  For example, the date the RTU received the event.	12	The date format used when [Alarm]ExtendedDate is set to 1 in the Citect.ini file.  For non-hardware alarms, extended date format (based on the system locale settings).  For example, "dd-mm-yyyy".  This works between UTC time January 1 1970 - January 18 2038, otherwise "".
RECEIPTMILLISEC	Millisecond precision for the receipt time.	6	For high resolution timestamped digital and timestamped analog alarms, it is the milliseconds part of the receipt time.
RECEIPTTIME	The time the master station received the event.  For example, the time the RTU received the event.	16	This can be in 12 hour format (for example, h:mm:ss tt) or 24 hour format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.
RECEIPTTIMEINT	Receipt time in UTC format.	12	An integer that represents a "time" value based on the number of seconds since Jan 1, 1970 (in UTC format not Local).
RECEIPTTIMETICKS	Receipt time measured	20	Time expressed as the

Field Name	Description	Length	Values
	using ticks.		number of ticks elapsed since 12:00:00 midnight, January 1, 1601 in UTC format. Each tick is 100 nanoseconds.
RESPONSE1	The first response defined for the alarm.	254	Up to eight responses can be defined for an alarm to help operators determine the most appropriate course of action.  See <a href="#">Add Cause and Response Information to Alarms</a> .
RESPONSE2	The second response defined for the alarm.	254	
RESPONSE3	The third response defined for the alarm.	254	
RESPONSE4	The fourth response defined for the alarm.	254	
RESPONSE5	The fifth response defined for the alarm.	254	
RESPONSE6	The sixth response defined for the alarm.	254	
RESPONSE7	The seventh response defined for the alarm.	254	
RESPONSE8	The eighth response defined for the alarm.	254	
RESPONSENUM	The number of alarm responses that have been configured for an alarm tag.	8	0 to 8.
SETPOINT	The set point value. This is only applicable to analog alarms.	16	An analog variable tag, expression or base value that determines if a deviation alarm is to be triggered.
STATE	Alarm state string.	16	For analog and time stamped analog alarms: "OFF", "DEVIATION", "RATE OF CHANGE", "LOW", "HIGH", "LOW LOW", "HIGH HIGH".

Field Name	Description	Length	Values
			For multi-digital alarms: "OFF", "ON", "ON State 2", "ON State 3", "ON State 4", "ON State 5", "ON State 6", "ON State 7".  For double point status alarms: The configured state name.  For all other alarms: "OFF", "ON".
STATE_DESC	Multi-digital state description.	8	"OFF", "ON", "ON State 2", "ON State 3", "ON State 4", "ON State 5", "ON State 6", "ON State 7".
STATE_DESC0	Multi-digital state 0.	64	For multi-digital alarms: "OFF".  For others: "INVALID".
STATE_DESC1	Multi-digital state 1.	64	For multi-digital alarms: "ON".  For others: "INVALID".
STATE_DESC2	Multi-digital state 2.	64	For multi-digital alarms: "ON state 2".  For others: "INVALID".
STATE_DESC3	Multi-digital state 3.	64	For multi-digital alarms: "ON state 3".  For others: "INVALID".
STATE_DESC4	Multi-digital state 4.	64	For multi-digital alarms: "ON state 4".  For others: "INVALID".
STATE_DESC5	Multi-digital state 5.	64	For multi-digital alarms: "ON state 5".  For others: "INVALID".
STATE_DESC6	Multi-digital state 6.	64	For multi-digital alarms: "ON state 6".

Field Name	Description	Length	Values
			For others: "INVALID".
STATE_DESC7	Multi-digital state 7.	64	For multi-digital alarms: "ON state 7".  For others: "INVALID".
SUMDESC	Event description text.	80	Analog alarm - event state text.  Otherwise - configured event [or alarm in case event not defined] description.
SUMSTATE	Event state text.	16	Displays the last active state of the alarm.  "OFF", "ON", "ON State 2", "ON State 3", "ON State 4", "ON State 5", "ON State 6", "ON State 7", "DEVIATION", "RATE OF CHANGE", "LOW", "HIGH", "LOW LOW", "HIGH HIGH", "Invalid".
SUMTYPE	Event state.	16	For non-hardware alarms: "DISABLED", "UNACKNOWLEDGED", "ACKNOWLEDGED", "Cleared".
TAG	Tag name.	80	The configured tag name.
TAGEX	Extended alarm tag.	32	<cluster>.<tag> when a cluster is defined.  Otherwise <tag>.
TAGGENLINK	Indicates a tag was imported from an I/O device.	16	Name of the I/O device from which this tag was generated.
TIME	The time the event occurred.	12	This can be in 12 hour format (hh:mm:ss tt), or 24 hour format (HH:mm:ss) depending on the current date and time settings on the local computer.

Field Name	Description	Length	Values
			<b>Note:</b> This works between UTC time January 1 1970 - January 18 2038, otherwise "".
TIMEDATE	Special SQL formatted time.	28	For non-hardware alarms: HH:MI:SS.  <b>Note:</b> The format can be configured in the citect.ini file using the [Alarm]TimeDate parameter.
TIMEINT	Event time in UTC format.	12	Integer that represents a time value based on the number of seconds since Jan 1, 1970 (in UTC format).
TIMETICKS	Event time measured using ticks.	20	Time expressed as the number of ticks elapsed since 12:00:00 midnight, January 1, 1601 in UTC format.  Each tick is 100 nanoseconds.
TSQUALITY	The quality of the alarm tag. This is passed to the alarm server by the I/O server when a value change occurs.	64	Expected time stamp quality strings are:  Time Good, Time Uncertain, Clock Not Synchronized, or empty string if no match is found.
TYPE	Alarm type.	16	"DISABLED", "UNACKNOWLEDGED", "ACKNOWLEDGED", "CLEARED"
TYPENUM	Alarm type represented as a numeric value.	4	Values are:  -1 - Invalid 0 - Digital 1 - Analog 2 - Advanced

Field Name	Description	Length	Values
			3 - Multi-Digital 4 - ArgAna 5 - User event 6 - Time stamped 7 - Hardware 8 - Time stamped digital 9 - Time stamped analog
USERDESC	The text related to a user event.	64	If you specify an asterisk '*' as the first character of the <i>sTag</i> argument in <a href="#">AlarmSumAppend</a> , the summary entry becomes a user event. This value is the text that follows the asterisk.
USERNAME	Event user name.	16	For non-hardware alarms, the configured name of the event user (if it exists). Otherwise "System".
USERLOCATION	The IP of the machine which last raised, modified, or performed an action on the alarm.	80	<b>Note:</b> If the last action performed is from a system machine, the IP will not over ride the last user machine IP address.
VALUE (alarm fields)	Formatted alarm value.	16	For analog alarms, a numeric value formatted according to configuration.

### AlarmGetDsp Fields

The fields in the following table can be used with the [AlarmGetDsp](#) Cicode function.

Field Name	Description	Length	Values
ACKDATE	Event acknowledgement date (short format).	12	<p>Short date format (based on the system locale settings). For example, "dd-mm-yy". This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p> <p><b>Note:</b> An extended date format is used by default. The short date format only applies when <a href="#">[Alarm]ExtendedDate</a> is set to 0 in the Citect.ini file.</p>
ACKDATEEXT	Event acknowledgement date (extended format).	12	<p>The date format used when <a href="#">[Alarm]ExtendedDate</a> is set to 1 in the Citect.ini file. For non-hardware alarms, extended date format (based on the system locale settings). For example, "dd-mm-yyyy". This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p>
ACKMILLI	Millisecond precision for the event acknowledgement time.	6	For high resolution time stamped digital and time stamped analog alarms, this value represents the milliseconds part of the acknowledgement time.
ACKTIME	Event acknowledgement time.	12	This can be in 12 hour format (for example, h:mm:ss tt), or 24 hour format (for example, H:mm:ss) depending on the regional date and

Field Name	Description	Length	Values
			time settings on the local computer. <b>Note:</b> This works between UTC time January 1 1970 - January 18 2038, otherwise "".
ACKUTC	Event acknowledgment time in UTC format.	12	Integer that represents a time value based on the number of seconds since Jan 1, 1970 (in UTC format).
ACQDESC	Acquisition error description.	254	Textual representation of an alarm acquisition error.
ACQERROR	Acquisition error.	6	Numeric value (integer).
ALARMTYPE	Alarm type.	16	Text describing the following alarm types: "Digital", "Analog", "Advanced", "Multi-Digital", "Time Stamped", "Time Stamped Digital", "Time Stamped Analog".
ALMCOMMENT	Alarm comment.	254	A text-based comment added to an alarm during configuration.
AREA	Alarm area.	16	Numeric value (integer) representing area.
ARR_SIZE	Array size.	16	Integer (1 means it is not an array).
CATEGORY	Alarm category.	16	Numeric value (integer) representing the alarm category.
CAUSE1	The first cause defined for the alarm.	254	Up to eight causes can be defined for an alarm to help operators determine the most appropriate course of action.  See <a href="#">Add Cause and Response Information to</a>
CAUSE2	The second cause defined for the alarm.	254	
CAUSE3	The third cause defined for the alarm.	254	

Field Name	Description	Length	Values
CAUSE4	The fourth cause defined for the alarm.	254	<a href="#">Alarms</a> .
CAUSE5	The fifth cause defined for the alarm.	254	
CAUSE6	The sixth cause defined for the alarm.	254	
CAUSE7	The seventh cause defined for the alarm.	254	
CAUSE8	The eighth cause defined for the alarm.	254	
CLASSIFICATION	The class of the event.	32	The classification applied to an event. For example:  Action - The event was logged due to an action being performed.  Comment - The event was logged due to a comment being created.  Configuration - The event was logged due to configuration changes being made.  System - The event has been logged due to an occurrence that affects the entire system, such as the server being stopped and restarted.  Alarm type - Type of alarm (for example, digital, multi-digital, etc.).
CLUSTER	The cluster to which the tag belongs.	32	The cluster name.
COMMENT	Comment.	64	If hardware alarm = "".  Or a configured event description or trend comment.
CONSEQUENCE1	The first consequence	254	Up to eight consequences

Field Name	Description	Length	Values
	defined for an alarm.		can be defined for an alarm to help operators determine the most appropriate course of action. See <a href="#">Add Cause and Response Information to Alarms</a> .
CONSEQUENCE2	The second consequence defined for an alarm.	254	
CONSEQUENCE3	The third consequence defined for an alarm.	254	
CONSEQUENCE4	The fourth consequence defined for an alarm.	254	
CONSEQUENCE5	The fifth consequence defined for an alarm.	254	
CONSEQUENCE6	The sixth consequence defined for an alarm.	254	
CONSEQUENCE7	The seventh consequence defined for an alarm.	254	
CONSEQUENCE8	The eighth consequence defined for an alarm.	254	
CUSTOM1	Alarm custom field #1	64	A user-defined string.
CUSTOM2	Alarm custom field #2	64	A user-defined string.
CUSTOM3	Alarm custom field #3	64	A user-defined string.
CUSTOM4	Alarm custom field #4	64	A user-defined string.
CUSTOM5	Alarm custom field #5	64	A user-defined string.
CUSTOM6	Alarm custom field #6	64	A user-defined string.
CUSTOM7	Alarm custom field #7	64	A user-defined string.
CUSTOM8	Alarm custom field #8	64	A user-defined string.
DATE	Alarm date in short format.	12	Short date format (based on the system locale settings). For example, "dd-mm-yy". This works between UTC time January 1 1970 - January 18 2038, otherwise "". <b>Note:</b> An extended date format is used by default.

Field Name	Description	Length	Values
			The short date format only applies when <a href="#">[Alarm]ExtendedDate</a> is set to 0 in the Citect.ini file.
DATEEXT	Alarm date in extended format.	12	<p>The date format used when <a href="#">[Alarm]ExtendedDate</a> is set to 1 in the Citect.ini file.</p> <p>For non-hardware alarms, extended date format (based on the system locale settings).</p> <p>For example, "dd-mm-yyyy".</p> <p>This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p>
DEADBAND	Alarm deadband.	12	For analog, and timestamped analog alarms, a numeric value (real).
DELAY	The delay configured for the alarm.	12	<p>The delay period in the following format:</p> <p>hh:mm:ss</p> <p>The value will be between 0 seconds (00:00:00) and 24 hours (24:00:00).</p>
DELTAMILLI	Millisecond precision for the delta time.	6	For high resolution time stamped digital and time stamped analog alarms, it is the milliseconds part of the delta time.
DELTATIME	The time difference between OnDate/OnTime and OffDate/OffTime.	12	The delta time in the following format:
DESC	Alarm description.	254	For analog alarms: "DEVIATION", "RATE OF"

Field Name	Description	Length	Values
			CHANGE", "LOW", "HIGH", "LOW LOW", "HIGH HIGH".  For other alarm types: Configured descriptions.
DEVDELAY	Deviation delay.	16	Delay value (in seconds) for analog alarms and time stamped analog alarms.
DEVIATION	Alarm deviation.	12	For analog and time stamped analog alarms: Numeric value (real).
DISABLECOMMENT	A comment added by a user when an alarm is shelved.	254	A user defined text string.
DISABLEDDATE	The date an alarm was disabled.	12	The date format is based on the system locale settings.  Extended date format: (for example, dd-mm-yyyy).  Short date format: (for example, dd-mm-yy).  This works between UTC time January 1 1970 - January 18 2038, otherwise "".  <b>Note:</b> Extended date format is used by default. The short date format only applies when [Alarm]ExtendedDate is set to 0 in the Citect.ini file.
DISABLEDTIME	The time an alarm was disabled.	12	A time string that indicates when an alarm was disabled.  This can be in 12 hour format (for example, h:mm:ss tt), or 24 hour

Field Name	Description	Length	Values
			format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.
DISABLEENDDATE	The disable end date for a shelved alarm (short format).	12	<p>Short date format (based on the system locale settings). For example, "dd-mm-yy". This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p> <p><b>Note:</b> An extended date format is used by default. The short date format only applies when <a href="#">[Alarm]ExtendedDate</a> is set to 0 in the Citect.ini file.</p>
DISABLEENDDATEEXT	The disable end date for a shelved alarm (extended format).	12	<p>The date format used when <a href="#">[Alarm]ExtendedDate</a> is set to 1 in the Citect.ini file. For non-hardware alarms, extended date format (based on the system locale settings). For example, "dd-mm-yyyy". This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p>
DISABLEENDTIME	The disable end time for a shelved alarm.	12	<p>A time string that indicates when a shelved alarm will no longer be disabled. This can be in 12 hour format (for example, h:mm:ss tt), or 24 hour</p>

Field Name	Description	Length	Values
			format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.
ENG_ZERO	The engineering zero scale for this value.	11	Numeric value (real).
EQUIPMENT	The name of the equipment associated with the alarm.	254	This can be a name that represents a single piece of equipment, or a name that also reflects the location of the equipment within the equipment hierarchy (where a period (.) is used to indicate levels in the hierarchy).
FORMAT	Alarm format.	12	For analog, and time stamped analog alarms, a numeric value (real).
FULLNAME	Event user full name.	20	For non-hardware alarms, the configured full name of the event user if exists. Otherwise "System".
GROUP	Alarm group.	16	For multi-digital alarms, a numeric value
HDELAY	High delay.	16	Delay value (in seconds) for analog alarms and time stamped analog alarms.
HELP	Alarm help.	254	The name of the help page.
HHDELAY	High high delay.	16	Delay value (in seconds) for analog alarms and time stamped analog alarms.
HIGH	Alarm high	12	For analog and time stamped analog alarms, a numeric value (real).

Field Name	Description	Length	Values
HIGHHIGH	Alarm high high	12	For analog and time stamped analog alarms, a numeric value (real).
HISTORIAN	Determines if the alarm will be included in an automated configuration process within the Historian environment.	6	True or False (blank).
ITEM	Name of equipment item.	63	The name configured in the alarm's <b>Item Name</b> field.
LDELAY	Low delay.	16	Delay value (in seconds) for analog alarms and time stamped analog alarms.
LLDELAY	Low low delay.	16	Delay value (in seconds) for analog alarms and time stamped analog alarms.
LOCALTIMEDATE	Alarm date and time.	24	yyyy-mm-dd hh:mm:ss[.ttt]. This works between: UTC time January 1 1970 - January 18 2038, otherwise "".
LOGSTATE	Log state text.	13	"ACTIVE", "INACTIVE", "DISABLED", "ENABLED", "ACKNOWLEDGED", "LOW", "HIGH", "LOW LOW", "HIGH HIGH", "RATE", "DEVIATION", "CLEARED", "UNACKNOWLEDGED".
LOW	Alarm low.	12	For analog and time stamped analog alarms, a numeric value (real).
LOWLOW	Alarm low low.	12	For analog and time stamped analog alarms, a numeric value (real).

Field Name	Description	Length	Values
MESSAGE	The event message.	254	Text entered in the <b>Alarm Desc</b> field of digital, advanced and time-stamped alarms.
MILLISEC	Alarm milliseconds.	6	Numeric value (integer).
NAME	Alarm name.	80	A meaningful description of the alarm defined in the <b>Alarm Name</b> property.
NATIVE_COMMENT	Event comment.	64	A text-based comment added to an event on the SOE page at runtime.
NATIVE_DESC	Alarm description.	80	For analog alarms, the alarm state text. Otherwise, the configured alarm description.
NATIVE_NAME	Alarm name.	80	Configured alarm name.
NATIVE_SUMDESC	Event description text.	80	For non-hardware analog alarms: the event state string. For non-hardware other alarms: the event [or if it does not exist] the alarm description.
OFFDATE	Event off date (short format).	12	Short date format (based on the system locale settings). For example, "dd-mm-yy". This works between UTC time January 1 1970 - January 18 2038, otherwise "". <b>Note:</b> An extended date format is used by default. The short date format only applies when <a href="#">[Alarm]ExtendedDate</a> is set to 0 in the Citect.ini file.

Field Name	Description	Length	Values
OFFDATEEXT	Extended event off date.	12	<p>The date format used when <a href="#">[Alarm]ExtendedDate</a> is set to 1 in the Citect.ini file.</p> <p>For non-hardware alarms, extended date format (based on the system locale settings).</p> <p>For example, "dd-mm-yyyy".</p> <p>This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p>
OFFMILLI	Millisecond precision for the off time.	6	<p>For high resolution timestamped digital and timestamped analog alarms, it is the milliseconds part of the off time.</p>
OFFTIME	Event off time.	12	<p>This can be in 12 hour format (for example, h:mm:ss tt), or 24 hour format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.</p> <p><b>Note:</b> This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p>
OFFTIMEDATE	Special SQL formatted date and time.	28	<p>For non-hardware alarms: HH:MI:SS.</p> <p><b>Note:</b> The format can be configured in the citect.ini file using the <a href="#">[Alarm]TimeDate</a> parameter.</p>
OFFUTC	Alarm off time in UTC format.	12	<p>Integer that represents a "time" value based on the</p>

Field Name	Description	Length	Values
			number of seconds since Jan 1, 1970 (in UTC format not Local).
OLD_DESC	Multi digital old state description.	8	"Invalid", "OFF", "ON", "ON State 2", "ON State 3", "ON State 4", "ON State 5", "ON State 6", "ON State 7".
ONDATE	Event on date (short format).	12	Short date format (based on the system locale settings). For example, "dd-mm-yy". This works between UTC time January 1 1970 - January 18 2038, otherwise "". <b>Note:</b> An extended date format is used by default. The short date format only applies when <a href="#">[Alarm]ExtendedDate</a> is set to 0 in the Citect.ini file.
ONDATEEXT	Event on date (extended format).	12	The date format used when <a href="#">[Alarm]ExtendedDate</a> is set to 1 in the Citect.ini file. For non-hardware alarms, extended date format (based on the system locale settings). For example, "dd-mm-yyyy". This works between UTC time January 1 1970 - January 18 2038, otherwise "".
ONMILLI	Millisecond precision for the on time.	6	For high resolution timestamped digital and timestamped analog alarms, it is the

Field Name	Description	Length	Values
			milliseconds part of the on time.
ONTIME	Event on time.	12	<p>This can be in 12 hour format (for example, h:mm:ss tt), or 24 hour format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.</p> <p><b>Note:</b> This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p>
ONTIMEDATE	Special SQL formatted date and time.	28	<p>For non-hardware alarms: HH:MI:SS.</p> <p><b>Note:</b> The format can be configured in the citect.ini file using the <a href="#">[Alarm]TimeDate</a> parameter.</p>
ONUTC	Alarm on time in UTC format.	12	Integer that represents a "time" value based on the number of seconds since Jan 1, 1970 (in UTC format not Local).
PAGING	Alarm paged flag.	8	A flag to indicate that the alarm is going to be paged. Values are 1 (TRUE) or 0 (FALSE).
PAGINGGROUP	Paging group for alarm.	80	A freeform text field indicating the sequence of people to notify in the event the alarm occurred.
PRIORITY	Alarm category priority.	4	Numeric value (integer).
PRIV	Alarm privilege.	16	Numeric value (integer) that represents the level of privilege an operator requires to acknowledge or disable the alarm.

Field Name	Description	Length	Values
RATE	Alarm rate.	12	For analog and time stamped analog alarms, a numeric value (real).
RECEIPTLOCAUTIMEDATE	The alarm's occurrence time.	28	Displays the alarm's occurrence time (if known), otherwise it displays the receipt time of the alarm.
RECEIPTDATE	The date the master station received the event (short format).  For example, the date the RTU received the event.	12	Short date format (based on the system locale settings).  For example, "dd-mm-yy". This works between UTC time January 1 1970 - January 18 2038, otherwise "".  <b>Note:</b> An extended date format is used by default. The short date format only applies when <a href="#">[Alarm]ExtendedDate</a> is set to 0 in the Citect.ini file.
RECEIPTDATEEXT	The date the master station received the event (extended format).  For example, the date the RTU received the event.	12	The date format used when <a href="#">[Alarm]ExtendedDate</a> is set to 1 in the Citect.ini file.  For non-hardware alarms, extended date format (based on the system locale settings).  For example, "dd-mm-yyyy".  This works between UTC time January 1 1970 - January 18 2038, otherwise "".
RECEIPTMILLISEC	Millisecond precision for the receipt time.	6	For high resolution timestamped digital and timestamped analog alarms, it is the

Field Name	Description	Length	Values
			milliseconds part of the receipt time.
RECEIPTTIME	The time the master station received the event.  For example, the time the RTU received the event.	16	This can be in 12 hour format (for example, h:mm:ss tt) or 24 hour format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.
RECEIPTTIMEINT	Receipt time in UTC format.	12	An integer that represents a "time" value based on the number of seconds since Jan 1, 1970 (in UTC format not Local).
RECEIPTTIMETICKS	Receipt time measured using ticks.	20	Time expressed as the number of ticks elapsed since 12:00:00 midnight, January 1, 1601 in UTC format.  Each tick is 100 nanoseconds.
RESPONSE1	The first response defined for the alarm.	254	Up to eight responses can be defined for an alarm to help operators determine the most appropriate course of action.  See <a href="#">Add Cause and Response Information to Alarms</a> .
RESPONSE2	The second response defined for the alarm.	254	
RESPONSE3	The third response defined for the alarm.	254	
RESPONSE4	The fourth response defined for the alarm.	254	
RESPONSE5	The fifth response defined for the alarm.	254	
RESPONSE6	The sixth response defined for the alarm.	254	
RESPONSE7	The seventh response defined for the alarm.	254	
RESPONSE8	The eighth response	254	

Field Name	Description	Length	Values
	defined for the alarm.		
RESPONSENUM	The number of alarm responses that have been configured for an alarm tag.	8	0 to 8.
SETPOINT	The set point value. This is only applicable to analog alarms.	16	An analog variable tag, expression or base value that determines if a deviation alarm is to be triggered.
STATE	Alarm state string.	16	For analog and time stamped analog alarms: "OFF", "DEVIATION", "RATE OF CHANGE", "LOW", "HIGH", "LOW LOW", "HIGH HIGH".  For multi-digital alarms: "OFF", "ON", "ON State 2", "ON State 3", "ON State 4", "ON State 5", "ON State 6", "ON State 7".  For double point status alarms: The configured state name.  For all other alarms: "OFF", "ON".
STATE_DESC	Multi-digital state description.	8	"OFF", "ON", "ON State 2", "ON State 3", "ON State 4", "ON State 5", "ON State 6", "ON State 7".
STATE_DESC0	Multi-digital state 0.	64	For multi-digital alarms: "OFF".  For others: "INVALID".
STATE_DESC1	Multi-digital state 1.	64	For multi-digital alarms: "ON".  For others: "INVALID".

Field Name	Description	Length	Values
STATE_DESC2	Multi-digital state 2.	64	For multi-digital alarms: "ON state 2". For others: "INVALID".
STATE_DESC3	Multi-digital state 3.	64	For multi-digital alarms: "ON state 3". For others: "INVALID".
STATE_DESC4	Multi-digital state 4.	64	For multi-digital alarms: "ON state 4". For others: "INVALID".
STATE_DESC5	Multi-digital state 5.	64	For multi-digital alarms: "ON state 5". For others: "INVALID".
STATE_DESC6	Multi-digital state 6.	64	For multi-digital alarms: "ON state 6". For others: "INVALID".
STATE_DESC7	Multi-digital state 7.	64	For multi-digital alarms: "ON state 7". For others: "INVALID".
SUMDESC	Event description text.	80	Analog alarm - event state text.  Otherwise - configured event [or alarm in case event not defined] description.
SUMSTATE	Event state text.	16	Displays the last active state of the alarm.  "OFF", "ON", "ON State 2", "ON State 3", "ON State 4", "ON State 5", "ON State 6", "ON State 7", "DEVIATION", "RATE OF CHANGE", "LOW", "HIGH", "LOW LOW", "HIGH HIGH", "Invalid".
SUMTYPE	Event state.	16	For non-hardware alarms: "DISABLED", "UNACKNOWLEDGED", "ACKNOWLEDGED",

Field Name	Description	Length	Values
			"CLEARED".
TAG	Tag name.	80	The configured tag name.
TAGEX	Extended alarm tag.	32	<cluster>.<tag> when a cluster is defined. Otherwise <tag>.
TAGGENLINK	Indicates a tag was imported from an I/O device.	16	Name of the I/O device from which this tag was generated.
TIME	The time the event occurred.	12	This can be in 12 hour format (hh:mm:ss tt), or 24 hour format (HH:mm:ss) depending on the current date and time settings on the local computer.  <b>Note:</b> This works between UTC time January 1 1970 - January 18 2038, otherwise "".
TIMEDATE	Special SQL formatted time.	28	For non-hardware alarms: HH:MI:SS.  <b>Note:</b> The format can be configured in the citect.ini file using the [Alarm]TimeDate parameter.
TIMEINT	Event time in UTC format.	12	Integer that represents a time value based on the number of seconds since Jan 1, 1970 (in UTC format).
TIMETICKS	Event time measured using ticks.	20	Time expressed as the number of ticks elapsed since 12:00:00 midnight, January 1, 1601 in UTC format.  Each tick is 100 nanoseconds.

Field Name	Description	Length	Values
TSQUALITY	The quality of the alarm tag. This is passed to the alarm server by the I/O server when a value change occurs.	64	Expected time stamp quality strings are: Time Good, Time Uncertain, Clock Not Synchronized, or empty string if no match is found.
TYPE	Alarm type.	16	"DISABLED", "UNACKNOWLEDGED", "ACKNOWLEDGED", "Cleared"
TYPENUM	Alarm type represented as a numeric value.	4	Values are: -1 - Invalid 0 - Digital 1 - Analog 2 - Advanced 3 - Multi-Digital 4 - ArgAna 5 - User event 6 - Time stamped 7 - Hardware 8 - Time stamped digital 9 - Time stamped analog
USERDESC	The text related to a user event.	64	If you specify an asterisk '*' as the first character of the <i>sTag</i> argument in <a href="#">AlarmSumAppend</a> , the summary entry becomes a user event. This value is the text that follows the asterisk.
USERNAME	Event user name.	16	For non-hardware alarms, the configured name of the event user (if it exists). Otherwise "System".
USERLOCATION	The IP of the machine which last raised, modified, or performed	80	<b>Note:</b> If the last action performed is from a system machine, the IP

Field Name	Description	Length	Values
	an action on the alarm.		will not over ride the last user machine IP address.
VALUE (alarm fields)	Formatted alarm value.	16	For analog alarms, a numeric value formatted according to configuration.

### AlarmGetFieldRec Fields

The fields in the following table can be used with the [AlarmGetFieldRec](#) Cicode function.

Field Name	Description	Length	Values
ACKDATE	Event acknowledgement date (short format).	12	<p>Short date format (based on the system locale settings).            For example, "dd-mm-yy".            This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p> <p><b>Note:</b> An extended date format is used by default. The short date format only applies when <a href="#">[Alarm]ExtendedDate</a> is set to 0 in the Citect.ini file.</p>
ACKDATEEXT	Event acknowledgement date (extended format).	12	<p>The date format used when <a href="#">[Alarm]ExtendedDate</a> is set to 1 in the Citect.ini file.            For non-hardware alarms, extended date format (based on the system locale settings).            For example, "dd-mm-yyyy".</p>

Field Name	Description	Length	Values
			This works between UTC time January 1 1970 - January 18 2038, otherwise "".
ACKMILLI	Millisecond precision for the event acknowledgement time.	6	For high resolution time stamped digital and time stamped analog alarms, this value represents the milliseconds part of the acknowledgement time.
ACKTIME	Event acknowledgement time.	12	This can be in 12 hour format (for example, h:mm:ss tt), or 24 hour format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.  <b>Note:</b> This works between UTC time January 1 1970 - January 18 2038, otherwise "".
ACKUTC	Event acknowledgment time in UTC format.	12	Integer that represents a time value based on the number of seconds since Jan 1, 1970 (in UTC format).
ACQDESC	Acquisition error description.	254	Textual representation of an alarm acquisition error.
ACQERROR	Acquisition error.	6	Numeric value (integer).
ALARMTYPE	Alarm type.	16	Text describing the following alarm types: "Digital", "Analog", "Advanced", "Multi-Digital", "Time Stamped", "Time Stamped Digital", "Time Stamped Analog".
ALMCOMMENT	Alarm comment.	254	A text-based comment added to an alarm during configuration.

Field Name	Description	Length	Values
AREA	Alarm area.	16	Numeric value (integer) representing area.
ARR_SIZE	Array size.	16	Integer (1 means it is not an array).
CATEGORY	Alarm category.	16	Numeric value (integer) representing the alarm category.
CAUSE1	The first cause defined for the alarm.	254	Up to eight causes can be defined for an alarm to help operators determine the most appropriate course of action.  See <a href="#">Add Cause and Response Information to Alarms</a> .
CAUSE2	The second cause defined for the alarm.	254	
CAUSE3	The third cause defined for the alarm.	254	
CAUSE4	The fourth cause defined for the alarm.	254	
CAUSE5	The fifth cause defined for the alarm.	254	
CAUSE6	The sixth cause defined for the alarm.	254	
CAUSE7	The seventh cause defined for the alarm.	254	
CAUSE8	The eighth cause defined for the alarm.	254	
CLASSIFICATION	The class of the event.	32	The classification applied to an event. For example:  Action - The event was logged due to an action being performed.  Comment - The event was logged due to a comment being created.  Configuration - The event was logged due to configuration changes being made.  System - The event has

Field Name	Description	Length	Values
			been logged due to an occurrence that affects the entire system, such as the server being stopped and restarted. Alarm type - Type of alarm (for example, digital, multi-digital, etc.).
CLUSTER	The cluster to which the tag belongs.	32	The cluster name.
COMMENT	Comment.	64	If hardware alarm = "". Or a configured event description or trend comment.
CONSEQUENCE1	The first consequence defined for an alarm.	254	Up to eight consequences can be defined for an alarm to help operators determine the most appropriate course of action.  See <a href="#">Add Cause and Response Information to Alarms</a> .
CONSEQUENCE2	The second consequence defined for an alarm.	254	
CONSEQUENCE3	The third consequence defined for an alarm.	254	
CONSEQUENCE4	The fourth consequence defined for an alarm.	254	
CONSEQUENCE5	The fifth consequence defined for an alarm.	254	
CONSEQUENCE6	The sixth consequence defined for an alarm.	254	
CONSEQUENCE7	The seventh consequence defined for an alarm.	254	
CONSEQUENCE8	The eighth consequence defined for an alarm.	254	
CUSTOM1	Alarm custom field #1	64	A user-defined string.
CUSTOM2	Alarm custom field #2	64	A user-defined string.
CUSTOM3	Alarm custom field #3	64	A user-defined string.
CUSTOM4	Alarm custom field #4	64	A user-defined string.

Field Name	Description	Length	Values
CUSTOM5	Alarm custom field #5	64	A user-defined string.
CUSTOM6	Alarm custom field #6	64	A user-defined string.
CUSTOM7	Alarm custom field #7	64	A user-defined string.
CUSTOM8	Alarm custom field #8	64	A user-defined string.
DATE	Alarm date in short format.	12	<p>Short date format (based on the system locale settings).  For example, "dd-mm-yy".  This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p> <p><b>Note:</b> An extended date format is used by default. The short date format only applies when <a href="#">[Alarm]ExtendedDate</a> is set to 0 in the Citect.ini file.</p>
DATEEXT	Alarm date in extended format.	12	<p>The date format used when <a href="#">[Alarm]ExtendedDate</a> is set to 1 in the Citect.ini file.  For non-hardware alarms, extended date format (based on the system locale settings).  For example, "dd-mm-yyyy".  This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p>
DEADBAND	Alarm deadband.	12	For analog, and timestamped analog alarms, a numeric value (real).
DELAY	The delay configured for	12	The delay period in the

Field Name	Description	Length	Values
	the alarm.		following format: hh:mm:ss  The value will be between 0 seconds (00:00:00) and 24 hours (24:00:00).
DELTAMILLI	Millisecond precision for the delta time.	6	For high resolution time stamped digital and time stamped analog alarms, it is the milliseconds part of the delta time.
DELTATIME	The time difference between OnDate/OnTime and OffDate/OffTime.	12	The delta time in the following format: hh:mm:ss
DESC	Alarm description.	254	For analog alarms: "DEVIATION", "RATE OF CHANGE", "LOW", "HIGH", "LOW LOW", "HIGH HIGH".  For other alarm types: Configured descriptions.
DEVDELAY	Deviation delay.	16	Delay value (in seconds) for analog alarms and time stamped analog alarms.
DEVIATION	Alarm deviation.	12	For analog and time stamped analog alarms: Numeric value (real).
DISABLECOMMENT	A comment added by a user when an alarm is shelved.	254	A user defined text string.
DISABLEDDATE	The date an alarm was disabled.	12	The date format is based on the system locale settings.  Extended date format: (for example, dd-mm-yyyy).  Short date format: (for example, dd-mm-yy).

Field Name	Description	Length	Values
			<p>This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p> <p><b>Note:</b> Extended date format is used by default. The short date format only applies when <a href="#">[Alarm]ExtendedDate</a> is set to 0 in the Citect.ini file.</p>
DISABLETIME	The time an alarm was disabled.	12	<p>A time string that indicates when an alarm was disabled.</p> <p>This can be in 12 hour format (for example, h:mm:ss tt), or 24 hour format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.</p>
DISABLEENDDATE	The disable end date for a shelved alarm (short format).	12	<p>Short date format (based on the system locale settings).</p> <p>For example, "dd-mm-yy".</p> <p>This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p> <p><b>Note:</b> An extended date format is used by default. The short date format only applies when <a href="#">[Alarm]ExtendedDate</a> is set to 0 in the Citect.ini file.</p>
DISABLEENDDATEEXT	The disable end date for a shelved alarm (extended format).	12	<p>The date format used when <a href="#">[Alarm]ExtendedDate</a> is set to 1 in the Citect.ini file.</p>

Field Name	Description	Length	Values
			For non-hardware alarms, extended date format (based on the system locale settings). For example, "dd-mm-yyyy". This works between UTC time January 1 1970 - January 18 2038, otherwise "".
DISABLEENDTIME	The disable end time for a shelved alarm.	12	A time string that indicates when a shelved alarm will no longer be disabled. This can be in 12 hour format (for example, h:mm:ss tt), or 24 hour format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.
ENG_ZERO	The engineering zero scale for this value.	11	Numeric value (real).
EQUIPMENT	The name of the equipment associated with the alarm.	254	This can be a name that represents a single piece of equipment, or a name that also reflects the location of the equipment within the equipment hierarchy (where a period (.) is used to indicate levels in the hierarchy).
FORMAT	Alarm format.	12	For analog, and time stamped analog alarms, a numeric value (real).
FULLNAME	Event user full name.	20	For non-hardware alarms, the configured full name of the event user if exists. Otherwise "System".
GROUP	Alarm group.	16	For multi-digital alarms, a

Field Name	Description	Length	Values
			numeric value
HDELAY	High delay.	16	Delay value (in seconds) for analog alarms and time stamped analog alarms.
HELP	Alarm help.	254	The name of the help page.
HHDELAY	High high delay.	16	Delay value (in seconds) for analog alarms and time stamped analog alarms.
HIGH	Alarm high	12	For analog and time stamped analog alarms, a numeric value (real).
HIGHHIGH	Alarm high high	12	For analog and time stamped analog alarms, a numeric value (real).
HISTORIAN	Determines if the alarm will be included in an automated configuration process within the Historian environment.	6	True or False (blank).
ITEM	Name of equipment item.	63	The name configured in the alarm's <b>Item Name</b> field.
LDELAY	Low delay.	16	Delay value (in seconds) for analog alarms and time stamped analog alarms.
LLDELAY	Low low delay.	16	Delay value (in seconds) for analog alarms and time stamped analog alarms.
LOCALTIMEDATE	Alarm date and time.	24	yyyy-mm-dd hh:mm:ss[.ttt]. This works between: UTC time January 1 1970 - January 18 2038,

Field Name	Description	Length	Values
			otherwise "".
LOGSTATE	Log state text.	13	"ACTIVE", "INACTIVE", "DISABLED", "ENABLED", "ACKNOWLEDGED", "LOW", "HIGH", "LOW LOW", "HIGH HIGH", "RATE", "DEVIATION", "CLEARED", "UNACKNOWLEDGED".
LOW	Alarm low.	12	For analog and time stamped analog alarms, a numeric value (real).
LOWLOW	Alarm low low.	12	For analog and time stamped analog alarms, a numeric value (real).
MESSAGE	The event message.	254	Text entered in the <b>Alarm Desc</b> field of digital, advanced and time-stamped alarms.
MILLISEC	Alarm milliseconds.	6	Numeric value (integer).
NAME	Alarm name.	80	A meaningful description of the alarm defined in the <b>Alarm Name</b> property.
NATIVE_COMMENT	Event comment.	64	A text-based comment added to an event on the SOE page at runtime.
NATIVE_DESC	Alarm description.	80	For analog alarms, the alarm state text. Otherwise, the configured alarm description.
NATIVE_NAME	Alarm name.	80	Configured alarm name.
NATIVE_SUMDESC	Event description text.	80	For non-hardware analog alarms: the event state string. For non-hardware other alarms: the event [or if it does not exist] the alarm

Field Name	Description	Length	Values
	description.		
OFFDATE	Event off date (short format).	12	<p>Short date format (based on the system locale settings).  For example, "dd-mm-yy".  This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p> <p><b>Note:</b> An extended date format is used by default. The short date format only applies when <a href="#">[Alarm]ExtendedDate</a> is set to 0 in the Citect.ini file.</p>
OFFDATEEXT	Extended event off date.	12	<p>The date format used when <a href="#">[Alarm]ExtendedDate</a> is set to 1 in the Citect.ini file.  For non-hardware alarms, extended date format (based on the system locale settings).  For example, "dd-mm-yyyy".  This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p>
OFFMILLI	Millisecond precision for the off time.	6	For high resolution timestamped digital and timestamped analog alarms, it is the milliseconds part of the off time.
OFFTIME	Event off time.	12	This can be in 12 hour format (for example, h:mm:ss tt), or 24 hour format (for example, H:mm:ss) depending on

Field Name	Description	Length	Values
			<p>the regional date and time settings on the local computer.</p> <p><b>Note:</b> This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p>
OFFTIMEDATE	Special SQL formatted date and time.	28	<p>For non-hardware alarms: HH:MI:SS.</p> <p><b>Note:</b> The format can be configured in the citect.ini file using the <a href="#">[Alarm]TimeDate</a> parameter.</p>
OFFUTC	Alarm off time in UTC format.	12	<p>Integer that represents a "time" value based on the number of seconds since Jan 1, 1970 (in UTC format not Local).</p>
OLD_DESC	Multi digital old state description.	8	<p>"Invalid", "OFF", "ON", "ON State 2", "ON State 3", "ON State 4", "ON State 5", "ON State 6", "ON State 7".</p>
ONDATE	Event on date (short format).	12	<p>Short date format (based on the system locale settings).</p> <p>For example, "dd-mm-yy".</p> <p>This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p> <p><b>Note:</b> An extended date format is used by default. The short date format only applies when <a href="#">[Alarm]ExtendedDate</a> is set to 0 in the Citect.ini file.</p>
ONDATEEXT	Event on date (extended format).	12	The date format used when

Field Name	Description	Length	Values
			<p>[Alarm]ExtendedDate is set to 1 in the Citect.ini file.</p> <p>For non-hardware alarms, extended date format (based on the system locale settings).</p> <p>For example, "dd-mm-yyyy".</p> <p>This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p>
ONMILLI	Millisecond precision for the on time.	6	<p>For high resolution timestamped digital and timestamped analog alarms, it is the milliseconds part of the on time.</p>
ONTIME	Event on time.	12	<p>This can be in 12 hour format (for example, h:mm:ss tt), or 24 hour format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.</p> <p><b>Note:</b> This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p>
ONTIMEDATE	Special SQL formatted date and time.	28	<p>For non-hardware alarms: HH:MI:SS.</p> <p><b>Note:</b> The format can be configured in the citect.ini file using the [Alarm]TimeDate parameter.</p>
ONUTC	Alarm on time in UTC format.	12	<p>Integer that represents a "time" value based on the number of seconds since Jan 1, 1970 (in UTC format)</p>

Field Name	Description	Length	Values
			not Local).
PAGING	Alarm paged flag.	8	A flag to indicate that the alarm is going to be paged. Values are 1 (TRUE) or 0 (FALSE).
PAGINGGROUP	Paging group for alarm.	80	A freeform text field indicating the sequence of people to notify in the event the alarm occurred.
PRIORITY	Alarm category priority.	4	Numeric value (integer).
PRIV	Alarm privilege.	16	Numeric value (integer) that represents the level of privilege an operator requires to acknowledge or disable the alarm.
RATE	Alarm rate.	12	For analog and time stamped analog alarms, a numeric value (real).
RECEIPTLOCALTIMEDATE	The alarm's occurrence time.	28	Displays the alarm's occurrence time (if known), otherwise it displays the receipt time of the alarm.
RECEIPTDATE	The date the master station received the event (short format).  For example, the date the RTU received the event.	12	Short date format (based on the system locale settings).  For example, "dd-mm-yy". This works between UTC time January 1 1970 - January 18 2038, otherwise "".  <b>Note:</b> An extended date format is used by default. The short date format only applies when [Alarm]ExtendedDate is set to 0 in the Citect.ini file.
RECEIPTDATEEXT	The date the master	12	The date format used

Field Name	Description	Length	Values
	<p>station received the event (extended format).</p> <p>For example, the date the RTU received the event.</p>		<p>when [Alarm]ExtendedDate is set to 1 in the Citect.ini file.</p> <p>For non-hardware alarms, extended date format (based on the system locale settings).</p> <p>For example, "dd-mm-yyyy".</p> <p>This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p>
RECEIPTMILLISEC	Millisecond precision for the receipt time.	6	For high resolution timestamped digital and timestamped analog alarms, it is the milliseconds part of the receipt time.
RECEIPTTIME	<p>The time the master station received the event.</p> <p>For example, the time the RTU received the event.</p>	16	This can be in 12 hour format (for example, h:mm:ss tt) or 24 hour format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.
RECEIPTTIMEINT	Receipt time in UTC format.	12	An integer that represents a "time" value based on the number of seconds since Jan 1, 1970 (in UTC format not Local).
RECEIPTTIMETICKS	Receipt time measured using ticks.	20	<p>Time expressed as the number of ticks elapsed since 12:00:00 midnight, January 1, 1601 in UTC format.</p> <p>Each tick is 100 nanoseconds.</p>
RESPONSE1	The first response defined	254	Up to eight responses can

Field Name	Description	Length	Values
	for the alarm.		be defined for an alarm to help operators determine the most appropriate course of action.
RESPONSE2	The second response defined for the alarm.	254	See <a href="#">Add Cause and Response Information to Alarms</a> .
RESPONSE3	The third response defined for the alarm.	254	
RESPONSE4	The fourth response defined for the alarm.	254	
RESPONSE5	The fifth response defined for the alarm.	254	
RESPONSE6	The sixth response defined for the alarm.	254	
RESPONSE7	The seventh response defined for the alarm.	254	
RESPONSE8	The eighth response defined for the alarm.	254	
RESPONSENUM	The number of alarm responses that have been configured for an alarm tag.	8	0 to 8.
SETPOINT	The set point value. This is only applicable to analog alarms.	16	An analog variable tag, expression or base value that determines if a deviation alarm is to be triggered.
STATE	Alarm state string.	16	For analog and time stamped analog alarms: "OFF", "DEVIATION", "RATE OF CHANGE", "LOW", "HIGH", "LOW LOW", "HIGH HIGH". For multi-digital alarms: "OFF", "ON", "ON State 2", "ON State 3", "ON State 4", "ON State 5", "ON State 6", "ON State 7". For double point status

Field Name	Description	Length	Values
			alarms: The configured state name. For all other alarms: "OFF", "ON".
STATE_DESC	Multi-digital state description.	8	"OFF", "ON", "ON State 2", "ON State 3", "ON State 4", "ON State 5", "ON State 6", "ON State 7".
STATE_DESC0	Multi-digital state 0.	64	For multi-digital alarms: "OFF". For others: "INVALID".
STATE_DESC1	Multi-digital state 1.	64	For multi-digital alarms: "ON". For others: "INVALID".
STATE_DESC2	Multi-digital state 2.	64	For multi-digital alarms: "ON state 2". For others: "INVALID".
STATE_DESC3	Multi-digital state 3.	64	For multi-digital alarms: "ON state 3". For others: "INVALID".
STATE_DESC4	Multi-digital state 4.	64	For multi-digital alarms: "ON state 4". For others: "INVALID".
STATE_DESC5	Multi-digital state 5.	64	For multi-digital alarms: "ON state 5". For others: "INVALID".
STATE_DESC6	Multi-digital state 6.	64	For multi-digital alarms: "ON state 6". For others: "INVALID".
STATE_DESC7	Multi-digital state 7.	64	For multi-digital alarms: "ON state 7". For others: "INVALID".
SUMDESC	Event description text.	80	Analog alarm - event state

Field Name	Description	Length	Values
			text. Otherwise - configured event [or alarm in case event not defined] description.
SUMSTATE	Event state text.	16	Displays the last active state of the alarm. "OFF", "ON", "ON State 2", "ON State 3", "ON State 4", "ON State 5", "ON State 6", "ON State 7", "DEVIATION", "RATE OF CHANGE", "LOW", "HIGH", "LOW LOW", "HIGH HIGH", "Invalid".
SUMTYPE	Event state.	16	For non-hardware alarms: "DISABLED", "UNACKNOWLEDGED", "ACKNOWLEDGED", "Cleared".
TAG	Tag name.	80	The configured tag name.
TAGEX	Extended alarm tag.	32	<cluster>.<tag> when a cluster is defined. Otherwise <tag>.
TAGGENLINK	Indicates a tag was imported from an I/O device.	16	Name of the I/O device from which this tag was generated.
TIME	The time the event occurred.	12	This can be in 12 hour format (hh:mm:ss tt), or 24 hour format (HH:mm:ss) depending on the current date and time settings on the local computer. <b>Note:</b> This works between UTC time January 1 1970 - January 18 2038, otherwise "".
TIMEDATE	Special SQL formatted time.	28	For non-hardware alarms: HH:MI:SS.

Field Name	Description	Length	Values
			<b>Note:</b> The format can be configured in the citect.ini file using the [Alarm]TimeDate parameter.
TIMEINT	Event time in UTC format.	12	Integer that represents a time value based on the number of seconds since Jan 1, 1970 (in UTC format).
TIMETICKS	Event time measured using ticks.	20	Time expressed as the number of ticks elapsed since 12:00:00 midnight, January 1, 1601 in UTC format. Each tick is 100 nanoseconds.
TSQUALITY	The quality of the alarm tag. This is passed to the alarm server by the I/O server when a value change occurs.	64	Expected time stamp quality strings are: Time Good, Time Uncertain, Clock Not Synchronized, or empty string if no match is found.
TYPE	Alarm type.	16	"DISABLED", "UNACKNOWLEDGED", "ACKNOWLEDGED", "CLEARED"
TYPENUM	Alarm type represented as a numeric value.	4	Values are: -1 - Invalid 0 - Digital 1 - Analog 2 - Advanced 3 - Multi-Digital 4 - ArgAna 5 - User event 6 - Time stamped 7 - Hardware 8 - Time stamped digital

Field Name	Description	Length	Values
			9 - Time stamped analog
USERDESC	The text related to a user event.	64	If you specify an asterisk '*' as the first character of the <i>sTag</i> argument in <a href="#">AlarmSumAppend</a> , the summary entry becomes a user event. This value is the text that follows the asterisk.
USERNAME	Event user name.	16	For non-hardware alarms, the configured name of the event user (if it exists). Otherwise "System".
USERLOCATION	The IP of the machine which last raised, modified, or performed an action on the alarm.	80	<b>Note:</b> If the last action performed is from a system machine, the IP will not over ride the last user machine IP address.
VALUE (alarm fields)	Formatted alarm value.	16	For analog alarms, a numeric value formatted according to configuration.

## AlmBrowseOpen Fields

The fields in the following table can be used with the [AlmBrowseOpen](#) Cicode function.

Field Name	Description	Length	Values
ACKDATE	Event acknowledgement date (short format).	12	Short date format (based on the system locale settings). For example, "dd-mm-yy". This works between UTC time January 1 1970 - January 18 2038, otherwise "".

Field Name	Description	Length	Values
			<b>Note:</b> An extended date format is used by default. The short date format only applies when [Alarm]ExtendedDate is set to 0 in the Citect.ini file.
ACKDATEEXT	Event acknowledgement date (extended format).	12	The date format used when [Alarm]ExtendedDate is set to 1 in the Citect.ini file.  For non-hardware alarms, extended date format (based on the system locale settings).  For example, "dd-mm-yyyy".  This works between UTC time January 1 1970 - January 18 2038, otherwise "".
ACKMILLI	Millisecond precision for the event acknowledgement time.	6	For high resolution time stamped digital and time stamped analog alarms, this value represents the milliseconds part of the acknowledgement time.
ACKTIME	Event acknowledgement time.	12	This can be in 12 hour format (for example, h:mm:ss tt), or 24 hour format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.  <b>Note:</b> This works between UTC time January 1 1970 - January 18 2038, otherwise "".
ACKUTC	Event acknowledgment time in UTC format.	12	Integer that represents a time value based on the

Field Name	Description	Length	Values
			number of seconds since Jan 1, 1970 (in UTC format).
ACQDESC	Acquisition error description.	254	Textual representation of an alarm acquisition error.
ACQERROR	Acquisition error.	6	Numeric value (integer).
ALARMTYPE	Alarm type.	16	Text describing the following alarm types: "Digital", "Analog", "Advanced", "Multi-Digital", "Time Stamped", "Time Stamped Digital", "Time Stamped Analog".
ALMCOMMENT	Alarm comment.	254	A text-based comment added to an alarm during configuration.
AREA	Alarm area.	16	Numeric value (integer) representing area.
ARR_SIZE	Array size.	16	Integer (1 means it is not an array).
CATEGORY	Alarm category.	16	Numeric value (integer) representing the alarm category.
CAUSE1	The first cause defined for the alarm.	254	Up to eight causes can be defined for an alarm to help operators determine the most appropriate course of action.  See <a href="#">Add Cause and Response Information to Alarms</a> .
CAUSE2	The second cause defined for the alarm.	254	
CAUSE3	The third cause defined for the alarm.	254	
CAUSE4	The fourth cause defined for the alarm.	254	
CAUSE5	The fifth cause defined for the alarm.	254	
CAUSE6	The sixth cause defined for the alarm.	254	

Field Name	Description	Length	Values
CAUSE7	The seventh cause defined for the alarm.	254	
CAUSE8	The eighth cause defined for the alarm.	254	
CLASSIFICATION	The class of the event.	32	The classification applied to an event. For example: Action - The event was logged due to an action being performed. Comment - The event was logged due to a comment being created. Configuration - The event was logged due to configuration changes being made. System - The event has been logged due to an occurrence that affects the entire system, such as the server being stopped and restarted. Alarm type - Type of alarm (for example, digital, multi-digital, etc.).
CLUSTER	The cluster to which the tag belongs.	32	The cluster name.
COMMENT	Comment.	64	If hardware alarm = "". Or a configured event description or trend comment.
CONSEQUENCE1	The first consequence defined for an alarm.	254	Up to eight consequences can be defined for an alarm to help operators determine the most appropriate course of action.  See <a href="#">Add Cause and Response Information to Alarms</a> .
CONSEQUENCE2	The second consequence defined for an alarm.	254	
CONSEQUENCE3	The third consequence defined for an alarm.	254	
CONSEQUENCE4	The fourth consequence	254	

Field Name	Description	Length	Values
	defined for an alarm.		
CONSEQUENCE5	The fifth consequence defined for an alarm.	254	
CONSEQUENCE6	The sixth consequence defined for an alarm.	254	
CONSEQUENCE7	The seventh consequence defined for an alarm.	254	
CONSEQUENCE8	The eighth consequence defined for an alarm.	254	
CUSTOM1	Alarm custom field #1	64	A user-defined string.
CUSTOM2	Alarm custom field #2	64	A user-defined string.
CUSTOM3	Alarm custom field #3	64	A user-defined string.
CUSTOM4	Alarm custom field #4	64	A user-defined string.
CUSTOM5	Alarm custom field #5	64	A user-defined string.
CUSTOM6	Alarm custom field #6	64	A user-defined string.
CUSTOM7	Alarm custom field #7	64	A user-defined string.
CUSTOM8	Alarm custom field #8	64	A user-defined string.
DATE	Alarm date in short format.	12	<p>Short date format (based on the system locale settings).  For example, "dd-mm-yy".  This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p> <p><b>Note:</b> An extended date format is used by default. The short date format only applies when <a href="#">[Alarm]ExtendedDate</a> is set to 0 in the Citect.ini file.</p>
DATEEXT	Alarm date in extended format.	12	The date format used when

Field Name	Description	Length	Values
			<p>[Alarm]ExtendedDate is set to 1 in the Citect.ini file.</p> <p>For non-hardware alarms, extended date format (based on the system locale settings).</p> <p>For example, "dd-mm-yyyy".</p> <p>This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p>
DEADBAND	Alarm deadband.	12	For analog, and timestamped analog alarms, a numeric value (real).
DELAY	The delay configured for the alarm.	12	<p>The delay period in the following format:</p> <p>hh:mm:ss</p> <p>The value will be between 0 seconds (00:00:00) and 24 hours (24:00:00).</p>
DELTAMILLI	Millisecond precision for the delta time.	6	For high resolution time stamped digital and time stamped analog alarms, it is the milliseconds part of the delta time.
DELTATIME	The time difference between OnDate/OnTime and OffDate/OffTime.	12	<p>The delta time in the following format:</p> <p>hh:mm:ss</p>
DESC	Alarm description.	254	<p>For analog alarms:</p> <p>"DEVIATION", "RATE OF CHANGE", "LOW", "HIGH", "LOW LOW", "HIGH HIGH".</p> <p>For other alarm types:</p> <p>Configured descriptions.</p>
DEVDELAY	Deviation delay.	16	Delay value (in seconds)

Field Name	Description	Length	Values
			for analog alarms and time stamped analog alarms.
DEVIATION	Alarm deviation.	12	For analog and time stamped analog alarms: Numeric value (real).
DISABLECOMMENT	A comment added by a user when an alarm is shelved.	254	A user defined text string.
DISABLEDDATE	The date an alarm was disabled.	12	<p>The date format is based on the system locale settings.</p> <p>Extended date format: (for example, dd-mm-yyyy).</p> <p>Short date format: (for example, dd-mm-yy).</p> <p>This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p> <p><b>Note:</b> Extended date format is used by default. The short date format only applies when [Alarm]ExtendedDate is set to 0 in the Citect.ini file.</p>
DISABLEDTIME	The time an alarm was disabled.	12	<p>A time string that indicates when an alarm was disabled.</p> <p>This can be in 12 hour format (for example, h:mm:ss tt), or 24 hour format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.</p>
DISABLEENDDATE	The disable end date for a	12	Short date format (based

Field Name	Description	Length	Values
	shelved alarm (short format).		<p>on the system locale settings).</p> <p>For example, "dd-mm-yy". This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p> <p><b>Note:</b> An extended date format is used by default. The short date format only applies when <a href="#">[Alarm]ExtendedDate</a> is set to 0 in the Citect.ini file.</p>
DISABLEENDDATEEXT	The disable end date for a shelved alarm (extended format).	12	<p>The date format used when <a href="#">[Alarm]ExtendedDate</a> is set to 1 in the Citect.ini file.</p> <p>For non-hardware alarms, extended date format (based on the system locale settings).</p> <p>For example, "dd-mm-yyyy".</p> <p>This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p>
DISABLEENDTIME	The disable end time for a shelved alarm.	12	<p>A time string that indicates when a shelved alarm will no longer be disabled.</p> <p>This can be in 12 hour format (for example, h:mm:ss tt), or 24 hour format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.</p>
ENG_ZERO	The engineering zero	11	Numeric value (real).

Field Name	Description	Length	Values
	scale for this value.		
EQUIPMENT	The name of the equipment associated with the alarm.	254	This can be a name that represents a single piece of equipment, or a name that also reflects the location of the equipment within the equipment hierarchy (where a period (.) is used to indicate levels in the hierarchy).
FORMAT	Alarm format.	12	For analog, and time stamped analog alarms, a numeric value (real).
FULLNAME	Event user full name.	20	For non-hardware alarms, the configured full name of the event user if exists. Otherwise "System".
GROUP	Alarm group.	16	For multi-digital alarms, a numeric value
HDELAY	High delay.	16	Delay value (in seconds) for analog alarms and time stamped analog alarms.
HELP	Alarm help.	254	The name of the help page.
HHDELAY	High high delay.	16	Delay value (in seconds) for analog alarms and time stamped analog alarms.
HIGH	Alarm high	12	For analog and time stamped analog alarms, a numeric value (real).
HIGHHIGH	Alarm high high	12	For analog and time stamped analog alarms, a numeric value (real).
HISTORIAN	Determines if the alarm will be included in an automated configuration	6	True or False (blank).

Field Name	Description	Length	Values
	process within the Historian environment.		
ITEM	Name of equipment item.	63	The name configured in the alarm's <b>Item Name</b> field.
LDELAY	Low delay.	16	Delay value (in seconds) for analog alarms and time stamped analog alarms.
LLDELAY	Low low delay.	16	Delay value (in seconds) for analog alarms and time stamped analog alarms.
LOCALTIMEDATE	Alarm date and time.	24	yyyy-mm-dd hh:mm:ss[.ttt]. This works between: UTC time January 1 1970 - January 18 2038, otherwise "".
LOGSTATE	Log state text.	13	"ACTIVE", "INACTIVE", "DISABLED", "ENABLED", "ACKNOWLEDGED", "LOW", "HIGH", "LOW LOW", "HIGH HIGH", "RATE", "DEVIATION", "CLEARED", "UNACKNOWLEDGED".
LOW	Alarm low.	12	For analog and time stamped analog alarms, a numeric value (real).
LOWLOW	Alarm low low.	12	For analog and time stamped analog alarms, a numeric value (real).
MESSAGE	The event message.	254	Text entered in the <b>Alarm Desc</b> field of digital, advanced and time-stamped alarms.
MILLISEC	Alarm milliseconds.	6	Numeric value (integer).

Field Name	Description	Length	Values
NAME	Alarm name.	80	A meaningful description of the alarm defined in the <b>Alarm Name</b> property.
NATIVE_COMMENT	Event comment.	64	A text-based comment added to an event on the SOE page at runtime.
NATIVE_DESC	Alarm description.	80	For analog alarms, the alarm state text. Otherwise, the configured alarm description.
NATIVE_NAME	Alarm name.	80	Configured alarm name.
NATIVE_SUMDESC	Event description text.	80	For non-hardware analog alarms: the event state string. For non-hardware other alarms: the event [or if it does not exist] the alarm description.
OFFDATE	Event off date (short format).	12	Short date format (based on the system locale settings). For example, "dd-mm-yy". This works between UTC time January 1 1970 - January 18 2038, otherwise "". <b>Note:</b> An extended date format is used by default. The short date format only applies when <a href="#">[Alarm]ExtendedDate</a> is set to 0 in the Citect.ini file.
OFFDATEEXT	Extended event off date.	12	The date format used when <a href="#">[Alarm]ExtendedDate</a> is set to 1 in the Citect.ini file. For non-hardware alarms,

Field Name	Description	Length	Values
			<p>extended date format (based on the system locale settings).  For example, "dd-mm-yyyy".  This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p>
OFFMILLI	Millisecond precision for the off time.	6	<p>For high resolution timestamped digital and timestamped analog alarms, it is the milliseconds part of the off time.</p>
OFFTIME	Event off time.	12	<p>This can be in 12 hour format (for example, h:mm:ss tt), or 24 hour format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.  <b>Note:</b> This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p>
OFFTIMEDATE	Special SQL formatted date and time.	28	<p>For non-hardware alarms: HH:MI:SS.  <b>Note:</b> The format can be configured in the citect.ini file using the <a href="#">[Alarm]TimeDate</a> parameter.</p>
OFFUTC	Alarm off time in UTC format.	12	<p>Integer that represents a "time" value based on the number of seconds since Jan 1, 1970 (in UTC format not Local).</p>
OLD_DESC	Multi digital old state description.	8	"Invalid", "OFF", "ON", "ON State 2", "ON State

Field Name	Description	Length	Values
			3", "ON State 4", "ON State 5", "ON State 6", "ON State 7".
ONDATE	Event on date (short format).	12	<p>Short date format (based on the system locale settings).  For example, "dd-mm-yy".  This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p> <p><b>Note:</b> An extended date format is used by default. The short date format only applies when <a href="#">[Alarm]ExtendedDate</a> is set to 0 in the Citect.ini file.</p>
ONDATEEXT	Event on date (extended format).	12	<p>The date format used when <a href="#">[Alarm]ExtendedDate</a> is set to 1 in the Citect.ini file.  For non-hardware alarms, extended date format (based on the system locale settings).  For example, "dd-mm-yyyy".  This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p>
ONMILLI	Millisecond precision for the on time.	6	For high resolution timestamped digital and timestamped analog alarms, it is the milliseconds part of the on time.
ONTIME	Event on time.	12	This can be in 12 hour format (for example, h:mm:ss tt), or 24 hour

Field Name	Description	Length	Values
			format (for example, H:mm:ss) depending on the regional date and time settings on the local computer. <b>Note:</b> This works between UTC time January 1 1970 - January 18 2038, otherwise "".
ONTIMEDATE	Special SQL formatted date and time.	28	For non-hardware alarms: HH:MI:SS. <b>Note:</b> The format can be configured in the citect.ini file using the <a href="#">[Alarm]TimeDate</a> parameter.
ONUTC	Alarm on time in UTC format.	12	Integer that represents a "time" value based on the number of seconds since Jan 1, 1970 (in UTC format not Local).
PAGING	Alarm paged flag.	8	A flag to indicate that the alarm is going to be paged. Values are 1 (TRUE) or 0 (FALSE).
PAGINGGROUP	Paging group for alarm.	80	A freeform text field indicating the sequence of people to notify in the event the alarm occurred.
PRIORITY	Alarm category priority.	4	Numeric value (integer).
PRIV	Alarm privilege.	16	Numeric value (integer) that represents the level of privilege an operator requires to acknowledge or disable the alarm.
RATE	Alarm rate.	12	For analog and time stamped analog alarms, a numeric value (real).
RECEIPTLOCALTIMEDATE	The alarm's occurrence	28	Displays the alarm's

Field Name	Description	Length	Values
	time.		occurrence time (if known), otherwise it displays the receipt time of the alarm.
RECEIPTDATE	The date the master station received the event (short format).  For example, the date the RTU received the event.	12	Short date format (based on the system locale settings).  For example, "dd-mm-yy". This works between UTC time January 1 1970 - January 18 2038, otherwise "".  <b>Note:</b> An extended date format is used by default. The short date format only applies when <a href="#">[Alarm]ExtendedDate</a> is set to 0 in the Citect.ini file.
RECEIPTDATEEXT	The date the master station received the event (extended format).  For example, the date the RTU received the event.	12	The date format used when <a href="#">[Alarm]ExtendedDate</a> is set to 1 in the Citect.ini file.  For non-hardware alarms, extended date format (based on the system locale settings).  For example, "dd-mm-yyyy".  This works between UTC time January 1 1970 - January 18 2038, otherwise "".
RECEIPTMILLISEC	Millisecond precision for the receipt time.	6	For high resolution timestamped digital and timestamped analog alarms, it is the milliseconds part of the receipt time.
RECEIPTTIME	The time the master station received the	16	This can be in 12 hour format (for example,

Field Name	Description	Length	Values
	event. For example, the time the RTU received the event.		h:mm:ss tt) or 24 hour format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.
RECEIPTTIMEINT	Receipt time in UTC format.	12	An integer that represents a "time" value based on the number of seconds since Jan 1, 1970 (in UTC format not Local).
RECEIPTTIMETICKS	Receipt time measured using ticks.	20	Time expressed as the number of ticks elapsed since 12:00:00 midnight, January 1, 1601 in UTC format. Each tick is 100 nanoseconds.
RESPONSE1	The first response defined for the alarm.	254	Up to eight responses can be defined for an alarm to help operators determine the most appropriate course of action.  See <a href="#">Add Cause and Response Information to Alarms</a> .
RESPONSE2	The second response defined for the alarm.	254	
RESPONSE3	The third response defined for the alarm.	254	
RESPONSE4	The fourth response defined for the alarm.	254	
RESPONSE5	The fifth response defined for the alarm.	254	
RESPONSE6	The sixth response defined for the alarm.	254	
RESPONSE7	The seventh response defined for the alarm.	254	
RESPONSE8	The eighth response defined for the alarm.	254	
RESPONSENUM	The number of alarm responses that have been configured for an alarm	8	0 to 8.

Field Name	Description	Length	Values
	tag.		
SETPOINT	The set point value. This is only applicable to analog alarms.	16	An analog variable tag, expression or base value that determines if a deviation alarm is to be triggered.
STATE	Alarm state string.	16	For analog and time stamped analog alarms: "OFF", "DEVIATION", "RATE OF CHANGE", "LOW", "HIGH", "LOW LOW", "HIGH HIGH".  For multi-digital alarms: "OFF", "ON", "ON State 2", "ON State 3", "ON State 4", "ON State 5", "ON State 6", "ON State 7".  For double point status alarms: The configured state name.  For all other alarms: "OFF", "ON".
STATE_DESC	Multi-digital state description.	8	"OFF", "ON", "ON State 2", "ON State 3", "ON State 4", "ON State 5", "ON State 6", "ON State 7".
STATE_DESC0	Multi-digital state 0.	64	For multi-digital alarms: "OFF".  For others: "INVALID".
STATE_DESC1	Multi-digital state 1.	64	For multi-digital alarms: "ON".  For others: "INVALID".
STATE_DESC2	Multi-digital state 2.	64	For multi-digital alarms: "ON state 2".  For others: "INVALID".

Field Name	Description	Length	Values
STATE_DESC3	Multi-digital state 3.	64	For multi-digital alarms: "ON state 3". For others: "INVALID".
STATE_DESC4	Multi-digital state 4.	64	For multi-digital alarms: "ON state 4". For others: "INVALID".
STATE_DESC5	Multi-digital state 5.	64	For multi-digital alarms: "ON state 5". For others: "INVALID".
STATE_DESC6	Multi-digital state 6.	64	For multi-digital alarms: "ON state 6". For others: "INVALID".
STATE_DESC7	Multi-digital state 7.	64	For multi-digital alarms: "ON state 7". For others: "INVALID".
SUMDESC	Event description text.	80	Analog alarm - event state text.  Otherwise - configured event [or alarm in case event not defined] description.
SUMSTATE	Event state text.	16	Displays the last active state of the alarm. "OFF", "ON", "ON State 2", "ON State 3", "ON State 4", "ON State 5", "ON State 6", "ON State 7", "DEVIATION", "RATE OF CHANGE", "LOW", "HIGH", "LOW LOW", "HIGH HIGH", "Invalid".
SUMTYPE	Event state.	16	For non-hardware alarms: "DISABLED", "UNACKNOWLEDGED", "ACKNOWLEDGED", "CLEARED".
TAG	Tag name.	80	The configured tag name.

Field Name	Description	Length	Values
TAGEX	Extended alarm tag.	32	<cluster>.<tag> when a cluster is defined. Otherwise <tag>.
TAGGENLINK	Indicates a tag was imported from an I/O device.	16	Name of the I/O device from which this tag was generated.
TIME	The time the event occurred.	12	This can be in 12 hour format (hh:mm:ss tt), or 24 hour format (HH:mm:ss) depending on the current date and time settings on the local computer. <b>Note:</b> This works between UTC time January 1 1970 - January 18 2038, otherwise "".
TIMEDATE	Special SQL formatted time.	28	For non-hardware alarms: HH:MI:SS. <b>Note:</b> The format can be configured in the citect.ini file using the [Alarm]TimeDate parameter.
TIMEINT	Event time in UTC format.	12	Integer that represents a time value based on the number of seconds since Jan 1, 1970 (in UTC format).
TIMETICKS	Event time measured using ticks.	20	Time expressed as the number of ticks elapsed since 12:00:00 midnight, January 1, 1601 in UTC format. Each tick is 100 nanoseconds.

Field Name	Description	Length	Values
TSQUALITY	The quality of the alarm tag. This is passed to the alarm server by the I/O server when a value change occurs.	64	Expected time stamp quality strings are: Time Good, Time Uncertain, Clock Not Synchronized, or empty string if no match is found.
TYPE	Alarm type.	16	"DISABLED", "UNACKNOWLEDGED", "ACKNOWLEDGED", "Cleared"
TYPENUM	Alarm type represented as a numeric value.	4	Values are: -1 - Invalid 0 - Digital 1 - Analog 2 - Advanced 3 - Multi-Digital 4 - ArgAna 5 - User event 6 - Time stamped 7 - Hardware 8 - Time stamped digital 9 - Time stamped analog
USERDESC	The text related to a user event.	64	If you specify an asterisk '*' as the first character of the <i>sTag</i> argument in <a href="#">AlarmSumAppend</a> , the summary entry becomes a user event. This value is the text that follows the asterisk.
USERNAME	Event user name.	16	For non-hardware alarms, the configured name of the event user (if it exists). Otherwise "System".
USERLOCATION	The IP of the machine which last raised, modified, or performed	80	<b>Note:</b> If the last action performed is from a system machine, the IP

Field Name	Description	Length	Values
	an action on the alarm.		will not over ride the last user machine IP address.
VALUE (alarm fields)	Formatted alarm value.	16	For analog alarms, a numeric value formatted according to configuration.

### AlmSummaryOpen Fields

The fields in the following table can be used with the [AlmSummaryOpen](#) Cicode function.

Field Name	Description	Length	Values
ACKDATE	Event acknowledgement date (short format).	12	<p>Short date format (based on the system locale settings).  For example, "dd-mm-yy".  This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p> <p><b>Note:</b> An extended date format is used by default. The short date format only applies when <a href="#">[Alarm]ExtendedDate</a> is set to 0 in the Citect.ini file.</p>
ACKDATEEXT	Event acknowledgement date (extended format).	12	<p>The date format used when <a href="#">[Alarm]ExtendedDate</a> is set to 1 in the Citect.ini file.  For non-hardware alarms, extended date format (based on the system locale settings).  For example, "dd-mm-yyyy".</p>

Field Name	Description	Length	Values
			This works between UTC time January 1 1970 - January 18 2038, otherwise "".
ACKMILLI	Millisecond precision for the event acknowledgement time.	6	For high resolution time stamped digital and time stamped analog alarms, this value represents the milliseconds part of the acknowledgement time.
ACKTIME	Event acknowledgement time.	12	This can be in 12 hour format (for example, h:mm:ss tt), or 24 hour format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.  <b>Note:</b> This works between UTC time January 1 1970 - January 18 2038, otherwise "".
ACKUTC	Event acknowledgment time in UTC format.	12	Integer that represents a time value based on the number of seconds since Jan 1, 1970 (in UTC format).
ACQDESC	Acquisition error description.	254	Textual representation of an alarm acquisition error.
ACQERROR	Acquisition error.	6	Numeric value (integer).
ALARMTYPE	Alarm type.	16	Text describing the following alarm types: "Digital", "Analog", "Advanced", "Multi-Digital", "Time Stamped", "Time Stamped Digital", "Time Stamped Analog".
ALMCOMMENT	Alarm comment.	254	A text-based comment added to an alarm during configuration.

Field Name	Description	Length	Values
AREA	Alarm area.	16	Numeric value (integer) representing area.
ARR_SIZE	Array size.	16	Integer (1 means it is not an array).
CATEGORY	Alarm category.	16	Numeric value (integer) representing the alarm category.
CAUSE1	The first cause defined for the alarm.	254	Up to eight causes can be defined for an alarm to help operators determine the most appropriate course of action.  See <a href="#">Add Cause and Response Information to Alarms</a> .
CAUSE2	The second cause defined for the alarm.	254	
CAUSE3	The third cause defined for the alarm.	254	
CAUSE4	The fourth cause defined for the alarm.	254	
CAUSE5	The fifth cause defined for the alarm.	254	
CAUSE6	The sixth cause defined for the alarm.	254	
CAUSE7	The seventh cause defined for the alarm.	254	
CAUSE8	The eighth cause defined for the alarm.	254	
CLASSIFICATION	The class of the event.	32	The classification applied to an event. For example:  Action - The event was logged due to an action being performed.  Comment - The event was logged due to a comment being created.  Configuration - The event was logged due to configuration changes being made.  System - The event has

Field Name	Description	Length	Values
			been logged due to an occurrence that affects the entire system, such as the server being stopped and restarted. Alarm type - Type of alarm (for example, digital, multi-digital, etc.).
CLUSTER	The cluster to which the tag belongs.	32	The cluster name.
COMMENT	Comment.	64	If hardware alarm = "". Or a configured event description or trend comment.
CONSEQUENCE1	The first consequence defined for an alarm.	254	Up to eight consequences can be defined for an alarm to help operators determine the most appropriate course of action.  See <a href="#">Add Cause and Response Information to Alarms</a> .
CONSEQUENCE2	The second consequence defined for an alarm.	254	
CONSEQUENCE3	The third consequence defined for an alarm.	254	
CONSEQUENCE4	The fourth consequence defined for an alarm.	254	
CONSEQUENCE5	The fifth consequence defined for an alarm.	254	
CONSEQUENCE6	The sixth consequence defined for an alarm.	254	
CONSEQUENCE7	The seventh consequence defined for an alarm.	254	
CONSEQUENCE8	The eighth consequence defined for an alarm.	254	
CUSTOM1	Alarm custom field #1	64	A user-defined string.
CUSTOM2	Alarm custom field #2	64	A user-defined string.
CUSTOM3	Alarm custom field #3	64	A user-defined string.
CUSTOM4	Alarm custom field #4	64	A user-defined string.

Field Name	Description	Length	Values
CUSTOM5	Alarm custom field #5	64	A user-defined string.
CUSTOM6	Alarm custom field #6	64	A user-defined string.
CUSTOM7	Alarm custom field #7	64	A user-defined string.
CUSTOM8	Alarm custom field #8	64	A user-defined string.
DATE	Alarm date in short format.	12	<p>Short date format (based on the system locale settings).  For example, "dd-mm-yy".  This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p> <p><b>Note:</b> An extended date format is used by default. The short date format only applies when <a href="#">[Alarm]ExtendedDate</a> is set to 0 in the Citect.ini file.</p>
DATEEXT	Alarm date in extended format.	12	<p>The date format used when <a href="#">[Alarm]ExtendedDate</a> is set to 1 in the Citect.ini file.  For non-hardware alarms, extended date format (based on the system locale settings).  For example, "dd-mm-yyyy".  This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p>
DEADBAND	Alarm deadband.	12	For analog, and timestamped analog alarms, a numeric value (real).
DELAY	The delay configured for	12	The delay period in the

Field Name	Description	Length	Values
	the alarm.		following format: hh:mm:ss  The value will be between 0 seconds (00:00:00) and 24 hours (24:00:00).
DELTAMILLI	Millisecond precision for the delta time.	6	For high resolution time stamped digital and time stamped analog alarms, it is the milliseconds part of the delta time.
DELTATIME	The time difference between OnDate/OnTime and OffDate/OffTime.	12	The delta time in the following format: hh:mm:ss
DESC	Alarm description.	254	For analog alarms: "DEVIATION", "RATE OF CHANGE", "LOW", "HIGH", "LOW LOW", "HIGH HIGH".  For other alarm types: Configured descriptions.
DEVDELAY	Deviation delay.	16	Delay value (in seconds) for analog alarms and time stamped analog alarms.
DEVIATION	Alarm deviation.	12	For analog and time stamped analog alarms: Numeric value (real).
DISABLECOMMENT	A comment added by a user when an alarm is shelved.	254	A user defined text string.
DISABLEDDATE	The date an alarm was disabled.	12	The date format is based on the system locale settings.  Extended date format: (for example, dd-mm-yyyy).  Short date format: (for example, dd-mm-yy).

Field Name	Description	Length	Values
			<p>This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p> <p><b>Note:</b> Extended date format is used by default. The short date format only applies when <a href="#">[Alarm]ExtendedDate</a> is set to 0 in the Citect.ini file.</p>
DISABLETIME	The time an alarm was disabled.	12	<p>A time string that indicates when an alarm was disabled.</p> <p>This can be in 12 hour format (for example, h:mm:ss tt), or 24 hour format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.</p>
DISABLEENDDATE	The disable end date for a shelved alarm (short format).	12	<p>Short date format (based on the system locale settings).</p> <p>For example, "dd-mm-yy".</p> <p>This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p> <p><b>Note:</b> An extended date format is used by default. The short date format only applies when <a href="#">[Alarm]ExtendedDate</a> is set to 0 in the Citect.ini file.</p>
DISABLEENDDATEEXT	The disable end date for a shelved alarm (extended format).	12	<p>The date format used when <a href="#">[Alarm]ExtendedDate</a> is set to 1 in the Citect.ini file.</p>

Field Name	Description	Length	Values
			For non-hardware alarms, extended date format (based on the system locale settings). For example, "dd-mm-yyyy". This works between UTC time January 1 1970 - January 18 2038, otherwise "".
DISABLEENDTIME	The disable end time for a shelved alarm.	12	A time string that indicates when a shelved alarm will no longer be disabled. This can be in 12 hour format (for example, h:mm:ss tt), or 24 hour format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.
ENG_ZERO	The engineering zero scale for this value.	11	Numeric value (real).
EQUIPMENT	The name of the equipment associated with the alarm.	254	This can be a name that represents a single piece of equipment, or a name that also reflects the location of the equipment within the equipment hierarchy (where a period (.) is used to indicate levels in the hierarchy).
FORMAT	Alarm format.	12	For analog, and time stamped analog alarms, a numeric value (real).
FULLNAME	Event user full name.	20	For non-hardware alarms, the configured full name of the event user if exists. Otherwise "System".
GROUP	Alarm group.	16	For multi-digital alarms, a

Field Name	Description	Length	Values
			numeric value
HDELAY	High delay.	16	Delay value (in seconds) for analog alarms and time stamped analog alarms.
HELP	Alarm help.	254	The name of the help page.
HHDELAY	High high delay.	16	Delay value (in seconds) for analog alarms and time stamped analog alarms.
HIGH	Alarm high	12	For analog and time stamped analog alarms, a numeric value (real).
HIGHHIGH	Alarm high high	12	For analog and time stamped analog alarms, a numeric value (real).
HISTORIAN	Determines if the alarm will be included in an automated configuration process within the Historian environment.	6	True or False (blank).
ITEM	Name of equipment item.	63	The name configured in the alarm's <b>Item Name</b> field.
LDELAY	Low delay.	16	Delay value (in seconds) for analog alarms and time stamped analog alarms.
LLDELAY	Low low delay.	16	Delay value (in seconds) for analog alarms and time stamped analog alarms.
LOCALTIMEDATE	Alarm date and time.	24	yyyy-mm-dd hh:mm:ss[.ttt]. This works between: UTC time January 1 1970 - January 18 2038,

Field Name	Description	Length	Values
			otherwise "".
LOGSTATE	Log state text.	13	"ACTIVE", "INACTIVE", "DISABLED", "ENABLED", "ACKNOWLEDGED", "LOW", "HIGH", "LOW LOW", "HIGH HIGH", "RATE", "DEVIATION", "CLEARED", "UNACKNOWLEDGED".
LOW	Alarm low.	12	For analog and time stamped analog alarms, a numeric value (real).
LOWLOW	Alarm low low.	12	For analog and time stamped analog alarms, a numeric value (real).
MESSAGE	The event message.	254	Text entered in the <b>Alarm Desc</b> field of digital, advanced and time-stamped alarms.
MILLISEC	Alarm milliseconds.	6	Numeric value (integer).
NAME	Alarm name.	80	A meaningful description of the alarm defined in the <b>Alarm Name</b> property.
NATIVE_COMMENT	Event comment.	64	A text-based comment added to an event on the SOE page at runtime.
NATIVE_DESC	Alarm description.	80	For analog alarms, the alarm state text. Otherwise, the configured alarm description.
NATIVE_NAME	Alarm name.	80	Configured alarm name.
NATIVE_SUMDESC	Event description text.	80	For non-hardware analog alarms: the event state string. For non-hardware other alarms: the event [or if it does not exist] the alarm

Field Name	Description	Length	Values
			description.
OFFDATE	Event off date (short format).	12	<p>Short date format (based on the system locale settings).  For example, "dd-mm-yy".  This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p> <p><b>Note:</b> An extended date format is used by default. The short date format only applies when <a href="#">[Alarm]ExtendedDate</a> is set to 0 in the Citect.ini file.</p>
OFFDATEEXT	Extended event off date.	12	<p>The date format used when <a href="#">[Alarm]ExtendedDate</a> is set to 1 in the Citect.ini file.  For non-hardware alarms, extended date format (based on the system locale settings).  For example, "dd-mm-yyyy".  This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p>
OFFMILLI	Millisecond precision for the off time.	6	For high resolution timestamped digital and timestamped analog alarms, it is the milliseconds part of the off time.
OFFTIME	Event off time.	12	This can be in 12 hour format (for example, h:mm:ss tt), or 24 hour format (for example, H:mm:ss) depending on

Field Name	Description	Length	Values
			<p>the regional date and time settings on the local computer.</p> <p><b>Note:</b> This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p>
OFFTIMEDATE	Special SQL formatted date and time.	28	<p>For non-hardware alarms: HH:MI:SS.</p> <p><b>Note:</b> The format can be configured in the citect.ini file using the <a href="#">[Alarm]TimeDate</a> parameter.</p>
OFFUTC	Alarm off time in UTC format.	12	<p>Integer that represents a "time" value based on the number of seconds since Jan 1, 1970 (in UTC format not Local).</p>
OLD_DESC	Multi digital old state description.	8	<p>"Invalid", "OFF", "ON", "ON State 2", "ON State 3", "ON State 4", "ON State 5", "ON State 6", "ON State 7".</p>
ONDATE	Event on date (short format).	12	<p>Short date format (based on the system locale settings).</p> <p>For example, "dd-mm-yy".</p> <p>This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p> <p><b>Note:</b> An extended date format is used by default. The short date format only applies when <a href="#">[Alarm]ExtendedDate</a> is set to 0 in the Citect.ini file.</p>
ONDATEEXT	Event on date (extended format).	12	The date format used when

Field Name	Description	Length	Values
			<p>[Alarm]ExtendedDate is set to 1 in the Citect.ini file.</p> <p>For non-hardware alarms, extended date format (based on the system locale settings).</p> <p>For example, "dd-mm-yyyy".</p> <p>This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p>
ONMILLI	Millisecond precision for the on time.	6	<p>For high resolution timestamped digital and timestamped analog alarms, it is the milliseconds part of the on time.</p>
ONTIME	Event on time.	12	<p>This can be in 12 hour format (for example, h:mm:ss tt), or 24 hour format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.</p> <p><b>Note:</b> This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p>
ONTIMEDATE	Special SQL formatted date and time.	28	<p>For non-hardware alarms: HH:MI:SS.</p> <p><b>Note:</b> The format can be configured in the citect.ini file using the [Alarm]TimeDate parameter.</p>
ONUTC	Alarm on time in UTC format.	12	<p>Integer that represents a "time" value based on the number of seconds since Jan 1, 1970 (in UTC format)</p>

Field Name	Description	Length	Values
			not Local).
PAGING	Alarm paged flag.	8	A flag to indicate that the alarm is going to be paged. Values are 1 (TRUE) or 0 (FALSE).
PAGINGGROUP	Paging group for alarm.	80	A freeform text field indicating the sequence of people to notify in the event the alarm occurred.
PRIORITY	Alarm category priority.	4	Numeric value (integer).
PRIV	Alarm privilege.	16	Numeric value (integer) that represents the level of privilege an operator requires to acknowledge or disable the alarm.
RATE	Alarm rate.	12	For analog and time stamped analog alarms, a numeric value (real).
RECEIPTLOCALTIMEDATE	The alarm's occurrence time.	28	Displays the alarm's occurrence time (if known), otherwise it displays the receipt time of the alarm.
RECEIPTDATE	The date the master station received the event (short format).  For example, the date the RTU received the event.	12	Short date format (based on the system locale settings).  For example, "dd-mm-yy". This works between UTC time January 1 1970 - January 18 2038, otherwise "".  <b>Note:</b> An extended date format is used by default. The short date format only applies when [Alarm]ExtendedDate is set to 0 in the Citect.ini file.
RECEIPTDATEEXT	The date the master	12	The date format used

Field Name	Description	Length	Values
	<p>station received the event (extended format).</p> <p>For example, the date the RTU received the event.</p>		<p>when [Alarm]ExtendedDate is set to 1 in the Citect.ini file.</p> <p>For non-hardware alarms, extended date format (based on the system locale settings).</p> <p>For example, "dd-mm-yyyy".</p> <p>This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p>
RECEIPTMILLISEC	Millisecond precision for the receipt time.	6	For high resolution timestamped digital and timestamped analog alarms, it is the milliseconds part of the receipt time.
RECEIPTTIME	<p>The time the master station received the event.</p> <p>For example, the time the RTU received the event.</p>	16	This can be in 12 hour format (for example, h:mm:ss tt) or 24 hour format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.
RECEIPTTIMEINT	Receipt time in UTC format.	12	An integer that represents a "time" value based on the number of seconds since Jan 1, 1970 (in UTC format not Local).
RECEIPTTIMETICKS	Receipt time measured using ticks.	20	<p>Time expressed as the number of ticks elapsed since 12:00:00 midnight, January 1, 1601 in UTC format.</p> <p>Each tick is 100 nanoseconds.</p>
RESPONSE1	The first response defined	254	Up to eight responses can

Field Name	Description	Length	Values
	for the alarm.		be defined for an alarm to help operators determine the most appropriate course of action.
RESPONSE2	The second response defined for the alarm.	254	See <a href="#">Add Cause and Response Information to Alarms</a> .
RESPONSE3	The third response defined for the alarm.	254	
RESPONSE4	The fourth response defined for the alarm.	254	
RESPONSE5	The fifth response defined for the alarm.	254	
RESPONSE6	The sixth response defined for the alarm.	254	
RESPONSE7	The seventh response defined for the alarm.	254	
RESPONSE8	The eighth response defined for the alarm.	254	
RESPONSENUM	The number of alarm responses that have been configured for an alarm tag.	8	0 to 8.
SETPOINT	The set point value. This is only applicable to analog alarms.	16	An analog variable tag, expression or base value that determines if a deviation alarm is to be triggered.
STATE	Alarm state string.	16	For analog and time stamped analog alarms: "OFF", "DEVIATION", "RATE OF CHANGE", "LOW", "HIGH", "LOW LOW", "HIGH HIGH". For multi-digital alarms: "OFF", "ON", "ON State 2", "ON State 3", "ON State 4", "ON State 5", "ON State 6", "ON State 7". For double point status

Field Name	Description	Length	Values
			alarms: The configured state name. For all other alarms: "OFF", "ON".
STATE_DESC	Multi-digital state description.	8	"OFF", "ON", "ON State 2", "ON State 3", "ON State 4", "ON State 5", "ON State 6", "ON State 7".
STATE_DESC0	Multi-digital state 0.	64	For multi-digital alarms: "OFF". For others: "INVALID".
STATE_DESC1	Multi-digital state 1.	64	For multi-digital alarms: "ON". For others: "INVALID".
STATE_DESC2	Multi-digital state 2.	64	For multi-digital alarms: "ON state 2". For others: "INVALID".
STATE_DESC3	Multi-digital state 3.	64	For multi-digital alarms: "ON state 3". For others: "INVALID".
STATE_DESC4	Multi-digital state 4.	64	For multi-digital alarms: "ON state 4". For others: "INVALID".
STATE_DESC5	Multi-digital state 5.	64	For multi-digital alarms: "ON state 5". For others: "INVALID".
STATE_DESC6	Multi-digital state 6.	64	For multi-digital alarms: "ON state 6". For others: "INVALID".
STATE_DESC7	Multi-digital state 7.	64	For multi-digital alarms: "ON state 7". For others: "INVALID".
SUMDESC	Event description text.	80	Analog alarm - event state

Field Name	Description	Length	Values
			text. Otherwise - configured event [or alarm in case event not defined] description.
SUMSTATE	Event state text.	16	Displays the last active state of the alarm. "OFF", "ON", "ON State 2", "ON State 3", "ON State 4", "ON State 5", "ON State 6", "ON State 7", "DEVIATION", "RATE OF CHANGE", "LOW", "HIGH", "LOW LOW", "HIGH HIGH", "Invalid".
SUMTYPE	Event state.	16	For non-hardware alarms: "DISABLED", "UNACKNOWLEDGED", "ACKNOWLEDGED", "Cleared".
TAG	Tag name.	80	The configured tag name.
TAGEX	Extended alarm tag.	32	<cluster>.<tag> when a cluster is defined. Otherwise <tag>.
TAGGENLINK	Indicates a tag was imported from an I/O device.	16	Name of the I/O device from which this tag was generated.
TIME	The time the event occurred.	12	This can be in 12 hour format (hh:mm:ss tt), or 24 hour format (HH:mm:ss) depending on the current date and time settings on the local computer. <b>Note:</b> This works between UTC time January 1 1970 - January 18 2038, otherwise "".
TIMEDATE	Special SQL formatted time.	28	For non-hardware alarms: HH:MI:SS.

Field Name	Description	Length	Values
			<b>Note:</b> The format can be configured in the citect.ini file using the [Alarm]TimeDate parameter.
TIMEINT	Event time in UTC format.	12	Integer that represents a time value based on the number of seconds since Jan 1, 1970 (in UTC format).
TIMETICKS	Event time measured using ticks.	20	Time expressed as the number of ticks elapsed since 12:00:00 midnight, January 1, 1601 in UTC format. Each tick is 100 nanoseconds.
TSQUALITY	The quality of the alarm tag. This is passed to the alarm server by the I/O server when a value change occurs.	64	Expected time stamp quality strings are: Time Good, Time Uncertain, Clock Not Synchronized, or empty string if no match is found.
TYPE	Alarm type.	16	"DISABLED", "UNACKNOWLEDGED", "ACKNOWLEDGED", "CLEARED"
TYPENUM	Alarm type represented as a numeric value.	4	Values are: -1 - Invalid 0 - Digital 1 - Analog 2 - Advanced 3 - Multi-Digital 4 - ArgAna 5 - User event 6 - Time stamped 7 - Hardware 8 - Time stamped digital

Field Name	Description	Length	Values
			9 - Time stamped analog
USERDESC	The text related to a user event.	64	If you specify an asterisk '*' as the first character of the <i>sTag</i> argument in <a href="#">AlarmSumAppend</a> , the summary entry becomes a user event. This value is the text that follows the asterisk.
USERNAME	Event user name.	16	For non-hardware alarms, the configured name of the event user (if it exists). Otherwise "System".
USERLOCATION	The IP of the machine which last raised, modified, or performed an action on the alarm.	80	<b>Note:</b> If the last action performed is from a system machine, the IP will not over ride the last user machine IP address.
VALUE (alarm fields)	Formatted alarm value.	16	For analog alarms, a numeric value formatted according to configuration.

## AlmTagsOpen Fields

The fields in the following table can be used with the [AlmTagsOpen](#) Cicode function.

Field Name	Description	Length	Values
ACKDATE	Event acknowledgement date (short format).	12	Short date format (based on the system locale settings). For example, "dd-mm-yy". This works between UTC time January 1 1970 - January 18 2038, otherwise "".

Field Name	Description	Length	Values
			<b>Note:</b> An extended date format is used by default. The short date format only applies when [Alarm]ExtendedDate is set to 0 in the Citect.ini file.
ACKDATEEXT	Event acknowledgement date (extended format).	12	The date format used when [Alarm]ExtendedDate is set to 1 in the Citect.ini file.  For non-hardware alarms, extended date format (based on the system locale settings).  For example, "dd-mm-yyyy".  This works between UTC time January 1 1970 - January 18 2038, otherwise "".
ACKMILLI	Millisecond precision for the event acknowledgement time.	6	For high resolution time stamped digital and time stamped analog alarms, this value represents the milliseconds part of the acknowledgement time.
ACKTIME	Event acknowledgement time.	12	This can be in 12 hour format (for example, h:mm:ss tt), or 24 hour format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.  <b>Note:</b> This works between UTC time January 1 1970 - January 18 2038, otherwise "".
ACKUTC	Event acknowledgment time in UTC format.	12	Integer that represents a time value based on the

Field Name	Description	Length	Values
			number of seconds since Jan 1, 1970 (in UTC format).
ACQDESC	Acquisition error description.	254	Textual representation of an alarm acquisition error.
ACQERROR	Acquisition error.	6	Numeric value (integer).
ALARMTYPE	Alarm type.	16	Text describing the following alarm types: "Digital", "Analog", "Advanced", "Multi-Digital", "Time Stamped", "Time Stamped Digital", "Time Stamped Analog".
ALMCOMMENT	Alarm comment.	254	A text-based comment added to an alarm during configuration.
AREA	Alarm area.	16	Numeric value (integer) representing area.
ARR_SIZE	Array size.	16	Integer (1 means it is not an array).
CATEGORY	Alarm category.	16	Numeric value (integer) representing the alarm category.
CAUSE1	The first cause defined for the alarm.	254	Up to eight causes can be defined for an alarm to help operators determine the most appropriate course of action.  See <a href="#">Add Cause and Response Information to Alarms</a> .
CAUSE2	The second cause defined for the alarm.	254	
CAUSE3	The third cause defined for the alarm.	254	
CAUSE4	The fourth cause defined for the alarm.	254	
CAUSE5	The fifth cause defined for the alarm.	254	
CAUSE6	The sixth cause defined for the alarm.	254	

Field Name	Description	Length	Values
CAUSE7	The seventh cause defined for the alarm.	254	
CAUSE8	The eighth cause defined for the alarm.	254	
CLASSIFICATION	The class of the event.	32	The classification applied to an event. For example: Action - The event was logged due to an action being performed. Comment - The event was logged due to a comment being created. Configuration - The event was logged due to configuration changes being made. System - The event has been logged due to an occurrence that affects the entire system, such as the server being stopped and restarted. Alarm type - Type of alarm (for example, digital, multi-digital, etc.).
CLUSTER	The cluster to which the tag belongs.	32	The cluster name.
COMMENT	Comment.	64	If hardware alarm = "". Or a configured event description or trend comment.
CONSEQUENCE1	The first consequence defined for an alarm.	254	Up to eight consequences can be defined for an alarm to help operators determine the most appropriate course of action.  See <a href="#">Add Cause and Response Information to Alarms</a> .
CONSEQUENCE2	The second consequence defined for an alarm.	254	
CONSEQUENCE3	The third consequence defined for an alarm.	254	
CONSEQUENCE4	The fourth consequence	254	

Field Name	Description	Length	Values
	defined for an alarm.		
CONSEQUENCE5	The fifth consequence defined for an alarm.	254	
CONSEQUENCE6	The sixth consequence defined for an alarm.	254	
CONSEQUENCE7	The seventh consequence defined for an alarm.	254	
CONSEQUENCE8	The eighth consequence defined for an alarm.	254	
CUSTOM1	Alarm custom field #1	64	A user-defined string.
CUSTOM2	Alarm custom field #2	64	A user-defined string.
CUSTOM3	Alarm custom field #3	64	A user-defined string.
CUSTOM4	Alarm custom field #4	64	A user-defined string.
CUSTOM5	Alarm custom field #5	64	A user-defined string.
CUSTOM6	Alarm custom field #6	64	A user-defined string.
CUSTOM7	Alarm custom field #7	64	A user-defined string.
CUSTOM8	Alarm custom field #8	64	A user-defined string.
DATE	Alarm date in short format.	12	<p>Short date format (based on the system locale settings).  For example, "dd-mm-yy".  This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p> <p><b>Note:</b> An extended date format is used by default. The short date format only applies when <a href="#">[Alarm]ExtendedDate</a> is set to 0 in the Citect.ini file.</p>
DATEEXT	Alarm date in extended format.	12	The date format used when

Field Name	Description	Length	Values
			[Alarm]ExtendedDate is set to 1 in the Citect.ini file.  For non-hardware alarms, extended date format (based on the system locale settings).  For example, "dd-mm-yyyy".  This works between UTC time January 1 1970 - January 18 2038, otherwise "".
DEADBAND	Alarm deadband.	12	For analog, and timestamped analog alarms, a numeric value (real).
DELAY	The delay configured for the alarm.	12	The delay period in the following format:  hh:mm:ss  The value will be between 0 seconds (00:00:00) and 24 hours (24:00:00).
DELTAMILLI	Millisecond precision for the delta time.	6	For high resolution time stamped digital and time stamped analog alarms, it is the milliseconds part of the delta time.
DELTATIME	The time difference between OnDate/OnTime and OffDate/OffTime.	12	The delta time in the following format:  hh:mm:ss
DESC	Alarm description.	254	For analog alarms: "DEVIATION", "RATE OF CHANGE", "LOW", "HIGH", "LOW LOW", "HIGH HIGH".  For other alarm types: Configured descriptions.
DEVDELAY	Deviation delay.	16	Delay value (in seconds)

Field Name	Description	Length	Values
			for analog alarms and time stamped analog alarms.
DEVIATION	Alarm deviation.	12	For analog and time stamped analog alarms: Numeric value (real).
DISABLECOMMENT	A comment added by a user when an alarm is shelved.	254	A user defined text string.
DISABLEDDATE	The date an alarm was disabled.	12	<p>The date format is based on the system locale settings.</p> <p>Extended date format: (for example, dd-mm-yyyy).</p> <p>Short date format: (for example, dd-mm-yy).</p> <p>This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p> <p><b>Note:</b> Extended date format is used by default. The short date format only applies when [Alarm]ExtendedDate is set to 0 in the Citect.ini file.</p>
DISABLEDTIME	The time an alarm was disabled.	12	<p>A time string that indicates when an alarm was disabled.</p> <p>This can be in 12 hour format (for example, h:mm:ss tt), or 24 hour format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.</p>
DISABLEENDDATE	The disable end date for a	12	Short date format (based

Field Name	Description	Length	Values
	shelved alarm (short format).		<p>on the system locale settings).</p> <p>For example, "dd-mm-yy". This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p> <p><b>Note:</b> An extended date format is used by default. The short date format only applies when <a href="#">[Alarm]ExtendedDate</a> is set to 0 in the Citect.ini file.</p>
DISABLEENDDATEEXT	The disable end date for a shelved alarm (extended format).	12	<p>The date format used when <a href="#">[Alarm]ExtendedDate</a> is set to 1 in the Citect.ini file.</p> <p>For non-hardware alarms, extended date format (based on the system locale settings).</p> <p>For example, "dd-mm-yyyy".</p> <p>This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p>
DISABLEENDTIME	The disable end time for a shelved alarm.	12	<p>A time string that indicates when a shelved alarm will no longer be disabled.</p> <p>This can be in 12 hour format (for example, h:mm:ss tt), or 24 hour format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.</p>
ENG_ZERO	The engineering zero	11	Numeric value (real).

Field Name	Description	Length	Values
	scale for this value.		
EQUIPMENT	The name of the equipment associated with the alarm.	254	This can be a name that represents a single piece of equipment, or a name that also reflects the location of the equipment within the equipment hierarchy (where a period (.) is used to indicate levels in the hierarchy).
FORMAT	Alarm format.	12	For analog, and time stamped analog alarms, a numeric value (real).
FULLNAME	Event user full name.	20	For non-hardware alarms, the configured full name of the event user if exists. Otherwise "System".
GROUP	Alarm group.	16	For multi-digital alarms, a numeric value
HDELAY	High delay.	16	Delay value (in seconds) for analog alarms and time stamped analog alarms.
HELP	Alarm help.	254	The name of the help page.
HHDELAY	High high delay.	16	Delay value (in seconds) for analog alarms and time stamped analog alarms.
HIGH	Alarm high	12	For analog and time stamped analog alarms, a numeric value (real).
HIGHHIGH	Alarm high high	12	For analog and time stamped analog alarms, a numeric value (real).
HISTORIAN	Determines if the alarm will be included in an automated configuration	6	True or False (blank).

Field Name	Description	Length	Values
	process within the Historian environment.		
ITEM	Name of equipment item.	63	The name configured in the alarm's <b>Item Name</b> field.
LDELAY	Low delay.	16	Delay value (in seconds) for analog alarms and time stamped analog alarms.
LLDELAY	Low low delay.	16	Delay value (in seconds) for analog alarms and time stamped analog alarms.
LOCALTIMEDATE	Alarm date and time.	24	yyyy-mm-dd hh:mm:ss[.ttt]. This works between: UTC time January 1 1970 - January 18 2038, otherwise "".
LOGSTATE	Log state text.	13	"ACTIVE", "INACTIVE", "DISABLED", "ENABLED", "ACKNOWLEDGED", "LOW", "HIGH", "LOW LOW", "HIGH HIGH", "RATE", "DEVIATION", "CLEARED", "UNACKNOWLEDGED".
LOW	Alarm low.	12	For analog and time stamped analog alarms, a numeric value (real).
LOWLOW	Alarm low low.	12	For analog and time stamped analog alarms, a numeric value (real).
MESSAGE	The event message.	254	Text entered in the <b>Alarm Desc</b> field of digital, advanced and time-stamped alarms.
MILLISEC	Alarm milliseconds.	6	Numeric value (integer).

Field Name	Description	Length	Values
NAME	Alarm name.	80	A meaningful description of the alarm defined in the <b>Alarm Name</b> property.
NATIVE_COMMENT	Event comment.	64	A text-based comment added to an event on the SOE page at runtime.
NATIVE_DESC	Alarm description.	80	For analog alarms, the alarm state text. Otherwise, the configured alarm description.
NATIVE_NAME	Alarm name.	80	Configured alarm name.
NATIVE_SUMDESC	Event description text.	80	For non-hardware analog alarms: the event state string. For non-hardware other alarms: the event [or if it does not exist] the alarm description.
OFFDATE	Event off date (short format).	12	Short date format (based on the system locale settings). For example, "dd-mm-yy". This works between UTC time January 1 1970 - January 18 2038, otherwise "". <b>Note:</b> An extended date format is used by default. The short date format only applies when <a href="#">[Alarm]ExtendedDate</a> is set to 0 in the Citect.ini file.
OFFDATEEXT	Extended event off date.	12	The date format used when <a href="#">[Alarm]ExtendedDate</a> is set to 1 in the Citect.ini file. For non-hardware alarms,

Field Name	Description	Length	Values
			<p>extended date format (based on the system locale settings).  For example, "dd-mm-yyyy".  This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p>
OFFMILLI	Millisecond precision for the off time.	6	<p>For high resolution timestamped digital and timestamped analog alarms, it is the milliseconds part of the off time.</p>
OFFTIME	Event off time.	12	<p>This can be in 12 hour format (for example, h:mm:ss tt), or 24 hour format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.  <b>Note:</b> This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p>
OFFTIMEDATE	Special SQL formatted date and time.	28	<p>For non-hardware alarms: HH:MI:SS.  <b>Note:</b> The format can be configured in the citect.ini file using the <a href="#">[Alarm]TimeDate</a> parameter.</p>
OFFUTC	Alarm off time in UTC format.	12	<p>Integer that represents a "time" value based on the number of seconds since Jan 1, 1970 (in UTC format not Local).</p>
OLD_DESC	Multi digital old state description.	8	"Invalid", "OFF", "ON", "ON State 2", "ON State

Field Name	Description	Length	Values
			3", "ON State 4", "ON State 5", "ON State 6", "ON State 7".
ONDATE	Event on date (short format).	12	<p>Short date format (based on the system locale settings).  For example, "dd-mm-yy".  This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p> <p><b>Note:</b> An extended date format is used by default. The short date format only applies when <a href="#">[Alarm]ExtendedDate</a> is set to 0 in the Citect.ini file.</p>
ONDATEEXT	Event on date (extended format).	12	<p>The date format used when <a href="#">[Alarm]ExtendedDate</a> is set to 1 in the Citect.ini file.  For non-hardware alarms, extended date format (based on the system locale settings).  For example, "dd-mm-yyyy".  This works between UTC time January 1 1970 - January 18 2038, otherwise "".</p>
ONMILLI	Millisecond precision for the on time.	6	For high resolution timestamped digital and timestamped analog alarms, it is the milliseconds part of the on time.
ONTIME	Event on time.	12	This can be in 12 hour format (for example, h:mm:ss tt), or 24 hour

Field Name	Description	Length	Values
			format (for example, H:mm:ss) depending on the regional date and time settings on the local computer. <b>Note:</b> This works between UTC time January 1 1970 - January 18 2038, otherwise "".
ONTIMEDATE	Special SQL formatted date and time.	28	For non-hardware alarms: HH:MI:SS. <b>Note:</b> The format can be configured in the citect.ini file using the <a href="#">[Alarm]TimeDate</a> parameter.
ONUTC	Alarm on time in UTC format.	12	Integer that represents a "time" value based on the number of seconds since Jan 1, 1970 (in UTC format not Local).
PAGING	Alarm paged flag.	8	A flag to indicate that the alarm is going to be paged. Values are 1 (TRUE) or 0 (FALSE).
PAGINGGROUP	Paging group for alarm.	80	A freeform text field indicating the sequence of people to notify in the event the alarm occurred.
PRIORITY	Alarm category priority.	4	Numeric value (integer).
PRIV	Alarm privilege.	16	Numeric value (integer) that represents the level of privilege an operator requires to acknowledge or disable the alarm.
RATE	Alarm rate.	12	For analog and time stamped analog alarms, a numeric value (real).
RECEIPTLOCALTIMEDATE	The alarm's occurrence	28	Displays the alarm's

Field Name	Description	Length	Values
	time.		occurrence time (if known), otherwise it displays the receipt time of the alarm.
RECEIPTDATE	The date the master station received the event (short format).  For example, the date the RTU received the event.	12	Short date format (based on the system locale settings).  For example, "dd-mm-yy". This works between UTC time January 1 1970 - January 18 2038, otherwise "".  <b>Note:</b> An extended date format is used by default. The short date format only applies when <a href="#">[Alarm]ExtendedDate</a> is set to 0 in the Citect.ini file.
RECEIPTDATEEXT	The date the master station received the event (extended format).  For example, the date the RTU received the event.	12	The date format used when <a href="#">[Alarm]ExtendedDate</a> is set to 1 in the Citect.ini file.  For non-hardware alarms, extended date format (based on the system locale settings).  For example, "dd-mm-yyyy".  This works between UTC time January 1 1970 - January 18 2038, otherwise "".
RECEIPTMILLISEC	Millisecond precision for the receipt time.	6	For high resolution timestamped digital and timestamped analog alarms, it is the milliseconds part of the receipt time.
RECEIPTTIME	The time the master station received the	16	This can be in 12 hour format (for example,

Field Name	Description	Length	Values
	event. For example, the time the RTU received the event.		h:mm:ss tt) or 24 hour format (for example, H:mm:ss) depending on the regional date and time settings on the local computer.
RECEIPTTIMEINT	Receipt time in UTC format.	12	An integer that represents a "time" value based on the number of seconds since Jan 1, 1970 (in UTC format not Local).
RECEIPTTIMETICKS	Receipt time measured using ticks.	20	Time expressed as the number of ticks elapsed since 12:00:00 midnight, January 1, 1601 in UTC format. Each tick is 100 nanoseconds.
RESPONSE1	The first response defined for the alarm.	254	Up to eight responses can be defined for an alarm to help operators determine the most appropriate course of action.  See <a href="#">Add Cause and Response Information to Alarms</a> .
RESPONSE2	The second response defined for the alarm.	254	
RESPONSE3	The third response defined for the alarm.	254	
RESPONSE4	The fourth response defined for the alarm.	254	
RESPONSE5	The fifth response defined for the alarm.	254	
RESPONSE6	The sixth response defined for the alarm.	254	
RESPONSE7	The seventh response defined for the alarm.	254	
RESPONSE8	The eighth response defined for the alarm.	254	
RESPONSENUM	The number of alarm responses that have been configured for an alarm	8	0 to 8.

Field Name	Description	Length	Values
	tag.		
SETPOINT	The set point value. This is only applicable to analog alarms.	16	An analog variable tag, expression or base value that determines if a deviation alarm is to be triggered.
STATE	Alarm state string.	16	For analog and time stamped analog alarms: "OFF", "DEVIATION", "RATE OF CHANGE", "LOW", "HIGH", "LOW LOW", "HIGH HIGH".  For multi-digital alarms: "OFF", "ON", "ON State 2", "ON State 3", "ON State 4", "ON State 5", "ON State 6", "ON State 7".  For double point status alarms: The configured state name.  For all other alarms: "OFF", "ON".
STATE_DESC	Multi-digital state description.	8	"OFF", "ON", "ON State 2", "ON State 3", "ON State 4", "ON State 5", "ON State 6", "ON State 7".
STATE_DESC0	Multi-digital state 0.	64	For multi-digital alarms: "OFF".  For others: "INVALID".
STATE_DESC1	Multi-digital state 1.	64	For multi-digital alarms: "ON".  For others: "INVALID".
STATE_DESC2	Multi-digital state 2.	64	For multi-digital alarms: "ON state 2".  For others: "INVALID".

Field Name	Description	Length	Values
STATE_DESC3	Multi-digital state 3.	64	For multi-digital alarms: "ON state 3". For others: "INVALID".
STATE_DESC4	Multi-digital state 4.	64	For multi-digital alarms: "ON state 4". For others: "INVALID".
STATE_DESC5	Multi-digital state 5.	64	For multi-digital alarms: "ON state 5". For others: "INVALID".
STATE_DESC6	Multi-digital state 6.	64	For multi-digital alarms: "ON state 6". For others: "INVALID".
STATE_DESC7	Multi-digital state 7.	64	For multi-digital alarms: "ON state 7". For others: "INVALID".
SUMDESC	Event description text.	80	Analog alarm - event state text.  Otherwise - configured event [or alarm in case event not defined] description.
SUMSTATE	Event state text.	16	Displays the last active state of the alarm. "OFF", "ON", "ON State 2", "ON State 3", "ON State 4", "ON State 5", "ON State 6", "ON State 7", "DEVIATION", "RATE OF CHANGE", "LOW", "HIGH", "LOW LOW", "HIGH HIGH", "Invalid".
SUMTYPE	Event state.	16	For non-hardware alarms: "DISABLED", "UNACKNOWLEDGED", "ACKNOWLEDGED", "CLEARED".
TAG	Tag name.	80	The configured tag name.

Field Name	Description	Length	Values
TAGEX	Extended alarm tag.	32	<cluster>.<tag> when a cluster is defined. Otherwise <tag>.
TAGGENLINK	Indicates a tag was imported from an I/O device.	16	Name of the I/O device from which this tag was generated.
TIME	The time the event occurred.	12	This can be in 12 hour format (hh:mm:ss tt), or 24 hour format (HH:mm:ss) depending on the current date and time settings on the local computer. <b>Note:</b> This works between UTC time January 1 1970 - January 18 2038, otherwise "".
TIMEDATE	Special SQL formatted time.	28	For non-hardware alarms: HH:MI:SS. <b>Note:</b> The format can be configured in the citect.ini file using the [Alarm]TimeDate parameter.
TIMEINT	Event time in UTC format.	12	Integer that represents a time value based on the number of seconds since Jan 1, 1970 (in UTC format).
TIMETICKS	Event time measured using ticks.	20	Time expressed as the number of ticks elapsed since 12:00:00 midnight, January 1, 1601 in UTC format. Each tick is 100 nanoseconds.

Field Name	Description	Length	Values
TSQUALITY	The quality of the alarm tag. This is passed to the alarm server by the I/O server when a value change occurs.	64	Expected time stamp quality strings are: Time Good, Time Uncertain, Clock Not Synchronized, or empty string if no match is found.
TYPE	Alarm type.	16	"DISABLED", "UNACKNOWLEDGED", "ACKNOWLEDGED", "Cleared"
TYPENUM	Alarm type represented as a numeric value.	4	Values are: -1 - Invalid 0 - Digital 1 - Analog 2 - Advanced 3 - Multi-Digital 4 - ArgAna 5 - User event 6 - Time stamped 7 - Hardware 8 - Time stamped digital 9 - Time stamped analog
USERDESC	The text related to a user event.	64	If you specify an asterisk '*' as the first character of the <i>sTag</i> argument in <a href="#">AlarmSumAppend</a> , the summary entry becomes a user event. This value is the text that follows the asterisk.
USERNAME	Event user name.	16	For non-hardware alarms, the configured name of the event user (if it exists). Otherwise "System".
USERLOCATION	The IP of the machine which last raised, modified, or performed	80	<b>Note:</b> If the last action performed is from a system machine, the IP

Field Name	Description	Length	Values
	an action on the alarm.		will not over ride the last user machine IP address.
VALUE (alarm fields)	Formatted alarm value.	16	For analog alarms, a numeric value formatted according to configuration.

## EquipBrowseOpen Fields

The fields in the following table can be used with the [EquipBrowseOpen](#) Cicode function.

Field Name	Description	Length	Values
ALIAS	The display name used to describe a piece of equipment.	254	A meaningful name for a piece of equipment, configured using the <b>Display Name</b> property.
AREA	The area number.	16	Numeric value (integer) representing the area to which the equipment belongs.  If the current user does not have access to the area, the equipment will not be returned by the browse session.
CLUSTER	Cluster name.	16	The name of the cluster to which the equipment is assigned.
COMMENT	Comment.	254	A user-configured comment.
CONTENT	Workspace content associated with the equipment.	254	A comma-separated list that names the content associated with the piece of equipment. This can include pages, faceplates and documents.

Field Name	Description	Length	Values
CUSTOM1	Custom field #1.	254	A user-defined string.
CUSTOM2	Custom field #2.	254	A user-defined string.
CUSTOM3	Custom field #3.	254	A user-defined string.
CUSTOM4	Custom field #4.	254	A user-defined string.
CUSTOM5	Custom field #5.	254	A user-defined string.
CUSTOM6	Custom field #6.	254	A user-defined string.
CUSTOM7	Custom field #7.	254	A user-defined string.
CUSTOM8	Custom field #8.	254	A user-defined string.
DEFSTATE	The default state.	64	The default state configured for the equipment.
DEVSCHED	Determines whether or not the report server retrieves the associated schedule from a BACnet device.	6	"TRUE" or "FALSE". Use SCHEDID to identify the associated schedule.
HIDDEN	Indicates if the equipment is visible in the equipment tree at runtime.	6	"TRUE" or "FALSE".
LOCATION	The location of the equipment.	254	A string describing the location of the equipment.
NAME	Equipment name.	254	This can be a name that represents a single piece of equipment, or a name that also reflects the location of the equipment within an equipment hierarchy (where a period (.) is used to indicate levels in the hierarchy).
PAGE	The name of the page on which the equipment appears.	254	Allows you to navigate directly to the page that hosts the piece of equipment. If the graphic object appears on more

Field Name	Description	Length	Values
			than one page, the page specified will represent the primary operational context.
PARENT	The parent equipment.	254	The name of the parent equipment derived from the name of the equipment.
SCHEDID	BACnet device schedule ID.	16	The ID used to identify the associated schedule on a BACnet device. This field is only used if DEVSCHED returns "TRUE".
SCHEDULED	Indicates if the equipment is included in any scheduled actions.	6	"TRUE" or "FALSE".
TYPE	The equipment type.	254	The name of the equipment type associated with the equipment, as defined in the Equipment Types database.

## EquipRefBrowseGetField Fields

The fields in the following table can be used with the [EquipRefBrowseGetField](#) Cicode function.

Field Name	Description	Length	Values
ASSOC	The association used by the <a href="#">AssEquipReferences</a> Cicode function.	63	A Super Genie association is created using the name specified in this field.
CLUSTER	Cluster name.	16	The name of the cluster the equipment is associated with.
COMMENT	Comment.	254	A user-defined string.

Field Name	Description	Length	Values
CUSTOM1	Custom field #1.	254	A user-defined string.
CUSTOM2	Custom field #2.	254	A user-defined string.
CUSTOM3	Custom field #3.	254	A user-defined string.
CUSTOM4	Custom field #4.	254	A user-defined string.
CUSTOM5	Custom field #5.	254	A user-defined string.
CUSTOM6	Custom field #6.	254	A user-defined string.
CUSTOM7	Custom field #7.	254	A user-defined string.
CUSTOM8	Custom field #8.	254	A user-defined string.
EQUIP	Equipment name.	254	The name of the main piece of equipment that the referenced equipment is linked to.
ORDER	Ordering index.	6	A unique index per reference category that is used in the ordering of the EquipRefBrowse functions.
REFCAT	Reference category.	63	A category that is used to filter equipment references using the EquipRefBrowse functions.
REFCLUST	Cluster of the referenced piece of equipment.	16	The name of the cluster to which the referenced piece of equipment is assigned.
REFEQUIP	Name of the referenced piece of equipment.	254	The name of the referenced piece of equipment.
REFITEM	Referenced equipment item.	63	The name of an item belonging to the referenced piece of equipment.

### EquipRefBrowseOpen Fields

The fields in the following table can be used with the [EquipRefBrowseOpen](#) Cicode function.

Field Name	Description	Length	Values
ASSOC	The association used by the <a href="#">AssEquipReferences</a> Cicode function.	63	A Super Genie association is created using the name specified in this field.
CLUSTER	Cluster name.	16	The name of the cluster the equipment is associated with.
COMMENT	Comment.	254	A user-defined string.
CUSTOM1	Custom field #1.	254	A user-defined string.
CUSTOM2	Custom field #2.	254	A user-defined string.
CUSTOM3	Custom field #3.	254	A user-defined string.
CUSTOM4	Custom field #4.	254	A user-defined string.
CUSTOM5	Custom field #5.	254	A user-defined string.
CUSTOM6	Custom field #6.	254	A user-defined string.
CUSTOM7	Custom field #7.	254	A user-defined string.
CUSTOM8	Custom field #8.	254	A user-defined string.
EQUIP	Equipment name.	254	The name of the main piece of equipment that the referenced equipment is linked to.
ORDER	Ordering index.	6	A unique index per reference category that is used in the ordering of the EquipRefBrowse functions.
REFCAT	Reference category.	63	A category that is used to filter equipment references using the EquipRefBrowse

Field Name	Description	Length	Values
			functions.
REFCLUST	Cluster of the referenced piece of equipment.	16	The name of the cluster to which the referenced piece of equipment is assigned.
REFEQUIP	Name of the referenced piece of equipment.	254	The name of the referenced piece of equipment.
REFITEM	Referenced equipment item.	63	The name of an item belonging to the referenced piece of equipment.

## EquipStateBrowseOpen Fields

The fields in the following table can be used with the [EquipStateBrowseOpen](#) Cicode function.

Field Name	Description	Length	Values
CLUSTER	Cluster name.	16	The name of the cluster to which the state belongs.
DELAY	The delay configured for the state's entry action.	12	The amount of time that needs to elapse before the state will initially become active.  If a delay is defined, the Entry Action for the state will not occur until the specified period of time has elapsed.
DESCRIPTION	A description of the state.	48	A user configured string.
DRMODE	Demand and response mode.	16	A numeric value (integer) that represents different level of energy consumption. See <a href="#">Configure a Demand and Response Mode</a>

Field Name	Description	Length	Values
			<a href="#">Response Solution.</a> The default mode is zero (0).
EQUIPMENT	Name of equipment.	254	The equipment associated with this state. This can be a name that represents a single piece of equipment, or a name that also reflects the location of the equipment within an equipment hierarchy (where a period (.) is used to indicate levels in the hierarchy).
NAME	State name.	64	Usually this string will represent an 'action' the associated equipment could be scheduled to do.
PERIOD	The frequency of the repeat action configured for the state.	16	In hh:mm:ss (hours:minutes:seconds).
PRIORITY	State priority.	16	Numeric value (integer) used to determine which schedule entry will run if a schedule conflict occurs between more than one state.

### TagBrowseOpen Fields

The fields in the following table can be used with the [TagBrowseOpen](#) Cicode function.

Field Name	Description	Length	Values
ADDR	The register address.	254	The address of the register in the I/O device that the variable is associated with.

Field Name	Description	Length	Values
			The format and prefix of the address will depend on the protocol the I/O device uses.
ARR_SIZE	Array size	11	An integer representing the size of the array configured for a variable tag. 1 means it is not an array.
CLUSTER	Cluster name.	16	The cluster the tag exists on.
COMMENT	Comment.	254	A user-configured comment.
CUSTOM1	Custom field #1.	64	A user-defined string.
CUSTOM2	Custom field #2.	64	A user-defined string.
CUSTOM3	Custom field #3.	64	A user-defined string.
CUSTOM4	Custom field #4.	64	A user-defined string.
CUSTOM5	Custom field #5.	64	A user-defined string.
CUSTOM6	Custom field #6.	64	A user-defined string.
CUSTOM7	Custom field #7.	64	A user-defined string.
CUSTOM8	Custom field #8.	64	A user-defined string.
DEADBAND	The deadband set for a tag.	11	A numeric value (real) that indicates how much the value of a variable tag can fluctuate within a defined threshold without updates being sent through to the system.  The threshold is represented as a percentage of the tag's engineering range. The default value is 0 (zero), which captures every value change.

Field Name	Description	Length	Values
ENG_FULL	The engineering full scale point for a tag.	11	Numeric value (real). This value represents engineering units. It is the upper limit used for trends and bar graphs. It is a scaled value derived from the Raw Full Scale property.
ENG_UNITS	Engineering units.	8	The engineering units that the value represents. The predefined values (see below) are in the Help.dbf in the bin directory, but the user may specify it as a free text: %, Amps, deg, ft, ft/min, ft/s, ft/sec, gal, gal/h, gal/min, gal/s, gal/sec, Hz, kg, kg/h, kg/min, kg/s, kg/sec, km/h, kPa, kW, litres, lt, lt/h, lt/min, lt/s, lt/sec, m/min, m/s, m/sec, metres, Rev, Rev/h, RPM, t, t/h, Tonnes, Volts, Watts.
ENG_ZERO	The engineering zero scale for a tag.	11	Numeric value (real). This value represents engineering units. It is the lower limit used for trends and bar graphs. It is a scaled value derived from the Raw Zero Scale property.
EQUIPMENT	Equipment name.	254	The name of the piece of equipment with which the tag is associated. This can be a name that represents a single piece of equipment, or a name that also reflects the location of the equipment

Field Name	Description	Length	Values
			within the equipment hierarchy (where a period (.) is used to indicate levels in the hierarchy).
FULLNAME	The full name of the variable tag.	254	The full name of the variable tag in the format: <ClusterName>.<TagName>.
HISTORIAN	Determines if the alarm will be included in an automated configuration process within the Historian environment.	6	True or False (blank).
ITEM	Equipment item.	63	The name of an item with which the tag is associated. Items form part of an equipment hierarchy. They can be used to associate tags, alarms and trends with a particular attribute of a physical piece of equipment.
RAW_FULL	The raw full scale for the tag.	11	Numeric value (real). It is a raw value read from the I/O device. It represents the upper limit used by Plant SCADA to calculate scaled engineering values. If not defined, Raw Zero Scale and Raw Full Scale will default to the full range value based on the data type.
RAW_ZERO	The raw zero scale for this value.	11	Numeric value (real). It is a raw value read from the I/O device. It represents the lowest value used by Plant SCADA to calculate scaled

Field Name	Description	Length	Values
			engineering values. If not defined, Raw Zero Scale and Raw Full Scale will default to the full range value based on the data type.
TAG	Tag name.	79	The configured tag name.
TYPE	Tag type string.	16	RDT_DIGITAL 0 RDT_INTEGER 1 RDT_REAL 2 RDT_BCD 3 RDT_LONG 4 RDT_LONG_BCD 5 RDT_STRING 7 RDT_BYTE 8 RDT_UINT32 10 RDT_ULONG 18
WRITE_ROLES	The roles that have write permissions for the variable tag.	254	Indicates which roles have write permissions for a variable tag when using an OPC UA or Industrial Graphics client.  Only users included in the specified role(s) will be able to send values to the variable tag from a client application.

### TrnBrowseOpen Fields

The fields in the following table can be used with the [TrnBrowseOpen](#) Cicode function.

Field Name	Description	Length	Values
ACQERROR	Acquisition error.	6	Numeric value (integer).
CLUSTER	Cluster name.	16	The name of the cluster the trend tag is associated with.

Field Name	Description	Length	Values
COMMENT	Comment	254	A user-defined string.
DEADBAND	The deadband set for a trend tag.	16	A numeric value (real) that indicates how much the value of a trend tag can fluctuate within a defined threshold without updates being sent through to the system. The threshold is represented as a percentage of the tag's engineering range. The default value is 0 (zero), which captures every value change.
ENG_UNITS	Engineering units.	8	The engineering units that the value represents. The predefined values (see below) are in the Help.dbf in the bin directory, but the user may specify it as a free text: %, Amps, deg, ft, ft/min, ft/s, ft/sec, gal, gal/h, gal/min, gal/s, gal/sec, Hz, kg, kg/h, kg/min, kg/s, kg/sec, km/h, kPa, kW, litres, lt, lt/h, lt/min, lt/s, lt/sec, m/min, m/s, m/sec, metres, Rev, Rev/h, RPM, t, t/h, Tonnes, Volts, Watts.
EQUIPMENT	The name of the associated piece of equipment.	254	This can be a name that represents a single piece of equipment, or a name that also reflects the location of the equipment within the equipment hierarchy (where a period (.) is used to indicate levels in the hierarchy).

Field Name	Description	Length	Values
EXPRESSION	Logged variable name.	65	The logged variable name (<clustername>.<tagname>).  If the expression contains simple Cicode containing a single tag name, such as "LT131" or "LT131<1000", the tag name is returned (in both these cases LT131).  If the expression contains a function call or more than one tag name, an empty string is returned.
FILENAME	File where the trend data is to be stored.	253	The complete path to the file or a path substitution.
FILES	The number of history files stored on the hard disk (for this tag).	4	The maximum number of files that can be specified per trend tag is 999.
FORMAT	Trend tag format.	11	The format of the variable/expression being logged.  The format is used by the trend scales and trend cursor displays.
HISTORIAN	Determines if the trend tag will be included in an automated configuration process within the Historian environment.	6	True or False (blank).
ITEM	Name of equipment item.	63	The name configured in the trend tag's <b>Item Name</b> field.
LSL	Lower specification limit.	16	This value is used by SPC tags as the lower limit to determine process capability.  When used in conjunction with the USL, it provides a tolerance for your

Field Name	Description	Length	Values
			process.
NAME	Trend tag name.	79	The name assigned to the trend data.
PRIV	Privilege.	16	Numeric value (integer) that represents the level of privilege an operator requires to display trend data.
SAMPLEPER	Sample period of the trend.	16	Sampling periods of greater than one second use the format hh:mm:ss. If a single digit is used without the colon (:), it will be represent seconds. Sampling periods of less than one second are entered as decimals. For example, a period of 200 milliseconds would be 0.2.
SDEVIATION	Standard deviation.	16	For SPC tags, this is the calculation override for process standard deviation (s bar).
SPCFLAG	SPC flag.	4	Indicates that a tag is a Statistical Process Control (SPC) tag.
STORMETHOD	Storage method for the data.	16	"Scaled" or "Floating Point".
SUBGRPSIZE	The size of each SPC subgroup.	8	Indicates the size of the subgroups for SPC tags. Valid values are 1 - 25 inclusive.
TAGGENLINK	Indicates if the tag was imported from an I/O	32	Name of the I/O device from which this tag was

Field Name	Description	Length	Values
	device.		generated.
TIME	File synchronization time.	32	The time of day when the beginning of the history file is synchronized (in hh:mm:ss). The time is specified in Greenwich Mean Time, not the local time zone.
TRIGGER	The variable tag that triggers data logging.	254	The configured tag name (<clustername>.<tagname>). If the trigger contains simple Cicode containing a single tag name, such as "LT131<50", the tag name is returned (in this case LT131). If the expression contains a function call or more than one tag name, an empty string is returned.
TYPE	Trend type.	16	"1" - Periodic "2" - Event "3" - Periodic event.
USL	Upper specification limit.	16	This value is used by SPC tags as the upper limit to determine process capability. When used in conjunction with the LSL, it provides a tolerance for your process.
XDOUBLEBAR	Process mean.	16	For SPC tags, determines the calculation override for process mean (X double bar).

## Server Browse Function Fields

Field Name	Description	Length	Values
CLUSTER	Cluster name.	16	The name of the cluster to which the server belongs.
COMMENT	Comment	48	A user-defined string.
MODE	Indicates whether the server is configured as a primary or standby.	16	For alarm, report and trend servers: 1 - primary 0 - standby. For I/O servers, the MODE field is set to "0".
NAME	Server name.	16	The name of the server
NETADDR	The network addresses associated with the server.	70	A comma-separated list of one or more names. The field contains the network address names as configured, and not IP addresses.
PORT	The port the server is listening on.	16	A number between 1 and 65535. If no port number was configured, this field contains the default port number for the server type.
TYPE	The type of server.	16	"Alarm", "I/O", "Report", or "Trend"

## Parameters

Parameters determine how each Plant SCADA computer operates in both the Plant SCADA configuration and runtime environments.

## ⚠ WARNING

### UNINTENDED EQUIPMENT OPERATION

- Read and understand the applicable material in this manual before changing or removing any Citect.ini parameters.
- Never change or remove any undocumented Citect.ini parameters.
- Before deleting sections of the Citect.ini file, confirm that no necessary or undocumented parameters will be deleted.
- Do not edit your configuration file while your project is running.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

- See [About Parameters](#) for information that explains how parameters operate in a Plant SCADA system.
- See [Configure Parameters](#) for task-based information that describes how to use parameters in a Plant SCADA system.
- See [Parameters Reference](#) for a technical description of the parameters that Plant SCADA supports.

## See Also

[Parameter Categories](#)

## About Parameters

Plant SCADA supports two types of parameters:

- **Project Database Parameters**

Project database parameters can be used to set nominal defaults for parameters that are local to a specific Plant SCADA project, rather than a particular computer. For example, you could use the project database parameters to specify login requirements for all computers in a Plant SCADA system.

To set (or change) the parameters in a project database, go to the **Setup** activity in Plant SCADA Studio and select **Parameters** from the Navigation Menu. Any changes to your project database parameters are only implemented following a project recompile.

- **Citect.ini File Parameters**

The Citect.ini file is a text file that stores values for a comprehensive set of operating parameter that are used to configure the operational settings for each computer in a Plant SCADA system. These values are read by Plant SCADA on startup to determine how the application should operate.

To view the complete list of built-in operating parameters that you can use in a Citect.ini file, see [Parameter Categories](#).

During installation, a default Citect.ini file is copied to the Plant SCADA Config folder in the Program Data directory. This configuration file contains a series of undocumented parameters used by Plant SCADA as well as a series of default settings.

**Note:** Parameter settings in the Citect.ini file take precedence over project database parameters (see [Parameter Precedence](#)).

## **WARNING**

### **UNINTENDED EQUIPMENT OPERATION**

- Do not under any circumstances change or remove any of the undocumented Citect.ini parameters.
  - Before deleting sections of the Citect.ini file, confirm that no undocumented parameters will be deleted.
- Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

The Citect.ini file has a defined structure made up of a **header**, a series of **sections** (containing parameters and their values), and **comments**.

- **Header**

The header of the Citect.ini file contains comments the user wants to document about the configuration settings contained within the file. Typically it would include a history of edits made to the file and reasons for those edits. For example:

```
# Originally set up by XX on XX for use on XX
# Modified by XX on XX at the recommendation of Technical Support.
```

Comments are located at the top of the file before the first definition of a section. Each line of the header starts with the "hash" or "pound" character (#).

For more information, see [Add Comments to the Citect.ini File](#).

- **Sections**

In a Citect.ini file, parameters are organized into sections according to their purpose.

The syntax used to define a section is as follows:

```
[Section Name]
<parameter name1> = <parameter value1>
<parameter name2> = <parameter value2>
<parameter nameX> = <parameter valueX>
```

For example:

```
[Alarm]
Primary = 1
SavePeriod = 600
SaveSecondary =
ScanTime = 500
```

The following rules apply when the Citect.ini is read at runtime:

- A section continues until a new section is defined or the end of file is reached.
- Each parameter definition finishes with a return.
- Any line starting with a hash or pound (#) character is considered to be a comment.
- Any line starting with an exclamation mark (!) is considered to be disabled and therefore treated as a

comment.

- The maximum length for a parameter is 254 characters.

Sections which relate to server components (Alarms, Trend, Reports, I/O Server) also support hierarchical inheritance to allow parameters to be fine tuned to the cluster or server component level. The syntax used is as follows:

```
[Section Name.ClusterName.ServerName]
<parameter name1> = <parameter value1>
<parameter name2> = <parameter value2>
<parameter nameX> = <parameter valueX>
```

For example:

```
[Alarm.Cluster1.Server1]
SavePeriod = 600
ScanTime = 500
```

- **Comments**

You can add comments to a parameters section or a particular parameter setting in the Citect.ini file.

Comments for a **section** commence with a hash or pound character (#) and occur on the line just above the declaration of the relevant section.

For example:

```
#Alarm Section comment would go here
[Alarm]
```

Comments for a **parameter** commence with a hash or pound character (#) and occur on the line just above the declaration of the relevant parameter.

For example:

```
[Alarm]
#Set to 1 by System Administrator on 30/06/2005 10:13:44 AM.
Primary = 1
```

For more information, see [Add Comments to the Citect.ini File](#).

## Example

An extract from a typical Citect.ini configuration file is shown below.

```
#
#Header Comment on Citect.ini file
#[Alarm]
#Set to 1 by System Administrator on 30/06/2015 10:13:44 AM.
Primary = 1
SavePeriod = 600
SaveSecondary =
ScanTime = 500
Server = 1
```

In most cases, if you set (or change) parameters in the Citect.ini file, you need to restart Plant SCADA before the new parameter settings are used. However, there are a few exceptions to this rule where Citect.ini parameters are read at regular intervals and can be changed during runtime. Where this is the case, the parameter is documented accordingly.

If a parameter applies to a particular process, setting changes are implemented as soon as the associated process is restarted. For example, an Events parameter for an Alarm Server will be used as soon as the specific Alarm Server is restarted.

- [Configure Citect.ini Parameters](#)

## Parameter Precedence

On a machine where a parameter is set in **both** the project database and the Citect.ini file, the value contained in the Citect.ini will be used by that machine.

For example, in the diagram below, the project value for "parameter X" (which is stored in the project database) is **n**. This is the value used for parameter X on every server and client EXCEPT the I/O server and trends server, both of which use the values set in their local Citect.ini files (**p** and **m** respectively).

A parameter which is global to a project and applies to the majority of servers running a project is recommended therefore to be defined in the project database where it can be centrally managed and controlled. Any exceptions to this global value can then be managed by modifying the Citect.ini file on the machine to which the exception applies.

## Included projects

If the Citect.ini has no parameter setting, the value used will be the value specified in the lowest level include project. This means that it will then ignore any value placed in the top level projects at Runtime in favor of the lowest level include project which has the parameter set. Naturally if the parameter is not set anywhere, then the default value for the parameter will be used.

For example, using the parameter[Alarm]SavePeriod. The default value is 600. In this example there is a main project and an included sub project with the parameter being set as shown below. The runtime result column in the table below shows what Plant SCADA considers the value to be, for example if the ParameterGet() Cicode was used.

Citect.ini	Main	Include	Runtime Result
None	None	None	600
None	300	None	300
None	None	400	400
None	300	400	400
500	300	400	500
600	300	400	600

## Duplicate Parameters

If the parameter is defined multiple times either in the same project or different include project, the effective value of the parameter is unpredictable. The compiler will pick up the first entry of the parameter found in the project hierarchy, but does not check for duplicate entries.

This means it is not possible to override parameters defined in the included project by defining the same parameter (with different value) in the including project. It is recommended that when you create a new parameter for your project and give it a default value, you define the default value inline rather than defining it as a project parameter in the included project. For example:

Call ParameterGet("MySection", "MyParameter", MyDefaultValue) whenever needing to read the parameter.

MyDefaultValue can be defined as a label so it is accessible outside Cicode files, or as a global variable if the parameter is only used in Cicode files. By doing this, the value of the parameter is overridden in the including project (by defining the value for the parameter in the system parameter database).

However, if the same parameter is defined in the local Citect.ini file, it will always take precedence over the parameter defined in the project. But , if the parameter is defined multiple times in the Citect.ini file, only the first entry will be picked up.

### See also

[Hierarchical Parameters](#)

## Hierarchical Parameters

As Plant SCADA supports clustering and the ability to run multiple servers of the same type on one machine, there are circumstances when the server component parameters (alarm, report, trend, I/O server) need to be tuned to a finer level than just machine level. For this reason, these parameters are hierarchical parameters that are capable of being implemented at a number of levels:

- **Component type level**

The widest scope, the parameter value will apply to every instance of the server type.

- **Cluster level**

The parameter value will apply to every instance of the server running in the specified cluster.

- **Server level**

The parameter value will apply to the instance of the server running in the specified cluster, on the specified machine.

These parameters support **hierarchical inheritance**, that is, a parameter will:

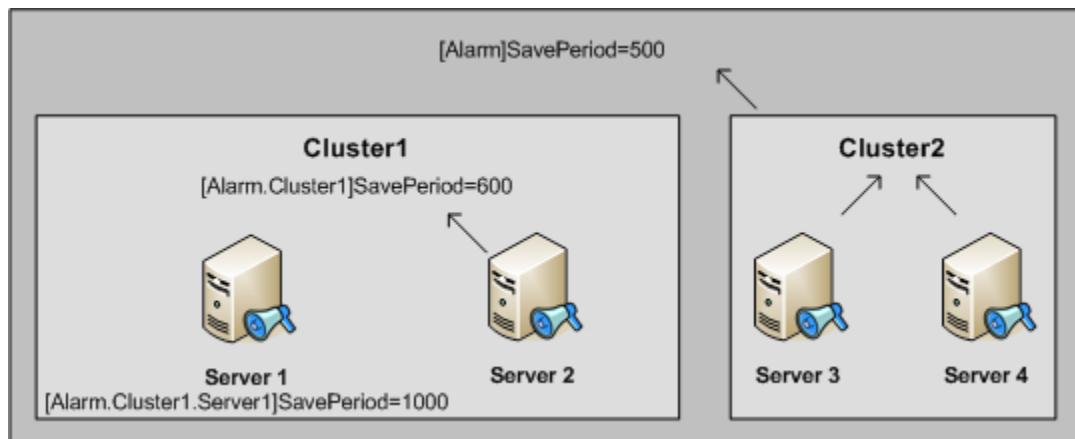

- Apply a value set for it at a server level;
- If that is not specified, apply a value set for it at a cluster level;
- If that is not specified, apply a value set for it at a component level;
- If that is not specified, apply the default value for that parameter.

## Example

The following Citect.ini file is applied to Server1 and Server2 (both in Cluster1), and to Server3 and Server4 (both in Cluster2).

```
[Alarm]SavePeriod = 500
[Alarm.Cluster1]SavePeriod = 600
[Alarm.Cluster1.Server1]SavePeriod = 1000
```

This is illustrated in the diagram below.

The values applied at each server for [Alarm]SavePeriod would be as follows:

Cluster Name	Computer Name	SavePeriod Value
Cluster1	Server1	1000
Cluster1	Server2	600
Cluster2	Server3	500
Cluster2	Server4	500

**Note:** Hierarchical parameters may be set in the parameters database. In this case normal rules of precedence will apply. For more information see [Parameter Precedence](#).

[Configure Alarm Parameters for a Specific Cluster or Process](#)

## Computer Setup Editor

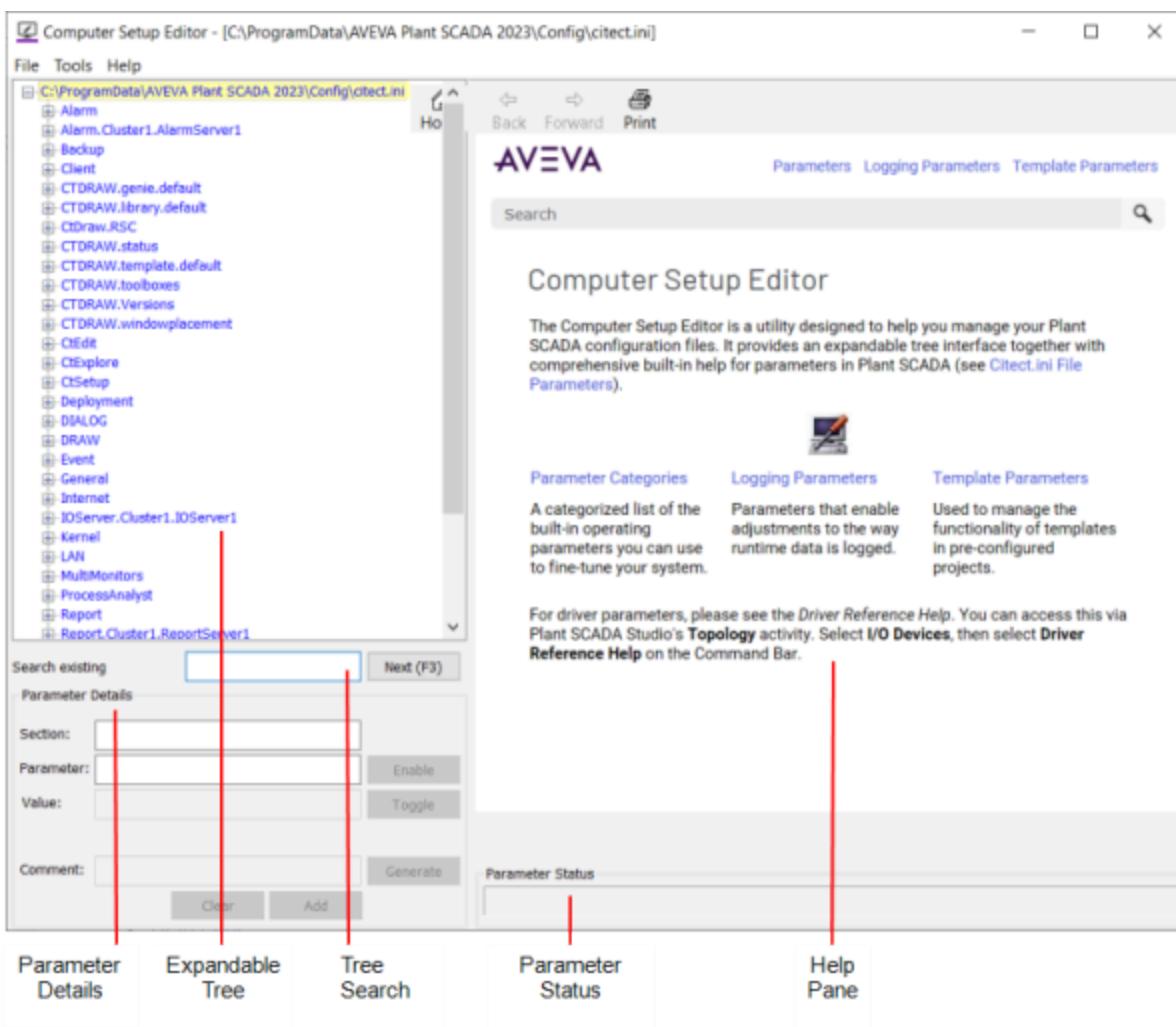

The Computer Setup Editor is a utility designed to help you manage your Citect.ini files. It combines a graphical user interface with an extensive Help system.

The interface provides a convenient way to view, search and modify parameters within a Citect.ini file. The Help system navigates the user through the parameter reference documentation, displaying the topic relevant to the current parameter.

You can use the Computer Setup Editor to perform the following tasks:

- Add or delete parameters
- Change the value of existing parameters (including the addition of optional comments)
- Save changes to disk, cancel all changes or backup to a new file
- Generate a Comparison Report between two separate configuration files, visually highlighting their differences
- Generate an Analysis Report on a configuration file, which provides a useful summary of parameter settings including validity checks on bounds and paths.

The Computer Setup Editor interface consists of the following components, which are described below.

## Expandable Tree

The expandable tree is used to display and navigate the contents of the Citect.ini file.

Each branch on the tree represents a section within the Citect.ini file. Each branch represents the parameters within that section. You can expand and collapse the tree nodes by clicking the "+" and "-" by each element, just as you would in Windows Explorer.

### To expand the tree:

1. Right-click the top element of the tree.
2. Choose Expand all from the shortcut menu.  
The configuration parameter tree expands to show all parameter entries.

### To collapse the tree:

1. Right-click the top element of the tree.
2. Choose Collapse all from the shortcut menu.  
The configuration parameter tree collapses to show only section entries.

## Parameter Details

You can use the Parameter Details pane to view and modify settings and comments for parameters and sections. For details see:

- [Edit Parameter Sections](#)
- [Edit Parameters](#)
- [Add Comments to the Citect.ini File.](#)

When a parameter or section entry is highlighted in the tree pane the corresponding values populate the Parameter Details pane and the corresponding Help files appear in the help pane.

Similarly, the Parameter Details pane populates when a Help topic is selected. This occurs whether or not the parameter exists in the current configuration file.

#### [Tree Search](#)

You can use the tree search to search for a particular element in the Computer Setup Editor's expandable tree.

#### **To search for a specific parameter in the tree:**

1. Type the search string in the **Search existing parameters** field.
  2. The tree expands and highlights the first occurrence of the text string you entered.
- 
- Note:** If the search string is not found a message appears in the Parameter Status pane. In this case, a hyperlink will appear in that pane which can be clicked to perform a search through the help reference topics.
- 
3. To continue to search for the next match within the parameter tree, click **Next** in the tree search pane, or press **F3**. To go to the previous instance, press **Shift + F3**.
  4. If the top or bottom of the Parameter Tree is reached, a message appears in the Parameter Reference pane.

#### [Help Pane](#)

The Help pane displays context-sensitive parameter reference topics.

When a section or parameter entry is selected in the expandable tree pane, the corresponding topic appears in the help pane. If the selected item does not have a help topic, a message to this effect appears in the help pane.

---

**Note:** The converse of the above is also true: when a Help topic is selected in the Help pane, the corresponding entry in the expandable tree pane (provided it exists) is automatically selected.

---

#### [Parameter Status](#)

The parameter status pane becomes active when either:

- A user selects a section or parameter entry in the expandable tree pane.
- A user selects a Help topic in the help pane.

Once active, the parameter status pane displays the name of the section entry being viewed, the name of the parameter entry being viewed (if applicable) and the status of that entry in the current configuration file.

The status shown will depend on whether a help topic exists for this parameter.

If there is no help topic the status pane will tell you so.

If there is a help topic the status pane will state whether:

- The section already exists in this configuration file;
- The parameter already exists in this configuration file;

- The section is not specified in this configuration file; or
- The parameter is not specified in this configuration file.

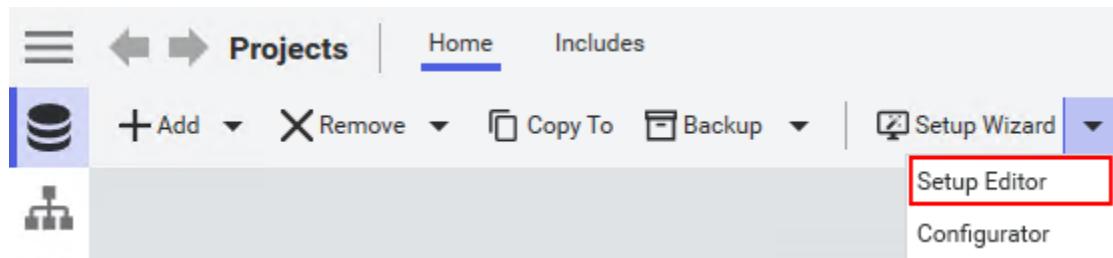

---

**Note:** Section and parameter names are active links that cause the corresponding help topics to be displayed in the help pane.

---

#### To open the Computer Setup Editor:

1. In Plant SCADA Studio, go to the **Projects** activity.
2. On the command bar, open the menu on the **Setup Wizard** button.
3. From the menu, select **Setup Editor**.

---

**Note:** The Computer Setup Editor cannot be used to maintain or set server parameters when being configured at the component or server level using Hierarchical Parameters.

---

[Configure Citect.ini Parameters](#)

## Configure Parameters

Plant SCADA supports both Project Database Parameters and Citect.ini File Parameters. The process you use to configure each type differs greatly.

Select one of the following topics depending on the type of parameter you would like to configure.

- [Configure Project Database Parameters](#)
- [Configure Citect.ini File Parameters](#)

#### See Also

[Parameter Categories](#)

## Configure Project Database Parameters

Project database parameters can be used to set nominal defaults for parameters that are local to a specific Plant SCADA project, rather than a particular computer. For example, you could use the project database parameters to specify login requirements for all computers in a Plant SCADA system.

To create or change parameters in the project database, you use the **Setup** activity.

**To set parameters in the project database:**

1. From the **Setup** activity, select **Parameters**.
2. Enter the **Section Name** of the parameter (16 characters or less).
3. Enter the **Name** of the parameter (16 characters or less).
4. Enter a **Value** for the parameter (254 characters or less).
5. Add a **Comment** if required.
6. Click **Save** to add the record to the database.

If you set (or change) parameters in the project database, you need to re-compile the project before the new parameter settings are used.

---

**Note:** Parameters that are set in the project database take lower precedence than those specified for a particular computer in the Citect.ini file. For more information, see [Parameter Precedence](#).

---

## Configure Citect.ini Parameters

This part of the help includes information that describes how to configure the Citect.ini file using the Computer Setup Editor. It includes the following sections:

- [Open the Citect.ini File](#)
- [Edit Parameter Sections](#)
- [Edit Parameters](#)
- [Add Comments to the Citect.ini File](#)
- [Configure Alarm Parameters for a Specific Cluster or Process](#)
- [Use the Comparison Wizard](#)
- [Saving the Citect.ini File.](#)

### Open the Citect.ini File

**To open the Citect.ini file:**

1. Choose **Open** from the **File** menu.
2. Highlight the required configuration file from the file selection window, then click **Open**.
3. The configuration file will open and display in the expandable tree pane.

**To view load notes:**

1. Choose **View Load Notes** from the **File** menu.
2. A Load Notes window opens and displays any notes taken while loading the configuration file.
3. Click **OK** to close the window.

## See Also

[Configure Citect.ini Parameters](#)

## Edit Parameter Sections

You can edit the sections settings in your Citect.ini file by performing the following tasks:

### To add a section to a Citect.ini file:

1. Right-click on an entry in the expandable tree pane.
2. Choose **Add Section** from the shortcut menu to display the Parameter Details pane.
3. The cursor moves to the **Section** text box in the Parameter Details pane. Type the name of the section you want to add.

Two shortcuts exist to reach this step:

- a. Enter a new section name in the Parameter Details pane. The Computer Setup Editor activates the **Add** button.
  - b. Navigate the Help reference topics within the help pane to locate the topic for the section to be added to the parameter tree, and click the relevant topic. The Computer Setup Editor populates the Parameter Details pane accordingly.
4. Click **Add** to add the new section to the parameter tree.
  5. The Computer Setup Editor checks to see whether the section name is recognized in the parameter reference topics. An alert window displays if the name specified is not recognized. Click **Yes** to proceed.

The new section appears in the parameter tree. It is highlighted as the currently selected entry, and its Help appears in the help pane.

### To delete a section:

1. Right-click the section to be deleted in the expandable tree pane.
2. Choose **Delete Section** from the shortcut menu to display a confirmation window.
3. The Computer Setup Editor opens an alert window requesting confirmation of this action. Click **Yes** to continue.
4. The section is deleted from the parameter tree.

If there are undocumented parameters not currently visible in the tree that exist in the file, an alert appears to advise you that you can view these undocumented parameters, and the undocumented parameters are not deleted. See [View Undocumented Parameters](#) for details.

### WARNING

#### UNINTENDED EQUIPMENT OPERATION

- Do not under any circumstances change or remove any of the undocumented Citect.ini parameters.
- Before deleting sections of the Citect.ini file, confirm that no undocumented parameters will be deleted.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Plant SCADA support personnel regarding undocumented features.

#### To disable a section in a Citect.ini file:

Disabling a section within the parameter tree causes the section and all associated parameters to be treated as a comment in the Citect.ini file when the file is read at startup time.

**Note:** Disabled sections are not deleted from the file and can be enabled later. See [Enable a Section](#) for details.

1. Right-click the section you want to disable in the expandable tree pane.
2. Choose **Disable** from the shortcut menu.
3. The section is disabled and the text in that section within the parameter tree changes to red to indicate its disabled status.

#### To enable a section in a Citect.ini file:

1. Right-click the section you want to enable in the expandable tree pane.
2. Choose **Enable** from the shortcut menu.

The section is enabled and the text in that section within the parameter tree changes to black to indicate its enabled status.

**Note:** Some alarm parameters can be applied to a specified cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

## See Also

[Configure Citect.ini Parameters](#)

## Edit Parameters

You can edit the parameters in a Citect.ini file in the following ways:

## Add a Parameter

#### To add a parameter to a Citect.ini file:

1. Right-click the section in the expandable tree pane you want to add the parameter to.
2. Choose **Add Parameter** from the shortcut menu.
3. The section name pre populates the Parameter Details pane. Type the name of the parameter you want to add in the **Parameter** text box.

Two shortcuts exist to reach this step:

- a. Locate the section for the new parameter in the expandable tree pane, click it, then enter a new parameter name in the **Parameter** text box of the Parameter Details pane. The Computer Setup Editor activates the add button.
- b. Navigate the Help reference topics within the help pane to locate the topic for the parameter to be

added to the parameter tree, and click the relevant topic. The Computer Setup Editor populates the Parameter Details pane. (In the case of Driver parameter reference topics - click on the **Add Parameter Wizard** link to populate the Parameter Details pane.)

4. Enter the value for this parameter in the value field.

The Parameter Details pane changes to reflect the type the parameter:

- If the parameter has a path value a **Browse** button becomes available to help you set this parameter.
- If the parameter has a Boolean value, a **Toggle** button becomes available to help you set this parameter.
- If the parameter has a string value, the button to the left of the field becomes unavailable. Type the value in the **Value** field.

5. Click **Add** to add the new parameter to the parameter tree.

The new parameter appears in the parameter tree. It is highlighted as the currently selected entry, and its Help appears in the help pane.

If the parameter being added to the tree belongs to a section yet to be defined in the tree, both the section and parameter are added to the parameter tree when you click **Add**.

If the parameter being added to the parameter tree is an undocumented parameter, it appears in the parameter tree. However, if you hide undocumented parameters, you'll only be able to see parameters when you view undocumented parameters. See [View Undocumented Parameters](#) for details.

## Edit a Parameter

### To edit a parameter value:

1. Click the parameter in the expandable tree pane.
2. The current value populates the Parameter Details pane.
3. Click in the **Value** text box. The last saved value in the Citect.ini file will be displayed in the area directly below the text box.
4. Change the entry in the **Value** text box to the required value. The changes automatically appear in the parameter tree.

---

**Note:** The changes will not occur to the configuration file until they are saved. See [Saving the Citect.ini File](#) for details.

## Delete a Parameter

### To delete a parameter value from the Citect.ini file:

1. Right-click the parameter in the expandable tree pane.
2. Choose **Delete Parameter** from the shortcut menu.
3. A window opens requesting confirmation to delete the parameter.
4. Click **Yes**. The parameter is deleted from the parameter tree.

---

**Note:** Deleting parameters from the configuration file sets them to the default value (if one exists).

## Disable a Parameter

Disabling a parameter within the parameter tree causes the parameter to be treated as a comment in the Citect.ini file when the file is read at startup time.

Parameter values which are disabled are not deleted from the file and can be enabled at a later time. See Enable a Parameter for details.

### To disable a parameter:

1. Right-click the parameter you want to disable in the expandable tree pane.
2. Choose **Disable** from the shortcut menu.

The parameter is disabled and the text for that parameter within the parameter tree changes to red to indicate it is now disabled.

## Enable a Parameter

### To enable a parameter in the Citect.ini file:

1. Right-click the parameter you wish to enable in the expandable tree pane.
2. Choose **Enable** from the shortcut menu.

The parameter is enabled and the text for that parameter within the parameter tree changes to black to indicate it is now enabled.

[View Undocumented Parameters.](#)

## Configure Alarm Parameters for a Specific Cluster or Process

Plant SCADA allows you to configure some alarm parameters for a specific cluster or alarm server process. This is defined in a Citect.ini file using the following syntax.

To define alarm parameters for a specific cluster:

```
[Alarm.<Cluster Name>]  
<Parameter Name>
```

To define alarm parameters for a specific server process:

```
[Alarm.<Cluster Name>.<Server Name>]  
<Parameter Name>
```

For example:

```
[Alarm.Cluster1.AlarmServer1]  
Clusters = Cluster1  
CPU = 0
```

An alarm parameter can also be defined on a client computer or a server computer, depending on the functionality it supports. This means there are five different ways you can use alarm parameters in a Citect.ini

file:

1. For all clusters and server processes in the general [**Alarm**] section.
2. For all alarms in a specific cluster in the [**Alarm.<ClusterName>**] section.
3. For a specific server process in the [**Alarm.<ClusterName>.<ServerName>**] section.
4. On a **client** computer.
5. On a **server** computer.

The following table lists Plant SCADA's alarm parameters and indicates the different ways each can be used.

Alarm Parameter	Supported Usage in Citect.ini				
	1. General	2. Cluster specific	3. Server specific	4. Client computer	5. Server computer

## View Undocumented Parameters

When a configuration file is loaded by the Computer Setup Editor, only those parameters that are documented in the Parameter Help are visible in the parameter tree. There are, however, many other parameters (mostly used by Plant SCADA itself) for which no help topics exist; these are known as undocumented parameters.

### To show undocumented parameter:

1. Right click the top element of the parameter tree.
2. Choose **Show undocumented Sections and Parameters** from the shortcut menu.  
The parameter tree expands to show all undocumented sections and parameters.

### To hide undocumented parameters:

1. Right click the top element of the parameter tree.
2. Choose **Hide undocumented Sections and Parameters** from the shortcut menu.  
The undocumented sections and parameters are hidden.

### Setting the default option for viewing undocumented parameters

1. Choose **Options** from the **Tools** menu.  
The Computer Setup Editor Options window opens.
2. Select the checkbox to display undocumented parameters by default.
3. Click **OK**.

When Computer Setup Editor next opens a configuration file, this setting will be used to determine whether undocumented parameters are displayed in the parameter tree.

## Add Comments to the Citect.ini File

You can add comments to your configuration file.

### To add a comment to a section entry:

1. In the expandable tree pane, click the section to which you would like to add a comment.
2. The Parameter Details pane populates with the section information.
3. Type the comment in the **Comment** field.

Or:

Click **Generate** to insert the auto-generated comment "Added by {username} on {date}".

The comment appears next to the section entry in the parameter tree.

**Note:**

- Comments can only be one line long. If the comment needs to be longer than one line, you should include it in the header of the file.
- Using the **Generate** button replaces any existing comment made in relation to that section. To append comments type your text into **Comment** field.

**To add a comment to a parameter entry:**

1. Click the parameter in the expandable tree you want to add a comment to.
2. The Parameter Details pane populates with the parameter information.
3. Type the comment in the **Comment** field.

Or:

Click **Generate** to insert the auto-generated comment "Added by {username} on {date}".

The comment appears next to the parameter entry in the parameter tree.

**Note:** Comments can only be one line long. If the comment needs to be longer than one line, you should include it in the header comment. See Enter Comments in the Header for details.

**To enter comments in the header:**

1. Choose **View Header** from the **File** menu.
2. The Header Information window opens. Comments added in this window are stored in the header of the configuration file.

**Note:** Click **Insert time/date** to enter the current date and time where the cursor is placed in the text window.

3. Click **OK** to store the changes made to the header file.

[Configure Citect.ini Parameters](#)

**Use the Comparison Wizard**

The Comparison Wizard allows you to compare the content of two separate configuration files. For further information see:

- [Run the Comparison Wizard](#)
- [Interpret the Comparison Wizard](#)
- [Copy Values Between Compared Files](#)
- [Save Changes to the Compared File](#)
- [Close Without Saving Changes](#)

## See Also

[Configure Citect.ini Parameters](#)

### Run the Comparison Wizard

#### To run the Comparison Wizard:

1. Open the source configuration file in the Computer Setup Editor.
  2. Choose **Compare INI File** from the **Tools** menu.
  3. A **Choose comparison file** window opens. Navigate to the file you want to compare (**comparison file**) with the file currently loaded in the Computer Setup Editor (**source file**). Click **Open**.
- The Comparison Wizard opens in a new window.

## See Also

[Use the Comparison Wizard](#)

### Interpret the Comparison Wizard

The Comparison Wizard displays the source file and the comparison file side by side.

It includes the following information:

<b>Number of differences between the files</b>	A summary of the number of lines different between the files is shown in the title of the window.
<b>Parameters with the same values</b>	Lines that are not highlighted indicate that the parameters are set in both files and have the same values.
<b>Parameters with different values</b>	Lines that are highlighted in yellow indicate that the parameters are set in both files but have different values.
<b>Parameters not set in both files</b>	Lines that are highlighted in gray indicate that the parameters are set in only one of the files.

## See Also

[Use the Comparison Wizard](#)

### Copy Values Between Compared Files

Where parameter values are different, the Comparison Wizard allows changes to be made to either file to make them the same.

**To copy a value from the source file to the comparison file:**

1. In the source file locate the parameter you want to copy to the comparison file.
2. Right-click the line, it is highlighted in blue and a menu appears with **Copy to RHS**. Select this menu.

The Parameter value copies to the comparison file and the line is no longer highlighted.

---

**Note:** To select multiple lines in the source file use the Ctrl and/or Shift keys in combination with the mouse, and then right-click any line of the selected lines and choose **Copy to RHS**.

---

**To copy a value from the comparison file to the source file:**

1. In the comparison file and locate the parameter you want to copy to the source file.
2. Right-click the line, it is highlighted blue and a menu appear with **Copy to LHS**. Select this menu.

The Parameter value copies to the Source File and the line is no longer highlighted.

---

**Note:** To select multiple lines in the comparison file use the Ctrl and/or Shift keys in combination with the mouse, and then right-click any line of the selected lines and choose **Copy to LHS**.

---

**See Also**

[Use the Comparison Wizard](#)

**Undo and Redo Changes to the Compared Files**

Where parameter values have been copied from one file to another, the **Undo** button becomes active providing you with an option to undo the change.

Undoing the change will return the file to the state before the copy was executed. The undo buffer is limited only by the available memory so all changes made in the file can be undone in the same sequence as they occurred. Once the Undo button has been used the **Redo** button becomes active.

Redoing the change will return the file to the state before the last change which was undone. The redo buffer is limited only by the available memory, so all undo actions can be redone in the same sequence as they occurred.

---

**Note:** As soon as a fresh copy between the files is executed the Redo buffer is reset and all previous undo actions can no longer be redone with the **Redo** button.

---

**See Also**

[Use the Comparison Wizard](#)

**Save Changes to the Compared File**

Changing either the source file or the comparison file activates the **Accept Changes** button. To save changes, click **Accept Changes** located above the relevant file.

Changes accepted to the comparison file are saved directly to the file.

Changes accepted to the Source File are only made to the copy rendered in the expandable tree pane. Use the **Save** command to save the changes to the file. See [Saving the Citect.ini File](#) for details.

## See Also

[Use the Comparison Wizard](#)

### Close Without Saving Changes

To close the Comparison Wizard without saving your changes, click **Cancel** located in the lower right corner of the window.

## See Also

[Use the Comparison Wizard](#)

### Saving the Citect.ini File

#### To save any changes to the Citect.ini file:

1. Choose **Save** from the **File** menu.
2. An alert window opens requesting confirmation that the changes are to be saved. Click **OK**.  
The configuration changes are saved to file.

#### UNINTENDED EQUIPMENT OPERATION

After changes to settings that are not online changes, recompile your project and restart the system to ensure all changed settings are applied.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

#### To save a backup of changes to the Citect.ini file:

1. Choose **Save As** from the **File** menu.
2. A Save As window opens. Enter the name and location of the backup file. Click **Save**.
3. An alert window opens requesting confirmation of the name and location of the file. Click **OK** to proceed.  
A confirmation window opens to confirm the backup has occurred. Click **OK** to continue.

#### To abandon changes to the configuration file:

1. Choose **Reload** from the **File** menu.
2. If there are unsaved changes to the currently loaded file, an alert window opens requesting confirmation that the unsaved changes are to be discarded. Click **Yes** to proceed.  
The configuration file will be reloaded without the unsaved changes.

## Parameters Reference

Plant SCADA has a comprehensive set of parameters that you can use to configure the following:

- Operational settings for a project
- Operational settings for each computer in a Plant SCADA system.

For more information, see [About Parameters](#).

This section of the help describes these parameters and the settings that each supports. It includes the following topics:

- [Parameter Categories](#) - a complete list of built-in operating parameters
- [Logging Parameters](#) - information on how parameters can be used to gather Runtime information about your Plant SCADA system
- [Template Parameters](#) - information on parameters you can use to configure templates in pre-configured projects.

### See also

[Configure Parameters](#)

## Parameter Categories

Plant SCADA has built-in operating parameters that you can use to fine-tune your system. The table below lists the parameter categories.

A	B	C
Accumulator Parameters	DisableIO Parameters	OpcDaServer Parameters
Address Forwarding Parameters	DiskDrv Parameters	P
Alarm Parameters	Driver Parameters	Page Parameters
Alarm Process Parameters	E	Path Parameters
AlarmFilterRule Parameters	Event Parameters	Privilege Parameters
Alarm Heading Parameters	F	ProcessAnalyst Parameters
Alarm Log Parameters	Font Parameters	Protocol Parameters
Animator Parameters	G	Proxi Parameters
AnmCursor Parameters	General Parameters	PubSub Parameters
B	I	R
Backup Parameters	Interlock Parameters	RemoteDB Parameters
BrowseTableView Parameters	IOServer Parameters	Report Parameters
		Report Process Parameters

<b>C</b>	<a href="#">IOServer Process Parameters</a> <a href="#">IPC Parameters</a> <a href="#">K</a> <a href="#">Kernel Parameters</a> <a href="#">Keyboard Parameters</a> <a href="#">L</a> <a href="#">LAN Parameters</a> <a href="#">Language Parameters</a> <a href="#">M</a> <a href="#">Memory Parameters</a> <a href="#">MultiMonitors Parameters</a>	<a href="#">Runtime Manager Parameters</a> <a href="#">S</a> <a href="#">[SA_Library.Meter] Parameters</a> <a href="#">Scheduling Parameters</a> <a href="#">Security Parameters</a> <a href="#">Server Parameters</a> <a href="#">Shutdown Parameters</a> <a href="#">SPC Parameters</a> <a href="#">SQL Parameters</a> <a href="#">T</a> <a href="#">Time Parameters</a> <a href="#">Trend Parameters</a> <a href="#">Trend Process Parameters</a> <a href="#">W</a> <a href="#">Win Parameters</a> <a href="#">Workspace Parameters</a>
<b>D</b>	<a href="#">DDE Parameters</a> <a href="#">Debug Parameters</a> <a href="#">Deployment Parameters</a> <a href="#">Device Parameters</a> <a href="#">Dial Parameters</a>	<a href="#">ODBC Parameters</a> <a href="#">OID Parameters</a>

## Computer-specific Parameters

The following parameters need to be set in the main Citect.INI file, and cannot be set via a profile.

- [\[CtEdit\]Data](#)
- [\[CtEdit\]Run](#)
- [\[CtEdit\]Logs](#)
- [\[CtEdit\]Config](#)
- [\[CtEdit\]User](#)
- [\[Client\]PartOfTrustedNetwork](#)

## See Also

[Parameter Categories](#)

## Accumulator Parameters

The Citect.ini file contains the following accumulator parameters:

- [\[Accumulator\]Debug](#) - Enables trace logging messages for accumulators.
- [\[Accumulator\]UpdateTime](#) - The time in seconds between writing the accumulator variables to the I/O device.
- [\[Accumulator\]WatchTime](#) - The time in seconds between each check of the accumulator trigger.

## See Also

[Parameter Categories](#)

### [Accumulator]Debug

Enables trace logging messages.

When set to "1", entries appear in the appropriate SYSLOG.DAT file. Entries are prefixed by "Accumulators:". 0 disables logging.

## Allowable Values:

- 0 = Logging is disabled.
- 1 = Logging is enabled.

## See Also

[Accumulator Parameters](#)

### [Accumulator]UpdateTime

The time in seconds between writing the accumulator variables to the I/O device. You can set this parameter to a small value to get faster update of accumulator values, but you would use more CPU and PLC communication bandwidth. You should set this parameter as high as possible to reduce the load on the PLC.

## Allowable Values:

1 to 36000

## Default Value:

1

## See Also

[Accumulator Parameters](#)

### [Accumulator]WatchTime

The time in seconds between each check of the accumulator trigger. You can set this parameter to a large value to conserve CPU and PLC communication time. If you set the WatchTime to a low value, Plant SCADA must poll the PLC more often for the trigger value, using CPU and PLC communication bandwidth.

**Allowable Values:**

1 to 36000 (seconds)

**Default Value:**

60

**See Also**

[Accumulator Parameters](#)

**Address Forwarding Parameters**

Use address forwarding to override the IP addresses that have been configured inside the project for the server processes. This allows you to quickly transfer responsibility of a server to another computer, or redirect a client to a different server. Address forwarding allows you to override the network address for each Plant SCADA server or client with a different address and port.

Forwarding is achieved by adding a special section to the Citect.ini.

[AddressForwarding]

<ClusterName>.<ServerName>=<IPv4 ipaddress>:<port>

Or:

[AddressForwarding]

<ClusterName>.<ServerName>=<[IPv6] ipaddress>:<port>

Address forwarding is only interpreted and checked at startup of Plant SCADA Runtime. Run the Computer Setup Wizard to confirm your changes. This is useful especially for Time Servers where you can configure a redirected Server as a new time server.

---

**Note:** When using this feature the compiler will not be able to apply consistency checks to your configuration. Therefore, you should not use this feature as the primary mechanism of specifying server/client communications.

---

**See Also**

[Parameter Categories](#)

**Alarm Heading Parameters**

The [AlarmHeading] section contains the following parameters:

- [\[AlarmHeading\]AlarmField](#) - Specifies alternative names for the standard alarm field names for display in the column heading of the new Tab\_Style alarm template.

**See Also**

[Alarm Parameters](#)

[Alarm Process Parameters](#)

## Parameter Categories

### [AlarmHeading]AlarmField

Specifies alternative names to use for the column headings in Tab\_Style and Situational Awareness projects.

#### Allowable Parameters:

Any valid alarm field name.

#### Allowable Values:

Non-blank string.

#### Default Value:

Specified alarm field name.

## Examples

Tab\_Style template:

```
[AlarmHeading]
OnDate = Date
OnTime = Time
SumDesc = Description
Custom1 = Equipment
Type = State
```

Situational Awareness project:

```
[AlarmHeading]
DisableEndDate=Shelve End Date
DisableEndTime=Shelve End Time
DisableComment=Shelve Comment.
```

## See Also

[Alarm Heading Parameters](#)

## Alarm Log Parameters

These parameters affect the Plant SCADA alarm log format. Alarm logs can be accessed through the CtAPI and searched for specific records via the CtAPI function ctFindFirst and using CtAPIAlarmLog for the szTableName parameter.

Log files are named in the format "YYYYMMDD.TXT" and reside in the Plant SCADA DATA directory.

The first line of an alarm log will list the log format used, and each alarm log entry will reside on subsequent separate lines.

Alarms are logged in the order they are received, except for time-stamped alarms, which are stored in the log relevant to the date of the alarm, which may not be the current date. Therefore, when retrieving alarm log records, you should sort the results appropriately.

Alarm logging is disabled by default and enabled by setting "NumFiles" to a value greater than zero.

The Citect.ini file contains the following alarm logging parameters:

- [\[AlarmLog\]DefaultSearchDays](#) - Determines the number of logs to search.
- [\[AlarmLog\]Format](#) - Determines the format of the alarm log files.
- [\[AlarmLog\]NumFiles](#) - Determines the number of log files to be maintained.

## See Also

[Alarm Parameters](#)

[Alarm Process Parameters](#)

[Parameter Categories](#)

### [AlarmLog]DefaultSearchDays

Determines the number of alarm logs to search for.

#### Allowable Values:

0 to 32767

#### Default Value:

The value of [\[AlarmLog\]NumFiles](#) if it has been set, otherwise 100.

## See Also

[Alarm Log Parameters](#)

### [AlarmLog]Format

Determines the format of the alarm log files.

---

**Note:** You should keep the format at its default, as Plant SCADA has been optimized for this format. If the logging format is changed, it is the user's responsibility to archive any existing log files of the previous format before startup.

---

A user specified format must contain the {Tag} and {Category} fields and either the {LocalTimeDate} field or both {Time} and {DateExt} fields. It may also contain any of the following fields: {Desc}, {State}, {LogState}, {Type}, {Name}, {Millisec}, {Help}, {Area}, {Priv} and {Value}.

By default, alarms are logged using the alarm field type of {LocalTimeDate}. This field generates a string in the fixed format "yyyy-mm-dd hh:mm:ss[.ttt]". The time and date are local, and the millisecond field is only appended when the alarm contains millisecond data. This field type is useful for international applications.

**Allowable Values:**

Any combination of Alarm Display Fields.

**Default Value:**

"{LocalTimeDate,23} {Tag,32} {Desc,80} {Category,16} {LogState,16} {State,16} {State\_Desc,16} {Type,16}"

**See Also**

[Alarm Log Parameters](#)

**[AlarmLog]NumFiles**

Alarm logging is disabled by default, and enabled by setting "NumFiles" to a value greater than zero.

Determines the number of log files to be maintained. When this number is exceeded, Plant SCADA deletes the oldest file. However, the user can retain logs by manually marking them as "Read Only".

**Allowable Values:**

- 0 - (Disabled)
- 1 to 32767 - (Enabled)

**Default Value:**

0

**See Also**

[Alarm Log Parameters](#)

**Alarm Parameters**

The Citect.ini file contains the following alarm parameters.

---

**Note:** Some alarm parameters can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

---

- [Alarm]Ack - Obsolete in version 7.30.
- [Alarm]AckHold - Determines whether alarms that have become inactive (and have been acknowledged) remain in the OFF ACKNOWLEDGED alarm list.
- [Alarm]Active - The period (in milliseconds) at which the clients are advised of a change in alarms.
- [Alarm]AlarmDisable - Enables/disables the processing of alarms.
- [Alarm]AlarmListRequestTimeout - Specifies the length of time (in seconds) that an alarm display will wait to receive data from all clusters.

- [\[Alarm\]ArchiveAfter](#) - Sets the amount of time between each archive of Event Journal data.
- [\[Alarm\]ArgyleTagValueTimeout](#) - Obsolete in version 2015.
- [\[Alarm\]BackgroundColorMode](#) - Sets the background color mode of the alarm list and alarm banner on the Tab\_Style templates.
- [\[Alarm\]BrowseRowLimit](#) - Defines the maximum number of rows per cluster that will be returned in an alarm browse.
- [\[Alarm\]CacheLength](#) - Obsolete in version 7.30.
- [\[Alarm\]CacheSize](#) - Defines the amount of memory (in megabytes) dedicated to the storage of event data.
- [\[Alarm\]DBLogDBServer](#) - Defines logging for the alarm server database.
- [\[Alarm\]DBLogHistoric](#) - Defines logging for Historian operations on the alarm server database.
- [\[Alarm\]DBLogServerCore](#) - Defines logging for the analysis of redundancy and synchronization issues.
- [\[Alarm\]DefaultSOETimeRange](#) - Obsolete in version 2015.
- [\[Alarm\]DefDspFmt](#) - Specifies an Alarm display format to use if the Alarms Display Format field is blank (in Alarm Categories).
- [\[Alarm\]DefSOEFmt](#) - Specifies an SOE display format to use if the SOE Display Format field is blank (in Alarm Categories).
- [\[Alarm\]DefSumFmt](#) - Specifies an Alarm Summary display format to use if the Summary Display Format field is blank (in Alarm Categories).
- [\[Alarm\]DeltaTimeUpdate](#) - Determines if DeltaTime (duration) field is set on non-OFF alarms by calculating volatile duration between current time and the time when the alarm was activated.
- [\[Alarm\]DisableFilterOptimization](#) - Allows you to turn off filter optimization.
- [\[Alarm\]DisableSOE](#) - Used to turn off the storage of events.
- [\[Alarm\]DisableSummary](#) -Used to turn off the storage of summary events.
- [\[Alarm\]DisplayDisable](#) - Changes the meaning of the AlarmDisable() function.
- [\[Alarm\]EnableErrorLogging](#) - Enables or disables the logging of operational errors.
- [\[Alarm\]EnableSmartCustomFilters](#) - Enables/disables the caching of custom alarm queries to facilitate the use of the same filter later.
- [\[Alarm\]EnableStateLogging](#) - Enables or disables the logging of major alarm system state changes.
- [\[Alarm\]EventFmt](#) - Specifies the format of the event queue string.
- [\[Alarm\]EventQue](#) - Enables/disables the Alarm event queue on the Alarms Server.
- [\[Alarm\]ExtendedDate](#) - Specifies if extended date format is used in alarm formatting.
- [\[Alarm\]FilterViewByPrivilege](#) - Obsolete in v7.30.
- [\[Alarm\]FlushTimeLimit](#) - The alarm server flushes Event Journal entries to disk periodically (every 60 seconds). Set this parameter to determine the maximum duration of each alarm server flush.
- [\[Alarm\]FutureMessages](#) - Defines the maximum amount of time in the future that is permitted for future Event Journal messages
- [\[Alarm\]HardHoldTime](#) - The time (in seconds) to hold a hardware alarm in its alarm state before it is reset.
- [\[Alarm\]HardReAlarm](#) - Obsolete in v7.0.
- [\[Alarm\]HardwareDisable](#) - Enables/disables the processing of hardware alarms.
- [\[Alarm\]HeadingFont](#) - Determines the text font used for column headings displayed on the alarm templates.

- [\[Alarm\]HeartbeatTimeout](#) - Defines how long a server will wait before terminating a link that has been used for receiving heartbeat poll requests from its pair server, but is currently idle.
- [\[Alarm\]HighResOff](#) - Sets the precision of time stamped alarms.
- [\[Alarm\]Hres24HrDeadBand](#) - Determines the "previous day" deadband on time stamped alarms.
- [\[Alarm\]HresTimerExprDelay](#) - Allows you to configure and fine tune time delay.
- [\[Alarm\]HresType](#) - Determines the time format used to record time stamped alarms.
- [\[Alarm\]HwAlarmFmt](#) - Defines the format of the data written into the hardware alarm queue and placed in the string field.
- [\[Alarm\]HwAlarmQueMax](#) - Specifies the maximum length of the hardware alarm queue.
- [\[Alarm\]HwExclude](#) - Specifies a list of hardware alarms that the hardware alarm system will not process.
- [\[Alarm\]IsolationDetectInterval](#) - Sets the interval between ICMP packets to detect network isolation on alarm servers.
- [\[Alarm\]IsolationDetectIP1](#) - Determines the status of the disconnected alarm server and keeps the disconnected alarm server in 'non-main' state. Use this parameter to apply setting to all servers on machine.
- [\[Alarm\]IsolationDetectIP2](#) - Determines the status of the disconnected alarm server and keeps the disconnected alarm server in 'non-main' state. Use this parameter to apply setting to all servers on machine.
- [\[Alarm\]IsolationDetectRetryCount](#) - Sets the ICMP retry count to detect network isolation on alarm servers.
- [\[Alarm\]KeepOnlineFor](#) - Sets the amount of time for which the Alarm Server stores event messages on-line.
- [\[Alarm\]LastAlarmCategories](#) - Determines which alarms are displayed on the alarms toolbar, based on category.
- [\[Alarm\]LastAlarmDisplayStyle](#) - Determines whether the last alarm is displayed by category or priority.
- [\[Alarm\]LastAlarmFmt](#) - Specifies the format of the last alarm as displayed on the included templates.
- [\[Alarm\]LastAlarmPriorities](#) - Determines which alarms are displayed on the alarms toolbar, based on priority.
- [\[Alarm\]LastAlarmType](#) - Determines which alarms are displayed in the alarms toolbar, based on type.
- [\[Alarm\]MaxOptimisedQueries](#) - Sets the number of queries that can be cached.
- [\[Alarm\]MaxQueryExecuteTime](#) - Creates a log entry if an internal SQL query takes longer than a specified amount of time.
- [\[Alarm\]MemoryWarningLimit](#) - Value in Mb, of the threshold of the alarm server memory.
- [\[Alarm\]MonitorConnectTimeout](#) - Defines the amount of time, in seconds, that the server will wait for a monitor connection to occur.
- [\[Alarm\]MonitorRequestTimeout](#) - Defines the amount of time, in seconds, that the server will wait for a response from the other server in the pair.
- [\[Alarm\]Period](#) - The period for rate of change alarms.
- [\[Alarm\]Primary](#) - Obsolete in version 7.0.
- [\[Alarm\]Process](#) - Obsolete in version 7.0.
- [\[Alarm\]QueryCPUUsage](#) - Defines the percentage of processor use you want allocate to query searches.
- [\[Alarm\]QueryRowLimit](#) - Defines the maximum number of rows that can be returned in the result set for a single query.
- [\[Alarm\]QueryTimeout](#) - Defines the amount of time (in seconds) that is permitted for query searches.
- [\[Alarm\]ReloadBackOffTime](#) - Back-off time configured to control the pace of the reload on an alarm server.
- [\[Alarm\]SavePeriod](#) - Obsolete in version 7.30.

- [\[Alarm\]SavePrimary](#) - The path to the primary save file.
- [\[Alarm\]SaveSecondary](#) - The path to the secondary save file.
- [\[Alarm\]SaveStyle](#) - Obsolete in version 7.30.
- [\[Alarm\]ScanTime](#) - Determines the rate at which an alarm server can receive updates from an I/O server.
- [\[Alarm\]Server](#) - Obsolete in version 7.0.
- [\[Alarm\]SetTimeOnAck](#) - Determines whether the {Time} field in the Alarm Display and Alarm Log Device contains the time when an alarm is triggered, or the time when the alarm is acknowledged.
- [\[Alarm\]SetTimeOnOff](#) - Determines whether the {Time} field in your Alarm Display and Alarm Log Device contains the time when an alarm is triggered, or the time when the alarm becomes inactive.
- [\[Alarm\]SOERowLimit](#) - Obsolete in version 2015.
- [\[Alarm\]ShowAllConfigured](#) - When set to true, it will show configured alarms on an alarm list using mode 4 (show configured alarms).
- [\[Alarm\]Sort](#) - Determines the order in which alarms are displayed in the alarm list.
- [\[Alarm\]SortMode](#) - Determines the sort order for displaying alarms.
- [\[Alarm\]Sound<n>](#) - Determines the wav file that is played when an alarm of priority <n> occurs.
- [\[Alarm\]Sound<n>Interval](#) - Determines the interval of time before the alarm sound for priority <n> alarms will be repeated.
- [\[Alarm\]SoundSilenceTimeoutOnAck](#) - Determines the timeout period in seconds for silencing alarm after the user acknowledges any alarms using the Tab\_Style templates.
- [\[Alarm\]StandbyCommandDelay](#) - Sets a delay that a standby alarm server will apply when executing alarm commands received from the main alarm server.
- [\[Alarm\]StartTimeout](#) - Sets the timeout period for loading each packet from the primary Alarms Server. This parameter has been reinstated for v2015 only.
- [\[Alarm\]StreamSize](#) - Defines the amount of data that is included in an event data file.
- [\[Alarm\]SummaryAutoRefreshMode](#) - Represents the default value for AlarmSetInfo type 15.
- [\[Alarm\]SummaryBufferSize](#) - Specifies the value to limit the size of the alarm summary buffer.
- [\[Alarm\]SummaryLength](#) - Obsolete in version 2015.
- [\[Alarm\]SummaryMode](#) - Specifies whether alarm summary events are logged to the Alarm Summary log device in the order they went ON, or in the order they went OFF.
- [\[Alarm\]SummarySort](#) - Specifies whether OnTime, OffTime or AckTime will be used to determine the order in which alarms will be listed on the alarm summary page.
- [\[Alarm\]SummarySortMode](#) - Specifies whether alarms listed on the alarm summary page will be displayed in ascending or descending order.
- [\[Alarm\]SummaryTimeout](#) - The length of time after which an alarm summary entry is considered timeout.
- [\[Alarm\]SummaryTimeoutTolerance](#) - The length of time from timeout after which an alarm summary entry is committed to Summary Device regardless the fact that Off Time is not set.
- [\[Alarm\]SummaryTolerance](#) - Obsolete is version 2015.
- [\[Alarm\]SummaryShutdownMode](#) - Specifies whether alarm summary entries that have not been logged are logged at shutdown.
- [\[Alarm\]SumStartupCopy](#) - Determines whether the alarm summary data is copied to the other Alarms Server on startup.

- [Alarm]SumStateFix - Obsolete is version 2015.
- [Alarm]SyncAllHistoricData - On multi-server systems, the Primary server and Standby server synchronize their data so that the Standby server contains an accurate, up to date backup of the Primary server's data.
- [Alarm]TimeDate - Specifies the time/date string format used by Cicode functions that support ONTIMEDATE or OFFTIMEDATE.
- [Alarm]TransferConnectTimeout - Defines the amount of time, in seconds, that the Primary server will wait for a connection to occur.
- [Alarm]TransferInterleave - Controls how often the data synchronization is triggered by the Primary to the Standby Server.
- [Alarm]TransferInterval - Defines the number of seconds between each attempt to update the data on the Standby server.
- [Alarm]TransferRequestTimeout - Defines the amount of time, in seconds, that the Primary server will wait for the Standby server to respond to a data transfer request.
- [Alarm]UseConfigLimits - Forces the Plant SCADA alarm server to use alarm property values from the runtime database.
- [Alarm]WebClientUpdatePollPeriod - Obsolete in version 2015.

## See Also

[Alarm Process Parameters](#)

[Parameter Categories](#)

### [Alarm]AckHold

Determines whether alarms that have become inactive (and have been acknowledged) remain in the OFF ACKNOWLEDGED alarm list. If you enable this parameter, the alarms remain in the list until the operator clears them.

---

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

---

## Allowable Values:

- 0 - (Disable)
- 1 - (Enable)

## Default Value:

0

[Alarm Parameters](#)

**[Alarm]Active**

The period (in milliseconds) at which the clients are advised of a change in alarms. For example, if [Alarm]Active is set to 1000, the Control Clients are advised every 1 second (if a change has occurred in the alarms held on the Alarms Server).

If you are communicating from a Plant SCADA client to the Alarm Server over a slow serial or Wide Area Network (WAN) link, you might want to increase the value of this parameter. This would use less network bandwidth and increase the overall performance of your system.

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

---

**Allowable Values:**

0 to 10000 (milliseconds)

**Default Value:**

1000

**See Also**

[Alarm Parameters](#)

**[Alarm]AlarmDisable**

Enables/disables the processing of all alarms.

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

---

**Allowable Values:**

- 0 - (Enable)
- 1 - (Disable)

**Default Value:**

0

**See Also**

[Alarm Parameters](#)

### [Alarm]AlarmListRequestTimeout

This parameter specifies the length of time (in seconds) that an alarm display will wait to receive data from all clusters. If data is still outstanding at end of this period, the alarm list will display the data that is available and a timeout notification will be generated as a hardware alarm. You can use the Cicode function AlarmGetInfo (type 16) to capture these notifications. Any data that arrives after this timeout period will be displayed as it is received.

When this parameter is set to zero (or a value less than zero), no timeout notification will be generated.

#### Allowable Values:

-1 to 2147483647

#### Default Value:

10 (seconds)

#### See Also

[Alarm Parameters](#)

### [Alarm]ArchiveAfter

This parameter specifies how long (in weeks) alarm summary and SOE data is kept before it is archived. When the specified period of time elapses, the data is archived to another medium (such as a portable hard drive).

If the archiving is enabled, the event messages can be archived on a variety of devices, including:

- Removable hard disk
- Removable flash memory
- DVD-R and DVD-RAM
- Network file share.

The volume where data is to be saved should be labeled. This includes any removable storage devices. If this is not the case, archiving will not succeed and a message will display on the SOE page.

For more information, refer to the topic [Configure the Archiving Parameters](#).

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

#### Allowable Values:

1 – the current value for [\[Alarm\]KeepOnlineFor](#)

If the value specified is out of this range, it will be automatically adjusted to equal the current value for [\[Alarm\]KeepOnlineFor](#). An out-of-range hardware alarm will be raised.

**Default Value:**

4 (weeks)

**Note:** Before upgrading to Plant SCADA 2015 from version 7.20 or 7.30, it is recommended that you extend the setting for this parameter so that it will capture all the data you would like to migrate, as any non-active data that is older than the time range specified may be lost when migration occurs. After upgrade is complete you can then archive your data and return this parameter to its normal setting.

**See Also**

[\[Alarm\]KeepOnlineFor](#)  
[Alarm Parameters](#)

**[Alarm]BackgroundColorMode**

Sets the background color mode of the alarm list and alarm banner on the Tab\_Style templates.

**Note:** This parameter is available only to projects based on the Tab\_Style templates.

**Allowable Values:**

- 0 - Dark blue color
- 1 - White color
- 2 - Transparent color (i.e. the actual color is determined by the background color of the page.)

**Default Value:**

0

**See Also**

[Alarm Parameters](#)

**[Alarm]BrowseRowLimit**

Defines the maximum number of rows per cluster that will be returned in an alarm browse.

Increasing the BrowseRowLimit may affect performance.

**Note:** When changing this parameter you need to restart the client.

**Allowable Values:**

0 to 4294967295.

**Default Value:**

200000

The performance of alarm browsing can be improved by changing the value of the parameter [Alarm]BrowseRowLimit. However, as Historian also uses this parameter to retrieve alarm data, changing the value of this parameter on Plant SCADA machines that Historian is connected to may result in a loss of data.

**See Also**

[Alarm Parameters](#)

**[Alarm]CacheSize**

This parameter defines the amount of memory (in megabytes) dedicated to the storage of event data.

For many systems, the default setting of 25 MB is appropriate. However, if your system is experiencing difficulties with server performance and the Cache Size needs to be adjusted, you can alter the Cache Size settings as required.

---

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

---

**Allowable Values:**

0 to 400

**Default Value:**

25

**See Also**

[Alarm Parameters](#)

**[Alarm]DBLogDBServer**

Use this parameter to turn on logging for the alarm server database.

---

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

---

**Allowable Values:**

An integer representing one of the following logging masks, or the sum total of integers representing multiple logging masks:

Logging Mask	Description	Integer
DBLIC	Server license	32
DBDRQ	Driver links	65536
WEBSVR	WebX server and threads	1048576
WEBLNK	WebX server links	2097152
WEBDAT	WebX server request raw data	4194304
WEBREQ	WebX server request content	8388608
WEBCK	WebX logon cookies	268435456

**Default Value:**

0 (logging is not enabled)

**Example**

To enable logging for driver links (set using "65536") and WebX server links (set using "2097152"), you would add the integers for each and set the parameter to the following:

[Alarm]DBLogDBServer=2162688

**See Also**

[\[Alarm\]DBLogServerCore](#)

[\[Alarm\]DBLogHistoric](#)

[Alarm Parameters](#)

**[Alarm]DBLogHistoric**

Use this parameter to define logging for Historian operations on the alarm server database.

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

**Allowable Values:**

An integer representing one of the following logging masks, or the sum total of integers representing multiple

logging masks:

Logging Mask	Description	Integer
HISERR	Historian errors	1
HISDAT	Historian file operations	2
HISSBY	Historian standby transfer	4
HISREC	Historian record operations	8
HISWRT	Historian new records	16
HISENUM	Historian enumerate files	32
HISDET	Historian detailed file operations	64

## Default Value:

0 (logging is not enabled)

## Example

To enable logging for Historian errors (set using "1") and Historian file operations (set using "2"), you would add the integers for each and set the parameter to the following:

[Alarm]DBLogHistoric=3

## See Also

[\[Alarm\]DBLogDBServer](#)

[\[Alarm\]DBLogServerCore](#)

[Alarm Parameters](#)

## [Alarm]DBLogServerCore

Use this parameter to enable logging for the analysis of redundancy and synchronization issues.

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

## Allowable Values:

An integer representing one of the following logging masks, or the sum total of integers representing multiple logging masks:

Logging Mask	Description	Integer
DBERR	Server errors	1
DBSTD	Server state management	2
DBTRN	Server transaction	4
DBDRV	Server driver control	8
DBADV	Server advise links	16
DBSVR	Server and threads	256
DBSLT	Standby links	512
DBSCX	Links	1024
DBDA	OPC DA links	2048
DBHDA	OPC HDA links	4096
DBAE	OPC AE links	8192
DBMAN	Manager links	16384
DBDIA	Diagnostic links	32768
DBLRW	Link read-write	524288
SBXFR	Standby transfer	16777216
SBDAT	Standby transfer data	33554432
SBPOL	Standby polls	67108864
SBPEX	Standby poll details	134217728
DBSLR	Server link reference counting	536870912

**Default Value:**

0 (logging is not enabled)

**Example**

To enable logging of server errors (set using "1") and server transactions (set using "4"), you would add the integers for each and set the parameter to the following:

[Alarm]DBLogServerCore=5

## See Also

[\[Alarm\]DBLogDBServer](#)  
[\[Alarm\]DBLogHistoric](#)  
[Alarm Parameters](#)

### [Alarm]DefDspFmt

Specifies an Alarm display format to use if the display fields are not defined via the [Format]FormatName parameter, and the Alarms Format field is blank for the Alarm Categories properties.

If all of your alarm display formats are the same, set your alarm display format once using this parameter (instead of repeating the format many times in the Alarm Categories database). You would then save memory and increase the performance of your project.

#### Allowable Values:

Any combination of [Alarm Display Fields](#).

#### Default Value:

{Time,12} {Tag,10} {Name,20} {Desc,32}

## See Also

[Alarm Parameters](#)

### [Alarm]DefSOEFmt

Specifies an SOE display format to use if the display fields are not defined via the [Format]FormatName parameter and the SOE Format field for the Alarm Categories properties is blank.

If the alarm SOE formats are the same, set your alarm SOE format once using this parameter (instead of repeating the format many times in the Alarm Categories database). You would then save memory and increase the performance of your project.

---

**Note:** You can also change the font and format of the system events on the SOE page using the SOE Format field for alarm category 0 (zero).

---

#### Allowable Values:

Any combination of [Alarm SOE Fields](#).

#### Default Value:

{DATE,16} {TIME,16} {TAG,10} {NAME,15} {MESSAGE,64} {STATE,16} {CLASSIFICATION,13} {USERNAME,16} {USERLOCATION,16}

## See Also

[Alarm Parameters](#)

### [Alarm]DefSumFmt

Specifies an Alarm Summary display format to use if the display fields are not defined via the [Format]FormatName parameter and the Summary Format field for the Alarm Categories properties is blank.

If the alarm summary formats are the same, set your alarm summary format once using this parameter (instead of repeating the format many times in the Alarm Categories database). You would then save memory and increase the performance of your project.

#### Allowable Values:

Any combination of [Alarm Summary Fields](#).

#### Default Value:

{Name,20} {OnTime,8} {OffTime,8} {DeltaTime,8} {Comment,22}

## See Also

[Alarm Parameters](#)

### [Alarm]DeltaTimeUpdate

Determines whether the DeltaTime (duration) field is set on non-OFF alarms, by calculating volatile duration between current time and the time when the alarm was activated. Thus providing you with a snapshot of the duration of alarms. This parameter is for display clients and does not affect server side or the alarm database.

---

**Note:** The deltatime field set by this parameter is not refreshed until a new event on an alarm is made, such as a new alarm, state change on an existing alarm or page navigation. For the deltatime to refresh automatically, you will need to implement auto-page refresh using Cicode functions.

---

#### Allowable Values

- 0 - (Disable)
- 1 - (Enable)

#### Default Value:

0

## See Also

[Alarm Parameters](#)

### [Alarm]DisableFilterOptimization

By default, Plant SCADA uses filter optimization for queries of historic alarm data. This turns the filter criteria for configured alarm fields into sets of alarm object IDs before applying them to the final queries.

This is effective when the number of object IDs required by a query is less than a threshold affected by the size of the project, the match rate of the filter and the density of the historic data kept on site. In general, the improvement is more prominent when filtering for a smaller subset of historic data. Its effectiveness drops as the filter becomes more inclusive. In unusual circumstances, the threshold may be crossed which can impact system performance.

This parameter allows you to turn off filter optimization to determine if it is having an impact on system performance.

---

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

#### Allowable Values:

- 0 - (Enable)
- 1 - (Disable)

#### Default Value:

0

#### See Also

[Alarm Parameters](#)

### [Alarm]DisableSummary

Use this parameter to turn off the storage of summary events. If set to 1 (disabled), the following will occur:

- The Alarm Summary page will not work
- Cicode functions that read or modify the alarm summary will not work
- The summary log device will not work
- Alarm summary information may be lost during upgrade.

---

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

#### Allowable Values:

- 0 - (Enable)
- 1 - (Disable)

**Default Value:**

0

**See Also**[Alarm Parameters](#)**[Alarm]DisableSOE**

Use this parameter to turn off the storage of events. If set to 1 (disabled), the following will occur:

- The Sequence of Events (SOE) page will not work
- Alarms will not display in the Process Analyst
- Alarms cannot be accessed through Historian.

---

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

---

**Allowable Values:**

- 0 - (Enable)
- 1 - (Disable)

**Default Value:**

0

**See Also**[Alarm Parameters](#)**[Alarm]DisplayDisable**

Adjusts the behavior of disabled alarms so they are "suppressed" rather than completely disabled.

By default, when an alarm is disabled it is no longer processed by the system. The alarm is not logged, it is not included on alarm lists (except the disabled list), and does not change state with the I/O device variable.

By setting this parameter to 1, disabled alarms are suppressed. This means they are still processed, logged, and listed on the Sequence Of Events (SOE) and Alarm Summary pages. However, they are not displayed on the Active Alarms page.

While this parameter is set to 1, the User Name and User Location recorded at the time an alarm was disabled will be maintained, despite any subsequent state changes. These properties will not be overwritten by the System User account.

---

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

---

---

[Configure Alarm Parameters for a Specific Cluster or Process.](#)

---

**Allowable Values:**

- 0 - (Offscan - disable completely)
- 1 - (Suppress - alarm will not display on the Active Alarms page)

**Default Value:**

0

---

**Note:** You need to decide whether you would like to suppress disabled alarms when designing your system. If you do decide to change the parameter to 1, you will have to keep the setting for the lifetime of your system (including after any upgrades to later versions of Plant SCADA). If you change the value of this parameter back to zero (0) after your system has been running, the integrity of the historical data will not be maintained correctly. This will cause issues when historical data is displayed on Process Analyst and the Alarm Summary page.

---

**See Also**

[Alarm Parameters](#)

**[Alarm]EnableErrorLogging**

Enables or disables the logging of operational errors to syslog.dat.

**Allowable Values:**

- 0 - (Disable)
- 1 - (Enable)

**Default Value:**

0

**See Also**

[Alarm Parameters](#)

**[Alarm]EnableSmartCustomFilters**

Enables/disables the caching of custom alarm queries to facilitate later use of the same filter.

---

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

---

**Allowable Values:**

- 0 - (Disable)
- 1 - (Enable)

**Default Value:**

1

**See Also**[Alarm Parameters](#)**[Alarm]EnableStateLogging**

Enables or disables the logging of major alarm system state changes to syslog.dat.

**Allowable Values:**

- 0 - (Disable)
- 1 - (Enable)

**Default Value:**

0

**See Also**[Alarm Parameters](#)**[Alarm]EventFmt**

Specifies the format of the event queue string.

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

**Allowable Values:**

Any combination of [Alarm Display Fields](#).

For example:

[Alarm]  
EventFmt={Date,16}{Time,16}{Name,79}{State,16}{Type,16}

## See Also

[Alarm Parameters](#)

### [Alarm]EventQue

Enables/disables the Alarm event queue on the Alarms Server. Only set this parameter if you are using the Alarm event queue, because it can increase CPU loading and reduce the performance of the Alarms Server.

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

#### Allowable Values:

- 0 - (Disable)
- 1 - (Enable)

#### Default Value:

0

## See Also

[Alarm Parameters](#)

### [Alarm]ExtendedDate

Determines whether the short (dd/mm/yy) or extended (dd/mm/yyyy) date format is used when interpreting the {DATE,n} alarm format.

#### Allowable Values:

- 0 - (Use short date format)
- 1 - (Use extended date format)

#### Default Value:

1

## See Also

[Alarm Parameters](#)

**[Alarm]FlushTimeLimit**

The alarm server flushes Event Journal entries to disk periodically (every 60 seconds). This parameter determines the maximum duration (in milliseconds) of each flush.

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

**Allowable Values:**

50-3000 ms

**Default Value:**

1000

**See Also**

[Alarm Parameters](#)

**[Alarm]FutureMessages**

Sequence of event records that have a time stamp with a date and time in the future can be stored historically. Typically, records with future dates and times relate forecasted data or data from a device that has different time settings, such as an outstation that has not had its clock set correctly.

You can use this parameter to define the lifetime in weeks for future messages. It defines the maximum amount of time in the future that is permitted for future messages. Any record that has a time stamp that is further in the future than the defined time is not stored historically.

For example, if the current date is October 1st 2021 and the FutureMessages is set to 1 week, any message that has a time stamp between October 2nd and October 7th will be stored historically. A message that has a time stamp beyond October 7th will be lost as the date of the future data is further in the future than the defined Future Message Life.

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

**Allowable Values:**

0 - 4294967295

**Default Value:**

4

**See Also**

[Alarm Parameters](#)

**[Alarm]HardHoldTime**

The time (in seconds) to hold a hardware alarm in its alarm state before it is reset.

**Allowable Values:**

1 to 86400

**Default Value:**

30

**See Also**

[Alarm Parameters](#)

**[Alarm]HardwareDisable**

Enables/disables the processing of hardware alarms.

**Allowable Values:**

- 0 - (Enable)
- 1 - (Disable)

**Default Value:**

0

**See Also**

[Alarm Parameters](#)

**[Alarm]HeadingFont**

Determines the text font used for column headings displayed on the alarm templates.

---

**Note:** This parameter is only available for projects based on Tab\_Style templates.

---

**Allowable Values:**

Any font that exists in the project

**Default Value:**

None.

If no heading font is specified, Arial font of point size 10 will be used for displaying the alarm column headings.

**See Also**

[Alarm Parameters](#)

**[Alarm]HeartbeatTimeout**

The HeartbeatTimeout parameter defines how long a server will wait before closing a link that has been used for receiving heartbeat poll requests from its pair server, but is currently idle. By default, the HeartbeatTimeout is set to 300 seconds, which means if there are no heartbeat request polls received via an open link within 300 seconds, the server will close the link.

The other server in the pair normally sends periodic server status polls every 10 seconds. When a server receives a poll request, it replies by sending a response that indicates its status. This allows the servers to check that they can send communications to, and receive communications from, each server in the architecture. During normal conditions, the servers in the Primary – Standby pair will:

- Send heartbeat poll requests to the other server
- Receive heartbeat poll requests from the other server
- Respond to heartbeat poll requests by sending a status response.

---

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

**Allowable Values:**

0 to 4294967295

**Default Value:**

300

**See Also**

[Alarm Parameters](#)

**[Alarm]HighResOff**

Sets the precision of time-stamped alarms. You can specify millisecond accuracy when alarms become active, or when alarms become active and when they become inactive. This parameter is used with time stamped alarms only.

---

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see

---

Configure Alarm Parameters for a Specific Cluster or Process.

---

**Allowable Values:**

- 0 - (Use millisecond (ms) accuracy only when becoming active)
- 1 - (Use millisecond (ms) accuracy for active and inactive transitions)

**Default Value:**

0

**See Also**

[Alarm Parameters](#)

**[Alarm]Hres24HrDeadBand**

Determines how many seconds the PLC time can be ahead of Plant SCADA time before the date field (if used) will show an alarm as occurring on the previous day. This parameter is only relevant if you are using 24 hour time stamped alarms. This is determined by [\[Alarm\]HresType](#). (If [Alarm]HresType is in mode 5, 6, or 7, you are using 24 hour time stamped alarms.) If you are not using 24 hour time stamped alarms, this parameter has no effect.

**Allowable Values:**

0 to 65,535 (seconds)

**Default Value:**

60

**See Also**

[Alarm Parameters](#)

**[Alarm]HresTimerExprDelay**

Allows you to configure the timer delay for HRes timestamped alarms.

**Allowable Values:**

0 to 2147483647 (milliseconds)

**Default Value:**

The same value that is set for the parameter [\[Alarm\]ScanTime](#).

## See Also

[Alarm Parameters](#)

### [Alarm]HresType

Determines the time format used to record time stamped alarms. When a time stamped alarm is triggered, Plant SCADA reads the time of the alarm from the PLC or RTU and stores it in one of the 10 formats listed below.

#### Allowable Values:

Value	Description
0	12 hour BCD timer (stored as hexadecimal)
1	Continuous counter
2	12 hour BCD timer (stored as decimal)
3	12 hour Millisecond timer (stored as decimal)
4	Number of seconds since 1970
5	24 hour BCD timer (stored as hexadecimal)
6	24 hour BCD timer (stored as decimal)
7	24 hour millisecond timer (stored as decimal)
8	Negative BCD Offset (stored as hexadecimal). Set the high byte to represent the total number of hours of the history. The maximum history is 99 hours (four days) from midnight of the next day.
9	Negative BCD Offset (stored as decimal). Set the high byte to represent the total number of hours of the history. The maximum history is 4923 hours (178 days) from midnight of the next day.
10	Negative Millisecond Offset in milliseconds from the next Midnight. The maximum history is 439 days from midnight. This is stored as a positive decimal whole number in a ULONG data type. Therefore, a value of 1 would mean 1ms before midnight today, a value of 4,233,600,000 would equate to 49D, 0H, 0M, 0S, 0ms before midnight today.

**Note:** The BCD types have a resolution of 100th of a second (10ms).

**Default Value:**

0

**See Also**

[Alarm Parameters](#)

**[Alarm]HwAlarmFmt**

Defines the format of the data written into the hardware alarm queue and placed in the string field.

**Allowable Values:**

Any combination of [Alarm Display Fields](#).

**Default Value:**

"Time:{Time,12} Date:{Date,11} Desc:{Desc,40}"

**See Also**

[Alarm Parameters](#)

**[Alarm]HwAlarmQueMax**

Specifies the maximum length of the hardware alarm queue.

**Allowable Values:**

0 - 32767

**Default Value:**

0

**See Also**

[Alarm Parameters](#)

**[Alarm]HwExclude**

Specifies a list of hardware alarms that the hardware alarm system will not process.

**Allowable Values:**

A comma-separated list of hardware error codes

**Default Value:**

NONE

**See Also**

[Alarm Parameters](#)

**[Alarm]IsolationDetectInterval**

This parameter sets the interval between Internet Control Message Protocol (ICMP) packets to detect network isolation on alarm servers. If the ICMP check fails to get a response in a row as configured on [\[Alarm\]IsolationDetectRetryCount](#) parameter, the server will regard itself as isolated and switch itself to an isolated main state.

This parameter is only valid if [\[Alarm\]IsolationDetectIP1](#) and/or [\[Alarm\]IsolationDetectIP2](#) parameters have been configured.

---

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

**Allowable Values:**

Length of time in milliseconds (500 - 120000)

**Default Value:**

5000 (5 seconds)

**See Also**

[Alarm Parameters](#)

**[Alarm]IsolationDetectIP1**

In a system that has redundant pairs of alarm servers, this parameter needs to be set to the IPAddress of a local piece of infrastructure (e.g. a router) on the network that can be pinged by the alarm server. This will be used by the alarm server to detect if it has become completely isolated from the network due to an outage. Setting this parameter will improve outcomes for alarm server redundancy as described below.

When a redundant pair of alarm servers are unable to connect to each other, both take on the primary responsibility for collecting and archiving alarm data. An alarm server taking on this responsibility is called the 'Main' alarm server. When the connection between the servers is reestablished, the alarm servers communicate with each other and decide which server will remain as 'Main', and which server will be 'Standby'.

Consider the situation whereby the alarm servers could not communicate to each other as one of the servers was completely isolated from the network. Being completely isolated from the network, the server would not have obtained any new alarm data during the outage. Whereas the peer alarm server may have still been obtaining data from the field during this time period. To insure all the data that was captured during the outage is maintained by the alarm system, the alarm server that was not isolated needs to stay 'Main' when the connection is recovered. Configuring this parameter correctly as described above will insure that the correct decision is made, as the alarm servers will know if they have been isolated from the network during the outage. Depending on your network topology, each alarm server in a redundant pair may require a different setting for this parameter, as they may have different infrastructure nearby their location in the network.

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

## Allowable Values:

- Machine name
- IP address
  - If the Plant SCADA system is using an IPv4 network, use a standard IPv4 address format. For example, 192.1.2.34
  - If the Plant SCADA system is using an IPv6 network, use a standard IPv6 address format (or any acceptable abbreviation). For example, 2001:0db8:0000:0000:8a2e:0123:1234 or 2001:db8::8a2e:123:1234 (abbreviated).

## Default Value:

None

## See Also

- [\[Alarm\]IsolationDetectInterval](#)
- [\[Alarm\]IsolationDetectRetryCount](#)
- [Alarm Parameters](#)

## [Alarm]IsolationDetectIP2

In a system that has redundant pairs of alarm servers, this parameter needs to be set to the IP address of a local piece of infrastructure (e.g. a router) on the network that can be pinged by the alarm server. This will be used by the alarm server to detect if it has become completely isolated from the network due to an outage. Setting this parameter will improve outcomes for alarm server redundancy as described below.

When a redundant pair of alarm servers are unable to connect to each other, both take on the primary responsibility for collecting and archiving alarm data. An alarm server taking on this responsibility is called the 'Main' alarm server. When the connection between the servers is reestablished, the alarm servers communicate with each other and decide which server will remain as 'Main', and which server will be 'Standby'.

Consider the situation whereby the alarm servers could not communicate to each other as one of the servers was completely isolated from the network. Being completely isolated from the network, the server would not have obtained any new alarm data during the outage. Whereas the peer alarm server may have still been

obtaining data from the field during this time period. To insure all the data that was captured during the outage is maintained by the alarm system, the alarm server that was not isolated needs to stay 'Main' when the connection is recovered. Configuring this parameter correctly as described above will insure that the correct decision is made, as the alarm servers will know if they have been isolated from the network during the outage. Depending on your network topology, each alarm server in a redundant pair may require a different setting for this parameter, as they may have different infrastructure nearby their location in the network

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

## Allowable Values:

- Machine name
- IP address
  - If the Plant SCADA system is using an IPv4 network, use a standard IPv4 address format. For example, 192.1.2.34
  - If the Plant SCADA system is using an IPv6 network, use a standard IPv6 address format (or any acceptable abbreviation). For example, 2001:0db8:0000:0000:0000:8a2e:0123:1234 or 2001:db8::8a2e:123:1234 (abbreviated).

## Default Value:

None

## See Also

- [\[Alarm\]IsolationDetectInterval](#)  
[\[Alarm\]IsolationDetectRetryCount](#)  
[Alarm Parameters](#)

## [Alarm]IsolationDetectRetryCount

This parameter sets the Internet Control Message Protocol (ICMP) retry count to detect network isolation on alarm servers. If ICMP check fails more times than this number in a row, the server will regard itself as isolated from the main network and then switch itself to isolated main state. The interval between ICMP packets is configured on [Alarm]IsolationDetectInterval.

This parameter is only valid if [\[Alarm\]IsolationDetectIP1](#) and/or [\[Alarm\]IsolationDetectIP2](#) parameters have been configured.

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

## Allowable Values:

0-5

**Default Value:**

2

**See Also**[Alarm Parameters](#)**[Alarm]KeepOnlineFor**

This parameter defines (in weeks) how long event data will remain on the Alarm Summary and SOE pages. When this time expires, the event data is deleted from disk and will no longer appear. This ensures disk space remains available to capture ongoing events.

For example, if this parameter is set to 1 (one week), events that are stored historically on Sunday will remain on the Alarm Summary and/or SOE pages for 7 days. They will then be deleted on the following Sunday. The event messages may be archived within the 7 days using the [\[Alarm\]ArchiveAfter](#) parameter.

During the period of time specified by this parameter, event data can change as new event messages are reported. However, if archiving is enabled, the event data will become read-only once it has been archived.

For more information, refer to the topic [Configure the Archiving Parameters](#) in the Plant SCADA documentation.

---

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

**Allowable Values:**

1 - 5200

If an out-of-range value is specified, the default value (6) will be used and a hardware alarm will be raised.

**Default Value:**

6

**See Also**[Alarm Parameters](#)**[Alarm]LastAlarmCategories**

Determines which alarms are displayed on the alarms toolbar, based on category. For example, if you want the list of alarms to just display category 1 alarms, you would set this parameter to 1.

---

**Note:** This parameter is only available for projects based on the Tab\_Style templates.

**Allowable Values:**

0 - 16375

**Default Value:**

0 - all categories

**See Also**

[Alarm Parameters](#)

**[Alarm]LastAlarmDisplayMode**

Determines whether the last alarm is displayed by category or priority. This parameter only affects the DisplayLastAlarm() Cicode function.

For example, if you set this parameter to Display by Priority, pages based on templates which call DisplayLastAlarm() will be affected. Instead of displaying the current alarm, the latest of those alarms with the highest priority will be displayed.

This parameter also applies to the Tab\_Style templates.

**Allowable Values:**

- 0 - Display by category
- 1 - Display by priority

**Default Value:**

0

**See Also**

[Alarm Parameters](#)

**[Alarm]LastAlarmFmt**

Specifies the format of the last alarm as displayed on the included templates.

---

**Note:** This parameter is available to all Plant SCADA projects, however, its default value is different when implemented as part of a project based on the Tab\_Style templates.

---

**Allowable Values:**

Any combination of Alarm Display Fields

**Default Value:**

- **For any project:**  
{Tag,32} {Name,32} {Desc,32}

- **For Tab\_Style templates:**

```
{Time,12}{Date,12}^t{Name,15}^t{Desc,35}^t{State,9}
```

## See Also

[Alarm Parameters](#)

### [Alarm]LastAlarmPriorities

Determines which alarms are displayed on the alarms toolbar, based on priority. For example, if you want the list of alarms to just display priority 1 alarms, you would set this parameter to 1.

**Note:** This parameter is available only to projects based on Tab\_Style templates.

## Allowable Values:

1 - 255

## Default Value:

0 - all priorities

## See Also

[Alarm Parameters](#)

### [Alarm]LastAlarmType

Determines which alarms are displayed in the alarms toolbar, based on type.

**Note:** This parameter is available only to projects based on Tab\_Style templates.

## Allowable Values:

0 - 14

Non-hardware alarms

- 0 - Active alarms, i.e. Types 1 and 2
- 1 - Unacknowledged alarms, ON and OFF
- 2 - Acknowledged ON alarms
- 3 - Disabled alarms
- 4 - Every configured (non-hardware) alarm, i.e. Types 0 to 3, plus acknowledged OFF alarms.

Hardware alarms

- 5 - Active alarms, i.e. Types 6 and 7

- 6 - Unacknowledged alarms, ON and OFF
- 7 - Acknowledged ON alarms
- 8 - Disabled alarms
- 9 - Every configured alarm, i.e. Types 5 to 8

#### Alarm Summary

- 10 - Summary alarms

#### Alarm General

- 11 - ON alarms
- 12 - OFF alarms
- 13 - ON hardware alarms
- 14 - OFF hardware alarms

### **Default Value:**

0

### **See Also**

[Alarm Parameters](#)

### [Alarm]MaxOptimisedQueries

Used when [Alarm]EnableSmartCustomFilters=1 is set. This is the number of queries that the alarm server caches. When the 101st new query occurs, the oldest query information is discarded. It is unlikely more queries than this will need to be cached.

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

---

### **Allowable Values:**

1 to 32000

### **Default Value:**

100

### **See Also**

[Alarm Parameters](#)

## [Alarm]MaxQueryExecuteTime

This parameter is used for commissioning or debugging purposes. It creates a log entry in the 'tracelog.Alarm.<ClusterName>.<ServerName>.dat' file if an internal SQL query takes longer to process than the specified amount of time (in milliseconds).

To disable this feature, set the parameter to -1.

### Allowable Values:

-1 (disabled), or 0 – 2147483647

### Default Value:

2000

### See Also

[Alarm Parameters](#)

## [Alarm]MemoryWarningLimit

Value in Mb, of the threshold of the alarm server memory.

If the threshold is reached a hardware alarm will be raised which will be visible on all clients connected to that cluster, whether they are connected to the standby or primary alarm servers.

To turn off the hardware alarm change the MemoryWarningLimit to 0.

The hardware alarm message is "Memory above safe limit".

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

---

### Allowable Values:

0 to 2147483647 (Mb)

### Default Value:

4000 (4Gb)

### See Also

[Alarm Parameters](#)

## [Alarm]MonitorConnectTimeout

Defines the amount of time, in seconds, that the server will wait for a monitor connection to occur. If there is no

monitor connection between the server you are configuring and the other server in the pair after the defined **MonitorConnectTimeout**, the other server will regard itself as isolated and will become Primary.

However, if you need the checks to detect lack of communication more quickly, you can reduce the timeout amount. But be aware that if the timeout is too short, a server may regard itself as isolated before it has had time to process a response to a request (or complete the connection establishment process).

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

---

## Allowable Values:

0 to 4294967295

## Default Value:

30

## See Also

[Alarm Parameters](#)

## [Alarm]MonitorRequestTimeout

Defines the amount of time, in seconds, that the server will wait for a response from the other server in the pair. If there is no response after the defined **MonitorRequestTimeout**, the other server will regard itself as isolated and will become Primary.

However, if you need the checks to detect faults more quickly, you can reduce the timeout amount. But be aware that if the timeout is too short, a server may regard itself as isolated before it has had time to process a response to a request (or complete the connection establishment process).

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

---

## Allowable Values:

0 to 4294967295

## Default Value:

30

## See Also

[Alarm Parameters](#)

## [Alarm]Period

The period used to determine when a Rate of Change alarm will be triggered for a variable tag. The Rate specified in Analog Alarm Properties is divided by this period to determine the 'maximum rate' at which the value of the variable tag can change. At each Scan Time (see [\[Alarm\]ScanTime](#)), Plant SCADA checks the value of the tag. If its rate of change is greater than the "maximum rate", a Rate of Change alarm is triggered.

For example, if your goal is to minimize the likelihood a tank from filling too quickly, you might configure a rate of change alarm, using an [\[Alarm\]Period](#) of 60 seconds, an [\[Alarm\]ScanTime](#) of 1 second, and a Rate (see above) of 300 liters. This means that the maximum allowable rate of change for the tank level is 5 l/sec (300 liters / 60 seconds). Plant SCADA calculates the actual rate of change at each ScanTime. i.e. every second, it checks the current level of the tank and compares it to the level recorded a second earlier. If the actual rate of change is, say, 8 l/sec, a Rate of Change Alarm is triggered immediately.

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

---

### Allowable Values:

1 to 3600 (seconds)

### Default Value:

60

### See Also

[Alarm Parameters](#)

## [Alarm]QueryCPUUsage

Defines the percentage of processor use you want to allocate to query searches.

If programs and other processes are experiencing 'freezing' during historic searches, you should reduce the CPU Usage value.

If your searches are slow and are taking longer than expected to return results, you may achieve better results by increasing the CPU Usage value.

However, we recommend that you try to reduce the number of records involved in the search before you increase the CPU usage settings. Increasing the CPU Usage above 90% may have a detrimental effect on drivers and client connections, so we recommend that you should not increase CPU Usage above 90% unless specifically instructed to do so by Technical Support.

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

---

### Allowable Values:

0 to 100

**Default Value:**

80

**See Also**

[Alarm Parameters](#)

**[Alarm]QueryRowLimit**

Defines the maximum number of rows that can be returned in the result set for a single query.

Increasing QueryRowLimit may affect performance.

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

---

**Allowable Values:**

0 to 4294967295

**Default Value:**

1000000

**See Also**

[Alarm Parameters](#)

**[Alarm]QueryTimeout**

Defines the amount of time (in seconds) that is permitted for query searches.

If the search has not completed when the timeout expires, the query will be abandoned.

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

---

**Allowable Values:**

0 to 4294967295

**Default Value:**

110

## See Also

[Alarm Parameters](#)

### [Alarm]ReloadBackOffTime

Adding or deleting alarm records too quickly may put pressure on the server, which could cause delays to the server response.

A back-off time can be configured to control the pace of the reload on an alarm server. The back-off time represents the minimal number of milliseconds for which the system will wait after adding or deleting an alarm record. The system will not attempt to reload another alarm record before this back-off time is out.

This configuration value is read at the beginning of each server reload.

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

---

## Allowable Values:

0 ~ 2147483647 (milliseconds)

## Default Value:

1 (millisecond)

## See Also

[Alarm Parameters](#)

### [Alarm]SavePrimary

This parameter is used to import the alarm history from previous versions of Plant SCADA. This parameter no longer affects how alarm events are recorded on disk. The value for this parameter should not be changed when upgrading.

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

---

## Allowable Values:

Any valid directory

## Default Value:

The directory specified in [\[CtEdit\]Run](#).

## See Also

[Alarm Parameters](#)

### [Alarm]SaveSecondary

This parameter is used to import the alarm history from previous versions of Plant SCADA. This parameter no longer affects how alarm events are recorded on disk. The value for this parameter should not be changed when upgrading.

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

## Allowable Values:

Any valid directory

## Default Value:

" " (none)

## See Also

[Alarm Parameters](#)

### [Alarm]ScanTime

Determines the maximum rate at which the alarm server receives updates from the I/O server. A value of 500 (the default value) indicates that the minimum time between alarm transitions for a single alarm tag will be 500ms.

If you increase the scan time, it may reduce the load on the I/O server due to a reduction in the required subscription rate. However, this will depend on whether or not any other servers have subscribed to a device at a higher rate.

This parameter is modified by the Computer Setup Wizard as well as the Computer Setup Editor.

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

## Allowable Values:

0 to 2147483647 (milliseconds)

## Default Value:

500

## See Also

[Alarm Parameters](#)

### [Alarm]SetTimeOnAck

Determines whether the {Time} field in your Alarm Display and Alarm Log Device contains the time when an alarm is triggered, or the time when the alarm is acknowledged.

When this parameter is enabled and the operator acknowledges an alarm, the {Time} field on the alarm page (and associated with the alarm record) is changed to the current time. If you want the {Time} field to remain at the time when the alarm was triggered, set this parameter to 0.

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

#### Allowable Values:

- 0 - (Set the alarm time to the time when the alarm is activated)
- 1 - (Set the alarm time to the time when the alarm is acknowledged)

#### Default Value:

1

**Note:** This parameter has no effect on the Alarm Summary Display and Alarm Summary Device, which have separate {OnTime} and {AckTime} fields.

## See Also

[Alarm Parameters](#)

### [Alarm]SetTimeOnOff

Determines whether the {Time} field in your Alarm Display and Alarm Log Device contains the time when an alarm is triggered, or the time when the alarm becomes inactive.

When this parameter is enabled and the alarm becomes inactive, the {Time} field on the alarm page (and in the associated alarm record) is changed to the current time. If you want the {Time} field to remain at the time when the alarm was triggered, set this parameter to 0.

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

#### Allowable Values:

- 0: (Set the alarm time to the time when the alarm is activated)
- 1: (Set the alarm time to the time when the alarm becomes inactive)

**Default Value:**

1

---

**Note:** This parameter has no effect on the Alarm Summary Display and Alarm Summary Device, which have a separate {OffTime} field.

---

**See Also**[Alarm Parameters](#)**[Alarm]ShowAllConfigured**

When set to true, it will show configured alarms on an alarm list using mode 4 (show configured alarms). Otherwise, it will only show alarms when the category setting ShowOnActive is true.

**Allowable Values:**

- 0 - Use ShowOnActive setting to determine if an Alarm is displayed when using the show configured alarms mode (mode 4).
- 1 - Show All Configured Alarms when using the show configured alarms mode (mode 4).

**Default Value:**

1

**See Also**[Alarm Parameters](#)**[Alarm]Sort**

Determines the order in which alarms are displayed in the active alarm list.

**Allowable Values:**

- 0 - lists the alarms in order of the most recent change of state
- 1 - lists the alarms in order of their occurrence (On Time).

**Default Value:**

0

If an alarm is acknowledged and OFF, it will no longer display on the active alarms list.

## See Also

[Alarm Parameters](#)

### [Alarm]SortMode

Determines the sort order for displaying alarms. The alarms are listed either in ascending order (the oldest alarms at the top) or descending order (the most recent alarms at the top).

#### Allowable Values:

- 0: (descending)
- 1: (ascending)

#### Default Value:

0

## See Also

[Alarm Parameters](#)

### [Alarm]Sound<n>

Determines the wav file that is used when an alarm sounds, based on the priority <n> of the alarm. For example, [Alarm]Sound1 identifies the .wav file that will be sounded when a priority 1 alarm is triggered.

#### LOSS OF CONTROL

- Do not use Plant SCADA's alarming system as the primary alert mechanism for safety-related alarms or notifications (that is, those classified as critical to process safety, the protection of the plant and equipment, or the protection of human life).
- Do not use Plant SCADA's audible alarm functionality as a replacement for safety-related warning systems critical to process safety, the protection of the plant and equipment or the protection of human life.
- Safety-related alarms and notifications should be independent and separate from the process control system. They should be implemented in the form of a stand-alone physical alarm system driving individual discrete alarm annunciators.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** This parameter is available only to projects based on Tab\_Style templates.

**Allowable Values:**

Any valid wav file name, including a full directory path.

**Note:** You can use Plant SCADA predefined path substitutions to locate a wav file; for example:  
Sound1=[RUN]:Alarm1.wav.

**Default Value:**

(no sound)

**See Also**

[Alarm Parameters](#)

**[Alarm]Sound<n>Interval**

Determines the time to wait before replaying the alarm sound for priority <n> alarms. For example, [Alarm]Sound1Interval identifies the interval of time between audible alerts when a priority 1 alarm is triggered.

**⚠ WARNING****LOSS OF CONTROL**

- Do not use Plant SCADA's alarming system as the primary alert mechanism for safety-related alarms or notifications (that is, those classified as critical to process safety, the protection of the plant and equipment, or the protection of human life).
- Do not use Plant SCADA's audible alarm functionality as a replacement for safety-related warning systems critical to process safety, the protection of the plant and equipment or the protection of human life.
- Safety-related alarms and notifications should be independent and separate from the process control system. They should be implemented in the form of a stand-alone physical alarm system driving individual discrete alarm annunciators.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** This parameter is available only to projects based on Tab\_Style templates.

**Allowable Values:**

250 - 30000 milliseconds

**Default Value:**

2000

## See Also

[Alarm Parameters](#)

### [Alarm]SoundSilenceTimeoutOnAck

Determines the timeout period in seconds for silencing an alarm after the user acknowledges any of the alarms using the Tab\_Style templates. After an alarm is silenced, if any higher priority alarms occur, alarm sound will playback again.

The user can silence alarm explicitly using the silence alarm icon / command on the templates. Alarm silence settings set this way take precedence over the alarm silence effect due to alarm acknowledgment.

**Note:** This parameter is available only to projects based on Tab\_Style templates.

## Allowable Values:

0 to 2147483647 seconds

## Default Value:

0 (silence alarm indefinitely until all alarms are acknowledged)

## See Also

[Alarm Parameters](#)

### [Alarm]StandbyCommandDelay

Sets a delay (in milliseconds) that a standby alarm server will apply when executing alarm commands received from the main alarm server.

You may need to set this parameter if you execute alarm commands within one alarm scan time (for example, you execute acknowledgment as soon as alarm changes state) and you observe the error "Alarm: Property write error: 582" in the syslog.dat file of the alarm server process.

This can occur because redundant alarm servers monitor alarm conditions independently of each other, and it takes up to one alarm scan time for alarm to reach the same state on both servers. If an alarm command is issued within this time period while the alarm states are out of synch, the standby alarm server will not be able to mirror the command.

Setting a command delay on both alarm servers will allow time for the alarm state to reach the same state before mirroring the command. The delay should be typically set to the alarm scan time specified by the alarm server [\[Alarm\]ScanTime](#) INI parameter.

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

## Allowable Values:

0 to 2147483647

**Default Value:**

0

**See Also**[Alarm Parameters](#)**[Alarm]StartTimeout**

---

**Note:** This parameter has been reinstated for those doing an online upgrade from 7.20 to v2015 only.

Sets the timeout period for loading each packet from the primary Alarms Server. When a second Alarms Server starts, it tries to get the alarm current states from the primary server. This parameter determines how long to wait for a reply from the primary server. At the end of the timeout period, the Alarms Server either loads the saved data or reads the alarm data (from the I/O devices).

If the Alarms Server is timing out, you will see the message "Timeout from RndAlarm Server" in the Plant SCADA Kernel window. This timeout should only occur if you have a large number of alarms, typically greater than 10,000. If you see this message, increase this parameter until the message no longer displays at startup.

---

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

**Allowable Values:**

10 to 3600 (seconds)

**Default Value:**

120

**See Also**[Alarm Parameters](#)**[Alarm]StreamSize**

This parameter defines the amount of data that is included in an event data file.

By default, the setting of Stream Size is 8 (256 Objects), which means that an event data file will contain an hour's worth of event data for a maximum of 256 database items. If the database contains more than 256 items, it will create extra files for the other database items (with each file containing the event data for a maximum of 256 items).

For many systems, the Stream Size setting of 256 Objects is suitable. However, if you are experiencing reduced performance when displaying and filtering event data, you may need to adjust the Stream Size.

There are several possible causes of slow performance relating to the event data files:

- Your system has a large database (over 100,000 items). The high number of database items can cause an

excessive number of files. In this situation, you may be able to improve performance by choosing a higher Stream Size.

- Your system is logging a high number of events. On especially active systems, the volume of events being logged can cause the individual event data files to become large in size (it is recommended that the size of the largest event data file not exceed 5MB). In this situation, you may be able to improve performance by choosing a lower Stream Size.

---

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

---

## Allowable Values:

0 (no streams) to 14 (16384 objects)

## Default Value:

8 (256 objects)

## See Also

[Alarm Parameters](#)

### [Alarm]SummaryAutoRefreshMode

This represents the default value for AlarmSetInfo type 15, which is documented as follows:

15 – Auto-refresh mode, where mode is:

- -1 : always auto refresh
- 0 : auto refresh disabled on alarm acknowledge, enable, disable and add comment operations
- 1 : auto refresh page 1, disable on all other pages

## Default Value:

-1

## See Also

[Alarm Parameters](#)

### [Alarm]SummaryBufferSize

Specifies the value to limit the size of the alarm summary buffer.

---

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

---

**Allowable Values:**

4096 to 2147483647

**Default Value:**

64000

**See Also**

[Alarm Parameters](#)

**[Alarm]SummaryMode**

Specifies how the alarm system commits timeout alarm summary entries into Summary Device.

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

**Allowable Values:**

- **0 or 1:** An alarm summary entry is timeout if the Off time is set, and the length between its On time and the current time is greater than the value of the parameter [\[Alarm\]SummaryTimeout](#).

If an alarm summary entry is not timeout, the uncommitted entries of which On time are newer than the On time of this entry will not be committed to log.

In these two modes the alarm system usually logs alarm summary entries into Summary Device in the order they went ON. The order may break if a delayed alarm with an old timestamp is generated, or if an alarm summary entry is appended or split with an old timestamp.

- **2 or 3:** An alarm summary entry is timeout if the Off time is set, and the length between its Off time and the current time is greater than the value of the parameter [\[Alarm\]SummaryTimeout](#).

In these two modes the alarm system does not guarantee the order of On time or Off time of the entries which are committed into Summary Device, but instead attempts to commit timeout entries to Summary Device as soon as possible.

**Note:** Modes 0 and 2 no longer remove alarm summary entries from the summary page.

**Default Value:**

0

**See Also**

[Alarm Parameters](#)

## [Alarm]SummarySort

This parameter allows you to customize the order in which alarms will be displayed on the historical event pages. It is important to use this parameter if you have remote I/O devices in your system and you want to be certain that alarms are listed according to the exact time they occurred as opposed to the time they were reported by the alarms server.

You can choose to organize alarms according to the time each alarm was activated (OnTime), inactivated (OffTime), or the time the alarm was acknowledged by the operator (AckTime). Changing this parameter at runtime will not affect the current way alarms are displayed. It will only take affect at Plant SCADA start up and is usually used in conjunction with the [\[Alarm\]SummarySortMode](#) parameter.

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

### Allowable Values:

- 0 None
- 1 OnTime
- 2 OffTime (obsolete in v2015)
- 3 AckTime (obsolete in v2015)

### Default Value:

0

### See Also

[Alarm Parameters](#)

## [Alarm]SummarySortMode

This parameter organizes alarms on the Historical events pages in ascending or descending order. Changing this parameter at runtime will not affect the current way alarms are displayed. It will only take affect at Plant SCADA start up and is usually used in conjunction with the [Alarm]SummarySort parameter.

### Allowable Values:

- 0 Descending order, most recent time at top
- 1 Ascending order, oldest time at top

### Default Value:

0

## See Also

[Alarm Parameters](#)

### [Alarm]SummaryTimeout

The length of time after which an alarm summary entry is considered timeout.

The alarm system searches for timeout entries in the order of On time from oldest to newest. The search may stop or skip entries depending on the value of parameter [\[Alarm\]SummaryMode](#).

The found timeout entries are then committed to the Summary Devices specified in the alarm categories of the entries.

Refer to the Cicode function AlarmSumCommit for committing process.

You can disable this parameter by setting it to -1.

This parameter is modified by the Computer Setup Wizard as well as the Computer Setup Editor.

---

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

## Allowable Values:

0 to 20000 (minutes)

## Default Value:

60

## See Also

[Alarm Parameters](#)

### [Alarm]SummaryTimeoutTolerance

The length of time from timeout after which an alarm summary entry is committed to Summary Device regardless the fact that Off Time is not set.

The purpose of this parameter is to prevent a pending active alarm with ON condition infinitely blocking other alarm summary entries from being committed when [\[Alarm\]SummaryMode](#) parameter is set to 0 or 1.

---

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

## Allowable Values:

0 to 20000 (minutes)

**Default Value:**

60

**See Also**[Alarm Parameters](#)**[Alarm]SummaryShutdownMode**

Specifies whether alarm summary entries (both complete and incomplete) that have not been logged are logged at shutdown. Alarm summary entries may be duplicated with redundant servers when one server is shutdown and restarted. This parameter should only be changed from the default if you are NOT using redundant alarm servers and/or alarm save files.

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

**Allowable Values:**

- 0 - (Do not flush summary entries to devices)
- 1 - (Flush summary entries to devices)

**Default Value:**

0

**See Also**[Alarm Parameters](#)**[Alarm]SumStartupCopy**

Determines whether the alarm summary data is copied to the other Alarms Server on startup. Normally, the second Alarms Server gets all the alarm and summary data from the first server on startup. With this parameter, you can disable the sending of the summary data.

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

**Allowable Values:**

- 0 - (Don't send data)
- 1 - (Send data)

**Default Value:**

1

**See Also**[Alarm Parameters](#)**[Alarm]SyncAllHistoricData**

On multi-server systems, the Primary server and Standby server synchronize their data so that the Standby server contains the most recent date backup of the Primary server's data. During the synchronization process, the Primary server and Standby server synchronize data, including historic data. However, the amount of historic data that is synchronized is dependent on the SyncAllHistoricData parameter in the server configuration.

When SyncAllHistoricData is set to TRUE, the Primary server will update the Standby server with both the writable and non-writable historic data. This provides the Standby server with a copy of the historic data on the Primary server, but takes considerably longer for the synchronization process to complete.

When SyncAllHistoricData is set to FALSE, the Primary server will only update the Standby server with the historic data that is writable, that is the historic data that can still be modified on the system. This is the default setting and is appropriate for many systems as it means the synchronization of historic data is as fast and efficient as possible. There is no need to synchronize the historic data that is non-writable as it does not change and so will be the same on both the Primary and Standby servers.

---

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

**Allowable Values:**

TRUE or FALSE

**Default Value:**

FALSE

**See Also**[Alarm Parameters](#)**[Alarm]TimeDate**

Specifies the time/date string format used by any Cicode functions that support an ONTIMEDATE or OFFTIMEDATE field.

These functions include AlmBrowseOpen, AlmBrowseGetField, AlmTagsOpen, and AlmSummaryOpen.

**Allowable Values:**

The recognizable elements in a time string format are:

- MM
- MONTH
- MON
- DY
- DAY
- HH12
- HH24
- HH
- MI
- SSSS
- SS
- DDD
- DD
- D
- AM
- PM
- A.M.
- P.M.
- Y,YYYY
- YYYY
- YYY
- YY
- Y
- AD
- BC
- A.D.
- B.C.
- TH

A maximum of 28 characters is supported for the formatted alarm field value.

**Default Value:**

HH:MI:SS

## See Also

[Alarm Parameters](#)

### [Alarm]TransferConnectTimeout

Defines the amount of time, in seconds, that the Primary server will wait for a connection to occur. This works in the same way as the **MonitorConnectTimeout** parameter, except that it applies to the server's attempts to establish a connection to the Standby Server for the purpose of transferring data (rather than establishing a connection for monitoring the other server).

Typically, the default setting is appropriate. You may need to increase the **TransferConnectTimeout** if the system incorrectly regards a connection as having been unsuccessful when it is still in the process of being established.

---

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

## Allowable Values:

0 to 4294967295

## Default Value:

30

## See Also

[Alarm Parameters](#)

### [Alarm]TransferInterleave

Controls how often the data synchronization is triggered by the Primary to the Standby Server.

Normally the Primary Server synchronizes the Standby Server on every transfer interval determined by the [\[Alarm\]TransferInterval](#) parameter. The TransferInterleave parameter can be used to make the Primary synchronize the Standby on every *n* intervals.

For example, if the **TransferInterval** = 5 sec and the **TransferInterleave** = 2, then the Standby will be updated every 10 sec.

---

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

## Allowable Values:

0 To 4294967295

**Default Value:**

1

**See Also**

[Alarm Parameters](#)

**[Alarm]TransferInterval**

Defines the number of seconds between each attempt to update the data on the Standby server. For many systems, you will not need to change the default setting of 5 seconds.

If you have a large system, the Primary server may be affected by a high load due to a high number of updates placing a large demand on the server's resources. If your system is experiencing slow performance, you may need to increase the TransferInterval so that the Primary server updates the Standby server less frequently. If the data on the Standby server is being updated too slowly, you may need to decrease the TransferInterval so that updates occur more frequently. Be aware that this may affect the load on the Primary server and so could lead to slow performance.

---

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

**Allowable Values:**

0 to 4294967295

**Default Value:**

5

**See Also**

[Alarm Parameters](#)

**[Alarm]TransferRequestTimeout**

Defines the amount of time, in seconds, that the Primary server will wait for the Standby server to respond to a data transfer request. If there is no response after the defined request timeout, the Standby server is deemed to have become inoperable.

---

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

**Allowable Values:**

0 to 4294967295

**Default Value:**

30

**See Also**[Alarm Parameters](#)**[Alarm]UseConfigLimits**

Use this parameter to force the Plant SCADA alarm server to use alarm property values from the runtime database (RDB), rather than using the values which may be stored in the database file (DBF).

---

**Note:** If you are using [CtEdit]Run and [CtEdit]Copy to manage file server redundancy, you need to set [Alarm]UseConfigLimits=0 so that the alarm properties are not persisted to the RDB files. If not, the RDB files will be overwritten the next time they are accessed by the system.

To permanently update alarm threshold limits using the function AlarmSetThresholdRec(), set the parameter [Alarm]UseConfigLimits to 1.

As part of alarm server reload setup, it is recommended the Citect.ini is read to retrieve the latest value for the [Alarm]UseConfigLimit parameter. This will determine if runtime changes made to an existing alarm will overwrite the alarm property values in the DBF.

**Allowable Values:**

0 or 1.

When set to zero (0):

- The value is set in memory only. Writing back to the RDB and the DBF does not occur.
- On server reload, the alarm property values are retrieved from the stored DBF. Any changes in the RDB will be lost.
- The server will get the alarm property values from the RDB only in the following instances:
  - The database is not populated.
  - If it is a newly configured alarm (hence no values exist).

When set to 1:

- Values are set in memory, the RDB and the DBF.
- On server reload, the alarm property values are retrieved from the disk RDB. The DBF will be updated with the values from RDB.

---

**Note:** Setting this parameter to 1 can result in complicated scenarios if you are writing to alarm properties at runtime, deploying project updates, or running redundant alarm servers. It is recommended that you carefully consider the impact of this parameter in these scenarios within your system setup and test its impact on a runtime system before you implement it within a production facility.

If the value is set to 1, it will affect the property write performance as it writes to RDB files.

## Default Value:

0

**Note:** This parameter can also be applied to a specific cluster or alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

## See Also

[Alarm Parameters](#)

[\[CtEdit\]Copy](#)

[\[CtEdit\]Run](#)

## Alarm Process Parameters

Plant SCADA allows you to specify some alarm parameters for an alarm server process (see [Configure Alarm Parameters for a Specific Cluster or Process](#)).

The following parameters need to be configured for a specific process.

**Note:** The <server name> is the name of the alarm server as specified in the **Topology** activity.

- [\[Alarm.<ClusterName>.<ServerName>\]ClientConnectTimeout](#) - Defines the amount of time in milliseconds, in which the client can attempt to make a connection to the server.
- [\[Alarm.<ClusterName>.<ServerName>\]ClientDisconnectTimeout](#) - Defines the amount of time in milliseconds, in which the client can attempt to terminate a connection to the server.
- [\[Alarm.<ClusterName>.<ServerName>\]ClientRequestTimeout](#) - Defines the amount of time in milliseconds, in which the client can request data from the server.
- [\[Alarm.<ClusterName>.<ServerName>\]ClientUpdatePollPeriod](#) - Obsolete in version 2015.
- [\[Alarm.<ClusterName>.<ServerName>\]Clusters](#) - Sets which clusters this Alarm Server process connects to at startup.
- [\[Alarm.<ClusterName>.<ServerName>\]CPU](#) - Sets the CPU that the Alarm Server process is assigned to.
- [\[Alarm.<ClusterName>.<ServerName>\]Events](#) - The list of events that this Plant SCADA Alarms Server process enables.
- [\[Alarm.<ClusterName>.<ServerName>\]ShutdownCode](#) - Determines the Cicode function to run when Plant SCADA Alarm Server process shuts down.
- [\[Alarm.<ClusterName>.<ServerName>\]StartupCode](#) - Determines the Cicode function to run when Plant SCADA Alarm Server process starts up.

You can also used the following parameters on any computer that connects to a specific server process:

- [\[Alarm.<ClusterName>.<ServerName>\]DisableConnection](#) - used to specify if a client should not connect to a server.
- [\[Alarm.<ClusterName>.<ServerName>\]Priority](#) - used to specify the client priority for the server connection.

## See Also

[Alarm Parameters](#)

### [Alarm.<ClusterName>.<ServerName>]ClientConnectTimeout

Defines the amount of time, in milliseconds, in which the client can attempt to make a connection. If the client is unable to establish a connection to the server within this time, the connection attempt was unsuccessful.

**Note:** This parameter needs to be applied to a specific alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

## Allowable Values:

0 to 4294967295

## Default Value:

30000

## See Also

[Alarm Process Parameters](#)

[Alarm Parameters](#)

### [Alarm.<ClusterName>.<ServerName>]ClientDisconnectTimeout

Defines the amount of time, in milliseconds, in which the client can attempt to terminate a connection to the server. If a disconnection has not occurred by the end of this time, the attempt has been unsuccessful. The Disconnect Timeout is used when the network connection can be detected, but the client cannot disconnect from the system.

**Note:** This parameter needs to be applied to a specific alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

## Allowable Values:

0 to 4294967295

## Default Value:

30000

## See Also

[Alarm Process Parameters](#)

## Alarm Parameters

### [Alarm.<ClusterName>.<ServerName>]ClientRequestTimeout

Defines the amount of time, in milliseconds, in which the client can request data from a server. If the server has not responded by the end of this time, the request has been unsuccessful.

**Note:** This parameter needs to be applied to a specific alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

#### Allowable Values:

0 to 4294967295

#### Default Value:

120000

#### See Also

[Alarm Process Parameters](#)

[Alarm Parameters](#)

### [Alarm.<ClusterName>.<ServerName>]Clusters

Selects which clusters this Alarms Server connects to at startup.

**Note:** This parameter needs to be applied to a specific alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#)

#### Allowable Values:

A comma separated list of configured cluster names.

#### Default Value:

If this parameter is blank, the alarms server will connect to every cluster defined for the project.

#### See Also

[Alarm Process Parameters](#)

[Alarm Parameters](#)

### [Alarm.<ClusterName>.<ServerName>]CPU

This parameter is by Plant SCADA Runtime Manager to determine which CPU(s) the alarm server process is

assigned to. The CPU parameter is configurable for every Plant SCADA process via the **CPU Setup** page in the Computer Setup Wizard (see [CPU Configuration](#)).

CPU numbers are specified in a comma separated list. CPU numbers need to be valid and a subset of the available CPUs on a computer. For example, if there are eight CPUs on a computer, a valid CPU range is 0 to 7.

If this parameter is modified while the Plant SCADA Runtime Manager is running, the changes will not take effect until every instance of Plant SCADA is restarted.

**Note:** This parameter needs to be applied to a specific alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

---

## Allowable Values:

A comma separated list in the range 0 to 31 (inclusive) where 0 is the first CPU (for example, "0, 1, 2" or "3, 4, 5").

If no value is entered, the process will run on all available CPUs.

**Note:** When a process is set to run on all available CPUs, be aware that performance issues may still occur when your CPU usage is less than 100%. You can detect these issues when your CPU usage for a process is fixed at 100 divided by the number of processors.

---

## Default Value:

No value (the process will run on all CPUs).

**Note:** You cannot manually specify CPU assignments on a computer with more than 32 CPUs. Under these circumstances, the Setup Wizard will automatically set this parameter to no value (all CPUs). Any changes you make to this parameter will be overwritten.

---

### See Also

[Alarm Process Parameters](#)

[\[Client\]CPU](#)

[\[IOServer.<ClusterName>.<ServerName>\]CPU](#)

[\[Report.<ClusterName>.<ServerName>\]CPU](#)

[\[Trend.<ClusterName>.<ServerName>\]CPU](#)

## [Alarm.<ClusterName>.<ServerName>]DisableConnection

This setting is used to specify whether or not the client sub system should connect to the given server. If the Citect.ini on a particular computer has [Type.ClusterName.ServerName]DisableConnection = 1 specified for a particular server, then the client sub system will establish a non-redundant connection to the other server in the redundant pair. If that connection becomes inoperative, the client sub system will not be redirected and will have no connection until the server is restored.

To define connection priority of a particular server use [\[Alarm.<ClusterName>.<ServerName>\]Priority](#).

**Note:** This parameter needs to be applied to a specific alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

---

**Allowable Values:**

- 0 - Allow the client to connect to the server
- 1 - Stop the client connecting to the server

**Default Value:**

0

**See Also**[Alarm Process Parameters](#)[Alarm Parameters](#)**[Alarm.<ClusterName>.<ServerName>]Events**

The list of events that this Plant SCADA Alarms Server will enable.

This parameter is modified by the Computer Setup Wizard. To set this parameter, we recommend you enable the required events in the "Events Setup" page of the Computer Setup Wizard (instead of entering the events in the Setup Editor).

---

**Note:** This parameter needs to be applied to a specific alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

---

**Allowable Values:**

List of events (comma separated).

**Default Value:**

NONE

---

**Note:** When Plant SCADA is running in single process mode only the events assigned to [\[Client\]Events](#) will be enabled. Events specified for particular Plant SCADA components are ignored.

---

**See Also**[Alarm Process Parameters](#)[Alarm Parameters](#)**[Alarm.<ClusterName>.<ServerName>]Priority**

This setting is used to specify the client sub system's priority for the connection to this specific server. The client sub system will connect to, or switch over to, any available server that has the highest priority (lowest number). If the priorities for multiple servers are set to the same value, the client sub system will only switch on a loss of the currently active connection.

This is the default operation to provide the same behavior as in versions of the product prior to v7.20.

To disable (not allow) the client to connect to the server use  
[\[Alarm.<ClusterName>.<ServerName>\]DisableConnection](#).

**Note:** This parameter needs to be applied to a specific alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

---

## Allowable Values:

1 to 32767.

## Default Value:

1

## See Also

[Alarm Process Parameters](#)

[Alarm Parameters](#)

## [Alarm.<ClusterName>.<ServerName>]ShutdownCode

Can be used to specify a Cicode function that runs at shutdown of the Plant SCADA Alarm Server component. Plant SCADA suspends the shutdown process until the function has finished running. The function needs to complete execution within the time specified by the [Code]ShutdownTime parameter, otherwise Plant SCADA will terminate it.

This parameter can be set using the Computer Setup Wizard.

**Note:** This parameter can also be applied to a specific cluster or all alarm server processes. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

---

## Allowable Values:

Any built-in or user-written Cicode function, 1-31 alpha-numeric characters.

## Default Value:

NONE

**Note:** When Plant SCADA is running in single process mode only the Cicode function assigned to [\[Client\]ShutdownCode](#) will be executed at shutdown. Cicode functions specified for particular Plant SCADA components are ignored.

---

## See Also

[Alarm Process Parameters](#)

[Alarm Parameters](#)

**[Alarm.<ClusterName>.<ServerName>]StartupCode**

Determines the Cicode function to run when the Plant SCADA Alarm Server component starts up.

You can only pass constant data to the startup function call. You cannot pass variables or other functions. For example, MyFunc(1, "str") is valid, but MyFunc(PLCTAG, "str") or MyFunc(YourFunc(), "str") is not supported.

---

**Note:** This parameter needs to be applied to a specific alarm server process. For more information, see [Configure Alarm Parameters for a Specific Cluster or Process](#).

---

This parameter is modified by the Computer Setup Wizard.

**Allowable Values:**

Any built-in or user-written Cicode function, 1-31 alpha-numeric characters.

**Default Value:**

NONE

---

**Note:** When Plant SCADA is running in single process mode only the Cicode function assigned to [\[Client\]StartupCode](#) will be executed at startup. Cicode functions specified for particular Plant SCADA components are ignored.

---

**See Also**

[Alarm Process Parameters](#)

[Alarm Parameters](#)

**AlarmFilterRule Parameters**

Using the AlarmFilterRules parameters you can add new rules or overwrite the pre-defined rules in the alarm filter form. You can define common rules that will appear in all filter forms regardless of alarm display type (for example, Active, SOE, Summary or Disabled), or define rules for a specific alarm display type.

For examples refer to the topic *Using the AlarmFilterRules Parameters* in the Alarm Filter Help (available at runtime).

The Citect.ini file contains the following alarm parameters:

- **[AlarmFilterRuleList.Active]Rule<n>** - Defines the name of the common rules to appear on the Simple Rule drop down list of the alarm active filter form.
- **[AlarmFilterRuleList.Disabled]Rule<n>** - Defines the name of the common rules to appear on the Simple Rule drop down list of the disabled alarm filter form.
- **[AlarmFilterRuleList]Rule<n>** - Defines the name of the common rules to appear on the Simple Rule drop down list of the alarm filter form .
- **[AlarmFilterRuleList.SOE]Rule<n>** - Defines the name of the common rules to appear on the Simple Rule drop down list of the alarm soe filter form.
- **[AlarmFilterRuleList.Summary]Rule<n>** - Defines the name of the common rules to appear on the Simple Rule drop down list of the alarm summary filter form.

- [\[AlarmFilterRules\]<RuleName>](#) - Defines the filter expression represented by the rule name.

## See Also

[Alarm Parameters](#)  
[Alarm Process Parameters](#)  
[Parameter Categories](#)

### [AlarmFilterRuleList.Active]Rule<n>

Defines the name of rules to appear on the Simple Rule drop down list of the active alarm filter form. Rules need to be defined in consecutive order, for example, Rule1, Rule2, Rule3. The content of each rule is defined under parameter [\[AlarmFilterRules\]<RuleName>](#).

For examples refer to the topic *Using the AlarmFilterRules Parameters* in the Alarm Filter Help (available at runtime).

#### Allowable Values:

Any valid rule name

#### Default Value:

Rule1 = Last 24 hours  
Rule2 = Last 7 days

## See Also

[AlarmFilterRule Parameters](#)

### [AlarmFilterRuleList.Disabled]Rule<n>

Defines the name of rules to appear on the Simple Rule drop down list of disabled alarm filter form. Rules need to be defined in consecutive order, for example, Rule1, Rule2, Rule3. The content of each rule is defined under parameter [\[AlarmFilterRules\]<RuleName>](#).

For examples refer to the topic *Using the AlarmFilterRules Parameters* in the Alarm Filter Help (available at runtime).

#### Allowable Values:

Any valid rule name

#### Default Value:

Rule1 = Last 24 hours  
Rule2 = Last 7 days

## See Also

[AlarmFilterRule Parameters](#)

### [AlarmFilterRuleList]Rule<n>

Defines the name of the common rules to appear in the Simple Rule dropdown list of the alarm filter form available at runtime. The common rules defined here are listed at the bottom of the dropdown list, after the rules specific to the filter form.

Rules need to be defined in consecutive order, (for example, Rule1, Rule2, Rule3, ... and so on). The content of each rule is defined under parameter [AlarmFilterRules]<RuleName>.

For examples refer to the topic *Using the AlarmFilterRules Parameters* in the Alarm Filter Help (available at runtime).

## Allowable Values:

Any valid rule name

## Default Value:

None

## See Also

[AlarmFilterRule Parameters](#)

### [AlarmFilterRuleList.SOE]Rule<n>

Defines the name of rules to appear on the Simple Rule drop down list of alarm soe filter form. Rules need to be defined in consecutive order (for example, Rule1, Rule2, Rule3). The content of each rule is defined under parameter [AlarmFilterRules]<RuleName>.

For examples refer to the topic *Using the AlarmFilterRules Parameters* in the Alarm Filter Help (available at runtime).

## Allowable Values:

Any valid rule name

## Default Value:

Rule1 = No system events  
Rule2 = Last 24 hours  
Rule3 = Last 7 days

## See Also

[AlarmFilterRule Parameters](#)

### [AlarmFilterRuleList.Summary]Rule<n>

Defines the name of rules to appear on the Simple Rule drop down list of alarm summary filter form. Rules need to be defined in consecutive order, for example, Rule1, Rule2, Rule3. The content of each rule is defined under parameter [AlarmFilterRules]<RuleName>.

For examples refer to the topic *Using the AlarmFilterRules Parameters* in the Alarm Filter Help (available at runtime).

## Allowable Values:

Any valid rule name

## Default Value:

Rule1 = Last 24 hours - OnTime

Rule2 = Last 7 days - OnTime

## See Also

[AlarmFilterRule Parameters](#)

### [AlarmFilterRules]<RuleName>

Defines the filter expression represented by the rule name. The rule name can be used under parameter group [AlarmFilterRuleList[.<FilterForm>]] so that the rule names are selectable on the respective filter form.

For examples refer to the topic *Using the AlarmFilterRules Parameters* in the Alarm Filter Help (available at runtime).

## Allowable Values:

Any valid filter expression.

Multiple filter expression can be defined, with each separated by semi-colon (;) character. A special keyword, #Now[<offset in seconds>] can be used to represent the current time with an optional offset.

## Default Value:

None

---

**Note:** The following rule names are pre-defined as part of the Library\_Controls project:

No system events = StateNumeric <> 0

Last 24 hours = LocalTimeDate >= #Now[-86400]

Last 7 days = LocalTimeDate >= #Now[-604800]

---

---

Last 24 hours - OnTime = OnTime >= #Now[-86400]

Last 7 days - OnTime = OnTime >= #Now[-604800]

---

[AlarmFilterRule Parameters](#)

## Animator Parameters

The Citect.ini file contains the following animator parameters:

- [\[Animator\]BoldWeight](#) - The weight of a text font when bold is specified - the larger the number, the heavier is the font.
- [\[Animator\]ButtonCancelMode](#) - The behavior of push button command cancellation.
- [\[Animator\]CacheSize](#) - The maximum number of symbols that can be held in the cache of a client.
- [\[Animator\]ConfigureMouseCommand](#) - Determines whether you can configure command keys for the mouse buttons (left and right).
- [\[Animator\]EatMouseClick](#) - Determines whether Plant SCADA ignores (eats) the mouse click (left button down or up, or right button down or up), if commands are defined for those keys.
- [\[Animator\]EatMouseFocus](#) - Determines whether Plant SCADA ignores (eats) the left button down message when you change the focus of a window with the mouse.
- [\[Animator\]EnableWebContent](#) - Determines if Web Content objects are enabled at runtime.
- [\[Animator\]FastDisplay](#) - Determines whether Plant SCADA displays fast runtime graphics pages.
- [\[Animator\]FlashTime](#) - The frequency with which colors are flashed.
- [\[Animator\]FormFontWidth](#) - Determines how the text field width for forms with text fields (Check Boxes, Radio Buttons, Prompts, etc) is displayed.
- [\[Animator\]FullScreen](#) - Determines whether pages will be displayed in fullscreen or restored state.
- [\[Animator\]InvalidRegionExpansion](#) - Objects which are less than this distance apart will be re-drawn as a group if they change simultaneously at runtime.
- [\[Animator\]InvalidRegionQueueDepth](#) - The maximum number of non-overlapping objects that will be individually re-drawn when a large number of objects change simultaneously at runtime.
- [\[Animator\]LibraryError](#) - Determines whether a dialog box displays for any symbol that cannot be found.
- [\[Animator\]LibraryLength](#) - The number of objects that will be held in the library cache.
- [\[Animator\]LibraryTime](#) - The period that imported symbols remain in the library cache.
- [\[Animator\]MaxAn](#) - The maximum number of animation points (ANs) on a graphics page.
- [\[Animator\]MaximizedWindow](#) - Defines whether the runtime window is run in maximized mode on start-up.
- [\[Animator\]PrintXScale](#) - The X scaling factor applied when the WinPrint() function is called to print the screen (on the printer).
- [\[Animator\]PrintYScale](#) - The Y scaling factor applied when the WinPrint() function is called to print the screen (on the printer).
- [\[Animator\]TabFactor](#) - Controls the distance between tab stops on the graphics display.
- [\[Animator\]TemplateUpdate](#) - Enables the update of linked graphics pages to reflect template modifications.

- [\[Animator\]TooltipFont](#) - Specifies the font to be used for Plant SCADA's Tooltips.
- [\[Animator\]UseCTGIfNewer](#) - Controls the loading of CTG and CTF files when opening a page.

## See Also

[Parameter Categories](#)

### [Animator]BoldWeight

The weight of a text font when bold is specified - the larger the number, the heavier is the font.

---

**Note:** Although this parameter is still valid, it is only used for V3.xx and V4.xx animations.

---

#### Allowable Values:

0 to 1000

#### Default Value:

600

## See Also

[Animator Parameters](#)

### [Animator]ButtonCancelMode

Specifies the behavior of push button command cancellation.

When set to 0 - On button down, the button down command is executed, and the button up command is executed only if the mouse button is released while the mouse cursor is on top of the button.

When set to 1 - The behavior of command cancellation is determined by the configuration of the button. If you have configured a down command then the up command cannot be cancelled. If you have not configured a down command the up command can be cancelled.

When set to 2 - Command cancellation is disabled. Irrespective of how the button was configured, the up command cannot be cancelled.

---

**Note:** Although this parameter is still valid, it is only used for V3.xx and V4.xx animations.

---

#### Allowable Values:

0, 1, 2

#### Default Value:

1

## See Also

[Animator Parameters](#)

### [Animator]CacheSize

The maximum number of symbols that can be held in the cache of a client. If you increase the cache size, you use Windows resources and could cause problems with other software packages. Note that all symbols are actually cached in memory-this cache is a secondary cache.

**Note:** Although this parameter is still valid, it is only used for V3.xx and V4.xx animations.

## Allowable Values:

10 to 200

## Default Value:

50

## See Also

[Animator Parameters](#)

### [Animator]ConfigureMouseCommand

Determines whether you can configure command keys for the mouse buttons (left and right).

## Allowable Values:

- 0 - (Disable mouse button configuration)
- 1 - (Enable mouse button configuration)

## Default Value:

1

## See Also

[Animator Parameters](#)

### [Animator]EatMouseClicked

Determines whether Plant SCADA ignores (eats) the mouse click (left button down or up, or right button down or up), if commands are defined for those keys.

**Allowable Values:**

- 0 - (Do not ignore mouse)
- 1 - (Ignore mouse)

**Default Value:**

0

**See Also**[Animator Parameters](#)**[Animator]EatMouseFocus**

Determines whether Plant SCADA ignores (eats) the left button down message when you change the focus of a window with the mouse. Normally, if you have two windows on the screen and you click with the mouse from one to the other (to change the focus), any keyboard commands using the left mouse button execute. In addition, if you click on a button, the button command executes.

If you set this option to 1, the left mouse button click is ignored when you change the window focus.

**Allowable Values:**

- 0 - (Do not ignore mouse)
- 1 - (Ignore mouse)

**Default Value:**

0

**See Also**[Animator Parameters](#)**[Animator]EnableWebContent**

Determines if [Web Content](#) objects are enabled at runtime.

You can use this parameter to avoid the creation of multiple Chromium subprocesses, which can cause unnecessary instances of the Plant SCADA runtime process.

If a page containing a Web Content control is displayed while this parameter is set to 0 (disabled), the control will not display and a hardware alarm will be raised.

**Allowable Values:**

- 0 - Web Content objects are disabled
- 1 - Web Content objects are enabled

**Default Value:**

1

**See Also**

[Animator Parameters](#)

**[Animator]FastDisplay**

Determines whether Plant SCADA displays fast runtime graphics pages. If you enable this parameter, the runtime system searches for a fast display image when you display a page. If a fast display image is not found, the runtime system searches for a normal display image.

If you disable this parameter, the runtime system does not search for a fast display image and Graphics Builder will not save a fast display image. This option may also be set using the Options dialog in Graphics Builder (change the "Fast runtime display" option). If you want to save disk space, you can delete all files with the extension CTF in your project when this parameter is disabled.

**Allowable Values:**

- 0 - (Do not display)
- 1 - (Display fast runtime pages)

**Default Value:**

1

**See Also**

[Animator Parameters](#)

**[Animator]FlashTime**

The frequency with which colors are flashed.

**Allowable Values:**

100 to 3000 (milliseconds)

**Default Value:**

500

**See Also**

[Animator Parameters](#)

**[Animator]FormFontWidth**

Determines how the text field width for forms with text fields (Check Boxes, Radio Buttons, Prompts, etc) is displayed. You should only use this parameter if you are using Plant SCADA v2.00 (or earlier) to size the text fields generated with the Cicode form functions.

**Allowable Values:**

- 0 - (String length in characters)
- 1 - (String length in pixels)

**Default Value:**

1

**See Also**

[Animator Parameters](#)

**[Animator]FullScreen**

Determines whether pages will be displayed in fullscreen or restored state.

A page in fullscreen state takes up the entire display area (assuming this does not affect its aspect ratio), and it cannot be resized. Also, a fullscreen page will display without a title bar when [\[Page\]DynamicSizing](#) is enabled or when the page resolution is the same as the screen resolution. Resizing pages can result in lower picture quality. If this is unacceptable, you should re-design the page using the desired resolution.

A page in restored state can be resized by clicking and dragging on the window frame. If you resize a page, subsequent pages will, by default, be resized using the same scale. However, if the [\[Page\]DynamicSizing](#) parameter is set to FALSE, resizing the window will not change the page size.

---

**Note:** This parameter is modified by the Computer Setup Wizard as well as the Computer Setup Editor.

**Allowable Values:**

- 0 - (Window is not started in fullscreen mode)
- 1 - (Runtime window will be started fullscreen mode without a title bar)
- 2 – (Runtime window will be started in fullscreen mode with a title bar.)

**Default Value:**

0

**See Also**

[Animator Parameters](#)

**[Animator]InvalidRegionExpansion**

Objects which are less than this distance apart will be re-drawn as a group if they change simultaneously at runtime. This parameter is useful for improving runtime page display times. For example, you could set this parameter to 64 pixels, and draw a group of 5 individual lights (driven by digital tags) with 50 pixels between each. During runtime, if neighboring lights (closer than 64 pixels) changed simultaneously, they would be re-drawn together, rather than individually.

**Allowable Values:**

0 to 32000

**Default Value:**

64

**See Also**

[Animator Parameters](#)

**[Animator]InvalidRegionQueueDepth**

The maximum number of non-overlapping objects (or objects that are further apart than the distance specified by the [\[Animator\]InvalidRegionExpansion](#) parameter) that will be individually re-drawn simultaneously at runtime. For example, if you set this parameter to 30, and you have a graphics page that contains 200 non-overlapping lights(driven by digital tags), and the associated tags change state at once, only 30 of the lights would be re-drawn individually; the remaining lights would be re-drawn (as a group) in one step.

**Allowable Values:**

1 to 32000

**Default Value:**

10

## See Also

[Animator Parameters](#)

### [Animator]LibraryError

Determines whether a dialog box displays for any symbol that cannot be found.

#### Allowable Values:

- 0 - (Do not display a dialog box)
- 1 - (Display a dialog box)

#### Default Value:

0

## See Also

[Animator Parameters](#)

### [Animator]LibraryLength

The number of objects that will be held in the library cache.

#### Allowable Values:

1 to 100000

#### Default Value:

100

## See Also

[Animator Parameters](#)

### [Animator]LibraryTime

The period that imported symbols remain in the library cache.

#### Allowable Values:

- -1 (Objects remain cached until the cache is full) OR

- 0 to 864000 (seconds)

**Default Value:**

600

**See Also**

[Animator Parameters](#)

**[Animator]MaxAn**

The maximum number of animation points (ANs) on a graphics page. You should avoid large values for this parameter. Each AN uses memory and a large number of ANs will reduce the performance of your runtime system.

**Note:** Although this parameter is still valid, it is only used when Graphic Page designers select to use older style v3 and v4 objects.

---

**Allowable Values:**

256 to 32000

**Default Value:**

2048

**See Also**

[Animator Parameters](#)

**[Animator]MaximizedWindow**

Defines whether the runtime window is run in maximized mode on start-up.

The MaximizedWindow parameter only works when DynamicSizing is set to 1 and FullScreen is set to 0. This parameter can also be configured on the "Security Menu Control" dialog in the Computer Setup Wizard.

**Allowable Values:**

- 0 – The runtime window will not be set to maximized state on start-up.
- 1 – The runtime window will be set to maximized state on start-up.

**Default Value:**

0

## See Also

[Animator Parameters](#)

### [Animator]PrintXScale

The X scaling factor applied when the WinPrint() function is called to print the screen (on the printer).

#### Allowable Values:

1 to 10

#### Default Value:

4

## See Also

[Animator Parameters](#)

### [Animator]PrintYScale

The Y scaling factor applied when the WinPrint() function is called to print the screen (on the printer).

#### Allowable Values:

1 to 10

#### Default Value:

4

## See Also

[Animator Parameters](#)

### [Animator]TabFactor

Controls the distance between tab stops on the graphics display. Plant SCADA calculates the width of a tab stop by counting the number of characters, times the average width, times the tab factor. Normally the average width, times the number of characters makes the tab stops too wide. Therefore the tab factor is set to 70% to reduce the width. If you have wide characters, or use a lot of upper case the default tab factor may be too narrow, and overlapping of the display may result. (Increase up to 100% for the widest tab stops.)

**Allowable Values:**

10 to 100

**Default Value:**

70

**See Also**

[Animator Parameters](#)

**[Animator]TemplateUpdate**

Enables the update of linked pages to reflect template modifications.

Setting this parameter allows linked graphics pages to be updated if the templates on which they are based have been modified. The update takes place when you click Update Pages in the Tools menu of Graphics Builder.

With this parameter set, updating linked pages will overwrite page properties with those of the template. This means that if you want to change the properties of a linked page, you must set the template properties. The next time you perform an Update Pages, the page will include the template modifications.

**Allowable Values:**

- 1 - (to enable)
- 0 - (to disable)

**Default Value:**

0

**See Also**

[Animator Parameters](#)

**[Animator]TooltipFont**

Specifies the font to be used for tool tip text. This parameter is checked each time you start Plant SCADA. (You can also use the function DspSetTooltipFont to set the font.)

Unlike other parameters where only one value is supplied, you can enter up to three values to set the tool tip font - the name of the font, the point size, and formatting attributes. Only the name of the font is required. If you don't set values for the other attributes, their default values are used.

**Allowable Values:**

Name, PointSize, BIU

**Default Value:**

12 (PointSize)

" " (BIU)

- Name is the name of the chosen Windows font
- PointSize is the size of the font in points
- B specifies Bold
- I specifies Italic
- U specifies Underline

**See Also**

[Animator Parameters](#)

**[Animator]UseCTGIfNewer**

When a page is opened and Fast Runtime Display is enabled, Plant SCADA searches for both the CTF and the CTG files and uses whichever is newer. Use this parameter to specify that only the CTG file is searched for if the CTF cannot be found.

**Allowable Values:**

- 1 - Always check to see if CTG is newer
- 0 - The CTG is located and loaded only if the CTF cannot be found

**Default Value:**

1

**See Also**

[Animator Parameters](#)

**AnmCursor Parameters**

The cursor is represented by a box with an internal and an external border. Symbols and text have imaginary borders that represent the inside border. When specifying cursor dimensions, you have to specify the size of the external border.

- [\[AnmCursor\]Color](#) - Sets the color of the cursor.
- [\[AnmCursor\]Colour](#) - Obsolete in v7.20 (replaced with [\[AnmCursor\]Color](#)).
- [\[AnmCursor\]Height](#) - The distance (in pixels) from the top and bottom of the inside border to the outside border (of the cursor).
- [\[AnmCursor\]InvertText](#) - Enables/disables the inversion of the color of the text within the cursor box.
- [\[AnmCursor\]MouseSnapToCursor](#) - Specifies the behavior of the Windows cursor in relation to the Plant SCADA cursor
- [\[AnmCursor\]RubberBandColor](#) - Sets the color of the trend selection rubber band.
- [\[AnmCursor\]Thickness](#) - The thickness of the outside cursor border (in pixels).
- [\[AnmCursor\]Width](#) - The distance (in pixels) from the left and right of the inside border to the outside border (of the cursor).

## See Also

[Parameter Categories](#)

### [AnmCursor]Color

Sets the color of the cursor.

### Allowable Values:

0x000000 to 0xFFFFFFFF

Colors defined as RGB values, for example:

- 0x00000000 - (Black)
- 0x00000080 - (Blue)
- 0x00008000 - (Green)
- 0x00008080 - (Cyan)
- 0x00800000 - (Red)
- 0x00800080 - (Magenta)
- 0x00808000 - (Brown)
- 0x00BFBFBF - (Grey)
- 0x007F7F7F - (Dark Grey)
- 0x000000FF - (Light blue)
- 0x0000FF00 - (Light green)
- 0x0000FFFF - (Light cyan)
- 0x00FF0000 - (Light red)
- 0x00FF00FF - (Light Magenta)
- 0x00FFFF00 - (Yellow)
- 0x00FFFFFF - (White)

- 0xFF000000 - (Transparent)

**Default Value:**

0xFFFF (white)

**See Also**

[AnmCursor Parameters](#)

**[AnmCursor]Height**

The distance (in pixels) from the top and bottom of the inside border to the outside border (of the cursor).

**Allowable Values:**

1 to 20

**Default Value:**

1

**See Also**

[AnmCursor Parameters](#)

**[AnmCursor]InvertText**

Enables/disables the inversion of the color of the text within the cursor box.

---

**Note:** Although this parameter is still valid, it is only used for V3.xx and V4.xx animations.

---

**Allowable Values:**

- 0 - (Disable)
- 1 - (Enable)

**Default Value:**

0

**See Also**

[AnmCursor Parameters](#)

## [AnmCursor]MouseSnapToCursor

Specifies the behavior of the Windows cursor in relation to the Plant SCADA cursor.

When set to FALSE the Windows cursor and the Plant SCADA cursor behave independently.

When set to TRUE the Windows cursor snaps to the center of the Plant SCADA cursor. In this case a page update will not result if the cursor position is changing.

### Allowable Values:

- 0 - (False)
- 1 - (True)

### Default Value:

0

### See Also

[AnmCursor Parameters](#)

## [AnmCursor]RubberBandColor

Sets the color of the trend selection rubber band.

### Allowable Values:

0x000000 to 0xFFFF

Colors defined as RGB values, for example:

- 0x000000 - (Black)
- 0x000080 - (Blue)
- 0x008000 - (Green)
- 0x008080 - (Cyan)
- 0x800000 - (Red)
- 0x800080 - (Magenta)
- 0x808000 - (Brown)
- 0xBFBFBF - (Grey)
- 0x7F7F7F - (Dark Grey)
- 0x0000FF - (Light blue)
- 0x00FF00 - (Light green)
- 0x00FFFF - (Light cyan)
- 0xFF0000 - (Light red)

- 0xFF00FF - (Light Magenta)
- 0xFFFF00 - (Yellow)
- 0xFFFFFFFF - (White)

**Default Value:**

0xFFFFFFFF (white)

**See Also**

[AnmCursor Parameters](#)

**[AnmCursor]Thickness**

The thickness of the outside cursor border (in pixels).

**Allowable Values:**

1 to 20

**Default Value:**

1

**See Also**

[AnmCursor Parameters](#)

**[AnmCursor]Width**

The distance (in pixels) from the left and right of the inside border to the outside border (of the cursor).

**Allowable Values:**

1 to 20

**Default Value:**

2

**See Also**

## Backup Parameters

The Citect.ini file contains the following backup parameters:

- [\[Backup\]SaveiniFiles](#) - Determines whether the "Save ini files" checkbox is checked by default during Backup.

## See Also

[Parameter Categories](#)

### [Backup]SaveiniFiles

Determines whether the **Save ini files** checkbox is checked or not when the Backup Project window is opened.

#### Allowable Values:

- 0 - unchecked
- 1 - checked

#### Default Value:

1

## See Also

[Backup Parameters](#)

### BrowseTableView Parameters

The [BrowseTableView] section contains the following parameters:

---

**Note:** These parameters are only available to pages created from the **tab\_style\_1.databrowse** page template.

- [\[BrowseTableView\]<BrowseType>.<ViewName>.ColWidths](#) - Sets the pixel widths of the columns of the current data browse table.
- [\[BrowseTableView\]<BrowseType>.<ViewName>.Fields](#) - Sets the field names of the columns in the current data browse table under a view name configured on the page.

## See Also

[Parameter Categories](#)

### [BrowseTableView]<BrowseType>.<ViewName>.ColWidths

Sets the widths of the columns in pixels for the current data browse table configured on the page. This parameter is only available to pages created from the "tab\_style\_1.databrowse" page template.

The view name is configured by opening the page in Graphics Builder and filling in the "View Name" field in the template form. To open the template form double-click it. Once saved in the INI file, the columns are automatically restored when the user re-enters the page or when the user chooses to restore them via the "Restore saved view" command under the Action menu tab.

The user can erase the saved view by selecting the "Reset view to default" command from the Action menu tab. The table columns is then reset to the original configuration of the project.

---

**Note:** If this parameter is configured as project parameter, it will act as the default configuration and be reset to when the user executes the "Reset view to default" command.

- <BrowseType> field can be any of the following values:

AccumBrowse, AlmBrowse, EquipBrowse, ServerBrowse, TagBrowse, TrnBrowse

This should be the same as the "Browse Type" field in the template parameter form of the Data Browse page.

- <ViewName> – allows the user to specify a name to identify the view that will be saved to or restored from. This should be the same as the "View Name" field in the template parameter form of the Data Browse page.

---

**Note:** You can specify the same view name on multiple Data browse pages The pages will then share the same view.

## Allowable Values:

The width of the columns in pixels, separated by the comma (,) character.

## Default Value:

N/A

## See Also

[BrowseTableView Parameters](#)

### [BrowseTableView]<BrowseType>.<ViewName>.Fields

Sets the field names of the columns in the current data browse table under 'view name' configured on the page. This parameter is only available to pages created from the "tab\_style\_1.databrowse" page template.

The view name is configured by opening the page in Graphics Builder and filling in the "View Name" field in the template form. To open the template form double-click it. Once saved in the INI file, the columns are automatically restored when the user re-enters the page or when the user chooses to restore them via the "Restore saved view" command under the Action menu tab.

The user can erase the saved view by selecting the "Reset view to default" command from the Action menu tab. The table columns is then reset to the original configuration of the project.

---

**Note:** If this parameter is configured as project parameter, it will act as the default configuration and be reset to when the user executes the "Reset view to default" command.

- <BrowseType> field can be any of the following values:

AccumBrowse, AlmBrowse, EquipBrowse, ServerBrowse, TagBrowse, TrnBrowse

This should be the same as the "Browse Type" field in the template parameter form of the Data Browse page.

- <ViewName> – allows the user to specify a name to identify the view that will be saved to or restored from. This should be the same as the "View Name" field in the template parameter form of the Data Browse page.

---

**Note:** You can specify the same view name on multiple Data browse pages. The pages will then share the same view.

---

## Allowable Values:

The name of the fields of the specified data browse type, separated by the comma (,) character.

## Default Value:

N/A

## See Also

[BrowseTableView Parameters](#)

## Client Parameters

The Citect.ini file contains the following client parameters that can be set manually. Other parameters, which are not listed below, can be set by using the Computer Setup Wizard.

- [\[Client\]AdditionalClientsArePartOfTrustedNetwork](#) - Tells an /X client process to authenticate using the stored server password.
- [\[Client\]AllowRPC](#) - Allows a client computer to run a procedure called remotely on a server by the Cicode function MsgRPC.
- [\[Client\]AutoLoginPage](#) - Set to enable auto login. Users can select one of six modes.
- [\[Client\]AutoLoginClearPassword](#) - Set to clear the cached client login credentials.
- [\[Client\]Clusters](#) - Selects which clusters the client is connected to at startup.
- [\[Client\]ComputerRole](#) - Specifies the role of the computer, either server and control client, view-only or control client.
- [\[Client\]CPU](#) - Sets the CPU that the client component is assigned to.
- [\[Client\]DisableDisplay](#) - Specifies that the client process will be run in the background without a visible page or window.
- [\[Client\]Display](#) - Obsolete in version 7.0.
- [\[Client\]Events](#) - Sets the events to be enabled on the client.
- [\[Client\]EvictTimeout](#) - The amount of time a tag reference is cached before it is evicted.
- [\[Client\]ForceClient](#) - Starts only the client process, and connects to configured servers using a network connection.

- [\[Client\]FullLicense](#) - Specifies that a Control Client will use a full license.
- [\[Client\]Manager](#) - Obsolete in version 7.0.
- [\[Client\]PartOfTrustedNetwork](#) - Tells a client process to authenticate using the stored server password.
- [\[Client\]PointCountRequired](#) - Specify what point count a client requires.
- [\[Client\]Primary](#) - Obsolete in version 7.0.
- [\[Client\]Process](#) - Obsolete in version 7.0.
- [\[Client\]ReadOnly](#) - Does not allow writes to any I/O device.
- [\[Client\]ResolveTimeout](#) - Time the clients will wait for a successful server response for a tag exists request.
- [\[Client\]ShutdownCode](#) - Determines the Cicode function to run when Plant SCADA DisplayClient component shuts down.
- [\[Client\]StalenessPeriod](#) - Specifies the total number of seconds that will elapse after the last update before extended quality of the tag element is set to "Stale".
- [\[Client\]StalenessPeriodTolerance](#) - Specifies a percentage value that will be tolerated for the staleness period.
- [\[Client\]Standby](#) - Obsolete in version 7.0.
- [\[Client\]StartupCode](#) - Determines the Cicode function to run when Plant SCADA DisplayClient component starts up.
- [\[Client\]TagReadCachedMode](#) - Specifies which mode TagInfo() and other CiCode functions use for retrieving Tag/Ass properties.
- [\[Client\]TagReadRoundToFormat](#) - Determines if the variable tag values returned by the TagRead and TagReadEx will be rounded to the format of the variable tag.
- [\[Client\]UseLocalLicense](#) - Determines where a Plant SCADA Anywhere client gets its license from.
- [\[Client\]WaitForConnectAtStartup](#) - Specifies that connection to a server will wait until it can establish a connection to the server processes before starting up.
- [\[Client\]WaitForValidDataTimeout](#) - Allows a client to display #COM errors on a project page if a response to a subscription is not received within the specified period of time.

---

**Note:** When Plant SCADA is running in single process mode, the client settings for Cluster, CPU, Events, ShutdownCode and StartupCode are used for the Plant SCADA process.

---

## See Also

[Parameter Categories](#)

### [Client]AdditionalClientsArePartOfTrustedNetwork

This parameter tells an /X Client process to attempt to authenticate using the stored server password, which results in the client node becoming part of a "trusted network".

---

**Note:** To run as part of the trusted network, the Windows user account that is running the process needs to be assigned to the Server Users security role (see the topic [Security Roles](#)).

---

In Plant SCADA, a network with nodes connected via trusted tran channels is called a "trusted network" and the nodes must use the same stored server password to trust each other. Only trusted tran channels can handle remote requests initiated by MsgRPC() and ServerRPC() Cicode functions.

Although all connections between servers are always trusted regardless of this parameter, the tran channel between server and client should be explicitly configured to be trusted by this parameter in order to process remote requests initiated from the client node.

### Allowable Values:

- 0 - /X client is not part of the trusted network
- 1 - /X client is part of the trusted network. Use the Computer Setup Wizard to configure the server password (if not previously done so).

### Default Value:

0

For more information refer to the following topics in the main help:

- [Server Password Configuration](#)
- [Page Table Tran.](#)

### See Also

[\[Client\]PartOfTrustedNetwork](#)

[Client Parameters](#)

### [Client]AllowRPC

Allows a client computer to run a procedure called remotely from a server, or another client, using the Cicode function MsgRPC.

---

**Note:** An MsgRPC call will only succeed if the current user on the remote computer is assigned to a Role that has the **AllowRPC** property set to "TRUE".

---

### Allowable Values:

- 0 – MsgRPC calls will not be successful.
- 1 – MsgRPC calls will be successful.

### Default Value:

0

### See Also

[Client Parameters](#)

## [Client]AutoLoginClearPassword

Set to clear the cached client login credentials for consistency with the server 'AutoLoginClearPassword' ini parameter.

### Allowable Values:

- 0 – Do nothing
- 1 – Clear the stored login credentials (resets to 0 after the login credentials have been cleared)

### Default Value:

0

### See Also

[Client Parameters](#)

## [Client]AutoLoginMode

Set to enable auto login. Users can select one of seven modes.

- **Mode 0** - Auto login is disabled.
- **Mode 1** - System logs in with the current windows user at Startup.
- **Mode 2** - System logs in with the current windows user at Startup and on logout. If the startup login fails the user will be prompted to login at startup and on logout so the system will not switch to view-only mode.

---

**Note:** Modes 1 and 2 act as the same as modes 3 and 4 if the start up login of current windows user fails.

- **Mode 3** - User will be prompted with an empty login form at startup.
- **Mode 4** - User will be prompted with an empty login form at startup and on log out. If the user selects cancel, the process will shut down.

---

**Note:** This mode should not be used on server process (where the ServerLogin is disabled).

- **Mode 5** - Automatically login with saved user credentials at startup. If login fails or there is no saved user credentials the user will be prompted to login.
- **Mode 6** - Attempt to automatically login with saved credential at startup and on logout. If saved credential is not available (or fails to login) it will prompt the user at startup to log in. The re-login of initial user on logout does not validate the user, therefore does not need to prompt even if the password is changed (e.g. in case of windows user).

To remove or change the credentials saved during modes 5 or 6, the user needs to set the mode to 3 or 4 and restart to be prompted for login. When the user successfully logs in the saved credential will be removed and the user can set the mode back to 5 or 6 and restart to be prompted again.

---

**Note:** In modes 1, 3 and 5 when the user logs out, system reverts to view-only mode and no further action is taken.

**Allowable Values:**

- 0 – (Auto login disabled. Control client starts in view-only mode, until valid user logs on)
- 1 – (Login current windows user at system start up)
- 2 - (Login current windows user as system default user at start up)
- 3 - (Prompt user for login at startup)
- 4 - (Prompt user for login at startup and logout)
- 5 - (Try login with saved credential at startup)
- 6 - (Try login with saved credential at startup and on logout)

**Default Value:**

0

**See Also**

[Client Parameters](#)

**[Client]Clusters**

Selects which clusters the client is connected to at startup.

**Allowable Values:**

Comma separated list of the names of any configured clusters.

**Default Value:**

All configured clusters.

---

**Note:** This parameter is used by Plant SCADA to specify the active clusters for all components at startup, when running in single process mode.

---

**See Also**

[Client Parameters](#)

**[Client]ComputerRole**

Specifies the role of the computer. This can be configured on the [Computer Role Setup](#) page of the Setup Wizard.

**Allowable Values:**

- 0 - Server and Control Client

- 1 - Control Client - enables [Client]FullLicense
- 2 - View-only Client
- 3 - HMI (Standalone, no networking)

**Default Value:**

NONE

**See Also**

[Client Parameters](#)

**[Client]CPU**

This parameter is by Plant SCADA Runtime Manager to determine which CPU(s) the client process is assigned to. The CPU parameter is configurable for every Plant SCADA process via the **CPU Setup** page in the Computer Setup Wizard (see [CPU Configuration](#)).

---

**Note:** When Plant SCADA is running in single process mode, this parameter is used to specify the CPU assignment for the Plant SCADA process.

If this parameter is modified while the Plant SCADA Runtime Manager is running, the changes will not take effect until every instance of Plant SCADA is restarted.

CPU numbers are specified in a comma separated list. CPU numbers need to be valid and a subset of the available CPUs on a computer. For example, if there are eight CPUs on a computer, a valid CPU range is 0 to 7.

**Allowable Values:**

A comma-separated list in the range 0 to 31 (inclusive), where 0 is the first CPU.

For example, "0, 1, 2" or "3, 4, 5".

If no value is entered, the process will run on all available CPUs.

---

**Note:** When a process is set to run on all available CPUs, be aware that performance issues may still occur when your CPU usage is less than 100%. You can detect these issues when your CPU usage for a process is fixed at 100 divided by the number of processors.

**Default Value:**

No value (the process will run on all CPUs).

---

**Note:** You cannot manually specify CPU assignments on a computer with more than 32 CPUs. Under these circumstances, the Setup Wizard will automatically set this parameter to no value (all CPUs). Any changes you make to this parameter will be overwritten.

**See Also**

[Client Parameters](#)

[\[Alarm.<ClusterName>.<ServerName>\]CPU](#)

[IOServer.<ClusterName>.<ServerName>]CPU  
[Report.<ClusterName>.<ServerName>]CPU  
[Trend.<ClusterName>.<ServerName>]CPU

### [Client]DisableDisplay

Specifies that the client process will run in the background without a visible page or window.

#### Allowable Values:

- 0 - Enable the display (The client display will be visible).
- 1 - Disable the display (The client will still run in a background process but the client window will not be shown).

#### Default Value:

0

### See Also

[Client Parameters](#)

### [Client]Events

The events to be enabled by the client.

**Note:** All events that have "Global" or nothing in the Name field are enabled automatically in the client.

#### Allowable Values:

List of events (comma separated).

**Note:**

- This parameter is used by Plant SCADA to specify the enabled events for the Plant SCADA process, when running in single process mode.
- To set this parameter, we recommend you enable the required events in the "Events Setup" page of the Computer Setup Wizard (instead of entering the events in the Setup Editor).

### See Also

[Client Parameters](#)

### [Client]EvictTimeout

The amount of time in milliseconds that a tag reference is held in cache without being requested by a client before it is evicted.

**Allowable Values:**

-1 to 2000000

A value of -1 means that [Client]EvictTimeout is turned off. This means that no tag references will be evicted for the life of a session, and this can consume a large amount of memory.

**Default Value:**

300000

**See Also**

[Client Parameters](#)

**[Client]ForceClient**

Starts only the client process and connects to a configured Plant SCADA servers using a network connection.

This is useful where multiple users login to the same server, for instance Windows 2003 Enterprise Edition or similar, and want to run Plant SCADA from their user accounts concurrently to an instance of Plant SCADA that is already running.

In such cases you should start RuntimeManager.exe with the /i option specifying an alternative Citect.ini file where [Client]ForceClient=1 is set.

**Allowable Values:**

- 0 - (Client and servers if they are configured).
- 1 - (Client only).

**Default Value:**

0

**See Also**

[Client Parameters](#)

**[Client]FullLicense**

Specifies that the client will use a full license. This parameter is ignored unless the computer is a client.

**Allowable Values:**

- 0 - do not use a full license
- 1 - use a full license

**Default Value:**

0

**See Also**

[Client Parameters](#)

**[Client]PartOfTrustedNetwork**

This parameter tells a client process to attempt to authenticate using the stored server password, which results in the client node becoming part of a "trusted network". This parameter is automatically set by the Computer Setup Wizard. You do not need to set this parameter on a computer that is running a server process.

**Note:** To run as part of the trusted network, the Windows user account that is running the process needs to be assigned to the Server Users security role (see the topic [Security Roles](#)).

In Plant SCADA, a network with nodes connected via trusted tran channels, is called a "trusted network" and the nodes must use the same stored server password to trust each other. You do not need to set this parameter on computers that are just accepting CTAPI connections. If the CTAPI connection is being used to access information on a remote server via MsgRCP or ServerRCP, then set this parameter manually.

Although all connections between servers with matching passwords are always trusted regardless of this parameter, the tran channel between server and client should be explicitly configured to be trusted by this parameter in order to process remote requests initiated from the client node. Accordingly, this parameter needs to be set to use the client process as a CtAPI server.

**Note:** To include an /X process in a trusted network, use the parameter [\[Client\]AdditionalClientsArePartOfTrustedNetwork](#).

**Allowable Values:**

- 0 - Client is not part of the trusted network
- 1 - Client is part of the trusted network. Use the Computer Setup Wizard to configure the server password (if not previously done so).

**Default Value:**

0

For more information refer to the following topics in the main help:

- [Server Password Configuration](#)
- [Page Table Tran](#).

**See Also**

[Client Parameters](#)

**[Client]PointCountRequired**

A client can specify what point count it requires by this parameter. If the parameter is not specified, the client will get the first available matching point count. If the parameter is specified, but the required point count is not found within the license, no point count (no license) is served to that client.

---

**Note:** This parameter only works with Sentinel Licensing USB keys. It does not apply when using AVEVA™ Enterprise Licensing.

---

**Allowable Values:**

Any integer >= 1 or 0 (unlimited)

**Default Value:**

1 (gets the first available point count)

**See Also**

[Client Parameters](#)

**[Client]ReadOnly**

Commands the Plant SCADA client not to write to any I/O device. This includes disk and physical I/O devices. This is useful when you want to minimize the likelihood that a client will modify the online system (e.g. when you are developing the client). When a write is made to a physical I/O device, and this parameter is set to 1, the following hardware error results: "Write location is protected".

**Allowable Values:**

- 0 - (Enable writes)
- 1 - (Disable writes)

**Default Value:**

0

**See Also**

[Client Parameters](#)

**[Client]ResolveTimeout**

The time period in milliseconds that clients will wait for a successful server response to a tag exists request. This setting may be increased to avoid "Tag resolve timeout" errors (error 532). However such errors are only expected to occur on heavily loaded systems or where communications are slow, and may indicate a

performance issue that requires investigation.

**Allowable Values:**

0 to 4 294 967 296

**Default Value:**

3000

**See Also**

[Client Parameters](#)

**[Client]ShutdownCode**

Can be used to specify a Cicode function that runs at shutdown of the Plant SCADA client component. Plant SCADA suspends the shutdown process until the function has finished running. The function must complete execution within the time specified by the [\[Code\]ShutdownTime](#) parameter, otherwise Plant SCADA will terminate it.

**Allowable Values:**

Any built-in or user-written Cicode function

You do not need to specify all the optional arguments, as the optional arguments will be given runtime defaults (not compiler defaults) as follows:

- Data type INT = 0
- Data type REAL = 0.0
- Data type STRING = ""

**Default Value:**

NONE

**See Also**

[Client Parameters](#)

**[Client]StalenessPeriod**

Specifies the total number of seconds that will elapse after the last update before extended quality of the tag element is set to "Stale". This parameter can be set on the server using the I/O Device configuration dialog.

**Allowable Values:**

- -1 - Use the I/O device setting
- 0 - Disable staleness period processing completely
- >0 - Local definition of staleness period (in seconds) Allowable values are 1 to 2147483647 seconds.

**Default Value:**

-1

**See Also**

[Client Parameters](#)

**[Client]StalenessPeriodTolerance**

Specifies the interval (as a percentage of the staleness period) at which displayed values will be evaluated to determine if they are stale.

**Allowable Values:**

1 to 100 percent of the staleness period

**Default Value:**

10

**See Also**

[Client Parameters](#)

**[Client]StartupCode**

Determines the Cicode function to run when Plant SCADA DisplayClient component starts up.

You can only pass constant data to the startup function call. You cannot pass variables or other functions. For example, MyFunc(1, "str") is valid, but MyFunc(PLCTAG, "str") or MyFunc(YourFunc(), "str") is not supported.

You do not need to specify all the optional arguments, as the optional arguments will be given runtime defaults (not compiler defaults) as follows:

- Data type INT = 0
- Data type REAL = 0.0
- Data type STRING = ""

---

**Note:** This parameter is modified by the Computer Setup Wizard.

---

**Allowable Values:**

Any built-in or user-written Cicode function

**Default Value:**

NONE

**Note:** This parameter is used by Plant SCADA to specify the Cicode function that runs at startup, when running in single process mode.

**See Also**

[Client Parameters](#)

**[Client]TagReadCachedMode**

Specifies which mode TagInfo() and other Cicode functions use for retrieving Tag/Ass properties.

**Allowable Values:**

- 0 - property is retrieved directly from the server
- 1 - property is retrieved from local cache
- 2 - property is retrieved from local configuration
- 3 - property is retrieved from local cache if the cached is loaded; otherwise from local configuration

**Default Value:**

3

**See Also**

[Client Parameters](#)

**[Client]TagReadRoundToFormat**

This setting determines if the variable tag values returned by the Cicode functions TagRead and TagReadEx will be rounded to the format of the variable tag.

Quite often, the value reported for a variable tag will not be precise, resulting in a large number of decimal places. When this parameter is set, the precision of the value returned is rounded to the format of the tag.

For example, if the value from an I/O device for a tag is 3.499999999999, but the format is ##.##, the rounded value will be 3.50.

**Allowable Values:**

- 0 - Values not rounded to format
- 1 - Values rounded to format

**Default Value:**

1

**See Also**[Client Parameters](#)**[Client]UseLocalLicense**

Determines where a Plant SCADA Anywhere client gets its license from.

**Allowable Values**

- 0 – a Plant SCADA Anywhere client will get its license from a remote license server, or directly from an AVEVA Enterprise License Server (if configured).
- 1 – a Plant SCADA Anywhere client will acquire its license from the local "SystemServices" process. This option is only valid if you are running as a service and have a Sentinel license attached to that computer.

**Default Value**

0

**See Also**[Client Parameters](#)**[Client]WaitForConnectAtStartup**

This is a Boolean parameter that specifies whether the client will wait until it can establish a connection to the server processes before starting up.

**Allowable Values:**

0 or 1.

**Default Value:**

For a new installation of Plant SCADA v7, the parameter exists in the Citect.ini file with a default setting of 0. For an existing installation that is being upgraded to v7, and the parameter is absent from this section of the

Citect.ini file, the application behaves as if the parameter existed and set to 1.

If the parameter is set to False (0), there is no delay and the client will attempt to connect in the background as Plant SCADA runtime starts up. If the parameter is set to True (1), the client will wait until it can establish a connection to the server processes before starting up.

## See Also

[Client Parameters](#)

### [Client]WaitForValidDataTimeout

Allows a client to display #COM errors on a project page if a response to a subscription is not received within the specified period of time.

#### Allowable Values:

1 - 60000 (milliseconds)

#### Default Value:

5000 (milliseconds)

## See Also

[Client Parameters](#)

## Code Parameters

The citect.ini file contains the following code parameters:

- [\[Code\]AlarmShutdown](#) - Obsolete in version 7.0.
- [\[Code\]AlarmStartup](#) - Obsolete in version 7.0.
- [\[Code\]AutoReRead](#) - Obsolete in version 7.0.
- [\[Code\]BackwardCompatibleErrHw](#) - Controls whether Plant SCADA Runtime should be backward compatible with versions prior to V5.20.
- [\[Code\]CallbackThreads](#) - Limits the number of tag subscription callback threads that will be executed simultaneously.
- [\[Code\]DebugMessage](#) - Enables/Disables the DebugMsg() logging functionality.
- [\[Code\]DIICallErrorPopup](#) - Creates a popup and logs errors on calls to third-party DLLs.
- [\[Code\]DIICallProtect](#) - Helps protects Plant SCADA Runtime from closing down in the event an external DLL is called and subsequently becomes inoperative.
- [\[Code\]DynamicCallDebug](#) - Allows you to control logging for Cicode that is called dynamically at runtime.
- [\[Code\]EchoError](#) - Controls whether Plant SCADA Runtime echoes errors in Cicode.
- [\[Code\]EnableErrorLogging](#) - Enables or disables the logging of issues with ErrSet() function and related

functions.

- [\[Code\]Export](#) - Controls if your Cicode is to be halted when an error occurs.
- [\[Code\]HaltOnError](#) - Stops your Cicode task if an error occurs in some key Cicode functions and generates a hardware error.
- [\[Code\]HaltOnInvalidTagData](#) - Stops Cicode when any tag read returns invalid data (bad quality).
- [\[Code\]IgnoreCase](#) - Controls whether Plant SCADA Runtime is case insensitive to string data in Cicode.
- [\[Code\]ProfilerEnabled](#) - Set this parameter to 1 to enable the Cicode Profiler when Plant SCADA Runtime starts.
- [\[Code\]IOServerShutdown](#) - Obsolete in version 7.0.
- [\[Code\]IOServerStartup](#) - Obsolete in version 7.0.
- [\[Code\]Process](#) - Obsolete in version 7.0.
- [\[Code\]Queue](#) - The maximum number of elements in queues.
- [\[Code\]ReportShutdown](#) - Obsolete in version 7.0.
- [\[Code\]ReportStartup](#) - Obsolete in version 7.0.
- [\[Code\]ScaleCheck](#) - Controls whether Plant SCADA Runtime checks for scaling over/under flow errors in Cicode.
- [\[Code\]Shutdown](#) - Obsolete in version 7.0.
- [\[Code\]ShutdownTime](#) - Specifies the maximum time allowed for the execution of any Cicode functions triggered by the [Code]Shutdown parameter.
- [\[Code\]Stack](#) - The size of the stack when Plant SCADA Runtime calls a user DLL function through the Cicode function DLLCall().
- [\[Code\]Startup](#) - Obsolete in version 7.0.
- [\[Code\]StrictArgumentCheck](#) - Determines whether the compiler checks for calls to functions missing parameters.
- [\[Code\]Threads](#) - The number of Cicode threads (tasks) that can run concurrently.
- [\[Code\]TimeData](#) - Determines how often (in milliseconds) the I/O server reads I/O device data in order to provide tags with up-to-date Cicode variables.
- [\[Code\]TimeSlice](#) - The period (in milliseconds) that a Cicode thread can run - before it is swapped out.
- [\[Code\]TimeSlicePage](#) - The period (in milliseconds) that a Cicode thread can run - before it is halted.
- [\[Code\]TrendShutdown](#) - Obsolete in version 7.0.
- [\[Code\]TrendStartup](#) - Obsolete in version 7.0.
- [\[Code\]Unsigned](#) - Determines if the capable protocols interpret 16 bit integers as unsigned or not.
- [\[Code\]VBASupport](#) - Enables and disables Plant SCADA VBA Support.
- [\[Code\]WriteLocal](#) - Controls whether Plant SCADA Runtime writes to a local run table in Cicode.

## See Also

[Parameter Categories](#)

## [Code]BackwardCompatibleErrHw

Enables/Disables the backward compatibility of Cicode functions **ErrGetHw** and **ErrSetHw** used after Plant SCADA v5.20

**Note:** Set this flag ONLY if you do not have less than 512 I/O devices in your project, AND you have used the ErrGetHw() or ErrSetHw() functions in that project. This will allow you to mask the "IODevNo" with the value of 512 in the "Device" argument of those functions.

### Allowable Values:

- 0 - (Disable backward compatibility)
- 1 - (Enable backward compatibility)

### Default Value:

0

### See Also

[Code Parameters](#)

## [Code]CallbackThreads

Limits the number of tag subscription callback threads that will executed simultaneously. The upper boundary of the parameter is based on the upper limit of [\[Code\]Threads](#), but in practice it is recommended not to use every available Cicode thread for callbacks .

### Allowable Values:

1 to 512

### Default Value:

5

### See Also

[Code Parameters](#)

## [Code]DebugMessage

Enables or disables the DebugMsg function, which provides inline debug messages to the Kernel and syslog.dat. Also controls the logging functionality of the Assert() function. This parameter can be set and reset at runtime with the DebugMsgSet() function.

**Allowable Values:**

- 0 - (Disable logging)
- 1 - (Enable logging)

**Default Value:**

0

**See Also**[Code Parameters](#)**[Code]DII Call Error Popup**

Creates a popup and logs errors on calls to third-party DLLs via Cicode, but only if the DII Call Protect parameter is set. The popup can be turned off by the global [\[Debug\]SysErrDsp=0](#) setting; however, the log data will be sent to the syslog.

**Allowable Values:**

- 0 - (Disable)
- 1 - (Enable)

**Default Value:**

0

**See Also**[Code Parameters](#)**[Code]DII Call Protect**

If, when calling an external DLL, the file has a software error, this may cause Plant SCADA Runtime to crash. You can help to protect Plant SCADA Runtime by setting the [\[Code\]DII Call Protect=1](#) value in your Citect.ini file.

Setting [\[Code\]DII Call Error Popup=1](#) also logs the Cicode function and arguments being used if it occurs.

Technical Support recommends that these parameters be set during commissioning.

As DLLs can use different languages and versions, it is possible for Plant SCADA Runtime to falsely catch an exception using the DII Call Protect=1 setting. We recommend a run is tried without the DII Call Protect setting, to see if it would happen in the called DLL.

**Allowable Values:**

- 0 - (Disable)
- 1 - (Enable protection)

**Default Value:**

0

**See Also**[Code Parameters](#)**[Code]DynamicCallDebug**

This parameter allows you to control logging for Cicode that is called dynamically at runtime.

If a Cicode function is called from the Cicode window in the Kernel or via the [TaskCall](#) function, this can only be detected at runtime. However, this will typically generate a message in the syslog indicating incorrect usage of Cicode.

If you set this parameter to zero (0), it will suppress the logging of syslog messages for Cicode that is used in this way.

**Allowable Values:**

- 1 - log syslog messages for dynamic Cicode calls  
0 - suppress syslog messages for dynamic Cicode calls

Default Value:

1

**See Also**[Code Parameters](#)**[Code]EchoError**

Controls whether Plant SCADA Runtime echoes errors in Cicode. When a simple user error occurs (for example, if the `PageDisplay()` function is passed a bad page name), Cicode displays an error message at the Error AN, and returns an error code from the function. If you disable this action, Cicode does not display the error message, and the output of the `DspError()` function is stopped. This parameter is global.

**Allowable Values:**

0 or 1

**Default Value:**

1 (Echo)

**See Also**

[Code Parameters](#)

**[Code]EnableErrorLogging**

Enables or disables the logging using the ErrSet Cicode function (and related functions).

When ErrSet(1) is used, this parameter allows watermark messages to the syslog of pairing issues with ErrSet(0) and ErrSet(1).

See the documentation for the [ErrSet](#) Cicode function.

**Allowable Values:**

0 - Disabled

1 - Enabled

**Default Value:**

0

**See Also**

[Code Parameters](#)

**[Code]Export**

Allows built-in Cicode functions to be exported to other DLLs or external applications.

**Allowable Values:**

0 or 1

**Default Value:**

1 (Enable export)

**See Also**

[Code Parameters](#)

**[Code]HaltOnError**

If an error occurs in some critical Cicode functions, your Cicode task will generate a hardware error and will halt. You may stop your Cicode task from being halted by using the ErrSet() function and checking for errors using the IsError() function. You may also stop your Cicode from being halted by setting this parameter to 0, however, the hardware error will still be generated. Setting this parameter is global to all Cicode threads, so you do not have to set ErrSet() for each Cicode tread.

The following functions can halt your current Cicode task when an error occurs: FormNew, DevOpen, DevHistory, DevNext, DevPrev, DevSeek, DevFind, DevFlush, DevRecNo, DevRead, DevReadLn, DevAppend, DevDelete, DevZap, DevControl, DevPrint, DevModify, ErrTrap, FileOpen, FileClose, FileReadBlock, FileWriteBlock, FileSeek, FileDelete, FileReName, FileSize, FileReadLn, FileCopy, SQLConnect, SQLTraceOn, SQLTraceOff, SQLErrMsg, TagReadEx.

**Allowable Values:**

- 1 (Halt Cicode when an error occurs in a function listed above)
- 0 (Do Not halt Cicode when an error occurs in a function listed above).

**Default Value:**

1

**See Also**[Code Parameters](#)**[Code]HaltOnInvalidTagData****WARNING****UNINTENDED EQUIPMENT OPERATION**

Enable the [Code]HaltOnInvalidTagData parameter if your application requires Plant SCADA Runtime to halt when invalid tag data is returned.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

When using compiled tags in Cicode, the LAST VALID VALUE could be returned when the latest tags value is unavailable, and this value may now be incorrect.

The new [Code]HaltOnInvalidTagDataINI parameter has been introduced to allow you to stop Cicode when invalid tag data is returned. The default handling is to NOT stop Cicode in such a case.

**Note:** Existing Cicode error checking FUNCTIONS can still be used instead of this option.

When enabled will cause the Cicode to halt when any tag read returns invalid data (bad quality). This will generate a hardware alarm.

**Note:**

- 
- The foreground code such as page animation and trend/alarm/report Cicode fields are exceptions and will not halt (page shows #COM); however button commands on a page will halt.
  - When enabled in the Citect.ini file you can still change this behavior in code by setting the ErrSet (1) and checking IsError() manually, in this case the code will not halt.
- 

**Allowable Values:**

- 0 - (Disable Halting)
- 1 - (Enable Halting)

**Default Value:**

0

**See Also**

[Code Parameters](#)

**[Code]IgnoreCase**

Controls whether Plant SCADA Runtime is case insensitive to string data in Cicode. Case sensitivity is used when a string comparison operation is performed. For example:

IF sStr1 = sStr2 THEN

Cicode is a case insensitive language and ignores the case of all variables, functions and reserved words. You can also make Plant SCADA Runtime case sensitive to strings within the just current thread, using the CodeSetMode() function.

**Note:** This parameter is global.

---

**Allowable Values:**

0 or 1

**Default Value:**

1 (Insensitive)

**See Also**

[Code Parameters](#)

**[Code]ProfilerEnabled**

Set this parameter to 1 to enable the Cicode Profiler when Plant SCADA Runtime starts. The Cicode Profiler enables you to gather information on how your Cicode is performing.

**Allowable Values:**

0 or 1

**Default Value:**

0 (disabled)

**See Also**

[Code Parameters](#)

**[Code]Queue**

The maximum number of elements in each queue. If you use a large number of queue elements, memory could be exhausted. See the Task functions for information about using queues.

**Allowable Values:**

-1 (Unlimited) or 0 to 1,073,741,824

**Default Value:**

32768

**See Also**

[Code Parameters](#)

**[Code]ScaleCheck**

Controls whether Plant SCADA Runtime checks for scaling over/under flow errors in Cicode. When a variable tag is modified, Cicode checks the new value of the variable against the Scales specified in the Variable Tags database. If the value of the variable is out of scale, Cicode generates a hardware error, and does not write to the I/O device. This parameter is global.

**Allowable Values:**

0 or 1

**Default Value:**

1 (Check)

## See Also

[Code Parameters](#)

### [Code]ShutdownTime

Specifies the maximum time allowed for the execution of any Cicode functions triggered by the [Code]Shutdown parameter. After the specified time passes, Plant SCADA will terminate the function.

#### Allowable Values:

1 to 120 (seconds)

#### Default Value:

30

## See Also

[Code Parameters](#)

### [Code]Stack

The size of the Cicode stack. If a "Cicode stack overflow" hardware error is displayed, increase the size of the Cicode stack. If Plant SCADA Runtime aborts with a "General stack overflow" error, increase the value of the [\[General\]Stack](#) parameter.

#### Allowable Values:

0 to 1024

#### Default Value:

256

## See Also

[Code Parameters](#)

### [Code]StrictArgumentCheck

**UNINTENDED EQUIPMENT OPERATION**

Do not set the [Code]StrictArgumentCheck parameter to a value of 0, except on the advice of Technical Support for this product. Setting this value to 0 can result in Cicode Functions behaving unexpectedly and raising a hardware alarm.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

Determines whether the compiler checks for calls to functions with missing parameters. The compiler will by default pass a 1 value or an empty string to function calls that do not have a parameter, and no default defined.

## Allowable Values:

- 0 (do not check for missing parameters)
- 1 (check for missing parameters)

## Default Value:

1

## Example

```
INT
FUNCTION
AddTwoNumbers(INT a, INT b)
RETURN a + b;
END
FUNCTION
CallFunction()
INT sum = AddToNumbers();
This will not compile by default, but will compile when [CODE]StrictArgumentCheck=0.
```

## See Also

[Code Parameters](#)

## [Code]Threads

The number of Cicode threads (tasks) that can run concurrently. Note that each report running simultaneously uses one thread, and each keyboard command running simultaneously uses one thread. If the hardware error "Out of Cicode threads" is displayed, increase the value of this parameter.

## Allowable Values:

5 to 512

## Default Value:

128

## See Also

[Code Parameters](#)

### [Code]TimeData

Determines how often (in milliseconds) the I/O Server reads I/O device data in order to provide tags with up-to-date Cicode variables.

#### Allowable Values:

1 to 60000 (milliseconds)

#### Default Value:

250

## See Also

[Code Parameters](#)

### [Code]TimeSlice

The period (in milliseconds) that a Cicode thread can run - before it is swapped out. After all other threads have run, it is swapped back in. This parameter does not apply to threads that update graphics pages.

#### Allowable Values:

20 to 5000 (milliseconds)

#### Default Value:

100

## See Also

[Code Parameters](#)

### [Code]TimeSlicePage

The period (in milliseconds) that a Cicode thread can run - before it is halted. This parameter applies only to threads that are called from the Graphics databases.

**Allowable Values:**

20 to 5000 (milliseconds)

**Default Value:**

500

**See Also**

[Code Parameters](#)

**[Code]Unsigned**

---

**Note:** This parameter is obsolete. Plant SCADA now supports unsigned integers as a standard data type.

---

This parameter used to determine if 16 bit integers were interpreted as unsigned or signed. But only the MODCELL and COMLI protocols supported this option, and setting this parameter affected both protocols.

Signed integers can have values from -32768 to +32767. Unsigned integers can have values from 0 to 65535.

**Allowable Values:**

- 0 - (Interpret as signed)
- 1 - (Interpret as unsigned)

**Default Value:**

0

**See Also**

[Code Parameters](#)

**[Code]VBASupport**

This parameter allows a user to disable Plant SCADA VBA support.

**Allowable Values:**

- 0 - VBA features disabled
- 1 - VBA features enabled

**Default Value:**

1

## See Also

[Code Parameters](#)

### [Code]WriteLocal

Controls whether Plant SCADA Runtime updates its cache on a tag write rather than waiting for a read from the I/O device to confirm the new value.

With this option on (default) the client initiating the write will immediately show the new value as the operation begins. Other clients connected to the I/O Server will be updated on confirmation of a successful write. If the write does not succeed, the initiating client will revert back to the previous value update for that tag. Turning this option off will make sure that a new value is read from the I/O device before it is shown in any client.

---

**Note:** This parameter is loaded by both clients and I/O servers, so all such machines have to have the same setting in order to avoid potential tag value flicker issues. It is recommended to set this value in the project parameters database to make sure that all clients and servers will use the same value.

---

## Allowable Values:

- 0 - Update the cache from the I/O device
- 1 - Update cache at start of write operation

## Default Value:

1

## See Also

[Code Parameters](#)

### COM Parameters

- [COM]StartTimeout - Obsolete in version 7.10.

## See Also

[Parameter Categories](#)

### CrashHandler Parameters

The Citect.ini file contains the following CrashHandler parameters:

- [\[CrashHandler\]Enable](#) - Enables the Crash Handler, which collects a number of log and data files that may be useful in determining the cause of an unexpected system shut down.
- [\[CrashHandler\]KeepLogFile](#)s - Determines if the log files associated with an unexpected shut down are kept in the default logs directory.

## See Also

[Parameter Categories](#)

### [CrashHandler]Enable

If Plant SCADA suffers an unexpected program shut down, the Crash Handler will create a compressed file containing a number of log and data files that may be useful in determining the cause of the shut down. These files include:

- syslog.dat
- Citect.ini
- tracelog.dat
- kernel.dat
- debug.log

In a multi-process system, these files will use extended names, for example:

`syslog.IOServer.Cluster1.dat`

The compressed file can be emailed to Technical Support for analysis.

You can also save the files to the default Plant SCADA Logs directory. See [\[CrashHandler\]KeepLogFiles](#).

---

**Note:** Technical Support may use the information included in an unexpected shut down email to help resolve problems in future releases, but cannot reply or follow up a problem with users directly. To discuss a particular issue, contact Technical Support.

### WARNING

#### UNINTENDED EQUIPMENT OPERATION

Do not change the [CrashHandler]Enable parameter in the Citect.ini file, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

## Allowable Values:

- 0 - Disabled
- 1 - Enabled

## Default Value:

1

## See Also

[CrashHandler Parameters](#)

## [CrashHandler]KeepLogFiles

This parameter determines if these log files gathered by the Plant SCADA Crash Handler are kept in the default logs directory.

By default, Plant SCADA will not keep files. If you would like to maintain a copy for analysis, you should set this parameter to 1.

If the zip file is saved, its path will be recorded in the syslog.dat. This will be the first entry in the file after an unexpected shut down occurs.

### Allowable Values:

- 0 - disable the keeping of log files
- 1 - enable the keeping of log files

### Default Value:

0

### See Also

[CrashHandler Parameters](#)

### CtAPI Parameters

The Citect.ini file contains the following CtAPI parameters:

- [\[CtAPI\]AcceptThousandsSeparator](#) - Configures the handling of a thousands separator in numeric values passed to ctTagWrite() and ctTagWriteEx().
- [\[CtAPI\]AllowLegacyServices](#) - When set the Plant SCADA Web Service and the Plant SCADA OLEDB Provider can connect to the CtAPI server.
- [\[CtAPI\]CpuLoadCount](#) - Avoids CPU overload when processing ctFindFirst() to make a Trend or Alarm query by controlling how often a request pauses while gathering information. (Used in conjunction with CPULoadSleepMS.)
- [\[CtAPI\]CpuLoadSleepMS](#) - Avoids CPU overload when processing ctFindFirst() to make a Trend or Alarm query by controlling how long a request pauses while gathering information. (Used in conjunction with CpuLoadCount.)
- [\[CtAPI\]Debug](#) - Plant SCADA server side CtAPI debugging information of the communication sessions to the various CtAPI clients.
- [\[CtAPI\]EventLogging](#) - Enables logging of the communications between CtAPI clients and Plant SCADA.
- [\[CtAPI\]MaxConnections](#) - Specifies the maximum number of connections supported by a CTAPI client.
- [\[CtAPI\]Remote](#) - Determines whether remote computers using the CtAPI interface can call in to this computer.
- [\[CtAPI\]RoundToFormat](#) - Indicates whether or not you want the values rounded to format.

## See Also

[Parameter Categories](#)

### [CtAPI]AcceptThousandsSeparator

Configures the handling of a thousands separator in numeric values passed to `ctTagWrite()` and `ctTagWriteEx()`, allowing the value to be written to a numeric variable tag.

**Note:** The only character that is accepted as a thousands separator is "," (comma).

#### Allowable Values:

- 0 - don't accept thousands separator
- 1 - accept thousands separator

#### Default Value:

0

## See Also

[CtAPI Parameters](#)

### [CtAPI]AllowLegacyServices

When set the Plant SCADA Web Service and the Plant SCADA OLEDB Provider can connect to the CtAPI server.

#### Allowable Values:

- 0 - (Disable connection)
- 1 - (Allow connection)

#### Default Value:

0

## See Also

[CtAPI Parameters](#)

### [CtAPI]CpuLoadCount

Depending on the capability of your hardware, it is sometimes possible to overload the server's CPU while making a Trend or Alarm query using `ctFindFirst()`. To avoid this you can use CpuLoadCount in conjunction with

the CpuLoadSleepMS parameter.

CpuLoadCount allows you to control how often the request pauses (sleeps) while it is collecting data. The load count corresponds approximately with the number of rows of query data processed by the server before it pauses. Decreasing this number means the request will pause more often and hence take longer to complete. However the workload will be stretched over a longer time period, decreasing the intensity of demand on the CPU.

---

**Note:** You will need to experiment to see which values are appropriate for optimum performance on your system. When experimenting you should adjust the value of CpuLoadSleepMS before CpuLoadCount.

---

## Allowable Values:

0 to any valid INT

## Default Value:

100

## See Also

[CtAPI Parameters](#)

## [CtAPI]CpuLoadSleepMS

Depending on the capability of your hardware, it is sometimes possible to overload the server's CPU while making a Trend or Alarm query using [ctFindFirst\(\)](#). To avoid this you can use CpuLoadSleepMS in conjunction with the CpuLoadCount parameter.

CpuLoadSleepMS allows you to control how long the request pauses (sleeps) while it is collecting data. Pausing for longer periods will cause the request to take longer but will decrease the intensity of the load on the CPU.

---

**Note:** You will need to experiment to see which values are appropriate for optimum performance on your system. When experimenting you should adjust the value of CpuLoadSleepMS before CpuLoadCount.

---

## Allowable Values:

0 to any valid INT (milliseconds)

## Default Value:

100

## See Also

[CtAPI Parameters](#)

## [CtAPI]Debug

**Note:** This parameter is designed to assist qualified technical support personnel with system diagnosis.

Enables logging of server-side CtAPI debugging information for the communication sessions to the various CtAPI clients. Output is to the Syslog.dat file. This is useful to diagnose CtAPI connection and message exchange issues.

To enable logging of the communications produced by the CTAPI client, see [\[CtAPI\]EventLogging](#).

### Allowable Values:

- 1 = True
- 0 = False

### Default Value:

0

**Note:** You can adjust this parameter during runtime using the SetLogging() function. For more information, see [Adjust Logging During Runtime](#).

### See Also

[CtAPI Parameters](#)

## [CtAPI]EventLogging

**Note:** This parameter is designed to assist qualified technical support personnel with system diagnosis.

Enables logging of the communications produced by the CTAPI client. Debugging traces are provided when a client generates requests for the CTAPI server and when it responds to replies. Logging goes to ipc.log under the "Logs" directory.

For server-side CtAPI debugging information, see [\[CtAPI\]Debug](#).

### Allowable Values:

- 0 - Off
- 1 - Errors
- 2 - Warnings
- 3 - Verbose
- 4 - Verbose Plus

The higher the value, the more logging will occur.

### Default Value:

0

---

**Note:** IPC logging uses the highest of the values set for [CtAPI]EventLogging and [IPC]EventLogging. This means if you try to debug a CtAPI client on a system running multiple Plant SCADA processes, you can not turn off the IPC logging that occurs between these processes.

---

## See Also

[CtAPI Parameters](#)

### [CtAPI]MaxConnections

Specifies the maximum number of connections supported by a CTAPI client. You can increase this value if a CTAPI application requires more than 20 simultaneous connections.

#### Allowable Values:

1 — 50

#### Default Value:

20

## See Also

[CtAPI Parameters](#)

### [CtAPI]Remote

Determines whether remote computers using the CtAPI interface can call in to this computer.

---

**Note:** To use CtAPI on a remote computer without installing Plant SCADA, you will need several CtAPI binaries. These binaries are packaged in the files **CtApi.Win32.Redist.zip** and **CtApi.x64.Redist.zip**, which can be found in the `\Extras\CtAPI` directory of the Plant SCADA installation media.

---

#### Allowable Values:

- 0 - disable remote access
- 1 - allow remote access

#### Default Value:

0

## See Also

[CtAPI Parameters](#)

### [CtAPI]RoundToFormat

This setting configures whether or not variable tag values returned by CTAPI functions [ctTagRead](#), [ctTagReadEx](#) and [ctListData](#) will be rounded to the format of the variable tag. Quite often, the value reported for a variable tag will not be precise, resulting in a large number of decimal places.

When this parameter is set the precision of the value returned is rounded to the format of the tag. For example, if the value coming from the IO device for the tag is 3.4999999999999, but the format is ##.##, the rounded value will be 3.50.

#### Allowable Values:

- 0 - Values not rounded to format
- 1- Values rounded to format

#### Default Value:

1

#### See Also

[CtAPI Parameters](#)

#### CtCicode Parameters

The Citect.ini file contains the following CtCicode parameters:

- [\[CtCicode\]FastFormat](#) - Controls whether fast formatting is used in the Cicode Editor.
- [\[CtCicode\]MLCommentThreshold](#) - Sets the maximum number of characters you can use in a code comment for automatic syntax coloring to be supported.

#### See Also

[Parameter Categories](#)

### [CtCicode]FastFormat

Determines whether or not the Cicode Editor uses fast formatting to format text in Cicode files.

If you are experiencing irregularities in the display of text in Cicode files (particularly the use of bold and italics), it may be related to fast formatting.

#### UNINTENDED EQUIPMENT OPERATION

Do not change the [CtCicode]FastFormat parameter in the Citect.ini file, except on the advice of Technical

Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

## Allowable Values:

- 0 - Fast formatting is not used
- 1 - Fast formatting is used

## Default Value:

0

## See Also

[CtCicode Parameters](#)

### [CtCicode]MLCommentThreshold

If the number of characters in a code comment is greater than this value, the comment will not be automatically syntax colored by the Cicode Editor.

**Note:** The higher the setting for this parameter, the longer multi-line comments will take to format when their start and end strings are modified.

## Allowable Values:

Any integer greater than zero

## Default Value:

1024

## See Also

[CtCicode Parameters](#)

### CtDraw.RSC Parameters

The Citect.ini file contains the following CtDraw.RSC parameters:

- [\[CtDraw.RSC\]AllowEditSuperGeniePage](#) -When set enables the user to choose whether or not to open and edit a Super Genie page.
- [\[CtDraw.RSC\]BitmapCompression](#) - Controls how much compression is applied to bitmaps and symbols on a page.

- [\[CtDraw.RSC\]LibraryCacheSize](#) - sets the maximum size of a cache used to store library objects.
- [\[CtDraw.RSC\]PurgeGenieLists](#) - This parameter is used if a modified genie is passing a substitution string that was specific to the genie before it was modified, but is now invalid.

## See Also

[Parameter Categories](#)

### [CtDraw.RSC]AllowEditSuperGeniePage

By default a page that is based on a Super Genie library object can not be opened for editing. The user is advised to edit the Super Genie library object directly. This parameter gives the user the choice to edit the page regardless.

#### Allowable Values:

- 0 - User is blocked from opening or editing a page based on a Super Genie library object
- 1 - User is prompted for confirmation before a page based on a Super Genie is opened for editing

#### Default Value:

0

## See Also

[CtDraw.RSC Parameters](#)

### [CtDraw.RSC]BitmapCompression

Controls how much compression is applied to bitmaps and symbols on a page. The higher the value, the smaller the file size. However, the time required for compression increases with a higher value.

#### Allowable Values:

0 - 9

- 0 - no compression used
- 9 - maximum compression used

#### Default Value:

5

## See Also

[CtDraw.RSC Parameters](#)

### [CtDraw.RSC]LibraryCacheSize

This parameter sets the maximum size of a cache used to store library objects (symbols, Genies and templates) that have been previously been opened or used by other graphics since Graphics Builder was last launched.

Increasing the value of this parameter may improve performance if library objects are opened or used again, as the in-memory version can be retrieved instead of a copy that needs to be loaded from disk. This can have an impact on startup performance for projects with a large number of Composite Genies. However, this will also increase Graphics Builder's memory usage.

#### Allowable Values:

128 — 16384

#### Default Value:

4096

## See Also

[CtDraw.RSC Parameters](#)

### [CtDraw.RSC]PurgeGenieLists

This parameter is used if a modified genie is passing a substitution string that was specific to the genie before it was modified, but is now invalid.

After you have restarted the Graphics Builder, perform an Update Pages on the project.

#### Allowable Values:

- 0 Genie Lists will not be purged
- 1 Genie Lists will be purged

#### Default Value:

1

## See Also

[CtDraw.RSC Parameters](#)

## CtEdit Parameters

The citect.ini file contains the following CtEdit parameters:

- [\[CtEdit\]ANSIToOEM](#) - Indicates whether Windows ANSI characters are converted to OEM characters.
- [\[CtEdit\]Backup](#) - The backup directory that is used if a runtime database cannot be located (due to a disk becoming inoperative or a file is unreadable).
- [\[CtEdit\]Bin](#) - The directory where the Plant SCADA binary files are located.
- [CompileEnquiry](#) - Obsolete (now available through options).
- [\[CtEdit\]CompileUnsuccessfulCommand](#) - Indicates to the compiler an optional application, script or batch file to execute after an unsuccessful compile.
- [\[CtEdit\]CompileSuccessfulCommand](#) - Indicates to the compiler an optional application, script or batch file to execute after a successful compile.
- [\[CtEdit\]Config](#) - The directory where the Plant SCADA configuration files, such as Citect.ini, are located.
- [\[CtEdit\]Copy](#) - Sets the COPY directory. Changes made in this directory will be automatically copied to the RUN directory (see below).
- [\[CtEdit\]Data](#) - The directory where the Plant SCADA data files are located.
- [\[CtEdit\]DbFiles](#) - The maximum number of .DBF files that can be open simultaneously.
- [\[CtEdit\]DbfNdxMode](#) - Sets the method used to read DBF files that are indexed for reading records that match a key value.
- [\[CtEdit\]Deploy](#) - The location where a project will be stored when a deployment package is received from the deployment server.
- [\[CtEdit\]DisplayEquipmentItem](#) - Used to control the population of the variable tag list, or equipment item list in Graphics Builder.
- [\[CtEdit\]IncludeProjectEquipmentUpdate](#) - Determines whether an equipment update will also update included projects.
- [\[CtEdit\]IncrementalCompile](#) - Determines whether an incremental compile will occur.
- [\[CtEdit\]IncrementalEquipmentUpdate](#) - Determines whether an incremental equipment update will occur.
- [\[CtEdit\]IncrementalEquipmentUpdateAutoClose](#) - Determines if the Update Equipment confirmation dialog displays when an incremental update is complete.
- [\[CtEdit\]Logs](#) - The directory where the Plant SCADA log files are located.
- [\[CtEdit\]LogLevel](#) - Specifies the level of detail used in the equipment update log file.
- [\[CtEdit\]MaxCicodeFunctions](#) - The maximum number of user functions that can be defined in a project.
- [\[CtEdit\]MaxHelpRec](#) - The maximum number of items that may be contained in a drop-down list box.
- [\[CtEdit\]Run](#) - The directory where the runtime database is located.
- [\[CtEdit\]SaveRetries](#) - Specifies the number of retry attempts Plant SCADA Studio can make to save the content in the data grid if a database file is not accessible.
- [\[CtEdit\]Starter](#) - Specifies the directory where the starter projects are located.
- [\[CtEdit\]SubtAnValue](#) - A string to replace a Genie substitution string of %An%.
- [\[CtEdit\]SubtPageValue](#) - A string to replace a Genie substitution string of %Page%.
- [\[CtEdit\]SuppressCompilerWarning](#) - Allows suppression of specific compiler warning messages.

- [\[CtEdit\]UpdateAnPage](#) - Enables the substitution text of a Genie to be changed when upgrading projects.
- [\[CtEdit\]UpdateAnPageVer5](#) - Enables the substitution text of a Genie to be changed when upgrading projects from v5.10.
- [\[CtEdit\]Upgrade](#) - Allows you to manually upgrade the projects in Plant SCADA.
- [\[CtEdit\]User](#) - The directory where databases are located.

## See Also

[Parameter Categories](#)

### [CtEdit]ANSIToOEM

Indicates whether Windows ANSI characters are converted to OEM characters when Plant SCADA writes to data files (like dBase). This parameter applies to conversion in both directions (OEM To ANSI also).

---

**Note:** The project must be compiled and run with the same setting of this parameter, otherwise string conversions and logins that rely on ANSI to OEM conversions will not work. For example, you cannot compile with the value of 0 and then run with a value of 1.

---

If using an Arabic version of Windows, you should set this parameter to 1.

---

**Note:** This parameter must be set to 0 to support multiple languages.

## Allowable Values

- 0 - (Characters are not converted)
- 1 - (Characters are converted)

## Default Value:

0

## See Also

[CtEdit Parameters](#)

### [CtEdit]Backup

The Backup directory that is searched if a runtime database cannot be located (due to a disk becoming inoperative or a file is not readable). Normally, the runtime database is located in the Run directory. See the [\[CtEdit\]Run](#) parameter.

When both the [CtEdit]Backup and [CtEdit]Run parameters are set, Plant SCADA first searches for the runtime databases in the Run directory, and then may search the directory specified by [CtEdit]Copy. If the files are not found, the Backup directory is searched. If the files are found, the project continues to run from the Backup directory and Plant SCADA issues a file server error message.

To use this parameter, you must ensure that:

- A complete copy of the project exists on both the local computer and the computer specified in the Backup directory
- Both copies have the same filename
- Only UNC paths are used. Using mapped drives may cause included projects to not work correctly

---

**Note:** This parameter is modified by the Computer Setup Wizard as well as the Computer Setup Editor.

---

## Allowable Values:

Any valid directory (as a UNC path)

## Default Value:

No default value

## See Also

[CtEdit Parameters](#)

### [CtEdit]Bin

The directory where the Plant SCADA binary files are located.

---

**Note:** This parameter is modified by the Computer Setup Wizard as well as the Computer Setup Editor.

---

## Allowable Values:

Any valid directory

## Default Value:

This value is initially set to <Installation Path>\BIN, where <Installation Path> is the directory you chose during product installation. The installer defaults is "%PROGRAMFILES(x86)%\AVEVA Plant SCADA\Bin".

---

**Note:** if running a <filename>.ini, the value for this parameter will always be taken from the local Citect.ini file.

---

## See Also

[CtEdit Parameters](#)

### [CtEdit]CompileSuccessfulCommand

Indicates to the compiler an optional command, script or batch file to execute after a successful compile. To execute an optional application, script or batch file to execute after an unsuccessful compile use the parameter

[\[CtEdit\]CompileUnsuccessfulCommand](#)

**Allowable Values:**

Any valid command line containing replacement strings that represent possible information that the compiler can provide, including such information as project name, project path, INI path, bin path, etc. Enclose the replacement strings in '%' characters, similar to DOS batch file notation. Use the escape character "^" if you want to include the '%' character literally.

If an undefined replacement string is specified in the command line a compiler warning will be generated, and the application will not be called. Compiler warnings will also be generated if the compiler does not execute the command line successfully. However, any errors that occur when the command is executing will not be logged, as they will not be known to the compiler.

**Allowable replacement strings**

Replacement Strings	Description
CtEnvBinPath	Path to the Bin folder of Plant SCADA
CtEnvConfigPath	Path to the config folder
CtEnvDataPath	Path to data folder
CtEnvIncludeProjects	List of include projects for the project being compiled
CtEnvErrors	Number of errors encountered during compile
CtEnvIncludeProjectPaths	List of the directory paths of the include projects for the project being compiled, in the same order as the projects are listed in CtEnvIncludeProjects
CtEnvIniPath	Path to the ini file
CtEnvLogPath	Path to log files
CtEnvProject	Name of the project that is being compiled
CtEnvProjectPath	Path to the project file that is being compiled
CtEnvWarnings	The number of warnings that were encountered during compile

**Example:**

This could be a notification - such as sending an email or network message to a person - or just a log entry to a text file as shown below:

1. Create a text file with the following content:

```
Echo %Date% %Time% '%CtEnvProject%' Compilation successful, [%1] >>
"%CtEnvLogPath%\Log.txt"
```

2. Save the file as a command / batch file, example 'MyError.cmd'
3. Set the INI parameter to run the above file, including the path to where the file was saved. Pass the list of

include projects as the first parameter to the command file.

```
CompileSuccessfulCommand=C:\Temp\MyError.cmd "%CtEnvIncludeProjects%"
```

A Log.txt file will be created and updated each time a project compile is successful.

The replacement strings can be used directly in the INI parameter value and can be accessed as application environment variables. The example demonstrates this method.

## See Also

[CtEdit Parameters](#)

### [CtEdit]CompileUnsuccessfulCommand

Indicates to the compiler an optional command, script or batch file to execute after an unsuccessful compile. Generally this would be used to create a log file to show warnings or errors generated during a compile. To execute an optional application, script or batch file to execute after a successful compile use the parameter [\[CtEdit\]CompileSuccessfulCommand](#).

### Allowable Values:

Any valid command line containing replacement strings that represent possible information that the compiler can provide, including such information as project name, project path, INI path, bin path, etc. Enclose the replacement strings in '%' characters, similar to DOS batch file notation. Use the escape character "^" if you want to include the '%' character literally.

If an undefined replacement string is specified in the command line a compiler warning will be generated, and the application will not be called. Compiler warnings will also be generated if the compiler does not execute the command line successfully. However, any errors that occur when the command is executing will not be logged, as they will not be known to the compiler.

### Allowable replacement strings

Replacement Strings	Description
CtEnvBinPath	Path to the Bin folder of Plant SCADA
CtEnvConfigPath	Path to the config folder
CtEnvDataPath	Path to data folder
CtEnvIncludeProjects	List of include projects for the project being compiled
CtEnvErrors	Number of errors encountered during compile
CtEnvIncludeProjectPaths	List of the directory paths of the include projects for the project being compiled, in the same order as the projects are listed in CtEnvIncludeProjects

Replacement Strings	Description
CtEnvIniPath	Path to the ini file
CtEnvLogPath	Path to log files
CtEnvProject	Name of the project that is being compiled
CtEnvProjectPath	Path to the project file that is being compiled

**Example:**

This could be a notification - such as sending an email or network message to a person - or just a log entry to a text file as shown below:

1. Create a text file with the following content:

```
Echo %Date% %Time% 'CtEnvProject%' Compilation unsuccessful, [%1] >>
"%CtEnvLogPath%\Log.txt"
```

2. Save the file as a command / batch file, example 'MyError.cmd'
3. Set the INI parameter to run the above file, including the path to where the file was saved. Pass the list of include projects as the first parameter to the command file.

```
CompileUnsuccessfulCommand=C:\Temp\MyError.cmd "%CtEnvIncludeProjects%"
```

A Log.txt file will be created and updated each time a project compile is unsuccessful.

The replacement strings can be used directly in the INI parameter value and can be accessed as application environment variables. The example demonstrates this method.

**See Also**

[CtEdit Parameters](#)

**[CtEdit]Config**

The directory where the Plant SCADA configuration files, except Citect.ini, are located. The Citect.ini file needs to be located in the <Config> directory you chose during installation.

Default locations of configuration files are listed in View a Project's Folders.

---

**Note:** if running a <filename>.ini, the value for this parameter will always be taken from the local Citect.ini file.

**Allowable Values:**

Any directory that can be written to by the Windows user account that is used to run Plant SCADA.

---

**Note:** You need to manually configure the access control list for a new folder location so that it matches the permissions that were applied to the original location during installation. See [Configure Directory Security for Modified Folder Locations](#).

## Default Value:

<User>/<Data>/Config, where <User>/<Data> is the directory you chose during installation.

**Note:** If you want the Citect.ini file to be somewhere other than the installed location, move the Citect.ini file to the new location and modify the shortcut to CtExplor.exe to specify an additional argument, e.g. "newpath\ Citect.ini"

## See Also

[CtEdit Parameters](#)

### [CtEdit]Copy

Sets the COPY directory. Changes made to runtime files in this directory will be copied to the RUN directory (set using the [CtEdit]Run parameter). It is strongly recommended that the COPY project is compiled for the changes to appear in the RUN project.

**Note:** Do not use the [CtEdit]Run and [CtEdit]Copy parameters if you intend to use Plant SCADA's Deployment functionality.

This feature is useful when you want to have a local copy of a network project, but don't want to be continually checking that the local copy is the same as the master on the server (i.e. manually copy changed files across to the local project etc.) Plant SCADA takes care of this by copying files whenever it detects that the timestamp of the local file is different to that of the file in the COPY directory. Note that even if the local file has a more recent timestamp, it will still be replaced. It is recommended, therefore, that you only make changes to the project on the server.

**Note:** When using COPY the user folder should be shared. If not shared the project may not update correctly.

For example, you could set up a client so that instead of running the server version of a project (\\\\$ERVER\\PLANT SCADA\\USER\\MYPROJ) across a slow RAS connection, it runs a local copy (C:\\PLANT SCADA\\USER\\MYPROJ). In this instance, you would set your RUN directory to C:\\PLANT SCADA\\USER\\MYPROJ, and your COPY directory to \\\\$ERVER\\PLANT SCADA\\USER\\MYPROJ. You need to specify a UNC path for this parameter, as specifying a mapped drive may have unexpected results.

The Copy parameter can be changed while the system is running, enabling you to switch the SCADA node to copy files from a different location than was utilized when the system started.. This makes it possible to switch to a new runtime configuration that is stored in a different location so that if the changes need to be rolled back, the copy parameter can be restored to its previous value.. The Citect.ini file is read every time an RDB is loaded (at startup, page transition, reload) and the setting is retrieved from the INI file to adjust to your current copy path.

**Note:** A hardware alarm of "Cicode library timestamp differs" will be raised if the Cicode library used by a page has a different timestamp from the one in memory. The timestamps will be different if the project has been fully recompiled, the project has been incrementally recompiled after the page has been modified, or if the project has been incrementally recompiled after any Cicode has been modified.

### WARNING

#### UNINTENDED EQUIPMENT OPERATION

Restart the client process if the hardware alarm "Cicode library timestamp differs" is raised after a page is opened.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:**

1. For RUN/COPY (File Server Redundancy) setup, use [\[Alarm\]UseConfigLimits=0](#) so that the alarm properties are not persisted to the DBF/RDB files. If not the RDB files will be over written the next time they are accessed by the system.
2. Set up the directories the same way on the local hard disk as you do on the remote file server. Files are not copied from the COPY directory to the RUN directory until they are accessed - uncompiled files will also be copied once accessed on the local machine when they are used by the Plant SCADA runtime system. Runtime changes in included projects are also copied across. The Citect.ini file is not copied. Any configuration changes implemented in the ini file need to be manually copied across to the local machine.

**Allowable Values:**

Any valid directory (as a UNC path)

**Default Value:**

No default value.

**Note:** For additional information refer to the topic "Client Side Online Changes" in the main help.

**See Also**

[CtEdit Parameters](#)

**[CtEdit]Data**

**⚠ WARNING**

**SYSTEM PERFORMANCE DEGRADATION**

The "on access" scan in anti-virus products can lock files used by Plant SCADA, usually having the effect of slowing Plant SCADA down whilst it waits for the scan of that file to finish.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**⚠ CAUTION**

**INOPERABLE SYSTEM OR LOSS OF DATA**

In some extreme cases, anti-virus software may (incorrectly) detect certain patterns within data files as being viruses. Depending on the anti-virus configuration, this may result in files being relocated or deleted, resulting in data being lost or the system being inoperable.

**Failure to follow these instructions can result in injury, or equipment damage.**

It is recommended that the following directories are excluded from scanning by any anti-virus products:

- Program Files installation directory (including files and sub directories)
- Data and Logs directories
- Any alarm server archive paths

The above exclusions are recommended for "on access" or "real time" scans that run continuously and scan each file that is read from or written to. Scheduled scans, which are usually daily or once a week, should also have these exclusions added with the exception of the Program Files exclusion.

The directory where the Plant SCADA data files are located. Default locations of configuration files are listed in New Locations for Configuration and Project Files topic in the main help.

---

**Note:** This parameter is modified by the Computer Setup Wizard as well as the Computer Setup Editor.

---

## Allowable Values:

Any valid directory. Be aware that Plant SCADA will not allow data to be stored in any subdirectory of ...\\Plant SCADA <VersionNumber> \\User\\.

---

**Note:** You need to manually configure the access control list for a new folder location so that it matches the permissions that were applied to the original location during installation. See [Configure Directory Security for Modified Folder Locations](#).

---

## Default Value:

<User>/<Data>/Data, where <User>/<Data> is the directory you chose during installation.

---

**Note:** If running a <filename>.ini, the value for this parameter will always be taken from the local Citect.ini file.

---

## See Also

[CtEdit Parameters](#)

### [CtEdit]DbFiles

The maximum number of .DBF files that can be open simultaneously. The Plant SCADA runtime system, Plant SCADA Studio, and the compiler all use this parameter. Increase this parameter if a "No more free handles" error message is displayed.

## Allowable Values:

50 to 32767

## Default Value:

1024

## See Also

[CtEdit Parameters](#)

### [CtEdit]DbfNdxMode

Sets the method used to read DBF files that are indexed for reading records that match a key value.

## Allowable Values

- 0 — Use associated NDX file to perform key based read.
- 1 — Read directly from DBF returning records that match the key value, for Graphics Builder page DBFs.
- 2 — In memory index.

## Default Value:

2

## See Also

[CtEdit Parameters](#)

### [CtEdit]Deploy

Sets the location where a project's runtime files will be stored when a deployment package is received from the deployment server and unpacked.

To run a project from this location, the [\[Deployment\]Enabled](#) parameter must be set to 1 (enabled).

## Allowable Values:

Any valid path on the local computer.

## Default Value:

%PROGRAMDATA%\AVEVA Plant SCADA\Deployment\Client\Projects

## See Also

[CtEdit Parameters](#)

### [CtEdit]DisplayEquipmentItem

Used to control the population of the variable tag list, or equipment item list in Graphics Builder. When set to 1, the equipment item list will be populated; when set to 0, variable tag list will be populated.

---

**Note:** This parameter is modified via the Plant SCADA Studio Options dialog.

---

**Allowable Values:**

0 or 1

**Default Value:**

1

**See Also**

[CtEdit Parameters](#)

**[CtEdit]IncludeProjectEquipmentUpdate**

Determines whether an equipment update will also update included projects.

**Allowable Values:**

- 0 - Equipment update will only update the selected project
- 1 - Equipment update will update both the selected project and its included projects

**Default Value:**

1

**See Also**

[CtEdit Parameters](#)

**[CtEdit]IncrementalCompile**

Determines whether an incremental compile will occur. When enabled, a compile will only include changes that have been made since the last compile occurred.

This parameter sets the **Incremental compile** option on the Plant SCADA Studio Options dialog.

**Allowable Values:**

- 0 - Incremental compile is disabled
- 1 - Incremental compile is enabled

**Default Value:**

1

**See Also**[CtEdit Parameters](#)**[CtEdit]IncrementalEquipmentUpdate**

Determines whether an incremental equipment update will occur. When enabled, an equipment update will only generate tags for equipment and equipment types that have been modified since the last update occurred.

This parameter sets the **Incremental equipment update** option on the Plant SCADA Studio Options dialog.

**Allowable Values:**

- 0 - Incremental equipment update is disabled
- 1 - Incremental equipment update is enabled

**Default Value:**

1

**See Also**[CtEdit Parameters](#)**[CtEdit]IncrementalEquipmentUpdateAutoClose**

Determines if the Update Equipment confirmation dialog displays when an incremental update is complete.

**Allowable Values:**

- 0 - the Update Equipment dialog will display, even if no changes were required during the equipment update. This provides access to the **Show Log** button.
- 1 - the Update Equipment dialog will automatically close if no changes were required during the equipment update. For this setting to work, you need to have incremental equipment updates enabled (see [\[CtEdit\]IncrementalEquipmentUpdate](#)).

**Default Value:**

1

## See Also

[CtEdit Parameters](#)

### [CtEdit]Logs

The directory where the Plant SCADA log files are located.

Default locations of configuration files are listed in New Locations for Configuration and Project Files in the main help.

#### Allowable Values:

Any directory to which is writable by the Windows user account that is used to run Plant SCADA.

---

**Note:** You need to manually configure the access control list for a new folder location so that it matches the permissions that were applied to the original location during installation. See [Configure Directory Security for Modified Folder Locations](#).

---

#### Default Value:

`<User>/<Data>/Logs`, where `<User>/<Data>` is the directory you chose during installation.

---

**Note:** If running a `<filename>.ini`, the value for this parameter will always be taken from the local Citect.ini file.

---

## See Also

[CtEdit Parameters](#)

### [CtEdit]LogLevel

Specifies the level of detail used in the equipment update log file (EquipGen.log).

#### Allowable Values:

- 0 — None
- 3 — Error
- 5 — Summary
- 10 — Details
- 15 — Verbose

#### Default Value:

## See Also

[CtEdit Parameters](#)

### [CtEdit]MaxCicodeFunctions

The maximum number of user functions that can be defined in a project. Increase this parameter if the "Too many Cicode functions" compile error occurs.

#### UNINTENDED EQUIPMENT OPERATION

Do not change the [CtEdit]MaxCicodeFunctions parameter in the citect.ini file, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

## Allowable Values:

10000 to 32767

## Default Value:

4500

---

**Note:** Increasing this parameter may affect system performance.

---

## See Also

[CtEdit Parameters](#)

### [CtEdit]MaxHelpRec

The maximum number of items that may be contained in a drop-down list box, generally a lower number such as 500 is easier for the user to select. This option is easily changed through the Plant SCADA Options dialog.

Although the upper limit of this parameter is only limited by the size of the INT 32 variable, the size it is set to doesn't affect runtime performance. If a project has 6000 tags, only these 6000 tags will consume memory, even if MaxHelpRec is set much higher.

## Allowable Values:

1 to 2,147,483,647.

## Default Value:

5000

## See Also

[CtEdit Parameters](#)

### [CtEdit]Run

The directory where the runtime project is located. If you run the project from Plant SCADA Studio, Graphics Builder, or Cicode Editor, this parameter will be automatically set to the name of the current project. If you want to run a project independently of these applications, you will need to set this parameter manually. It is recommended that the directory chosen should be a sub directory of the ..\Plant SCADA\User directory.

**Note:** Do not use the [CtEdit]Run and [CtEdit]Copy parameters if you intend to use Plant SCADA's Deployment functionality.

### WARNING

#### UNINTENDED EQUIPMENT OPERATION

Restart the client process if the hardware alarm "Cicode library timestamp differs" is raised after a page is opened.

A hardware alarm of "Cicode library timestamp differs" will be raised if the Cicode library used by a page has a different timestamp from the one in memory. The timestamps will be different if the project has been fully recompiled, the project has been incrementally recompiled after the page has been modified, or if the project has been incrementally recompiled after any Cicode has been modified.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

#### Note:

1. For RUN/COPY (deployment) setup, use [\[Alarm\]UseConfigLimits=0](#) so that the alarm properties are not persisted to the DBF/RDB files. If not the RDB files will be over written the next time they are accessed by the system.
2. If you have set a COPY directory (using the [\[CtEdit\]Copy](#) parameter), any changes made and compiled in that directory will be automatically copied to the RUN directory. Any file with a name that matches one of the files changed in the COPY directory will be overwritten during this process. This copy only occurs when the files are accessed at runtime.

## Allowable Values:

Any valid directory under the ..\Plant SCADA\User directory.

## Default Value:

No default value.

**Note:** If running a <filename>.ini, the value for this parameter will always be taken from the local Citect.Ini file.

For additional information, refer to the topic *Client Side Online Changes* in the main Plant SCADA documentation.

## See Also

[CtEdit Parameters](#)

### [CtEdit]SaveRetries

If any database files are not accessible when you attempt to save the content in the data grid, Plant SCADA Studio can make some retry attempts to save the content.

This parameter represents the number of retry attempts Plant SCADA Studio will make before an error message appears. The duration between two consecutive retry attempts is one second.

Any changes to this parameter will be implemented after you restart Plant SCADA Studio.

## Allowable Values:

0 to 10

## Default Value:

3

## See Also

[CtEdit Parameters](#)

### [CtEdit]Starter

This parameter specifies the directory where the starter projects are located.

## Allowable Values:

Any directory that can be written to by the Windows user account that is used to run Plant SCADA.

---

**Note:** You need to manually configure the access control list for a new folder location so that it matches the permissions that were applied to the original location during installation. See [Configure Directory Security for Modified Folder Locations](#).

---

## Default Value:

<User>/<Data>/Starter, where <User>/<Data> is the directory you chose during installation.

## See Also

[CtEdit Parameters](#)

### [CtEdit]SubtAnValue

A string to replace a Genie substitution string of %An%.

When upgrading Plant SCADA from versions 3.xx or 4.xx to version 5.20 or higher, you need to rename any Genie substitution strings called %An%.

The substitution text will change during the upgrade if you enable [CtEdit]UpdateAnPage. If [CtEdit]UpdateAnPage is enabled, but you do not specify a new Genie substitution string, the string will be renamed to the default value.

#### Allowable Values:

New Genie substitution string (up to 256 characters)

#### Default Value:

AnSubt

#### See Also

[CtEdit Parameters](#)

### [CtEdit]SubtPageValue

A string to replace a Genie substitution string of %Page%.

When upgrading Plant SCADA from versions 3.xx or 4.xx to version 5.20 or higher, you need to rename any Genie substitution strings called %Page%.

The substitution text will change during the upgrade if you enable [CtEdit]UpdateAnPage. If [CtEdit]UpdateAnPage is enabled, but you do not specify a new Genie substitution string, the string will be renamed to the default value.

#### Allowable Values:

New Genie substitution string (up to 256 characters)

#### Default Value:

PageSubt

#### See Also

[CtEdit Parameters](#)

### [CtEdit]SuppressCompilerWarning

Allows suppression of specific compiler warning messages using an associated warning message number.

When a compiler warning message is displayed, it will include a number prefixed by "W". For example:

The specified language is not supported (W1027)

To suppress a particular type of warning message, apply the associated warning number to this parameter. For example, to suppress the unsupported language message demonstrated above, set the parameter to the following value:

[CtEdit]SuppressCompilerWarning=W1027

#### Allowable Values:

One or more warning message numbers. If more than one is used, separate them with commas.

#### Default Value:

No messages suppressed.

#### See Also

[CtEdit Parameters](#)

### [CtEdit]UpdateAnPage

Allows genie substitution strings of %Page% or %An% to be renamed during project upgrades from versions 3.xx or 4.xx to version 5.21 or higher.

Without setting this parameter, you will be unable to specify a value for the substitution strings, as %Page% will automatically be set to the name of the current page, and %An% will be set to the AN of the current page. You will also be unable to change these values.

The substitution strings will be renamed during an upgrade if this parameter is enabled. Use [\[CtEdit\]SubtAnValue](#) and [\[CtEdit\]SubtPageValue](#) to specify the new substitution strings.

#### Allowable Values:

- 0 to disable
- 1 to enable

#### Default Value:

0

#### See Also

[CtEdit Parameters](#)

### [CtEdit]UpdateAnPageVer5

Allows genie substitution strings of %Page% or %An% to be renamed during project upgrades from version 5.10.

Without setting this parameter, you will be unable to specify a value for the substitution strings, as %Page% will automatically be set to the name of the current page, and %An% will be set to the AN of the current page. You will also be unable to change these values.

The substitution strings will be renamed during an upgrade if this parameter is enabled. Use [CtEdit]SubtAnValue and [CtEdit]SubtPageValue to specify the new substitution strings.

This parameter will be reset to 0 (zero) once you have restarted Plant SCADA.

#### Allowable Values:

- 0 to disable
- 1 to enable

#### Default Value:

0

#### See Also

[CtEdit Parameters](#)

### [CtEdit]Upgrade

Allows you to manually upgrade the projects in Plant SCADA when a new version or service pack is installed and the automatic upgrade was not successful, or you chose not to upgrade at that time.

To perform a manual upgrade, set the parameter to 1 then close and restart Plant SCADA.

This parameter will be reset to 0 (zero) once you have restarted Plant SCADA.

#### Allowable Values:

- 0 to disable
- 1 to enable

#### Default Value:

0

#### See Also

[CtEdit Parameters](#)

## [CtEdit]User

The directory where databases are located.

**Note:** This parameter is modified by the Computer Setup Wizard as well as the Computer Setup Editor.

### Allowable Values:

Any valid directory.

### Default Value:

<User>/<Data>/User, where <User>/<Data> is the directory you chose during installation.

**Note:** You need to manually configure the access control list for a new folder location so that it matches the permissions that were applied to the original location during installation. See [Configure Directory Security for Modified Folder Locations](#).

### See Also

[CtEdit Parameters](#)

## CtExplore Parameters

The Citect.ini file contains the following default parameters of the Plant SCADA projects page settings:

- [\[CtExplore\]DefaultTemplateStyle](#) - controls the default page setting for *Template style* used in Plant SCADA projects.
- [\[CtExplore\]DefaultTemplateResolution](#) - controls the default page setting for *Template resolution* used in Plant SCADA projects.
- [\[CtExplore\]DefaultTemplateTitleBar](#) - controls the default page setting for *Show template title bar* used in Plant SCADA projects.

### See Also

[Parameter Categories](#)

## [CtExplore]DefaultTemplateStyle

This parameter controls the default page setting for *Template style* used in Plant SCADA projects.

If this INI parameter specifies XP\_Style then the screen resolution will be XGA and the title bar not displayed no matter how the [\[CtExplore\]DefaultTemplateResolution](#) and [\[CtExplore\]DefaultTemplateTitleBar](#) parameters are set.

If this INI parameter specifies a style other than XP\_Style then XP\_Style will not be available from the NewProject | Template Style drop-down list.

**Allowable Values:**

- Standard
- Top
- Bottom
- XP\_Style
- Tab\_Style\_1

**Default Value:**

Tab\_Style\_1

**See Also**

[CtExplore Parameters](#)

**[CtExplore]DefaultTemplateResolution**

This parameter controls the default page setting for *Template resolution* used in Plant SCADA projects.

**Allowable Values:**

- VGA
- SVGA
- XGA
- SXGA
- WUXGA
- HD1080
- User
- Default

**Default Value:**

Default

**See Also**

[CtExplore Parameters](#)

**[CtExplore]DefaultTemplateTitleBar**

The parameter controls the default page setting for *Show template title bar* used in Plant SCADA projects.

**Allowable Values:**

0 or 1

**Default Value:**

0

**See Also**

[CtExplore Parameters](#)

**DBClient Parameters**

The Citect.ini file contains the following DBClient parameters:

- [\[DBClient\]Enabled](#) - enables ODBC logging.
- [\[DBClient\]FileBase](#) - specifies a location for the ODBC log files and a file name prefix.
- [\[DBClient\]MaxFiles](#) - specifies the maximum number of ODBC log files to retain.
- [\[DBClient\]MaxSize](#) - specifies the maximum size for an ODBC log file (in kilobytes).
- [\[DBClient\]OldFiles](#) - specifies the maximum number of log file sets to retain.

**See Also**

[Parameter Categories](#)

**[DBClient]Enabled**

Can be used to enable ODBC logging.

**Allowable Values:**

- 0 = disable ODBC logging
- 1 = enable ODBC logging

**Default Value:**

0

**See Also**

[DBClient Parameters](#)

## [DBClient]FileBase

Specifies the location where ODBC log files are stored, and a prefix for the file names. The following format is used for the parameter value:

{file path}\{file name prefix}

The file name prefix you specify will be appended by "\_<nnn>" when a log file is created, where "nnn" is an incremental numeric value.

For example, you may specify the following parameter value:

%PROGRAMDATA%\MyLogs\DBClient

This would generate the following log file:

%PROGRAMDATA%\MyLogs\DBClient\_001.log

### Allowable Values:

Any valid path and file name prefix in the following format:

{file path}\{file name prefix}

### Default Value:

%PROGRAMDATA%\AVEVA Plant SCADA <VersionNumber>\Logs\DBClient\DBClient

### See Also

[DBClient Parameters](#)

## [DBClient]MaxFiles

Specifies the maximum number of ODBC log files to retain.

If the maximum number of files is reached and a new ODBC log file is created (due to an existing file reaching its maximum size), the oldest ODBC log file will be deleted.

### Allowable Values:

0 - 2,147,483,647

### Default Value:

2

### See Also

[DBClient Parameters](#)

**[DBClient]MaxSize**

Sets the maximum size for an ODBC log file (in kilobytes).

By limiting the size of individual log files, you can make the files more manageable. For example, you can limit their size so that they are suitable for viewing in Notepad or sending via e-mail.

**Allowable Values:**

0 - 2,147,483,647

**Default Value:**

2048

**See Also**

[DBClient Parameters](#)

**[DBClient]OldFiles**

Specifies the number of sets of log files that can be stored for each instance of the application.

If the number of log file sets reaches the defined limit, any new sets of log files will replace the oldest existing log files (which are deleted). The existing files are renamed (incremented by one).

**Allowable Values:**

0 - 2,147,483,647

**Default Value:**

1

**See Also**

[DBClient Parameters](#)

**DDE Parameters**

The Citect.ini file contains the following DDE parameters:

- [\[DDE\]AllowCicode](#) - Allows Cicode to be run on the Plant SCADA server via the DDE Execute command.
- [\[DDE\]AllowWrites](#) - Allows tag writes to the Plant SCADA server via the DDE Poke command.
- [\[DDE\]Enable](#) - Allows Plant SCADA runtime to function as a DDE server.
- [\[DDE\]Timeout](#) - The period (in milliseconds) that Plant SCADA waits after a call to an external application -

before it assumes the application does not exist.

## See Also

[Parameter Categories](#)

### [DDE]AllowCicode

Allows Cicode to be run on the Plant SCADA server via the DDE Execute command.

#### Allowable Values:

0 or 1

#### Default Value:

0

## See Also

[DDE Parameters](#)

### [DDE]AllowWrites

Allows tag writes to the Plant SCADA server via the DDE Poke command.

#### Allowable Values:

0 or 1

#### Default Value:

0

## See Also

[DDE Parameters](#)

### [DDE]Enable

Use this parameter to allow Plant SCADA runtime to function as a DDE server. By default, the parameter is set to disable DDE.

**Allowable Values:**

- 0 = disable DDE
- 1 = enable DDE

**Default Value:**

0

**See Also**[DDE Parameters](#)**[DDE]Timeout**

The period (in milliseconds) that Plant SCADA waits after a call to an external application - before it assumes the application does not exist.

**Allowable Values:**

0 to 32767 (milliseconds)

**Default Value:**

30000

**See Also**[DDE Parameters](#)**Debug Parameters**

The Citect.ini file contains the following debug parameters:

- [\[Debug\]ArchiveFiles](#) - Archives log files once maximum size is reached.
- [\[Debug\]CategoryFilter](#) - Enables log message filtering by component category.
- [\[Debug\]CategoryFilterMode](#) - Enables or disables logging of categories declared by the [Debug]CategoryFilter value.
- [\[Debug\]ChromiumDevToolsPort](#) - Enables debugging for a Web Content object located on a Plant SCADA graphics page.
- [\[Debug\]CodeDebug](#) - Enables Cicode debugging for the process containing a specified component.
- [\[Debug\]CrashOnError](#) - Determines whether Plant SCADA generates a protection violation whenever it detects a software error, for example, a memory corruption error such as "Invalid Heap" , "Already Free", 'try to free bad or unknown memory" or "local free no heap".

- [\[Debug\]CrashReserveManagedMB](#) - Specifies how much memory is reserved at startup to allow crash handling to occur for managed code.
- [\[Debug\]CrashReserveNativeMB](#) - Specifies how much memory is reserved at startup to allow crash handling to occur for native code.
- [\[Debug\]DBLogEnable](#) - Controls whether alarm database logs are enabled.
- [\[Debug\]DBLogMaxFiles](#) - Controls the maximum number of alarm database log files to keep for the current run of the server.
- [\[Debug\]DBLogMaxSize](#) - Controls the maximum size of an individual alarm database log file.
- [\[Debug\]DBLogOldFiles](#) - Controls the maximum number of runs to keep for alarm database log files.
- [\[Debug\]DebugAllTrans](#) - Allows TRAN session logging to be turned on or off.
- [\[Debug\]DebugLogHistoryFiles](#) - Determines how many "debug.<process name>.log" files are kept when rolled over.
- [\[Debug\]DebugLogSize](#) - Sets the maximum size of the "debug.<process name>.log" file.
- [\[Debug\]DriverTrace](#) - An extension of the Kernel that can be used to display the commands and information being issued to a driver.
- [\[Debug\]DriverTracePort](#) - Allows a driver trace to be limited to a particular driver port.
- [\[Debug\]DriverTraceMask](#) - Defines a bit mask that can be used to either include or exclude driver commands from a driver trace.
- [\[Debug\]DriverCheck](#) - Defines the maximum number of data buffer elements to be displayed in a driver trace.
- [\[Debug\]DebugAllTrans](#) - Allows TRAN sessions to be logged to the Kernel window for debugging purposes.
- [\[Debug\]DisableWinTop](#) - Allows you to minimize the likelihood of windows or popups from being forced to the top of the screen.
- [\[Debug\]DriverCheck](#) - Monitors the structure used to talk to drivers.
- [\[Debug\]DrWatson](#) - Starts DrWatson when Plant SCADA starts running (if DrWatson is not already running).
- [\[Debug\]EnableHardwareAlarmLogging](#) - Enables or disables logging of stack traces for hardware alarms to syslog.
- [\[Debug\]EnableLogging](#) - Enables or disables the logging mechanism.
- [\[Debug\]EnablePSICounters](#) - Enables or disables the Citect.Platform.PSI.Client and Citect.Platform.PSI.Server performance counters.
- [\[Debug\]EnableTaskFrameworkCounters](#) - Enables or disables Citect.Platform.Tasks.TaskManager, Citect.Platform.Tasks.TaskQueue and Citect.Platform.Tasks.TaskThread performance counters.
- [\[Debug\]EnableTransportCounters](#) - Enables or disables Citect.Platform.Transport.SessionTransport and Citect.Platform.Transport.TransportHost performance counters.
- [\[Debug\]EnableReloadLogging](#) - Enables additional debugging output for server reloads.
- [\[Debug\]FlushPeriod](#) - Sets the period at which Tracelog file entries are to be flushed to the file system.
- [\[Debug\]LogDirect](#) - Indicates whether to log directly to a log file or via the Kernel logging system.
- [\[Debug\]LogsDriveMinimumFreeSpace](#) - Specifies the minimum amount of free space required on the drive that hosts the log directory.
- [\[Debug\]LogShutdown](#) - Only required if ShutdownProtect is set to log the shutdown sequence.
- [\[Debug\]MaximumFileSize](#) - Sets the maximum size of an archive file.

- [\[Debug\]MaxMiniDumps](#) - Sets the maximum number of mini-dump files that are stored in the log directory.
- [\[Debug\]MaxTableOutputLength](#) - When set will limit the length of tables when they are output to a kernel.dat file.
- [\[Debug\]Memory](#) - Obsolete in v7.30.
- [\[Debug\]Menu](#) - Determines whether the Kernel option is displayed on the control menu of the Plant SCADA runtime system.
- [\[Debug\]MiniDumpType](#) - Defines the type of mini-dump that is performed.
- [\[Debug\]Priority](#) - Allows you to filter logging messages by priority.
- [\[Debug\]SeverityFilter](#) - Enables log message filtering by severity.
- [\[Debug\]SeverityFilterMode](#) - Enables or disables logging of severities declared by the [Debug]SeverityFilter value.
- [\[Debug\]Shutdown](#) - Determines whether the Shutdown option is displayed on the control menu of the Plant SCADA runtime system.
- [\[Debug\]ShutDownProtect](#) - Enables shutdown protection.
- [\[Debug\]SnapshotEnable](#) - Controls whether periodic diagnostic snapshots are enabled for the alarm database.
- [\[Debug\]SnapshotInterval](#) - Sets the number of minutes between periodic alarm database snapshots.
- [\[Debug\]SnapshotMaxFiles](#) - Controls the maximum number of alarm database snapshots to keep for the current run of the server.
- [\[Debug\]SnapshotMaxSize](#) - Controls the maximum size of an alarm database snapshot.
- [\[Debug\]SnapshotOldFiles](#) - Controls the maximum number of runs to keep for alarm database snapshot files.
- [\[Debug\]SysErrDsp](#) - Disables many system error logs and popup boxes.
- [\[Debug\]SysLogArchive](#) - Causes the syslog to automatically timestamp files as they are rolled over.
- [\[Debug\]SysLogSize](#) - Sets the size of the SYSLOG.DAT file.
- [\[Debug\]UserTraceMode](#) - Allows you to filter messages logged to the syslog.dat.

## See Also

[Parameter Categories](#)

### [Debug]ArchiveFiles

Enables or disables the archiving of the tracelog.dat log file once the maximum size specified by [\[Debug\]MaximumFileSize](#) is reached.

### Allowable Values:

- 0 - disable archiving
- 1 - enable archiving

## Default Value:

0

The following format is used for the file name:

tracelog.[server][timestamp].dat

where:

- [server] = <type>.<cluster>.<username>
- [timestamp] = \_YYMMDD\_HHMMSS

For example:

tracelog.Alarm.Cluster1.AlarmServer1\_051231\_235959.dat

The files are located in the following directory:

%PROGRANDATA%\AVEVA Plant SCADA <VersionNumber>\Logs

---

**Note:** Consider the amount of available disk space before you start archiving log files, as the disk space required to store traces may be significant. A long term archiving strategy is recommended to avoid running a system close to its limitations. If the system runs out of physical resources such as memory or disk space, it may cease to operate.

## See Also

[Debug Parameters](#)

### [Debug]CategoryFilter

Allows you to filter the logging messages sent to the tracelog.dat file by component category.

The [\[Debug\]CategoryFilterMode](#) parameter indicates whether messages of the specified categories will be included or excluded from the log.

---

**Note:** By default, the setting for [\[Debug\]CategoryFilterMode](#) will exclude the categories specified by [\[Debug\]CategoryFilter](#).

## Allowable Values:

Zero or more of the following categories specified as a comma-separated string:

- AlarmClient - traces events from the display layer of the alarm client
- AlarmClientAdaptor - traces events from the adapter layer of the alarm client that marshals between the old and new alarm system
- AlarmClientComms - traces events from the client side of alarm communications
- AlarmClientModel - traces events from the model layer of the alarm client
- AlarmFilterParse - alarm filter parsing logging
- AlarmServer - traces events from the Alarm Server
- AlarmServerAdaptor - traces events from the adapter layer of the alarm server that marshals between the

old and new alarm system

- AlarmServerComms - traces events from the server side of alarm communications
- AlarmServerModel - traces events from the model layer of the alarm server
- CSAToPSI - traces events from the interface between the Client-Side Adapter (CSA) and the Publisher-Subscriber Infrastructure (PSI)
- DataSource - traces setup and cache changes for data sources on the server side
- Instrumentation - traces information from the instrumentation components
- Logging - traces events from the logging subsystem
- ManagedUtil - traces information from the managed utility module
- OpcDaServerComApi - enables tracing of calls at a COM API level
- OpcDaBrowse205 - enables tracing related to OPC DA v2.05 item browsing
- OpcDaBrowse300 - enables tracing related to OPC DA v3.00 item browsing
- OpcDaServer - enables extensive tracing of OPC DA Server object APIs
- OpcDaGroup - enables extensive tracing of OPC DA Server object APIs
- PlatformHost - traces events from the Plant SCADA platform components that are hosted by runtime
- PSIClient - traces events from the client-side handling of tag requests
- PSIInterfaces - traces events from the PSI interfaces
- PSIServer - traces events from the server-side handling of tags requests
- RuntimeManager - traces events from the Runtime Manager
- TaskFramework - traces events from the framework that handles the scheduling and execution of work tasks at runtime
- TagBrowsing - traces events from the client and server handling of tag browsing requests
- Transport - traces events from the platform networking subsystem
- XmlUtils - traces information from the XML utilities module

## Default Value:

Empty string, that is, no categories excluded or included depending on [\[Debug\]CategoryFilterMode](#).

## Example

The following setting will trace tag requests to the point where the data originates:

```
[DEBUG]
CategoryFilter=CSAToPSI,PSIClient,PSIServer,DataSource
CategoryFilterMode=0
```

When combined with the implementation of [\[Debug\]DriverTrace](#), [\[PubSub\]LogDevice](#) and [\[PubSub\]LogLevel](#), this provides a top to bottom data flow trace.

---

**Note:** You can adjust this parameter during runtime using the `SetLogging()` function. For more information, search the Plant SCADA Help for the topic *Adjusting Logging During Runtime*.

## See Also

[Debug Parameters](#)

### [Debug]CategoryFilterMode

Allows or denies logging of categories declared by the [\[Debug\]CategoryFilter](#).

#### Allowable Values:

- 0 - Log only categories defined by the CategoryFilter value
- 1 - Allow logging of all categories except the ones defined by the CategoryFilter value.

#### Default Value:

1

---

**Note:** You can adjust this parameter during runtime using the SetLogging() function. For more information, search the Plant SCADA Help for the topic *Adjusting Logging During Runtime*.

In addition to setting this parameter you need to also set the [\[Debug\]SeverityFilterMode](#) and the [\[Debug\]SeverityFilter](#) parameters. Other parameters associated with syslog.dat file are; [\[Debug\]ArchiveFiles](#), [\[Debug\]EnableLogging](#), [\[Debug\]MaximumFileSize](#)

## See Also

[Debug Parameters](#)

### [Debug]ChromiumDevToolsPort

This parameter enables debugging for a Web Content object located on a Plant SCADA graphics page.

It lets you specify a port number that Chrome can connect to, allowing you to analyze the Web Content browser using Chrome's developer tools.

For example, if you set this parameter to 1026, you can access information about the Web Content browser by pointing a new instance of Chrome at the following address:

`http://localhost:1026`

---

This URL displays a list of links that represent the contents of any Web Content controls that are currently active. The text used for each link will be the title of the page that is displayed. If any controls are using frames, the list may include additional entries. Select a link to access the developer tools for a particular Web Content control.

---

**Note:** You should confirm that the port you select is not used by a Plant SCADA process or any other application.

#### Allowable Values:

1024 - 65535

**Default Value:**

0 (disabled)

**Note:** It is recommended that you set this parameter back to 0 (disabled) when you have finished debugging a Web Content object.

**See Also**

[Debug Parameters](#)

**[Debug]CodeDebug**

Enables Cicode debugging for the process containing the component specified by this parameter.

The default value is "Client" meaning that the client process has Cicode debugging enabled.

**Allowable Values:**

- Client
- Report or ClusterName.Report
- Alarm or ClusterName.Alarm
- Trend or ClusterName.Trend
- IOServer or ClusterName.IOServer

**Default Value:**

Client

**Note:** You cannot debug a process that is running as a Windows™ service.

**See Also**

[Debug Parameters](#)

**[Debug]CrashOnError**

Determines whether Plant SCADA generates a protection violation whenever it detects a software error, for example, a memory corruption error such as "Invalid Heap", "Already Free", 'try to free bad or unknown memory" or "local free no heap". If you enable this parameter, you must ensure that DrWatson is running. (DrWatson will trap the error and produce a trace.) Note that DrWatson is not supplied with some versions of Windows.

When you have reproduced the error, you must disable this parameter. Otherwise any error found by Plant SCADA will cause a General Protection Fault (and if DrWatson is not running, Plant SCADA will be aborted).

**Allowable Values:**

- 0 - (Disable)
- 1 - (Enable)

**Default Value:**

0

**See Also**[Debug Parameters](#)**[Debug]CrashReserveManagedMB**

This parameter specifies how much memory is reserved at startup to allow crash handling to occur for managed code. In a situation where a process runs out of memory, this reserved memory is released to allow the crash handling package to work.

The default value for this parameter (2 MB) is a minimum value. Values below this default are not accepted.

---

**Note:** It is recommended that you do not change the value for this parameter unless instructed by Technical Support.

---

**Allowable Values:**

2 - 1000 (MB)

**Default Value:**

2 (MB)

**See Also**[\[Debug\]CrashReserveNativeMB](#)[Debug Parameters](#)**[Debug]CrashReserveNativeMB**

This parameter specifies how much memory is reserved at startup to allow crash handling to occur for native code. In a situation where a process runs out of memory, this reserved memory is released to allow the crash handling package to work.

The default value for this parameter (40 MB) is a minimum value. Values below this default are not accepted.

---

**Note:** It is recommended that you do not change the value for this parameter unless instructed by Technical Support.

---

**Allowable Values:**

40 - 1000 (MB)

**Default Value:**

40 (MB)

**See Also**

[\[Debug\]CrashReserveManagedMB](#)

[Debug Parameters](#)

**[Debug]DBLogEnable**

Controls whether alarm database log files are enabled under:

[Logs]\DBLog.Alarm.<cluster>.<server>\DB\_<nnn>.log.

**Allowable Values:**

- 1 = On
- 0 = Off

**Default Value:**

1

**See Also**

[Debug Parameters](#)

**[Debug]DBLogMaxFiles**

Controls the maximum number of alarm database log files to keep for current run of the server.

A rolling log system is used, starting with “DB\_001.log”. When this file reaches the maximum size (as specified by [\[Debug\]DBLogMaxSize](#)), it will be closed and “DB\_002.log” will be opened, and so on.

This parameter determines how many of these files will be retained. When the maximum number is reached, the earliest file will be deleted.

For example, when this parameter is set to 5 and DB\_005.log reaches its maximum size, then DB\_001.log will be deleted and DB\_006.log will be opened.

**Allowable Values**

1-50

## Default Value

2

## See Also

[Debug Parameters](#)

### [Debug]DBLogMaxSize

Controls the maximum size (in kilobytes) of an individual alarm database log file.

A rolling log system is used, starting with “DB\_001.log”. When this file reaches the specified maximum size, it will be closed and “DB\_002.log” will be opened, and so on.

## Allowable Values:

10240 (10 MB) - 204800 (200 MB)

## Default Value:

51200 (50 MB)

## See Also

[Debug Parameters](#)

### [Debug]DBLogOldFiles

Controls the maximum number of runs to keep for alarm database log files. When an alarm server is started, any old files from a previous run will be renamed.

For example, “DBLog\_xxx.log” will be renamed “DBLog\_xxx.log\_2”, “DBLog\_xxx.log\_2” will be renamed “DBLog\_xxx.log\_3”, and so on.

The oldest run will be deleted when the specified maximum is reached. For example, a setting of 1 will keep one set of old files (the current files and “DBLog\_xxx.log\_2” )

## Allowable Values:

0-10

## Default Value:

1

## See Also

[Debug Parameters](#)

**[Debug]DebugAllTrans**

### UNINTENDED EQUIPMENT OPERATION

Do not change [Debug]DebugAllTrans or set the [TranDebug] parameter in the Citect.ini file, except on the advice of Technical Support.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

Allows TRAN session logging to be turned on or off. This allows startup messages to be seen during start-up, so that fresh TRAN sessions during runtime can be traced. TRAN is Plant SCADA's PC-to-PC low-level communications protocol. TRAN sessions are logged to the Kernel and the syslog.dat file.

## Allowable Values:

- 0 - Default
- 1 - Enable TRAN logging

## Default Value:

0

---

**Note:** You can adjust [Debug]DebugAllTrans during runtime using the SetLogging() function. For more information, search the Plant SCADA Help for the topic *Adjusting Logging During Runtime*.

---

## Logging a specific TRAN session

You can log a specific TRAN session by entering the following into the Citect.ini file:

[TranDebug]<name>

Where:

- <name> is the name of a TRAN session as viewed in the Kernel.

This will produce the same logs as [Debug]DebugTranAll, though only for the session specified.

## See Also

[Debug Parameters](#)

## [Debug]DebugLogHistoryFiles

Determines how many "debug.<process name>.log" files are kept when rolled over. When a log file is rolled over, it is renamed "debug.<process name>.001". The next is named "debug.<process name>.002", and so on.

If the specified number of files is reached, the oldest file will be deleted when the next rollover occurs. The occurrence of rollovers is determined by the parameter [\[Debug\]DebugLogSize](#).

### Allowable Values:

1 to 10

### Default Value:

1

### See Also

[Debug Parameters](#)

## [Debug]DebugLogSize

Sets the maximum size of the "debug.<process name>.log" file. When the file reaches the specified size, it is rolled over.

When a log file is rolled over, it is renamed "debug.<process name>.001". The next is named "debug.<process name>.002", and so on. The number of log files that are stored is determined by the parameter [\[Debug\]DebugLogHistoryFiles](#), which has a default value of 1.

### Allowable Values:

1 to 10240 (KB)

### Default Value:

4096

### See Also

[Debug Parameters](#)

## [Debug]DisableWinTop

Allows you to disable windows or popups from being forced to the top of the screen. This allows an engineer to perform Kernel debugging or to run Cicode from the Kernel without windows appearing. This INI is intended for commissioning when you need to use the "Kernel".

**Allowable Values:**

- 0 - (Normal)
- 1 - (Disable win on top)

**Default Value:**

0

**See Also**[Debug Parameters](#)**[Debug]DriverCheck**

This parameter is designed for driver developers, to assist users who are experiencing non-recoverable errors due to driver issues.

When this parameter is set, the data structure used for communication between a driver and the I/O server (referred to as the DCB) is monitored for changes. If an error occurs, a Kernel and syslog message is generated.

**Allowable Values:**

- 0 - Disabled
- 1 - Enabled
- 2 - Enabled (with additional confirmation of DCB validity)

**Default Value:**

0

**Example**

With **[debug]drivercheck=1** set, the DCB is checksummed.

On return, the checksum is checked as well as a flag at the end of the DCB buffer; for example:

```
*** WARNING: DriverCheck=1 DCB->buffer overrun ***
```

or

```
*** WARNING: DriverCheck=1 DCB corrupted/changed ***
```

Receipt of this message may not represent a serious error. If a driver cleared the whole DCB buffer of 554 bytes, then expect this error.

If a driver modifies the point information, expect notification via a DCB corruption message.

**[debug]drivercheck=2** will additionally verify that a DCB belongs to a given unit. If this is not the case, an error will be logged.

## See Also

[Debug Parameters](#)

[\[Debug\]DriverTrace](#)

### UNINTENDED EQUIPMENT OPERATION

Do not change the [Debug]DriverTrace parameter in the Citect.ini file, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

The DriverTrace utility is an extension of the Plant SCADA Kernel that can be used to display the commands and information being issued to a driver by Plant SCADA. It can be useful in debugging a driver, for example, it can help determine why a driver is unable to fully initialize.

## Allowable Values:

- OFF - Turns the DriverTrace off.
- CMDS - Turns the DriverTrace on, but does not display the contents of the data buffer associated with the command. Be aware that specific driver commands need to be enabled with the DriverTraceMask INI parameter (or associated Kernel command).
- VER - Turns the DriverTrace on, and includes the contents of the data buffer in the display. Be aware that specific driver commands need to be enabled with the DriverTraceMask INI parameter (or associated Kernel command).
- ERR - Turns the DriverTrace on, but only traces DCBs with errors. (DCBs are the internal data structures used for communication between the I/O server and a driver.)

## Default Value:

OFF

**Note:** You can adjust this parameter during runtime using the SetLogging() function. For more information, search the Plant SCADA Help for the topic Adjusting Logging During Runtime.

## See Also

[Debug Parameters](#)

[\[Debug\]DriverTracePort](#)

[\[Debug\]DriverTraceMask](#)

[\[Debug\]DriverTraceElements](#)

[\[Debug\]DriverTracePort](#)

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not change the [Debug]DriverTracePort parameter in the Citect.ini file, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

This parameter allows a driver trace to be limited to a particular driver port.

**Allowable Values:**

- <port name> = a specified port
- \* = all ports

**Default Value:**

( \* ) all ports

**See Also**

[Debug Parameters](#)

[\[Debug\]DriverTrace](#)

[\[Debug\]DriverTraceMask](#)

[\[Debug\]DriverTraceElements](#)

**[Debug]DriverTraceMask****⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not change the [Debug]DriverTraceMask parameter in the Citect.ini file, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

Uses a 4-byte hexadecimal number to define a bit mask that can be used to either include or exclude driver commands from a driver trace.

**Allowable Values:**

The driver commands and their values are as follows:

<b>Command</b>	<b>Bit Position</b>
CTDRV_INIT	00000001
CTDRV_OPEN	00000002
CTDRV_INIT_CHANNEL	00000004
CTDRV_INIT_UNIT	00000008
CTDRV_READ	00000010
CTDRV_WRITE	00000020
CTDRV_CONVERT	00000040
CTDRV_CANCEL	00000080
CTDRV_CPU	00000100
CTDRV_DATABASE	00000200
CTDRV_STOP_UNIT	00000400
CTDRV_STOP_CHANNEL	00000800
CTDRV_CLOSE	00001000
CTDRV_FORMAT	00002000
CTDRV_STATS	00004000
CTDRV_DEBUG	00008000
CTDRV_INFO	00010000
CTDRV_STATUS_UNIT	00020000
CTDRV_INIT_CARD	00040000
CTDRV_UPDATE_INFO	00080000
CTDRV_UI_READ	00100000
CTDRV_UI_WRITE	00200000
CTDRV_EXIT	00400000
CTDRV_UNITACTIVATES	01000000
CTDRV_SUBSCRIPTIONS	02000000
CTDRV_EVENTUPDATES	04000000

Command	Bit Position
CTDRV_STATUS_DISCONNECT	40000000

**Default Value:**

FFFFFFFF

The <mask> used to include only the CTDRV\_OPEN, CTDRV\_INIT\_UNIT and CTDRV\_READ commands would be:  
 [Debug]DriverTraceMask=0000001A

---

**Note:** You may want to exclude the CPU function call, as this happens often. Do this by setting a mask of:  
 [Debug]DriverTraceMask=7ffffeff

---

**Examples**

```
-> 07f96fdc Cmd: 03 CTDRV_INIT_UNIT ,MOCKOPC, Port: PORT1, Unit: IODev1
(UR0,N1)
| 07f96fdc UnitType: 0 (0x0), UnitAddr: 0 (0x0), BitWidth: 1, UnitCount: 16
<-07f96fdc Cmd: 03 CTDRV_INIT_UNIT ErrDriver 23 (0x17) and took 0ms
-> 07ff1584 Cmd: 04 CTDRV_READ ,DISKDRV, Port: DISKDRV, Unit: IODevDisk
(UR1,N2)
| 07ff1584 UnitType: 1 (0x1), UnitAddr: 1 (0x1), BitWidth: 16, UnitCount: 5,
RawType: INTEGER
<+07ff1584 Cmd: 04 CTDRV_READ ErrDriver 0 (0x0) and took 0ms
<+07ff1584 UnitType: 1 (0x1), UnitAddr: 1 (0x1), BitWidth: 16, UnitCount: 5,
RawType: INTEGER
<+07ff1584 000: 1 0 0 0 5
~> 00000000 Cmd: 25 CTDRV_SUBSCRIBE ,MOCKOPC, Port: PORT1, Unit: IODev1
(UR0,N1)
>-00000000 SUBSCRIBE Tag=Tag4 UpdateRate=500ms
~< 000003e9 Cmd: 26 CTDRV_EVENTUPDATES,MOCKOPC, Port: PORT1, Unit: IODev1
(UR0,N1)
<-000003e9 DS Event UPDATE_MODE=ALL Tag=Tag4 RawValue=0x00
Timestamp=<time_not_set> RawQual=0x0000 DSError=0 (0x0)
```

Explanation of arrows used above:

-> Flags information going down to the driver

<- Flags information back from the driver straight away

<+ Flags information back from the driver asynchronously (i.e. after some small time delay)

~> Flags subscription based calls into the driver

>-

~< Flags subscription based updated from the driver

<-

**(URx,Ny) addition to UNIT and Data driver traces**

UR stands for Unit Record number and is 0 based, so a value of 3 would be the 4th device in the IODevice settings. N stands for the (Network) Number in the IODevice settings. The use of this is to distinguish between redundant units which may use the same unit name. Thus, the trace will positively confirm which unit is in use.

[\[Debug\]DriverTraceElements](#)

### [Debug]DriverTraceElements

#### **WARNING**

##### **UNINTENDED EQUIPMENT OPERATION**

Do not change the [Debug]DriverTraceElements parameter in the Citect.ini file, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

Defines the maximum number of data buffer elements to be displayed in a driver trace. This parameter can be used to limit the printouts for drivers with large blocking values. For example if 128 are read, and parameter is set to 10 then 10 are displayed. If 5 are being read, then only 5 are displayed.

## Allowable Values:

1 to 256

## Default Value:

256

## See Also

[Debug Parameters](#)  
[\[Debug\]DriverTrace](#)  
[\[Debug\]DriverTraceMask](#)

### [Debug]DrWatson

Starts DrWatson when Plant SCADA starts running (if DrWatson is not already running). Note that DrWatson is not supplied with some versions of Windows.

## Allowable Values:

- 0 - (Disable)
- 1 - (Enable)

**Default Value:**

0

**See Also**[Debug Parameters](#)**[Debug]EnableHardwareAlarmLogging**

Enables or disables logging of stack traces for hardware alarms to syslog. Use this parameter to identify the source of hardware alarms in your Cicode.

**Allowable Values:**

- 0 - Disables logging of stack traces for hardware alarms
- 1 - Enables logging of stack traces for unsuppressed hardware alarms. The Cicode function ErrSet() can be used to suppress hardware alarms.
- 2 - Enables logging of stack traces for all hardware alarms, even if they are suppressed.

**Default Value:**

0

When the value of this parameter is set to 1, the stack trace is displayed as follows:

Date and Time of hardware alarm	Stack frame number	Cicode function with the hardware alarm	Approximate line number in the Cicode file
<i>A (simulated mode 1) hardware alarm looks like this;</i>			
2018-04-26 11:36:02.994	+10:00	Hardware alarm code 274 Page="AssInfo" Desc="TabSuspendUpdate" Code="Navigation_ShowTargetPage>" hPage=6 "Info_Bank_HD1080" hAn=-1	
2018-04-26 11:36:02.994	+10:00	[01] Navigation_ShowTargetPage["","","","",""];	299
2018-04-26 11:36:02.994	+10:00	[02] Workspace_SetContext["","","1"];	468
2018-04-26 11:36:02.995	+10:00	[03] Workspace_SelectEquipment[1];	429
2018-04-26 11:36:02.995	+10:00	[04] _Workspace_ContextChange[""];	1159
2018-04-26 11:36:02.995	+10:00	[05] _Workspace_DisplayAllocatedPages@Workspace@SA_Include(6, 5, "", "");	2107
2018-04-26 11:36:02.995	+10:00	[06] _Workspace_RefreshPanes@Workspace@SA_Include(6, 0, "", "");	2409
2018-04-26 11:36:02.995	+10:00	[07] _Workspace_RefreshPanes@Workspace@SA_Include(6, 0, "", "");	2395
2018-04-26 11:36:02.995	+10:00	[08] _Workspace_ShowContent@Workspace@SA_Include(0, "Info_Bank_HD1080", "Info", "", "", 1);	3267
2018-04-26 11:36:02.995	+10:00	[09] _Workspace_PlaceContent@Workspace@SA_Include(0, "Info_Bank_HD1080", "Info", "", "", 1, 1);	3542
2018-04-26 11:36:02.995	+10:00	[10] AssInfo["TabSuspendUpdate", "0", -1]	
<i>Function call that triggered the hardware alarm indicated by "</i>			

When the value of this parameter is set to 2, the trace includes the word "SUPPRESSED" as shown below:

2018-04-26 11:36:02.566	+10:00	SUPPRESSED hardware alarm code 274 Page="" Desc="" Code="Workspace_InitPanes" hPage=0 "Master_PageMenu1_HD1080" hAn=-1	
2018-04-26 11:36:02.567	+10:00	[01] _Workspace_InitPanes[0, 1];	2817
2018-04-26 11:36:02.567	+10:00	[02] _Workspace_StrToDisplayMode@Workspace@SA_Include("MaintainSize");	4563
2018-04-26 11:36:02.567	+10:00	[03] StrToInt("MaintainSize")	

**See Also**[Debug Parameters](#)

## [Debug]EnableLogging

Enables or disables logging to the tracelog.dat file.

### Allowable Values:

- 0 - Disables logging to tracelog.dat
- 1 - Enables logging to tracelog.dat

### Default Value:

1

---

**Note:** You can adjust this parameter during runtime using the SetLogging() function. For more information, search the Plant SCADA Help for the topic *Adjusting Logging During Runtime*.

---

### See Also

[Debug Parameters](#)

## [Debug]EnablePSICounters

Enables or disables the following performance counters:

- Citect.Platform.PSI.Client
- Citect.Platform.PSI.Server.

When enabled, the results will appear in the Kernel's Page Table (see [Page Table PerformanceCounter](#) in the main Plant SCADA documentation).

---

**Note:** It is recommended that you only enable this parameter when instructed by Technical Support.

---

This parameter can be changed without having to restart the SCADA process. The counter settings are dynamically read every five seconds.

---

**Note:** If you remove this parameter from your Citect.ini file during runtime, it will retain the last setting. For example, if the parameter is set to enabled when you remove it, the performance counters will remain enabled. The setting will not be updated until a server restart occurs.

---

### Allowable Values:

- 0 - Disables the performance counters
- 1 - Enables the performance counters

### Default Value:

0

## See Also

[Debug Parameters](#)

### [Debug]EnableReloadLogging

Enables or disables additional debugging output for server reloads.

When enabled, a server reload will write additional log entries to syslog.dat that identify any added, deleted and modified records. The configuration value is read at the beginning of each server reload.

#### Allowable Values:

- 0 - Disables the reload debugging output
- 1 - Enables the reload debugging output

#### Default Value:

0

## See Also

[Debug Parameters](#)

### [Debug]EnableTaskFrameworkCounters

Enables or disables the following performance counters:

- Citect.Platform.Tasks.TaskManager
- Citect.Platform.Tasks.TaskQueue
- Citect.Platform.Tasks.TaskThread.

When enabled, the results will appear in the Kernel's Page Table (see [Page Table PerformanceCounter](#) in the main Plant SCADA documentation).

---

**Note:** It is recommended that you only enable this parameter when instructed by Technical Support.

This parameter can be changed without having to restart the SCADA process. The counter settings are dynamically read every five seconds.

---

**Note:** If you remove this parameter from your Citect.ini file during runtime, it will retain the last setting. For example, if the parameter is set to enabled when you remove it, the counters will remain enabled. The setting will not be updated until a server restart occurs.

#### Allowable Values:

- 0 - Disables the performance counters
- 1 - Enables the performance counters

**Default Value:**

0

**See Also**[Debug Parameters](#)**[Debug]EnableTransportCounters**

Enables or disables the following performance counters:

- Citect.Platform.Transport.SessionTransport
- Citect.Platform.Transport.TransportHost.

When enabled, the results will appear in the Kernel's Page Table (see [Page Table PerformanceCounter](#) in the main Plant SCADA documentation).

---

**Note:** It is recommended that you only enable this parameter when instructed by Technical Support.

This parameter can be changed without having to restart the SCADA process. The counter settings are dynamically read every five seconds.

---

**Note:** If you remove this parameter from your Citect.ini file during runtime, it will retain the last setting. For example, if the parameter is set to enabled when you remove it, the transport counters will remain enabled. The setting will not be updated until a server restart occurs.

**Allowable Values:**

- 0 - Disables the performance counters
- 1 - Enables the performance counters

**Default Value:**

0

**See Also**[Debug Parameters](#)**[Debug]FlushPeriod**

Sets the period at which Tracelog file entries are to be flushed to the file system.

**Allowable Values:**

Number of seconds (minimum of 1 second)

**Default Value:**

1

**See Also**[Debug Parameters](#)**[Debug]LogDirect**

Indicates whether to log directly to a log file or via the Kernel logging system.

**Allowable Values:**

- 0 - (log via the Kernel logging system)
- 1 - (log directly to the syslog file)

**Default Value:**

0

**See Also**[Debug Parameters](#)**[Debug]LogsDriveMinimumFreeSpace**

Specifies the minimum amount of free space required on the drive that hosts the log directory. If less than this amount of space is available on the drive, then a hardware alarm will be raised, as if a mini-dump does occur, there may be insufficient space to save it.

**Allowable Values:**

0 – 2147483647

- 0 - disable checking of the free space on the drive where the log directory resides.
- $n$  - the amount of available space (in Mb) required on the log directory drive to avoid a hardware alarm being raised.

**Default Value:**

2000 (Mb)

## See Also

[Debug Parameters](#)

### [Debug]LogShutdown

---

**Note:** This parameter is designed to assist qualified technical support personnel with system diagnosis.

---

Logs the shutdown function addresses to syslog.dat.

With default handling, a non-recoverable error can be investigated by determining what was happening at the time logging stopped. If a recoverable error is detected, it will be indicated by a trace marker between shutdown function addresses.

You may be requested to provide this information to Technical Support.

#### Allowable Values:

- 0 - (Disable)
- 1 - (Enable)

#### Default Value:

0

---

**Note:** You can adjust this parameter during runtime using the SetLogging() function. For more information, search the Plant SCADA Help for the topic *Adjusting Logging During Runtime*.

---

## See Also

[Debug Parameters](#)

### [Debug]MaximumFileSize

Sets the maximum size for the tracelog.dat log file, in kilobytes. This works in tandem with [\[Debug\]ArchiveFiles](#) to maintain an ongoing archiving strategy.

#### Allowable Values:

Maximum log file size in kilobytes

#### Default Value:

2048

## See Also

[Debug Parameters](#)

## [Debug]MaxMiniDumps

Sets the maximum number of mini-dump files that are stored in the log directory.

This impacts the following zip files:

- Citect32Exception\_[timestamp].zip (32-bit process)
- CitectException\_[timestamp].zip (64-bit process)

For more information, see *Configure User.dmp* in [The Crash Handler](#).

If an exception occurs while the maximum number of mini-dump files is stored, the oldest file will be deleted to make space.

### Allowable Values:

0 – 32767

- 0 - no mini-dumps are ever deleted
- $n$  - the maximum number of mini dumps that can be stored

### Default Value:

5

### See Also

[\[Debug\]MiniDumpType](#)

[Debug Parameters](#)

## [Debug]MaxTableOutputLength

When set will limit the length of tables when they are output to a kernel.dat file.

### Allowable Values:

- 0 – 32000
- -1 =unlimited

### Default Value:

200

### See Also

[Debug Parameters](#)

## [Debug]Menu

Determines whether the **Kernel** option is displayed on the control menu of the Plant SCADA runtime system. The Kernel option provides access to the Kernel window when Plant SCADA is running.

**Note:** This parameter is modified by the Computer Setup Wizard as well as the Computer Setup Editor.

Be aware of the following:

- You should be experienced with Plant SCADA and Cicode before attempting to use the Kernel. These facilities are powerful and, if used incorrectly, can corrupt your system.
- You should only use the Kernel for diagnostics and debugging purposes, and not for normal Plant SCADA operation.
- You need to restrict access to the Kernel. When you are in the Kernel, you can execute any Cicode function with **no** privilege restrictions. You therefore have total control of Plant SCADA (and subsequently your plant and equipment).

### WARNING

#### UNINTENDED EQUIPMENT OPERATION

Do not change the [Debug]Menu parameter in the Citect.ini file, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

## Allowable Values:

- 0 - (Do not display the Kernel option)
- 1 - (Display Kernel option)

## Default Value:

0

## See Also

[Debug Parameters](#)

## [Debug]MiniDumpType

Defines the type of mini-dump that is performed to capture the state of the process when an unexpected system shutdown occurs.

For more information, see [Configure User.dmp](#) in [The Crash Handler](#).

## Allowable Values:

- 0 - No mini-dump is created when a crash occurs.
  - 1 - A light mini-dump is created (containing local stack memory for unmanaged code).
  - 2 - A medium mini-dump is created (containing local stack memory, global variables and basic thread information for unmanaged code).
- 
- Note:** This type of mini-dump is not supported when running a 64-bit process, such as an alarm server operating in Extended Memory mode. If this setting is applied to a 64-bit process, a light mini-dump will be generated.
- 3 - A heavy mini-dump is created (containing accessible memory from the process, and thread information for unmanaged and managed coding environments).

## Default Value:

3

## See Also

[\[Debug\]MaxMiniDumps](#)

[Debug Parameters](#)

## [Debug]Priority

Allows you to filter messages logged to the tracelog.dat file according to their priority. Only messages with a priority less than or equal to this value will be logged.

### UNINTENDED EQUIPMENT OPERATION

More messages will be logged as the value for this parameter is increased. This may have the potential to seriously degrade performance of the system. This can render a system unresponsive to user input and delay the viewing of data.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

## Allowable Values:

Value	Description	Performance impact
0	Normal	Will have little impact on system performance (~1 message/sec)
10	Brief	May have some impact on system performance (~10 messages/sec)

Value	Description	Performance impact
20	Information	Allows a system to run, with some impact on performance (~100 messages/sec)
30	Verbose	Is unlikely to allow a system to run efficiently as the logging load may approach 100 percent of CPU usage.
40	Chatty	System will only operate under debug conditions (~100,000 messages/sec). Users may apply intermediate levels for finer control.

**Default Value:**

0

**Note:** You can adjust this parameter during runtime using the SetLogging() function. For more information, search the Plant SCADA Help for the topic *Adjusting Logging During Runtime*.

**See Also**

[Debug Parameters](#)

**[Debug]SeverityFilter**

Allows you to filter messages logged to the tracelog.dat file according to their severity.

The [\[Debug\]SeverityFilterMode](#) parameter indicates whether messages of the specified severities should be included or excluded from the log.

**Allowable Values:**

Zero or more of the following categories specified as a comma-separated string:

- **Critical** - any detected non-recoverable errors
- **Error** - any detected recoverable errors
- **Warning** - any detected minor issues
- **Information** - informative notifications
- **Verbose** - debugging trace

Include all the required values in the comma-separated string (including Critical and Error), as more critical error levels will not be automatically included if only a lower severity error category is specified.

**Default Value:**

Critical,Error

**Note:** You can adjust this parameter during runtime using the SetLogging() function. For more information, search the Plant SCADA Help for the topic *Adjusting Logging During Runtime*.

**See Also**

[Debug Parameters](#)

**[Debug]SeverityFilterMode**

Enables or disables logging of severities declared by the [\[Debug\]SeverityFilter](#).

**Allowable Values:**

- 0 - Log only categories defined by the SeverityFilter value
- 1 - Allow logging of all categories except the ones defined by the SeverityFilter value.

**Default Value:**

0

**Note:** You can adjust this parameter during runtime using the SetLogging() function. For more information, search the Plant SCADA Help for the topic *Adjusting Logging During Runtime*.

**See Also**

[Debug Parameters](#)

**[Debug]Shutdown**

Determines where the **Shutdown** option is displayed in the Plant SCADA runtime system. The Shutdown option allows users to shut down the Plant SCADA system from a graphics page. It can be set to display on the main control menu (the parent graphics page), or only on graphics pages accessed from the control menu (child graphics pages). You can also set the Shutdown option to not display at all.

**Note:**

- When this setting is set to 0, shutdown will also be disabled in the Plant SCADA Runtime Manager.
- This parameter is modified by the Computer Setup Wizard as well as the Computer Setup Editor.

**Allowable Values:**

- 0 - (The Shutdown option is not displayed)
- 1 - (The Shutdown option is displayed on the control menu)
- 2 - (The Shutdown option is displayed only on child graphics pages)

**Default Value:**

1

**See Also**[Debug Parameters](#)**[Debug]ShutDownProtect**

Enables protection to veto a non-recoverable error if it occurs during shutdown.

**UNINTENDED EQUIPMENT OPERATION**

Do not change the [Debug]ShutDownProtect parameter in the Citect.ini file, except on the advice of Technical Support.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Allowable Values:**

- 0 - (Disable)
- 1 - (Enable)

**Default Value:**

0

**See Also**[Debug Parameters](#)**[Debug]SnapshotEnable**

Controls whether periodic diagnostic snapshots for the alarms database are created under:

[Logs]\DBLog.Alarm.<cluster>.<server>\DBSnapshot\_<nnn>.log.

**Allowable Values:**

- 1 = On
- 0 = Off

**Default Value:**

0

**See Also**[Debug Parameters](#)**[Debug]SnapshotInterval**

Sets the number of minutes between periodic alarm database snapshots.

**Allowable Values:**

1 - 1440

**Default Value:**

5

**See Also**[Debug Parameters](#)**[Debug]SnapshotMaxFiles**

Controls the maximum number of alarm database snapshot files to keep for current run of the server.

A rolling log system is used, starting with “DBSnapshot\_001.log”. When this file reaches the maximum size (as specified by [\[Debug\]SnapshotMaxSize](#)), it will be closed and “DBSnapshot\_002.log” will be opened, and so on.

This parameter determines how many of these files will be retained. When the maximum number is reached, the earliest file will be deleted.

For example, when this parameter is set to 5 and DBSnapshot\_005.log reaches its maximum size, then DBSnapshot\_001.log will be deleted and DBSnapshot\_006.log will be opened.

**Allowable Values**

1-50

**Default Value**

2

## See Also

[Debug Parameters](#)

### [Debug]SnapshotMaxSize

Controls the maximum size (in kilobytes) of an alarm database snapshot.

A rolling log system is used for snapshots, starting with “DBSnapshot\_001.log”. When this file reaches the specified maximum size, it will be closed and “DBSnapshot\_002.log” will be opened, and so on.

#### Allowable Values:

10240 (10 MB) - 204800 (200 MB)

#### Default Value:

51200 (50 MB)

## See Also

[Debug Parameters](#)

### [Debug]SnapshotOldFiles

Controls the maximum number of runs to keep for alarm database snapshot files.

When an alarm server is started, any old files from a previous run will be renamed. For example:

“DBSnapshot\_xxx.log” will be renamed to “DBSnapshot\_xxx.log\_2”, “DBSnapshot\_xxx.log\_2” will be renamed to “DBSnapshot\_xxx.log\_3”, and so on.

The oldest run will be deleted when the specified maximum is reached.

For example, a setting of 1 will keep one set of old files (the current files and “DBSnapshot\_xxx.log\_2”).

#### Allowable Values:

0-10

#### Default Value:

1

## See Also

[Debug Parameters](#)

## [Debug]SysErrDsp

Enables display of a popup message when a system error occurs. Setting this to 1 will result in the system being paused (stop any communication to clients) whilst the error is displayed. When this is set to 0 and a system error occurs, a hardware alarm will be raised and the error will be logged to the syslog.dat. Users should only enable this on a temporary basis for the purposes of debugging.

### Allowable Values:

- 0 - (No popups are displayed)
- 1 - (Allow popups are displayed)

### Default Value:

0

### See Also

[Debug Parameters](#)

## [Debug]SysLogArchive

Use this parameter to archive the syslog.dat files. The files roll over with timestamp and facilitate the retrieval of logged data from a historical archive.

The time taken for a syslog to fill and roll over depends on the amount of logging being recorded, and the current setting for [\[Debug\]SysLogSize](#).

### Allowable Values:

- 0 (disable syslog.dat archiving)
- 1 (enable syslog.dat archiving)

### Default Value:

0

---

**Note:** Consider the amount of available disk space before you start archiving log files, as the disk space required to store traces may be significant. A long term archiving strategy is recommended to avoid running a system close to its limitations.

The following format is used for the file name:

`syslog.[server][timestamp].dat`

where:

`[server] = <type>.<cluster>.<username>`

`[timestamp] = _YYMMDD_HHMMSS`

For example:

syslog.Alarm.Cluster1.AlarmServer1\_051231\_235959.dat

The files are located in the following directory:

%PROGRAMDATA%\AVEVA Plant SCADA <VersionNumber>\Logs

---

**Note:** You can update this parameter within the Citect.ini file while online, as the runtime system will read its value periodically or on demand. For more information, see the topic *Adjusting Logging During Runtime*.

---

## See Also

[Debug Parameters](#)

[\[Debug\]SysLogSize](#)

### [Debug]SysLogSize

Sets the maximum size of the syslog.dat file. When the file reaches this size, it is rolled over.

The syslog.dat file is a low-level logging file used by Plant SCADA. This file is in the Windows directory. Plant SCADA logs debugging information to this file. You should check this file occasionally to see if Plant SCADA has detected any issues.

#### Allowable Values:

0 to 2,000,000 (kilobytes) (i.e. maximum size is 2GB)

#### Default Value:

100000

---

**Note:** You can adjust this parameter during runtime using the SetLogging() function. For more information, search the Plant SCADA Help for the topic *Adjusting Logging During Runtime*.

---

## See Also

[Debug Parameters](#)

[\[Debug\]SysLogArchive](#)

### [Debug]UserTraceMode

Sets the level of tracing for user Cicode. Allows you to filter messages logged to the **syslog.dat** according to their trace level when using the Situational Awareness project. Only messages with a trace level less than or equal to this value will be logged.

#### Allowable Values:

- 0: Nothing
- 1: Error
- 2: Warning

- 3: Information

**Default Value:**

2

**Note:** You can adjust this parameter during runtime using the Debug\_SetTraceLevel() function.

**See Also**[Debug Parameters](#)**Deployment Parameters**

The Citect.ini file contains the following Deployment parameters:

- [\[Deployment\]AskRestartArgs](#) — Passes arguments to the Cicode function called by [\[Deployment\]AskRestartFunc](#).
- [\[Deployment\]AskRestartFunc](#) — Calls a Cicode function instead of displaying a restart notification dialog when a prompted deployment occurs.
- [\[Deployment\]Enabled](#) — Determines if Runtime Manager runs a project that has been deployed from the deployment server, or the Active Project.

**See Also**[Parameter Categories](#)**[Deployment]AskRestartArgs**

This parameter allows you to pass arguments to the Cicode function called by the parameter [\[Deployment\]AskRestartFunc](#).

The arguments need to be defined as a set of comma-separated values, with each argument enclosed in double quote marks. For example:

```
AskRestartArgs = "Hello", "Hey"
```

If any of the arguments include a space, you need to place single quotes around all of the arguments:

```
AskRestartArgs = '"Hello There", "Hey"'  
AskRestartArgs = '"Hello There", "Hey Dude"'
```

**Allowable Values:**

A string defining a set of comma-separated values.

**Default Value:**

No values.

## See Also

[Deployment Parameters](#)

### [Deployment]AskRestartFunc

If "prompt" is specified as the update method for deployment, you can use this parameter to call a Cicode function instead of displaying the inbuilt restart notification dialog.

The Cicode function should return 0 if the restart is approved, or an error code if it is not.

You can use the parameter [\[Deployment\]AskRestartArgs](#) to pass arguments to the specified Cicode function.

## Allowable Values:

Any valid Cicode function.

## Default Value:

Display the inbuilt restart notification dialog.

## See Also

[Deployment Parameters](#)

### [Deployment]Enabled

Determines if Runtime Manager will run a project that has been deployed from the deployment server, or the Active Project (the project that is currently selected in Plant SCADA Studio).

If this parameter is enabled (1), the Runtime Manager will run the project located in the directory specified by the parameter [\[CtEdit\]Deploy](#). This is where unpacked project files are stored after a deployment package has been received from the deployment server.

If disabled (0), the Runtime Manager will run the Active Project.

---

**Note:** This parameter will be set to 1 (enabled) when you use the Configurator to set up a computer as a deployment client.

---

## Allowable Values:

- 0 - Disabled (run the Active Project).
- 1 - Enabled (run the project located in the directory specified by [\[CtEdit\]Deploy](#))

## Default Value:

0

## See Also

[Deployment Parameters](#)

## Device Parameters

The Citect.ini file contains the following device parameters:

- [\[Device\]AlwaysCreateHistory](#) - Determines whether history files will be created even if no alarms have been logged.
- [\[Device>CreateHistoryFiles](#) - Determines whether history files will be created for devices that don't have time and period specified.
- [\[Device\]DiscardSpoolOnError](#) - Discards or retains data in the spooling system.
- [\[Device\]ForceHistoryOpenMode](#) - Determines whether device history files are maintained for data logged by keyboard commands.
- [\[Device\]FormLength](#) - The number of lines that are printed on a page before a new page (form feed) is selected.
- [\[Device\]LptDosANSIToOEM](#) - Indicates whether Windows ANSI characters are converted to OEM characters when printing alarms.
- [\[Device\]MaxSpool](#) - The maximum number of records that Plant SCADA retains in the spool buffer for logging devices (before the log record is discarded).
- [\[Device\]SQLSelect](#) - Performs a SQL Select query when a SQL device is opened.
- [\[Device\]WatchTime](#) - The frequency (in milliseconds) that Plant SCADA checks devices for history files and flushes logging data to disk.

## See Also

[Parameter Categories](#)

### [Device]AlwaysCreateHistory

Before enabling this INI parameter, if you are running multi-process you will need to modify the system include project and add the 'Process' field for all devices. Enter the process type relevant for your usage of that device. Additionally, if a nominated process can run on multiple clusters on the same machine, you will need to add the 'Cluster Name' field for that device, otherwise the process may not startup and you will receive an error in the Runtime Manager.

Determines whether history files will be created even if no alarms have been logged. The normal operation of Plant SCADA is that a history file will not be produced if no alarms were logged for that period. Setting this parameter to 1 creates an empty history file in these cases.

### Allowable Values:

- 0 - (History files not created)
- 1 - (History files created)

**Default Value:**

0

**See Also**[Device Parameters](#)**[Device]CreateHistoryFiles**

Determines whether history files will be created for devices that don't have time and period specified.

**Allowable Values:**

- 0 - (History files not created)
- 1 - (History files created)

**Default Value:**

1

**See Also**[Device Parameters](#)**[Device]DiscardSpoolOnError**

Discards or retains data in the spooling system. Normally, if a device becomes inoperative, the data in the spooling system is discarded. By disabling this option, the data is retained.

**Allowable Values:**

- 0 - (Do not discard data)
- 1 - (Discard data)

**Default Value:**

1

**See Also**[Device Parameters](#)

**[Device]ForceHistoryOpenMode**

Determines whether device history files are maintained for data logged by keyboard commands. By disabling this option, logged data associated with keyboard commands will be appended to the current device file, irrespective of the history setup of your device file.

**Allowable Values:**

- 0 - (Device history files not maintained)
- 1 - (Device history files maintained)

**Default Value:**

1

**See Also**

[Device Parameters](#)

**[Device]FormLength**

The number of lines that are printed on a page before a new page (form feed) is selected. This parameter only applies to a printer device.

**Allowable Values:**

0 to 512 (lines)

**Default Value:**

60

**See Also**

[Device Parameters](#)

**[Device]LptDosANSIToOEM**

Indicates whether Windows ANSI characters are converted to OEM characters when printing alarms and reports to LPTx.DOS. The conversion is required due to differences between Windows and DOS character sets.

**Allowable Values:**

- 0 - (Characters are not converted)
- 1 - (Characters are converted)

**Default Value:**

1

**See Also**

[Device Parameters](#)

**[Device]MaxSpool**

The maximum number of records that Plant SCADA retains in the spool buffer for logging devices (before the log record is discarded).

**Allowable Values:**

0 (Keep unlimited) to 32000

**Default Value:**

4000

**See Also**

[Device Parameters](#)

**[Device]SQLSelect**

Performs an SQL Select query when an SQL device is opened.

**Allowable Values:**

- 0 - (Perform a query to retrieve only table headers when an SQL device is opened)
- 1 - (Perform a query to retrieve table headers and table data when an SQL device is opened)

**Default Value:**

1

**See Also**

[Device Parameters](#)

## [Device]WatchTime

The frequency (in milliseconds) that Plant SCADA checks devices for history files and flushes logging data to disk.

### Allowable Values:

1000 to 3600000 (milliseconds)

### Default Value:

5000

### See Also

[Device Parameters](#)

## Dial Parameters

The Citect.ini file contains the following dial parameters:

- [\[Dial\]CacheRefresh](#) - Enables or disables automatic cache refresh on connection to a remote I/O device.
- [\[Dial\]CallerIDTimeout](#) - The maximum time the I/O Server will wait for a valid caller ID during dial in.
- [\[Dial\]ConnectionRetries](#) - For PSTN connected devices - the number of times the I/O Server will try to dial a dial-up I/O device before declaring that it is OFFLINE. For non-PSTN connected Devices - the number of times the I/O Server will try to bring a device online before declaring that it is offline.
- [\[Dial\]Debug](#) - Enables/disables scheduled I/O device debugging.
- [\[Dial\]DebugLevel](#) - Specifies the level of dial debug traces.
- [\[Dial\]DefaultCallerID](#) - Specifies the caller id to use when taking dial in calls where [Dial]CallerIDTimeout has expired.
- [\[Dial\]MaxConnectionTime](#) - The maximum time a dial-up I/O device will stay connected (not including persistent connections).
- [\[Dial\]MaxQueueTime](#) - The maximum time a dial-up I/O device will remain in the dial queue.
- [\[Dial\]MaxTimeAfterDisconnect](#) - The maximum number of seconds to wait following a disconnect request to allow the dial system time to finish servicing requests.
- [\[Dial\]MissedScheduleTolerance](#) - Specifies how many consecutive scheduled dial attempts can be missed.
- [\[Dial\]ModemRetryDelay](#) - The minimum time to wait (in seconds) between disconnecting from a modem and attempting to use the modem again.
- [\[Dial\]PersistCache](#) - Prevents the cache for remote IO devices being persisted to disk after disconnection and at shutdown.
- [\[Dial\]ReadThroughCache](#) - Determines whether the I/O server will read through the data cache while it is connected to a remote I/O device.
- [\[Dial\]RingCount](#) - The number of rings the I/O Server will wait before it answers a call from a dialing I/O device.

- [\[Dial\]WatchTime](#) - The period at which the I/O Server checks for I/O devices to contact and checks for incoming calls from dialing I/O devices.

## See Also

[Parameter Categories](#)

### [Dial]CacheRefresh

Enables or disables automatic cache refresh on connection to a remote I/O device. By default, the I/O Server will automatically cache data for all variable tags defined for the device. Setting the [Dial]CacheRefresh parameter to 0 will turn off the automatic refresh.

#### Allowable Values:

- 0 to disable
- 1 to enable

#### Default Value:

1

## See Also

[Dial Parameters](#)

### [Dial]CallerIDTimeout

The maximum time the I/O Server will wait for a valid caller ID during dial in.

#### Allowable Values:

1 to 43200 (secs)

#### Default Value:

The value of MaxConnectionTime is converted to seconds and inserted here.

## See Also

[Dial Parameters](#)

### [Dial]ConnectionRetries

For PSTN connected devices - the number of times the I/O Server will try to dial a dial-up I/O device before

declaring that it is OFFLINE.

For non-PSTN connected devices - the number of times the I/O Server will try to bring a device online before declaring that it is OFFLINE.

---

**Note:** If the modem is busy, the attempt will not succeed. If more than one modem is configured on the I/O Server computer, a different one will be selected for the next attempt. If there is only one modem, the I/O Server will try it again. This process will continue until an available modem is found or until the number of retries has been reached.

---

## Allowable Values:

1 to 10

## Default Value:

2

## See Also

[Dial Parameters](#)

## [Dial]Debug

Enables or disables the logging of debug messages to syslog.dat for scheduled I/O devices.

The parameter determines the level of logging used for scheduled communication.

## Allowable Values:

- 0 - (Disable debugging)
- 1 - (Enable debugging)

## Default Value:

0

## See Also

[Dial Parameters](#)

## [Dial]DebugLevel

Allows dynamic control over the amount of dial debug traces sent to syslog.dat.

---

**Note:** [\[Dial\]Debug](#) needs to be set to 1 for this parameter to take effect.

---

**Allowable Values:**

- 0 - No logging performed
- 1 - Minimum amount of logging performed
- 2 - Standard amount of logging performed (default)
- 3 - Maximum logging (everything) useful for debugging

**Default Value:**

2

---

**Note:** You can update this parameter within the Citect.ini file while online, as the runtime system will read its value periodically or on demand. For more information, search the Plant SCADA Help for the topic *Adjusting Logging During Runtime*.

---

**See Also**[Dial Parameters](#)**[Dial]DefaultCallerID**

Specifies the caller id to use when taking dial in calls.

---

**Note:** This is only used if the amount of time specified by [\[Dial\]CallerIDTimeout](#) has been exceeded.

---

**Allowable Values:**

Any string

**Default Value:**

" "

**See Also**[Dial Parameters](#)**[Dial]MaxConnectionTime**

The maximum time a dial-up I/O device will stay connected (not including persistent connections).

**Allowable Values:**

1 to 720 (mins)

**Default Value:**

20 (mins)

**See Also**

[Dial Parameters](#)

**[Dial]MaxQueueTime**

The maximum time a dial-up I/O device will remain in the dial queue, if no modems (or physical ports in the case of non-PSTN connections) are available.

**Allowable Values:**

1 to 720 (mins).

**Default Value:**

The value of [\[Dial\]MaxConnectionTime](#) is inserted here.

**See Also**

[Dial Parameters](#)

**[Dial]MaxTimeAfterDisconnect**

The maximum number of seconds to wait following a disconnect request to allow the dial system time to finish servicing requests. This setting allows some time for the dial-up system to clear any outstanding requests, but will force the connection to close after the specified time even if a problem is preventing the queues being emptied.

**Allowable Values:**

1 to 86400 (seconds)

**Default Value:**

120 (seconds)

**See Also**

[Dial Parameters](#)

**[Dial]MissedScheduleTolerance**

Specifies how many consecutive scheduled dial attempts can be missed before the cache becomes stale.

**Allowable Values:**

1 to 10

**Default Value:**

2

**See Also**

[Dial Parameters](#)

**[Dial]ModemRetryDelay**

The minimum time to wait (in seconds) between disconnecting from a modem and attempting to use the modem again.

**Allowable Values:**

1 to 60

**Default Value:**

10

**See Also**

[Dial Parameters](#)

**[Dial]PersistCache**

Prevents the cache for remote IO devices being persisted to disk after disconnection and at shutdown. Default value is 1 - data is persisted to disk. Setting this to 0 stops persisting data to disk.

If no cache exists on startup, values for remote units will display #WAIT until dialed. If a cache file exists on startup, cached data will be used.

**Allowable Values:**

0 or 1

**Default Value:**

1

**See Also**

[Dial Parameters](#)

**[Dial]ReadThroughCache**

Determines whether the I/O Server will read through the data cache while it is connected to a remote I/O device.

**Allowable Values:**

0 or 1

**Default Value:**

0

**See Also**

[Dial Parameters](#)

**[Dial]RingCount**

The number of rings the I/O Server will wait before it answers a call from a dialing I/O device.

**Allowable Values:**

1 to 10 (rings)

**Default Value:**

3

**See Also**

[Dial Parameters](#)

**[Dial]WatchTime**

The period at which the I/O Server checks for I/O devices to contact and checks for incoming calls from dialing I/O devices. The WatchTime should be less than your modem's inactivity timeout (if you are using dial back),

otherwise the modem will hang up and Plant SCADA will miss the call.

### Allowable Values:

1 to 600 (seconds)

### Default Value:

20

### See Also

[Dial Parameters](#)

### DisableIO Parameters

The Citect.ini file contains the following DisableIO parameters:

- **[DisableIO]<DeviceName>** - Permanently disables the named I/O device for the current session.
- **[DisableIO]<ServerName>** - Permanently disables all I/O devices associated with the named I/O server for the current session.

### See Also

[Parameter Categories](#)

### [DisableIO]<DeviceName>

Permanently disables a named I/O device for the current session so that no hardware errors are generated.

This means that the "PLC Server I/O device off-line" hardware error message will not be seen for the device when the I/O Server is not available.

The effect of this setting is therefore similar to issuing the Cicode function **IODeviceControl** twice with Type set as 0 and 1 respectively, and with the value of the INI setting used as the 'Data' argument (enable or disable).

To enable this IO device, delete the settings from Citect.ini file or assign 0. If you want to comment out the setting, use the exclamation mark character ("!"), not a semi-colon (";"), otherwise Plant SCADA might hang on start-up.

---

**Note:** Parameters of [DisableIO] are not standard ones. On start-up, Plant SCADA tries to load all device names into a symbol table and use ";" to separate them. If ";" is used to comment out [DisableIO] parameters, it sends the initialization of the client system into a dead loop.

---

### Allowable Values:

<I/O device> = 0 or 1

## Default Value:

None

## Example

```
[DisableIO]  
IODevice01=1
```

IODevice01 is an I/O device in your project, and this setting disables IODevice01.

## See Also

[DisableIO Parameters](#)

### [DisableIO]<ServerName>

Permanently disables all I/O devices associated with the named I/O Server for the current session.

This means that the "PLC Server I/O device off-line" hardware error message will not be seen for these devices when the I/O server is not available.

This parameter is useful to bypass the connection to I/O servers on start-up when there are many I/O devices and some of them don't yet exist.

The effect of this setting is therefore similar to issuing the Cicode function **IODevControl** twice with Type set as 0 and 1 respectively, and with the value of the INI setting used as the 'Data' argument (enable or disable).

To enable this I/O server, delete the setting from Citect.ini file or assign 0. If you want to comment out the setting, use the exclamation mark character (!), not a semicolon (;), otherwise Plant SCADA may hang on start-up.

---

**Note:** Parameters of [DisableIO] are not standard ones. On start-up, Plant SCADA tries to load all device names into a symbol table and use ";" to separate them. If ";" is used to comment out [DisableIO] parameters, it will send initialization of the client system into a dead loop.

## Allowable Values:

<I/O server> = 0 or 1

## Default Value:

None

## Example

```
[DisableIO]  
IOServer03=1
```

where IOServer03 is an I/O server in your project. This setting will disable all I/O devices associated with IOServer03.

## See Also

[DisableIO Parameters](#)

### DiskDrv Parameters

The Citect.ini file contains the following DiskDrv parameters:

- [\[DiskDrv\]UpDateTime](#) - The update (write) time for a disk I/O device.

## See Also

[Parameter Categories](#)

### [DiskDrv]UpDateTime

The update (write) time for a Disk I/O device.

#### Allowable Values:

0 to unlimited (secs)

#### Default Value:

5

## See Also

[DiskDrv Parameters](#)

### Driver Parameters

The Citect.ini file contains the following generic driver parameters:

- [\[<DriverName>\]OverrideOSProtection](#) - Determines whether to override the protection mechanism built-in to the I/O Server for drivers that may not be compatible with newer Windows® versions.

## See Also

[Parameter Categories](#)

### [<DriverName>]OverrideOSProtection

Determines whether to override the protection mechanism built-in to the I/O server for drivers that may not be compatible with the current Windows® operating system (OS). You should only set this if you have conducted

your own testing of the driver on the current OS and are satisfied that its operation is correct and reliable.

**Allowable values:**

0, 1

**Default value:**

0

**See Also**

[Driver Parameters](#)

**Event Parameters**

The Citect.ini file contains the following event parameters:

- [Event]Alarm - Obsolete in version 7.0.
- [Event]IOServer - Obsolete in version 7.0.
- [\[Event\]InhibitEvent](#) - Inhibiting events to be enabled.
- [Event]Name - Obsolete in version 7.0.
- [Event]Report - Obsolete in version 7.0.
- [\[Event\]Server](#) - Determines whether this computer is an Events Server.
- [Event]Trend - Obsolete in version 7.0.
- [\[Event\]WatchTime](#) - The time (in seconds) between checks for due events.

**See Also**

[Parameter Categories](#)

**[Event]InhibitEvent**

Inhibits events on startup. For example, you might have an event that is triggered off the rising edge of a bit on startup. The Events Server notices the bit come on, and runs the event. If this parameter is enabled, the Events Server does not run this event until it has read the I/O devices a second time.

**Allowable Values:**

- 0 - (Do not inhibit)
- 1 - (Inhibit)

**Default Value:**

1

**See Also**[Event Parameters](#)**[Event]Server**

Determines whether this computer is an Events Server.

**Note:** This parameter is modified by the Computer Setup Wizard as well as the Computer Setup Editor.

**Allowable Values:**

- 0 - (Not an Events Server)
- 1 - (Events Server)

**Default Value:**

0

**See Also**[Event Parameters](#)**[Event]WatchTime**

The time (in seconds) between checks for due events. You can set this parameter to a large value to conserve CPU time; however you should ensure that any Time and Period-based events in the project are a direct multiple of the WatchTime, otherwise they will not be checked.

**Allowable Values:**

1 to 36000 (seconds)

**Default Value:**

1

**See Also**[Event Parameters](#)

## Font Parameters

The Citect.ini file contains the following font parameters:

- **[Font]Echo** - The text font used to echo keyboard commands on the screen (if they are set to echo).
- **[Font]Error** - The text font used to display an error message at an animation point.
- **[Font]General** - The text font used for general text display (other than keyboard commands, error messages, and prompt messages).
- **[Font]Print** - The text font used to print data to the printer device.
- **[Font]Prompt** - The text font used to display a prompt message at an animation point.

## See Also

[Parameter Categories](#)

### [Font]Echo

The text font used to echo keyboard commands on the screen (if they are set to echo).

#### Allowable Values:

Any font that exists in the project.

#### Default Value:

DefaultFont

## See Also

[Font Parameters](#)

### [Font]Error

The text font used to display an error message at an animation point.

#### Allowable Values:

Any font that exists in the project.

#### Default Value:

DefaultFont

## See Also

[Font Parameters](#)

### [Font]General

The text font used for general text display (other than keyboard commands, error messages, and prompt messages).

#### Allowable Values:

Any font that exists in the project.

#### Default Value:

DefaultFont

## See Also

[Font Parameters](#)

### [Font]Print

The text font used to print data to the printer device.

#### Allowable Values:

Any font that exists in the project.

#### Default Value:

PrintFont

## See Also

[Font Parameters](#)

### [Font]Prompt

The text font used to display a prompt message at an animation point.

#### Allowable Values:

Any font that exists in the project.

## Default Value:

DefaultFont

## See Also

[Font Parameters](#)

## Format Parameters

The [Format] section contains the following parameters:

- [\[Format\]FormatName](#) - Define a display format under a specified name.

## See Also

[Parameter Categories](#)

### [Format]FormatName

Defines a display format for tabular data and identifies it with a specified name. This allows you to name a customized display format that you can then apply to a list.

The way the format name is applied depends on the Starter project from which a project was originally created.

## Allowable Values:

Any valid format string.

## Default Values:

- **Situational Awareness projects**

In a project based on the Situational Awareness the display format can be used for alarm, interlock and equipment reference lists.

### Alarm List Display Formats

The display format can be used for alarms lists such as those on alarms pages, the Information Zone on the Operator Dashboard, and the Top Alarms list.

---

**Note:** The syntax of the format string is the same as the standard alarm display format string, with the exception of the width attribute being interpreted as pixels instead of characters.

---

The default values are:

```
[Format]
Top5Alarm = {PriorityAndState,24}{OnDate,90}{OnTime,90}{Name,220}{Desc,300}{State,50}
```

This is the alarm list format for the Top 5 alarm pop-up box in the Header Bar.

```
[Format]
TopActiveAlarms_UHD4K =
```

```
{PriorityAndState,24}{Date,120}{Time,130}{Name,190}{Desc,180}{State,50}
```

This is the alarm list format for the Active Alarms Zone pane in a 4K resolution workspace.

```
[Format]
```

```
InfoAlarm_HD1080 = {PriorityandState,24}{OnTime,90}{Item,160}{Name,180}
```

This is the alarm list format for the Information Zone in 1080 resolution.

```
[Format]
```

```
InfoAlarm_UHD4K = {PriorityandState,24}{OnTime,130}{Item,300}{Name,328}
```

This is the alarm list format for the Information Zone in 4K resolution.

```
[Format]
```

```
Alarm =
```

```
{PriorityAndState,25}{OnDate,80}{OnTime,90}{Name,250}{State,40}{Cluster,70}{Equipment,220}{Item,160}{UserName,100}{Comment,250}{Category,60}
```

This is the alarm list format for the generic alarm page.

```
[Format]
```

```
Summary =
```

```
{PriorityAndState,25}{Name,250}{SumState,40}{OnDate,80}{OnTime,90}{OffDate,80}{OffTime,90}{DeltaTime,90}{Cluster,70}{Equipment,150}{Item,100}{Comment,250}{Category,60}
```

This is the alarm list format for the generic alarm summary page.

```
[Format]
```

```
SOE =
```

```
{PriorityAndState,25}{Date,80}{Time,90}{Message,250}{Name,250}{State,40}{Cluster,70}{Equipment,150}{Item,100}{UserName,100}{UserLocation,100}{Category,60}
```

This is the alarm list format for the generic sequence of events page.

```
[Format]
```

```
Disabled={PriorityAndState,25}{OnDate,80}{OnTime,90}{Name,250}{State,40}{Cluster,70}{Equipment,150}{Item,100}{DisableEndDate,80}{DisableEndTime,90}{DisableComment,250}{UserName,100}{UserLocation,100}{Category,60}
```

This is the alarm list format for the generic disabled alarms page.

```
[Format]
```

```
AlarmPageSOE_HD1080 =
```

```
{PriorityAndState,24}{Date,90}{Time,90}{Message,165}{State,50}{UserName,100}{UserLocation,100}
```

This is the alarm list format for the historical events side panel on the default alarm pages (in HD1080 resolution).

```
[Format]
```

```
AlarmPageSOE_UHD4K =
```

```
{PriorityAndState,24}{Date,120}{Time,130}{Message,325}{State,50}{UserName,100}{UserLocation,100}
```

This is the alarm list format for the historical events side panel on the default alarm pages (in UHD4K resolution).

**Note:** If you use the `AlarmListCreate()` function to create an alarms list and do not specify a format name, the "Alarm", "Summary", "SOE", or "Disabled" format will be used by default, based on the type of alarm list being created.

## Interlocks

The default values are:

```
[Format]Interlock_HD1080 = {Interlock,25}{Bypass,25}{Description,370}
```

This is the Interlock list format for the information zone in 1080HD format.

```
[Format]Interlock_UHD4K = {Interlock,25}{Bypass,25}{Description,720}
```

This is the Interlock list format for the information zone in UHD4K resolution.

### Equipment References

The default values are:

```
[Format]EquipRef_HD1080 = {Checked,24}{Equipment,240}{Category,120}
```

This is the Equipment Reference List format for alarm page in 1080 format.

```
[Format]EquipRef_UHD4K = {Checked,24}{Equipment,240}{Category,120}
```

This is the Equipment Reference List format for alarm page in UHD4K resolution.

- **Tab\_Style and StruxureWare projects**

**Note:** The syntax of the format string is the same as the standard alarm display format string, with the exception of the width attribute being interpreted as pixels instead of characters.

The Tab\_Style alarm templates assume the alarm display format is defined under the following names if no specified format name is specified for an alarm page:

- Alarm - for normal alarm display type except Summary and Hardware
- LastAlarm - for alarm banner
- Summary - for summary alarm display type
- SOE – for Sequence Of Event (SOE) alarm display type

The default values are:

```
[Format]
Alarm = {Date,80}{Time,80}{Tag,120}{Name,120}{Desc,120}
[Format]
LastAlarm = {Date,80}{Time,80}{Tag,120}{Name,120}{Desc,120}
[Format]
Summary = {Date,80}{Time,80}{Tag,120}{Name,120}{Desc,120}
[Format]
SOE = {Date,80}{Time,80}{Tag,120}{Name,120}{Desc,120}
```

This will show the alarm fields Date, Time, Tag, Name and Desc with each field taking up the specified pixel width on the active / disabled alarm pages.

You can assign a format name to an alarm page by opening the page in the Graphics Builder, then double-clicking on the alarm template and entering the name in the pop-up form.

Tab-style templates do not support text-justification operators because the templates already support proper column handling.

[Alarm Parameters](#)

## General Parameters

The Citect.ini file contains the following general parameters:

- [\[General\]AdvancedDDEPoll](#) - The rate at which Plant SCADA polls I/O devices for data requested by another application (using DDE).
- [\[General\]AELManagerUrl](#) - This parameter stores the current URL for the AVEVA™ Enterprise License

Manager.

- [\[General\]BadOptimise](#) - Obsolete in version 7.0.
- [\[General\]BufferIO](#) - The size of the compiler's file buffer.
- [\[General\]CheckAddressBoundary](#) - Determines whether the compiler checks for correctly-aligned I/O device variables.
- [\[General\]ClusterReplication](#) - Controls whether tag or tag reference will be replicated in a multi-cluster system.
- [\[General\]CitectRunningCheck](#) - Obsolete in version 7.0.
- [\[General\]Ctl3D](#) - Determines whether dialog boxes in the runtime system display with a three-dimensional effect.
- [\[General\]DeadlockTimeout](#) - Specifies the number of seconds to wait before await on an event is considered timed-out.
- [\[General\]DeadlockWarning](#) - Specifies whether an error message is displayed if a time-out occurs.
- [\[General\]DebugInfo](#) - Determines whether symbolic information is included in the compiled Cicode. This controls whether Cicode can be debugged or not.
- [\[General\]DisablePlotSetupForm](#) - Determines whether the Plot Setup form displays when the TrnPrint() function is used.
- [\[General\]DisableRemoteBlocking](#) - Disables blocking on a remote I/O device.
- [\[General\]EnforceTagGlobalUniqueness](#) - Determines if the compiler generates warning messages for tag names that are not globally unique.
- [\[General\]FormatCheck](#) - Determines whether alarm values are truncated when they are longer than the field in which they are to display.
- [\[General\]InfoDestroy](#) - Determines whether the VARIABLE.DBF file is closed automatically after a call to the DspInfoField() function.
- [\[General\]LicensingFullLogging](#) - Enables licensing information to be logged.
- [\[General\]LicenseReservationTimeout](#) - Specifies the number of seconds to reserve a license for a given IP address in cases where a remote client connection is lost.
- [\[General\]LockDelay](#) - Sets the time delay in millisecond between file operation retries.
- [\[General\]LockRetry](#) - The number of times to retry an operation that does not succeed because a file is locked.
- [\[General\]LongFilename](#) - Enables long filename support for Plant SCADA projects, pages, and filenames.
- [\[General\]Multiprocess](#) - Detemines whether Plant SCADA runs as a multi-process or single-process application.
- [\[General\]OSErrors](#) - Enables/disables Plant SCADA trapping of Operating System errors.
- [\[General\]PasswordExpiry](#) - Determines how long your user and operator passwords will take to expire.
- [\[General\]PointCountHigh](#) - The percentage figure at which the first watermark message will be displayed.
- [\[General\]PointCountHighHigh](#) - The percentage figure at which the second watermark message will be displayed.
- [\[General\]PointLimitMsg](#) - Obsolete in version 7.0.
- [\[General\]PrinterColourMode](#) - Determines the default setting (black & white, or color) for trends printed using the TrnPrint() function.
- [\[General\]RegionalNumbersFormat](#) - Determines how Plant SCADA outputs data containing decimal numbers.

- [\[General\]ServerMonitoringPeriod](#) - Defines how often a Alarm Client will send an additional transaction to its server.
- [\[General\]ShareFiles](#) - Enables/disables the opening of projects by the compiler in Shared Mode.
- [\[General\]ShowDriverError](#) - Determines whether an error dialog displays when an internal driver error occurs.
- [\[General\]Stack](#) - The size of the Plant SCADA general-purpose stack.
- [\[General\]StartDelay](#) - Delays the startup of Plant SCADA for a specified period.
- [\[General\]SymbolicInfo](#) - Enables/disables AN help information.
- [\[General\]TagAssMode](#) - Obsolete in version 7.20. Refer to [\[General\]TagDB](#) instead.
- [\[General\]TagDB](#) - Determines whether the Variable Tags database is loaded when the project is compiled.
- [\[General\]TagDBReloadOnChange](#) - Determines whether the Variable Tags database is checked for changes and reloaded when a new page is displayed.
- [\[General\]TagStartDigit](#) - Allows you to use tags that have a number as the first digit.
- [\[General\]TagWriteEventFmt](#) - Allows the formatting of writes to the TagWriteEventQue.
- [\[General\]TagWriteEventQue](#) - Enables/disables logging of tags from IO Devices to a queue called TagWriteEventQue
- [\[General\]TrnPrinter](#) - The default printer port used in the TrnPrint() function.
- [\[General\]TypeRemapAllowed](#) - When set the Data Type field on the form is not editable when the variable tag is linked .
- [\[General\]Verbose](#) - Enables/disables the display of the startup dialog box, which shows the opening runtime databases and other information.
- [\[General\]VerboseToSysLog](#) - Enables startup messages displayed by the Kernel in "Verbose" mode to be logged in the SYSLOG.DAT file.
- [\[General\]WatermarkedPointCount](#) - A flag indicating if watermarking is to be displayed for proximity to point count limits

## See Also

[Parameter Categories](#)

### **[General]AdvancedDDEPoll**

The rate at which Plant SCADA polls I/O devices for data requested by another application (using DDE).

This parameter is only relevant to data accessed by the Plant SCADA DDE Server (Advanced DDE) using "hot" links. (These links are referred to as "automatic" links by some applications, such as Excel).

### **Allowable Values:**

1000 to 32000 ms

### **Default Value:**

2000

## See Also

[General Parameters](#)

### [General]AELManagerUrl

This parameter stores the current URL for the AVEVA™ Enterprise License Manager.

The URL is specified via the Configure Enterprise License Manager dialog. To access this dialog, go to Plant SCADA Studio's **Licensing** activity and select the **Configure** button on the Enterprise License Manager tile.

## Allowable Values:

A valid URL ending with "/AELicenseManager".

## Default Value:

`http://localhost/AELicenseManager`

## See Also

[General Parameters](#)

### [General]BufferIO

The size of the compiler's file buffer.

## Allowable Values:

0 to 32000

## Default Value:

4096

## See Also

[General Parameters](#)

### [General]CheckAddressBoundary

Determines whether the compiler checks for correctly-aligned I/O device variables. Each analog variable in an I/O device usually occupies a word location (16 bits wide). If the first word is V1, the next is V2, V3, V4, and so on. With some I/O devices, you can access two words as a long or real value (32 bits wide). The first long will be V1 and the next V3, V5, V7, and so on.

For Plant SCADA to read these variables correctly, all double-register variables must be aligned on the same

boundary, either an even or odd boundary. When Plant SCADA compiles your project and finds a double-register variable, it remembers which boundary it is on and checks that all other double register variables are on the same boundary. So, if Plant SCADA finds a double register variable on address V5, Plant SCADA checks that all other double register variables are also on odd boundaries.

The Plant SCADA compiler displays the "Address on bad boundary" message if the address of a long or real variable is not aligned correctly.

### Allowable Values:

- 0 - (Disable checking)
- 1 - (Enable checking and report as errors)
- 2 - (Enable checking and report as alerts)

### Default Value:

1

### See Also

[General Parameters](#)

### [General]ClusterReplication

Determines whether tags and tag references will be replicated in a multi-cluster system.

**Note:** After upgrading Plant SCADA, you will need to change this parameter to 1 if you want cluster replication to be enabled.

### Allowable Values:

- 0 — Disable replication.  
A cluster must be explicitly specified for a tag or tag reference, otherwise a compiler error message will be generated.
- 1 — Enable replication.  
A cluster need not be defined for a tag or tag reference for replication to occur. If the same tag exists in multiple clusters in the variables database, the cluster name will be replicated down to an I/O device via the I/O server to which it is connected.

### Default Value:

0

### See Also

[General Parameters](#)

**[General]Ctl3D**

Determines whether dialog boxes in the runtime system display with a three-dimensional effect.

**Allowable Values:**

- 0 - (No 3-D effect)
- 1 - (Show 3-D effect)

**Default Value:**

1

**See Also**

[General Parameters](#)

**[General]DeadlockTimeout**

Specifies the number of seconds to wait before a wait on an event is considered timed-out. Setting this parameter to 0 would mean that Plant SCADA will wait indefinitely and is not recommended. The value should not be changed from the default unless required for troubleshooting by technical support.

**Default Value:**

300

**See Also**

[General Parameters](#)

**[General]DeadlockWarning**

Specifies whether an error message is displayed if a time-out occurs.

**Allowable Values:**

- 0 - Do not display an error message.
- 1 - Display an error message.

**Default Value:**

1

## See Also

[General Parameters](#)

### [General]DebugInfo

Determines whether symbolic information is included in the compiled Cicode. Symbolic information is used to debug Cicode. The performance gained by turning this option off is only about 1%.

#### Allowable Values:

- 0 - (Do not include symbolic information)
- 1 - (Include symbolic information - allow debugging)

#### Default Value:

1

## See Also

[General Parameters](#)

### [General]DisablePlotSetupForm

The DisablePlotSetupForm parameter works in conjunction with the DisplayForm argument of the **TrnPrint()** function. It determines whether the Plot Setup form displays when TrnPrint() is called, but it will only take effect if TrnPrint() is called, and the DisplayForm argument is set to -1.

This parameter can be set from the Plot Setup form, by clicking in the Do not display this form next time check box.

#### Allowable Values:

- 0 - (Plot Setup form is enabled)
- 1 - (Plot Setup form is disabled)

#### Default Value:

0

## See Also

[General Parameters](#)

### [General]DisableRemoteBlocking

Disables the blocking of remote I/O devices.

To optimize data transfer, multiple requests to an I/O device are blocked into one single request. However, some blocked requests are not satisfied from the I/O Server data cache, resulting in variable tags being displayed as #WAIT.

To disable blocking and send client requests for data individually, set this parameter to 1.

#### Allowable Values:

- 0 - (Remote Blocking is enabled)
- 1 - (Remote Blocking is disabled)

#### Default Value:

0

#### See Also

[General Parameters](#)

### [General]EnforceTagGlobalUniqueness

The Connectivity Server manages tag subscriptions for the OPC UA Server and the Industrial Graphics Server. If a subscription request does not have a cluster explicitly defined, all the tags in the Plant SCADA system need to be unique across all clusters (in respect to both their tag name and equipment.item name) otherwise the subscription will be rejected.

When you compile a Plant SCADA project, the compiler provides a flag to the Connectivity Server indicating whether or not all tags are unique across all clusters. The Connectivity Server can refer to this flag when it encounters a tag subscription request that does not specify a cluster. If the flag indicates that all tags are globally unique, the Connectivity Server can safely broadcast a tag exists request to all clusters. If the flag indicates that this is not the case, any tag subscription requests that do not specify a cluster will be rejected.

When the [\[General\]EnforceTagGlobalUniqueness](#) parameter is enabled (1), the compiler will generate a warning message for each tag name that is not globally unique. These messages can be used to diagnose which tags are not unique across all clusters.

#### Allowable Values:

- 0 — the compiler will not generate warning messages for tags that are not unique across all clusters
- 1 — the compiler will generate warning messages for tags that are not unique across all clusters

#### Default Value:

0

## See Also

[General Parameters](#)

### [General]FormatCheck

Determines whether alarm values are truncated when they are longer than the field they are to display in (as specified in Alarm Categories). For example, if, in your Alarm Format, you allot 12 characters to the Analog Value field (i.e. {Value,12} ), the alarm page will display up to 12 characters of the value. If the value happens to be longer than 12 characters, it will be truncated or replaced with the #OVR ("overflow of format width") error.

#### Allowable Values:

- 0 - (#OVR string used to designate an "overflow of format width")
- 1 - (Numeric value is truncated to fit in field)

#### Default Value:

1

## See Also

[General Parameters](#)

### [General]InfoDestroy

Determines whether the VARIABLE.DBF file is closed automatically after a call to the DspInfoField() function. You can disable this parameter for optimization, but you must call the DspInfoDestroy() function to close the VARIABLE.DBF file. If the VARIABLE.DBF file is not closed, the Plant SCADA compiler will not be able to open VARIABLE.DBF file.

#### Allowable Values:

- 0 - (Disabled (VARIABLE.DBF is not closed))
- 1 - (VARIABLE.DBF is automatically closed)

#### Default Value:

1

## See Also

[General Parameters](#)

**[General]LicenseReservationTimeout**

Specifies the number of seconds to reserve a license for a given IP address in cases where a remote client connection is lost. This does not apply to FULL licenses.

**Default Value:**

10

**See Also**

[General Parameters](#)

**[General]LicensingFullLogging**

Enables licensing information to be logged. This parameter is set to false (0) by default to avoid the same licensing information being repeatedly logged.

**Allowable Values:**

- 0 - (Disable licensing logging)
- 1 - (Enable licensing logging)

**Default Value:**

0

**See Also**

[General Parameters](#)

**[General]LockDelay**

Sets the time delay in millisecond between file operation retries. This parameter is ignored if [\[General\]LockRetry](#) is set to 0. Note that if you set this parameter to a high value, you could reduce performance.

**Allowable Values:**

0 to 100

**Default Value:**

30

## See Also

[General Parameters](#)

### [General]LockRetry

The number of times to retry an operation that does not succeed because a file is locked. Some networks do not unlock files as quickly as you would expect, causing the error message "dBASE record locked by another user" to display frequently. Note that if you set this parameter to a high value, you could reduce performance. The period between retries is determined by the [\[General\]LockDelay](#) parameter.

#### Allowable Values:

0 to 20

#### Default Value:

3

## See Also

[General Parameters](#)

### [General]LongFilename

Enables long filename support. With this parameter set, Plant SCADA project names and page names can be up to 64 characters in length, and filenames can be up to 254 characters, including the path.

#### Allowable Values:

- 1 - (to enable)
- 0 - (to disable)

#### Default Value:

1

---

**Note:** If you disable long filename support, you must ensure that the path of the directory where Plant SCADA is installed uses short filenames and does not include any spaces. Long file names in the path will be invalid, and you will be unable to create or save projects to the directory.

---

## See Also

[General Parameters](#)

## [General]Multiprocess

Determines whether Plant SCADA will run as a multi process or single process application.

**Note:** You can modify this parameter using only the Computer Setup Wizard or the Computer Setup Editor. It cannot be set in the parameters database.

**Note:** During an installation of V7.20 or later, this parameter is set to 1 and included in the INI file. If removed from the INI file, the behavior will return to single-process mode.

### Allowable Values:

- 0 - (single process)
- 1 - (multi process)

### Default Value:

0 (set to 1 by the installer)

### See Also

[General Parameters](#)

## [General]OSErrors

Enables/disables Plant SCADA trapping of operating system errors. Plant SCADA traps disk, network, floating-point, and other system errors. If you disable this parameter, Plant SCADA will not trap these errors and could abort if an error occurs.

### UNINTENDED EQUIPMENT OPERATION

Do not change the [General]OSErrors parameter in the Citect.ini file, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

### Allowable Values:

- 0 - (Disable checking)
- 1 - (Enable checking)

### Default Value:

1

## See Also

[General Parameters](#)

### [General]PasswordExpiry

Determines how long your user and operator passwords will take to expire. Whenever you create a user and assign a password, or edit an existing password, Plant SCADA time and date stamps this change. A user will be permitted to log in while the current time and date is not later than the stamped time and date plus the Password Expiry number of days.

If a user tries to log in with an expired password, the log in will not succeed and a message will appear indicating that the password has expired.

#### Allowable Values:

0 (default: no expiry) to 365 days

#### Default Value:

0

## See Also

[General Parameters](#)

### [General]PointCountHigh

The percentage figure at which the first watermark message will be displayed if the [\[General\]WatermarkedPointCount](#) parameter has been set to true.

#### Allowable Values:

Any value between 0 and 100.

#### Default Value:

95

## See Also

[General Parameters](#)

### [General]PointCountHighHigh

The percentage figure at which the second watermark message will be displayed if the

[General]WatermarkedPointCount parameter has been set to true.

### Allowable Values:

Any value between 0 and 100.

### Default Value:

98.

### See Also

[General Parameters](#)

## [General]PrinterColourMode

The PrinterColourMode parameter works in conjunction with the iModeColour argument of the TrnPrint() function. It determines whether the trends printed using TrnPrint() will be black and white, or color, however, it will only take effect if the iModeColour argument is set to -1.

### Allowable Values:

- 0 - (color)
- 1 - (Black & White)

### Default Value:

1

### See Also

[General Parameters](#)

## [General]RegionalNumbersFormat

Determines how Plant SCADA outputs data containing decimal numbers. When set to 1, Plant SCADA uses the decimal separator from the Windows Regional Numbers setting. When set to 0, the hard coded symbol (.) is used.

### Allowable Values:

0, 1

**Default Value:**

1

**See Also**

[General Parameters](#)

**[General]ServerMonitoringPeriod**

Defines how often a Alarm Client will issue an additional transaction to its server to monitor the health of the active server. If the transaction is not completed successfully and redundancy is available, the client will automatically swap to the alternate server.

**Minimum:**

1 second

**Maximum:**

600 seconds (10 minutes)

**Default Value:**

10 seconds

**See Also**

[General Parameters](#)

**[General]ShareFiles**

Enables/disables the opening of projects by the compiler in Shared Mode. If you enable Shared Mode, you will increase the compilation time, but you are allowed to compile while other users have the project open.

**Allowable Values:**

- 0 - (Exclusive)
- 1 - (Shared)

**Default Value:**

0

## See Also

[General Parameters](#)

### [General]ShowDriverError

Determines whether an error dialog displays when an internal driver error occurs.

#### Allowable Values:

- 0 - No error dialog
- 1 - Display error dialog

#### Default Value:

0

---

**Note:** You can update this parameter within the Citect.ini file while online, as the runtime system will read its value periodically or on demand. For more information, search the Plant SCADA Help for the topic Adjusting Logging During Runtime.

---

## See Also

[General Parameters](#)

### [General]Stack

The size of the Plant SCADA general-purpose stack. Increase this parameter if Plant SCADA aborts with a "General stack overflow" error. This stack is different from the Cicode Stack. If a "Cicode stack overflow" hardware error is displayed, increase the value of the Code Stack parameter.

#### Allowable Values:

5000 to 32000

#### Default Value:

32000

## See Also

[General Parameters](#)

## [General]StartDelay

Delays the startup of Plant SCADA for a specified period (in seconds). If the Plant SCADA runtime application is started, it will not actually run until the delay period ends. This allows you to delay Plant SCADA startup if it must wait for some other process to start/complete.

### Allowable Values:

0 to 3600

### Default Value:

0

### See Also

[General Parameters](#)

## [General]SymbolicInfo

Enables/disables AN help information. See the InfoForm() Cicode function for information about AN help information. Plant SCADA will run faster and use less memory if AN help information is disabled.

### Allowable Values:

- 0 - (Disable)
- 1 - (Enable)

### Default Value:

1

### See Also

[General Parameters](#)

## [General]TagDB

Determines whether the Variable Tags database is loaded at runtime. The Variable Tags database needs to be loaded to allow tags to be referenced with the Equipment.Item syntax, as well as, to obtain the tag list shown by the TagDebug function, for Instant trends, if you are performing CtAPI ctFindFirst requests on the TAG table, for Super Genie associations and if you are using functions such as TagInfo, TagScaleStr and AssScaleStr.

If you do not need to use any of these features, you can save memory by disabling this parameter. Because the information needs to be loaded into memory, this parameter can use a large amount of memory. The amount of memory used by one tag is 30 bytes + the length of the name + 1. If you have 10,000 tags with an average name

length of 16 characters, this parameter will use  $(30 + 16 + 10) \times 10,000 = 470,000$  bytes. This memory usage would only be a problem if you are low on memory or have many variables.

### Allowable Values:

- 0 - Disable variable tag database load
- 1 - Enable variable tag database load

### Default Value:

1

---

**Note:** Plant SCADA can automatically resolve tags without a cluster context being specified if every tag name in the project is unique. However, this feature will only function correctly if this parameter is set to 1 (enabled). Confirm that this feature is not required before you disable this parameter.

---

### See Also

[General Parameters](#)

#### [General]TagDBReloadOnChange

Determines whether the Variable Tags database is checked for changes and reloaded when a new page is displayed. Enabling this parameter allows online changes to the Variable Tags database to be automatically made effective for next page display. The Variable Tags database needs to be loaded to allow tags to be referenced with the Equipment.Item syntax, obtain the tag list shown by the TagDebug function, for Instant trends, if you are performing CtAPI ctFindFirst requests on the TAG table, for Super Genie associations and if you are using functions such as TagInfo, TagScaleStr and AssScaleStr.

This parameter is ignored if [General]TagDB is set to 0. In this case, variable tags database will not be loaded on display client.

### Allowable Values:

- 0 - Disable variable tag database reload on page open
- 1 - Enable variable tag database reload on page open

### Default Value:

1

### See Also

[General Parameters](#)

## [General]TagStartDigit

Allows you to use tags, tag items, or equipment names that have a number as the first digit.

Using a number as the first digit of a tag is not a good engineering practice. Tags starting with numbers are not supported by modern programming languages and they are not allowed in the industrial control systems standard IEC 1131-3. This is because it creates confusion when tags are used in complex expressions. This was not a problem with older simpler systems when you could only get the value of a tag.

This functionality is supported primarily for users converting large existing databases to Plant SCADA.

Only variable tags and Cicode variables can start with numbers. You cannot start labels or label arguments with numbers.

As Plant SCADA supports several types of numbers there can be confusion with tags starting with number clashing with the special types of numbers. For example the following may look like tags:

0X1234	is hex number
0B0011	is binary number
007777	is octal number
0E23	is floating point number

When [General]TagStartDigit is set to 0 (zero), the above tags are treated as valid numbers.

However, if you have [General]TagStartDigit set to 1, and you have these types of numbers in your project, you must observe the following conventions:

- Numbers such as 0E12334 must contain a decimal point to distinguish them from tags, For example, 0E23 is a tag and 0.E23 is a float when the [General]TagStartDigit parameter is enabled.
- Numbers such as 0O01234567 (that's an O as in Orange), 0X01234, and 0B01, must use lowercase for alpha characters, and any potentially conflicting tags must use uppercase. For example, 0x10 will be considered a hex number, and 0X10 a tag. Note that if you use lower case to denote a number, but the number is illegal, it will be considered a tag. For example:

0xG	G is not valid hex digit.
0b2	2 is not valid binary digit.
0o8	8 is not valid octal digit.
0x123456789	more than 8 digits for 4 byte integer

Because of the above considerations you cannot define tags which look like valid numbers. For example 0x123 will be treated as a number, not a tag. You should always use upper case for tags starting with a number and the tag must contain at least one alpha (A..Z) or underscore (\_) character.

Also you cannot define numbers which look like tags. When TagStartDigit=0, then 0X123 will be treated as a hex number. When [General]TagStartDigit=1, 0X123 will be treated as a tag. This can cause problems if you have existing Cicode from older projects which has numbers defined this way. When you switch this option on, you may find you will get the "Tag not found" compiler error. This will occur because Plant SCADA will think that some of your numbers are tags and so try to find them in the Tag database.

---

**Note:** CitectVBA does not recognize Plant SCADA variable tags which are named with an initial digit (0-9).

---

### Allowable Values:

- 0 - (Do not allow tags with number as first digit)
- 1 - (Allow tags with number as first digit)

### Default Value:

0

### See Also

[General Parameters](#)

### [General]TagWriteEventFmt

By default, log messages stored in TagWriteEventQue allocate only 32 characters for the tag name and 12 for the value. Since tag names may be up to 79 characters long and strings tags may be up to 128 characters long, the format may be customized by setting the TagWriteEventFmt parameter. For example:

[General]TagWriteEventFmt = {Name,79} {Value,128}

### See Also

[General Parameters](#)

[\[General\]TagWriteEventQue](#)

### [General]TagWriteEventQue

Enables/disables logging of tag writes to a queue called TagWriteEventQue on the client. When this parameter is enabled, writes will be logged for all tags whose IODevices have their LogWrite parameter enabled.

### Allowable Values:

0 or 1

### Default Value:

0 (disabled)

### See Also

[\[General\]TagWriteEventFmt](#)

[General Parameters](#)

**[General]TrnPrinter**

The default printer port used in the TrnPrint function.

**Allowable Values:**

Any valid printer port

**Default Value:**

LPT1:

**See Also**

[General Parameters](#)

**[General]TypeRemapAllowed**

This setting controls the way the <Variable Tag> FORM displays the "Data Type" field for variable tags that are linked to an external data source (ie:marked as "Linked:Yes").

**Allowable Values:**

- 0 - Data Type field is editable on the form when the tag is linked
- 1 - Data Type field is not editable on the form when the tag is linked

**Default Value:**

0

**See Also**

[General Parameters](#)

**[General]Verbose**

Enables or disables the display of the startup dialog box, which shows the opening runtime databases and other information.

**Allowable Values:**

- 0 - not display
- 1 - display

**Default Value:**

1

---

**Note:** You can adjust this parameter during runtime using the SetLogging() function. For more information, search the Plant SCADA Help for the topic Adjusting Logging During Runtime.

---

**See Also**

[General Parameters](#)

**[General]VerboseToSysLog**

Enables startup messages displayed by the Kernel in "Verbose" mode to be logged in the syslog.dat file.

**Allowable Values:**

- 0 - No logging of "Verbose"
- 1 - Log Kernel messages

**Default Value:**

0

---

**Note:** You can adjust this parameter during runtime using the SetLogging() function. For more information, search the Plant SCADA Help for the topic Adjusting Logging During Runtime.

---

**See Also**

[General Parameters](#)

**[General]WatermarkedPointCount**

Enables two preconfigured "watermark" messages that can display to the user when the dynamic point count reaches 2 defined percentages of their point license limit.

**Allowable Value:**

- True - (Display alert message)
- Yes - (Display alert message)
- False - (Do not display alert message)
- No - (Do not display alert message)

Not case sensitive.

## Default Value:

False

## See Also

[General Parameters](#)

[\[General\]PointCountHigh](#)

[\[General\]PointCountHighHigh](#)

## Interlock Parameters

The Citect.ini file contains the following internet parameters:

- [\[Interlock\]StateItem](#) - Sets the global value of the item if not using the default item name "Running" for all pieces of Equipment.

## See Also

[Parameter Categories](#)

### [Interlock]StateItem

Sets the global default value if using a different item name rather than "Running" for pieces of Equipment with an interlock condition.

---

**Note:** This is a global value and not per instance. To set a value per instance configure using the item name for the target interlocked equipment in the Equipment Runtime Parameter grid. Refer to the topic [Configure Interlocks](#) in the main help for more information.

---

If this parameter and Equipment Runtime Parameters have been defined then the Equipment Runtime Parameters will take precedence.

For example: if there is a piece of equipment named "InterlockedDevice" the precedence would work as follows:

- If there is no Equipment Runtime Parameter and INI parameter set, "InterlockedDevice.Running" will be used to detect interlock status.
- If INI parameter [Interlock]StateItem = PV and no Equipment Runtime Parameter configured, "InterlockedDevice.PV" will be used. This is the same for all other pieces of equipment.
- If INI parameter [Interlock]StateItem = PV is set with an Equipment Runtime Parameter set for "InterlockedDevice" as Interlock\_StateItem = "RunningState", InterlockedDevice.RunningState will be used, whilst all other pieces of equipment will use "PV".

## Allowable Values:

Value for item name e.g. PV

**Default Value:**

"Running"

**See Also**

[Interlock Parameters](#)

**IOServer Parameters**

The Citect.ini file contains the following IOserver parameters:

- [\[IOServer\]AlwaysCallStopChannel](#) - Determines whether Plant SCADA calls the StopChannel() function for a driver.
- [\[IOServer\]AlwaysCallStopUnit](#) - Determines whether Plant SCADA calls the StopUnit function for a driver.
- [\[IOServer\]AsyncConnect](#) - Determines whether Plant SCADA will follow its default behavior and attempt to connect to all configured I/O servers on start-up.
- [\[IOServer\]BlockWrites](#) - Determines whether Plant SCADA will try to block optimize writes to I/O devices.
- [\[IOServer\]CacheDebug](#) - Enables/disables I/O Server cache debugging.
- [\[IOServer\]CacheIgnoreDriver](#) - Ignore the request from the protocol driver not to cache the remote I/O device.
- [\[IOServer\]CacheOptMode](#) - Reduces #COM when using dial-up or scheduled devices.
- [\[IOServer\]CacheReadAhead](#) - Determines whether Plant SCADA will use read ahead caching or not.
- [\[IOServer\]CancelTimeout](#) - Determines how long the I/O server will wait on a reply from a driver before giving up.
- [\[IOServer\]CPU](#) - Obsolete in version 7.0.
- [\[IOServer\]DisableConnectivityPropertiesAndExtensions](#) - Disables properties and tag extensions to improve the performance of the I/O servers.
- [\[IOServer\]DebugLogTagHandshake](#) - Enables detailed tag handshake logging.
- [\[IOServer\]EnableEventQueue](#) - Enables the event queue.
- [\[IOServer\]HeartTime](#) - The period at which the I/O Server sends out heartbeats (to the clients) on the status of each I/O device.
- [\[IOServer\]HWAlarmOnDeviceDisable](#) - Controls whether hardware alarms for disabled IO devices are displayed or suppressed.
- [\[IOServer\]InitMsg](#) - Determines whether communication information is displayed in the Kernel (at startup).
- [\[IOServer\]LogTagHandshake](#) - Enables basic tag handshake logging.
- [\[IOServer\]MaxEventsDrop](#) - Sets the number of events that are dropped when too many are queued.
- [\[IOServer\]MaxEventsQueued](#) - Sets the maximum number of events that can be queued.
- [\[IOServer\]MaxTagHandshakeSize](#) - Sets the maximum number of bytes a tag validation check requests during validation.
- [\[IOServer\]MaxTimeInQueueMs](#) - Sets the maximum time for which an event can be queued.
- [\[IOServer\]Name](#) - Obsolete in version 7.0.

- [\[IOServer\]PeerServerConnectTimeOut](#) - Defines how long an IOServer will attempt to connect to peer IOServers.
- [\[IOServer\]Process](#) - Obsolete in version 7.0.
- [\[IOServer\]RedundancyDebug](#) - Enables/disables I/O device redundancy debugging.
- [\[IOServer\]SaveBackup](#) - Obsolete in version 7.0.
- [\[IOServer\]SaveFile](#) - The indicative name and path of the local I/O device persistence cache files on an I/O Server.
- [\[IOServer\]SaveNetwork](#) - The UNC name of the Persistence Cache file on this I/O Server.
- [\[IOServer\]SavePeriod](#) - Obsolete in version 7.20.
- [\[IOServer\]SaveTime](#) - Obsolete in version 7.20.
- [\[IOServer\]Server](#) - Obsolete in version 7.0.
- [\[IOServer\]StrictTagHandshake](#) - Enforces that the I/O Server contains a matching OID for every OID on the client.
- [\[IOServer\]TagAddressNoCase](#) - Determines if case-sensitivity needs to be considered when validating tag addresses.
- [\[IOServer\]WatchDog](#) - Determines whether Plant SCADA periodically checks the communication connection to your standby I/O devices.
- [\[IOServer\]WatchDogPrimary](#) - Determines whether Plant SCADA periodically checks the communication connection to your primary I/O devices.

## See Also

[Parameter Categories](#)

[IOServer Process Parameters](#)

### [IOServer]AlwaysCallStopChannel

Determines whether Plant SCADA attempts to call the StopChannel() function for a driver.

The StopChannel call releases resources allocated for a PLC connection. Under normal circumstances, this occurs when the PLC is online at shutdown, or disabled. Since the PLC may not get a StopChannel when it is offline at shutdown, its resources may not have been released and Plant SCADA crashes can occur.

By default this parameter is set to 1 which means that a StopChannel is called, and may prevent crashes at shutdown. Usually if setting AlwaysCallStopUnit, you would set AlwaysCallStopChannel.

## Allowable Values:

- 0 - StopChannel is not called.
- 1 - StopChannel is called.

## Default Value:

1

## See Also

[IOServer Parameters](#)

### [IOServer]AlwaysCallStopUnit

Determines whether Plant SCADA attempts to call the StopUnit function for a driver when the unit goes offline so as to release resources allocated for an I/O Device.

The StopUnit call releases resources allocated for a PLC. Under normal circumstances, this occurs when the PLC is online at shutdown, or disabled. Since the unit may not get a StopUnit when it is offline at shutdown, its resources may not have been released and Plant SCADA crashes can occur.

By default this parameter is set to 1 and commands that a StopUnit is called. This may prevent crashes at shutdown. Usually if setting AlwaysCallStopUnit, you would set AlwaysCallStopChannel.

#### Allowable Values:

- 0 - Stop Unit is not called
- 1 - StopUnit is called

#### Default Value:

1

## See Also

[IOServer Parameters](#)

### [IOServer]AsyncConnect

Determines whether Plant SCADA will follow its default behavior and attempt to connect to all configured I/O servers on start-up.

When the AsynConnect parameter is set to 1, Plant SCADA will defer the connection attempt for each I/O Server until that I/O Server is required.

This option may be required in order to speed up the start-up process on sites which have many I/O Servers that do not yet exist.

#### Allowable Values:

- 0 - (I/O Servers will be connected on start-up)
- 1 - (Connection of I/O Servers will be bypassed on start-up)

#### Default Value:

0

## See Also

[IOServer Parameters](#)

### [IOServer]BlockWrites

Determines whether Plant SCADA will try to dynamically optimize writes to I/O devices. This includes combining writes to consecutive memory locations into a single large write, and ignoring unnecessary writes to the same memory location (i.e. when the data is the same).

#### Allowable Values:

- 0 - (Turn dynamic write optimization off)
- 1 - (Turn dynamic write optimization on)

#### Default Value:

1

## See Also

[IOServer Parameters](#)

### [IOServer]CacheDebug

Enables/disables I/O Server cache debugging.

*Allowable Values:*

- 0 - (Disable debugging)
- 1 - (Enable debugging)

*Default Value:*

0

## See Also

[IOServer Parameters](#)

### [IOServer]CacheIgnoreDriver

Ignore the request from the protocol driver not to cache the remote I/O device.

#### Allowable Values:

- 0 - (Observe the request)

- 1 - (Ignore the request)

**Default Value:**

0

**See Also**[IOServer Parameters](#)**[IOServer]CacheOptMode**

This parameter is designed to reduce #COMs when using dialup or scheduled devices. The #COM is often a result of how tags are blocked together in the IOServer.

This is the global INI setting. This setting is allowed at a per device level by:

[<unitname>] CacheOptMode = x

By default, the IOServer only searches for tag data requests to be within or equal to a single cached tag set; for example, cache has tag address points 1 to 10, and then 11 to 20, and a request wants addresses 5 to 6, this is permitted. If, however, the request was for items 9 to 11, the system would not return a match and would request a read from the driver. For a disconnected dialup unit, this would cause a #COM or #WAIT.

CacheOptMode values are:

- 1 - First come first served - Tells the IOServer to search through cached points looking for the data, once it is found return.
- 2 - Scan cache for latest entries - Forces the scan to look through cached items to find data which is the MOST recent.
- 4 - An incomplete match is OK - Tells the system that if some items match and some are not found, to consider this OK.
- +8 - Allow behavior on all devices, by default the settings above only apply to remote units.
- +16 - Allow written data not to remove cache item and update value on return, e.g. 1 to 10 in the cache, write to 8. The default behavior would be to remove the whole cache item so that a fresh read of 1 to 10 would be needed on a write to 8. With +16 added, then 1 to 10 stays in the cache, and item 8 would be updated on the REPLY from the driver.

For dialup devices, CacheOptMode=1 covers the majority of needs.

**Allowable Values:**

- 0 - No login
- 1 to 31 - Combination of above values

**Default Value:**

0

## See Also

[IOServer Parameters](#)

### [IOServer]CacheReadAhead

Determines if read ahead caching is enabled on the I/O Server. When read ahead caching is enabled, the I/O Server will try to read any I/O device data which is coming close to cache 'timeout' time. The I/O Server will only read this data if the communication channel to the I/O device is idle - to give higher priority to other read requests.

#### Allowable Values:

- 0 - (Disable read ahead caching)
- 1 - (Enable read ahead caching)

#### Default Value:

1

## See Also

[IOServer Parameters](#)

### [IOServer]CancelTimeout

Determines how long the I/O server will wait on a reply from a driver before giving up and cancelling the request. This timeout can be used to diagnose driver "not responding issues".

#### **WARNING**

##### **UNINTENDED EQUIPMENT OPERATION**

Do not change the [IOServer]CancelTimeout parameter in the Citect.ini file, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

#### Allowable Values:

1 to 1000000 (in seconds)

#### Default Value:

300

## See Also

[IOServer Parameters](#)

### [IOServer]DisableConnectivityPropertiesAndExtensions

The Connectivity Server manages tag subscriptions for the OPC UA Server and the Industrial Graphics Server, and passes these subscriptions on to the I/O servers. The tag may be in the format of either TagName or Equipment.Item.

If a subscribed tag also specifies a property or extension, extra processing is required by the I/O server. The greater the number of I/O devices, the greater the processing load.

If your project does not require properties or extensions for the OPC UA Server or the Industrial Graphics Server, then support for these can be disabled. This will improve the performance of the I/O servers.

This parameter is only available globally and cannot be set per individual I/O server. For consistency in behavior, it is recommended that the INI is applied uniformly across all computers in your system.

---

**Note:** This parameter only applies to subscriptions from the Connectivity Server. It has no relevance to subscriptions made from alarm, trend or report servers, or from Plant SCADA clients or web clients.

---

## Allowable values:

- 0 — properties and extensions are enabled
- 1 — properties and extensions are disabled

## Default Value:

0

## See Also

[IOServer Parameters](#)

### [IOServer]DebugLogTagHandshake

Enables detailed tag handshake logging during tag validation. This allows you to view detailed individual results for each variable tag as they are validated by system checks. The volume of tags that are processed per check request can be configured via the parameter [\[IOServer\]MaxTagHandshakeSize](#).

## Allowable Values:

- 0 - disables detailed tag handshake logging
- 1 - enable detailed tag handshake logging

**Default Value:**

1

**See Also**

[IOServer Parameters](#)

**[IOServer]EnableEventQueue**

Enables the event queue.

To stop events accumulating in the queue, you should use the Cicode function TagEventQueue to read events, as once an event is read it is removed from the queue.

**Allowable values:**

- 0 - disable event queue
- 1 - enable event queue

**Default Value:**

0

**See Also**

[IOServer Parameters](#)

**[IOServer]HeartTime**

The period at which the I/O Server sends out heartbeats (to the clients) on the status of each I/O device.

**Allowable Values:**

2000 to 60000 (milliseconds)

**Default Value:**

60000

**See Also**

[IOServer Parameters](#)

**[IOServer]HWAlarmOnDeviceDisable**

Determines whether hardware alarms for disabled IO devices will be displayed or suppressed.

**Allowable Values:**

- 0 - (Suppress hardware alarms)
- 1 - (Display hardware alarms)

**Default Value:**

1

**Note:**

- On the Plant SCADA machine that is configured as an IOServer and a client, Plant SCADA will display an initial hardware alarm once to indicate that the device has been disabled and its state is offline. This is true if you only disabled the IO device on the IOServer only by calling IODeviceControl(x, 1,1). Plant SCADA will not display additional hardware alarms for disabled devices if the parameter [IOSERVER]HWAlarmOnDeviceDisable = 0 is set.
- On the Plant SCADA machine that is configured as a Control Client only, Plant SCADA will display an initial hardware alarm once to indicate that the device state is offline. Plant SCADA will not display additional hardware alarms for disabled devices if the parameter [IOSERVER]HWAlarmOnDeviceDisable = 0 is set.
- On the Plant SCADA machine that is configured as an IOServer and a Control Client, if you disabled the IO device on both the IO Server and the Plant SCADA Control Client (by calling both IODeviceControl(x, 1,1) and IODeviceControl(x, 0,1)), Plant SCADA will not display an initial hardware alarm for the disabled IO device. Plant SCADA will not display any additional hardware alarms for disabled devices if the parameter [IOSERVER]HWAlarmOnDeviceDisable = 0 is set.

**See Also**

[IOServer Parameters](#)

**[IOServer]InitMsg**

Determines whether communication information is displayed in the Kernel (at startup).

**Allowable Values:**

- 0 - (Disable)
- 1 - (Displays I/O device status at startup)

**Default Value:**

0

## See Also

[IOServer Parameters](#)

### [IOServer]LogTagHandshake

Enables tag handshake logging during tag validation. See also [\[IOServer\]DebugLogTagHandshake](#).

#### Allowable Values:

- 0 - disables tag handshake logging
- 1 - enables tag handshake logging

#### Default Value:

0

## See Also

[IOServer Parameters](#)

### [IOServer]MaxEventsDrop

Sets the number of events that are dropped when too many events become queued.

#### Allowable values:

An integer representing number of events. Value should be a fraction of the integer set for MaxEventsQueued (for example, 10%).

#### Default Value:

30000

## See Also

[IOServer Parameters](#)

### [IOServer]MaxEventsQueued

Sets the maximum number of events that can accumulate in the events queue. If the maximum number events is reached, events will be removed due to queue overflow.

**Allowable values:**

An integer representing number of events. For example an integer between 1000 -1,000 000.

**Default Value:**

300000

**See Also**

[IOServer Parameters](#)

**[IOServer]MaxTagHandshakeSize**

Allows you to set the maximum size of bytes for a tag validation request when handshaking.

**Default Value:**

4096

**See Also**

[IOServer Parameters](#)

**[IOServer]MaxTimeInQueueMs**

Sets the maximum time (in milliseconds) for which an event can be queued before it is timed out.

**Allowable values:**

An integer representing milliseconds. For example any integer between 1000 ms (1 sec) to 86 400 000 ms (1 day).

**Default Value:**

600000

**See Also**

[IOServer Parameters](#)

**[IOServer]PeerServerConnectTimeOut**

Defines the period the I/O Server will attempt to connect to peer I/O Servers before timeout.

I/O Servers are unable to activate any I/O Devices configured as 'Exclusive' = TRUE until this period expires, or the I/O Server has successfully connected to its peer I/O Servers (thus identifying if any of the Peer I/O Servers have activated any I/O Devices).

**Default Value:**

30000

**See Also**

[IOServer Parameters](#)

**[IOServer]RedundancyDebug**

Enables or disables the logging of I/O device redundancy debug messages to syslog.dat.

*Allowable Values:*

- 0 - (Disable debugging)
- 1 - (Enable debugging)

*Default Value:*

0

---

**Note:** You can adjust this parameter during runtime using the SetLogging() function. For more information, search the Plant SCADA Help for the topic *Adjusting Logging During Runtime*.

**See Also**

[IOServer Parameters](#)

**[IOServer]SaveFile**

The indicative name and path of the local I/O device persistence cache files on an I/O Server.

**Allowable Values:**

Any valid directory.

**Default Value:**

The current project directory.

**See Also**

[IOServer Parameters](#)

**[IOServer]SaveNetwork**

The UNC name of the Persistence Cache file on this I/O Server.

**Allowable Values:**

Any valid UNC filename.

**Default Value:**

None

**See Also**

[IOServer Parameters](#)

**[IOServer]StrictTagHandshake**

Enforces that the I/O Server contains a matching OID for every OID on the client.

**Allowable Values:**

- 0 - Disable
- 1 - Unknown tags will cause a mismatch. Client and Server needs to have identical variable databases (for that unit) to be able to communicate.

**Default Value:**

0

**See Also**

[IOServer Parameters](#)

**[IOServer]TagAddressNoCase**

Determines if case-sensitivity needs to be considered when validating tag addresses for the implementation of Object IDs and the variables database.

**Allowable Values:**

- 0 - the comparison must be case sensitive.
- 1 - the comparison will ignore case sensitivity.

**Default Value:**

0

**See Also**[IOServer Parameters](#)**[IOServer]WatchDog**

Determines whether Plant SCADA periodically checks the communication connection to your standby I/O devices.

If you set this parameter to 1, Plant SCADA will check the Standby devices every watch time (as specified by the WatchTime parameter of the device driver). If you set this parameter to 0, this periodic checking is disabled, but Plant SCADA will still communicate with the I/O device on startup to verify that the connection is valid.

**Note:** If you disable periodic checking, you will not receive a hardware error if the standby I/O device becomes inoperative when Plant SCADA is communicating with the Primary.

**Allowable Values:**

- 0 - disables Watch Dog functionality for standby I/O devices
- 1 - enables Watch Dog functionality for standby I/O devices

**Default Value:**

1

**See Also**[IOServer Parameters](#)**[IOServer]WatchDogPrimary**

Determines whether Plant SCADA periodically checks the communication connection to your primary I/O devices. If you set this parameter to 1, Plant SCADA will check the Primary devices every watch time (as specified by the WatchTime parameter of the device driver). If you set this parameter to 0, you will not be notified of a communication error until a read to the device is attempted.

**Note:** If you disable periodic checking, and no read activity is occurring, you will not receive a hardware error if the primary I/O device becomes inoperative.

**Allowable Values:**

- 0 - disables Watch Dog functionality for primary I/O devices
- 1 - enables Watch Dog functionality for primary I/O devices

**Default Value:**

0

**See Also**[IOServer Parameters](#)**IOServer Process Parameters**

Plant SCADA allows you to specify some parameters for an I/O server process (see [Hierarchical Parameters](#) in the Plant SCADA documentation).

The following parameters need to be configured for a specific process.

**Note:** The <server name> is the name of the I/O server as specified in the **Topology** activity.

- [\[IOServer.<ClusterName>.<ServerName>\]Clusters](#) - Sets the clusters that the IO Server process will connect to at startup.
- [\[IOServer.<ClusterName>.<ServerName>\]CPU](#) - Sets the CPU that the IO Server process is assigned to.
- [\[IOServer.<ClusterName>.<ServerName>\]Events](#) - The list of events that this Plant SCADA IO Server process enables.
- [\[IOServer.<ClusterName>.<ServerName>\]ShutdownCode](#) - Determines the Cicode function to run when Plant SCADA IO Server process shuts down.
- [\[IOServer.<ClusterName>.<ServerName>\]StartupCode](#) - Determines the Cicode function to run when Plant SCADA IO Server process starts up.

**See Also**[Parameter Categories](#)[IOServer Parameters](#)**[IOServer.<ClusterName>.<ServerName>]Clusters**

Sets which clusters this IO Server will connect to at startup.

This parameter needs to be defined at the finest level of hierarchical granularity:  
`IOServer.<ClusterName>.<ServerName>Clusters`.

See [Hierarchical Parameters](#) for more information.

**Allowable Values:**

A comma separated list of configured cluster names.

**Default Value:**

If this parameter is blank, the IO Server will connect to every cluster defined for the project.

## See Also

[IOServer Process Parameters](#)

### [IOServer.<ClusterName>.<ServerName>]CPU

This parameter is by Plant SCADA Runtime Manager to determine which CPU(s) the I/O Server process is assigned to. The CPU parameter is configurable for every Plant SCADA process via the **CPU Setup** page in the Computer Setup Wizard (see [CPU Configuration](#)).

This parameter needs to be defined at the finest level of hierarchical granularity:

`IOServer.<ClusterName>.<ServerName>Clusters`. See [Hierarchical Parameters](#) for more information.

CPU numbers are specified in a comma separated list. CPU numbers need to be valid and a subset of the available CPUs on a computer. For example, if there are eight CPUs on a computer, a valid CPU range is 0 to 7.

---

**Note:** If this parameter is modified while the Plant SCADA Runtime Manager is running, the changes will not take effect until every instance of Plant SCADA is restarted.

## Allowable Values:

A comma separated list in the range 0 to 31 (inclusive) where 0 is the first CPU (for example, "0, 1, 2" or "3, 4, 5").

If no value is entered, the process will run on all available CPUs.

---

**Note:** When a process is set to run on all available CPUs, be aware that performance issues may still occur when your CPU usage is less than 100%. You can detect these issues when your CPU usage for a process is fixed at 100 divided by the number of processors.

## Default Value:

No value (the process will run on all CPUs).

---

**Note:** You cannot manually specify CPU assignments on a computer with more than 32 CPUs. Under these circumstances, the Setup Wizard will automatically set this parameter to no value (all CPUs). Any changes you make to this parameter will be overwritten.

## See Also

[IOServer Process Parameters](#)

[\[Client\]CPU](#)

[\[Alarm.<ClusterName>.<ServerName>\]CPU](#)

[\[Report.<ClusterName>.<ServerName>\]CPU](#)

[\[Trend.<ClusterName>.<ServerName>\]CPU](#)

### [IOServer.<ClusterName>.<ServerName>]Events

The list of events that this Plant SCADA IO Server will enable.

This parameter needs to be defined at the finest level of hierarchical granularity:  
`IOServer.<ClusterName>.<ServerName>Clusters`.

See [Hierarchical Parameters](#) for more information.

---

**Note:** This parameter is modified by the Computer Setup Wizard. To set this parameter, we recommend you to enable the required events in the "Events Setup" page of the Computer Setup Wizard (instead of entering the events in the Setup Editor).

---

## Allowable Values:

List of events (comma separated).

## Default Value:

NONE

---

**Note:** When Plant SCADA is running in single process mode only the events assigned to [Client]Events will be enabled. Events specified for particular Plant SCADA components are ignored.

---

## See Also

[IOServer Process Parameters](#)

### [IOServer.<ClusterName>.<ServerName>]ShutdownCode

Can be used to specify a Cicode function that runs at shutdown of the Plant SCADA IO Server component. Plant SCADA suspends the shutdown process until the function has finished running. The function needs to complete execution within the time specified by the [Code]ShutdownTime parameter, otherwise Plant SCADA will terminate it.

This parameter needs to be defined at the finest level of hierarchical granularity:  
`IOServer.<ClusterName>.<ServerName>Clusters`.

See [Hierarchical Parameters](#) for more information.

---

**Note:** This parameter is modified by Computer Setup Wizard.

---

## Allowable Values:

Any built-in or user-written Cicode function, 1-31 alpha-numeric characters.

## Default Value:

NONE

---

**Note:** When Plant SCADA is running in single process mode only the Cicode function assigned to [Client]ShutdownCode will be executed at shutdown. Cicode functions specified for particular Plant SCADA components are ignored.

---

## See Also

[IOServer Process Parameters](#)

### [IOServer.<ClusterName>.<ServerName>]StartupCode

Determines the Cicode function to run when the Plant SCADA IO Server component starts up.

You can only pass constant data to the startup function call. You cannot pass variables or other functions. For example, MyFunc(1, "str") is valid, but MyFunc(PLCTAG, "str") or MyFunc(YourFunc(), "str") is not supported.

This parameter needs to be defined at the finest level of hierarchical granularity:

IOServer.<ClusterName>.<ServerName>Clusters.

See [Hierarchical Parameters](#) for more information.

---

**Note:** This parameter is modified by the Computer Setup Wizard.

## Allowable Values:

Any built-in or user-written Cicode function, 1-31 alpha-numeric characters.

## Default Value:

NONE

---

**Note:** When Plant SCADA is running in single process mode only the Cicode function assigned to [Client]StartupCode will be executed at startup. Cicode functions specified for particular Plant SCADA components are ignored.

## IPC Parameters

IPC stands for Interprocess Communications and is a layer used by Plant SCADA for connections to CtAPI clients and Plant SCADA processes on the same PC. Be aware that not all process to process communication is via this interface.

- [\[IPC\]bPipeToSocket](#) - When set, for local process communications a socket is used instead of a pipe.
- [\[IPC\]EventLogging](#) -Enables logging of the communications between processes.
- [\[IPC\]HeartBeat](#) - Checks if the shared memory connection is still valid and reports an error.
- [\[IPC\]SocketSendTimeout](#) - Time to wait for the status of the last socket write.
- [\[IPC\]SocketShutdownTimeout](#) - Is the time to wait before closing the socket.

## See Also

[Parameter Categories](#)

## [IPC]bPipeToSocket

**Note:** This parameter is designed to assist qualified technical support personnel with system diagnosis.

If this is set TRUE, for local Plant SCADA process communications, a socket is used instead of a pipe. This may be useful for debugging purposes. Only change under direction from Plant SCADA support.

### Allowable Values:

- 1 = True
- 0 = False

### Default Value:

0

### See Also

[IPC Parameters](#)

## [IPC]EventLogging

**Note:** This parameter is designed to assist qualified technical support personnel with system diagnosis.

Enables logging of the communications between processes. Logging goes to ipc.log under the "Logs" directory.

### Allowable Values:

- Off - 0
- Errors - 1
- Warnings -2
- Verbose - 3
- Verbose Plus - 4

The higher the value, the more logging will occur.

### Default Value:

0

### See Also

[IPC Parameters](#)

**[IPC]HeartBeat**

---

**Note:** This parameter is designed to assist qualified technical support personnel with system diagnosis.

Checks if the shared memory connection is still valid and reports the error. Setting this to FALSE means we would find out the connection was lost when we went to use the connection. Only change under direction from technical support.

**Allowable Values:**

- 1 = True
- 0 = False

**Default Value:**

1

**See Also**

[IPC Parameters](#)

**[IPC]SocketSendTimeout**

---

**Note:** This parameter is designed to assist qualified technical support personnel with system diagnosis.

The time in milliseconds to wait for the status of the last socket write.

**Allowable Values:**

- 0 - Wait forever (not recommended)
- 1 to 10000 (milliseconds)

**Default Value:**

500

**See Also**

[IPC Parameters](#)

**[IPC]SocketShutdownTimeout**

---

**Note:** This parameter is designed to assist qualified technical support personnel with system diagnosis.

The time in milliseconds to wait before closing the socket after telling the other end it is to be closed.

**Allowable Values:**

100 to 10000 (milliseconds)

**Default Value:**

1000

**See Also**

[IPC Parameters](#)

**Kernel Parameters****WARNING****UNINTENDED EQUIPMENT OPERATION**

- Do not use the kernel for normal Plant SCADA operation. The kernel is only for diagnostics and debugging purposes.
- Configure your security so that only approved personnel can view or use the kernel.
- Do not view or use the kernel unless you are an expert user of Plant SCADA and Cicode, or are under the direct guidance of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

The Citect.ini file contains the following Kernel parameters:

- [\[Kernel\]AlwaysOnTop](#) - Determines if the Kernel window remains on top of all other windows.
- [\[Kernel\]BufPoolProtect](#) - Enables buffer pool debugging.
- [\[Kernel\]DeltaLateCount](#) - Specifies the number of times the DeltaCheckTask can run late before an entry is logged to the syslog.dat file.
- [\[Kernel\]DeltaLateTime](#) - Specifies the time that is used to determine if the DeltaCheckTask is running late.
- [\[Kernel\]DeltaSleepTime](#) - Determines how often the DeltaCheckTask runs.
- [\[Kernel\]ErrorBuffers](#) - The maximum number of error buffers available for logging to the syslog.dat file.
- [\[Kernel\]ExceptionWatchdog](#) - Determines if the Unhandled exception handler has been reset by a third party dll, and set it back to the Plant SCADA Exception Mailer.
- [\[Kernel\]Idle](#) - Determines how many of the Plant SCADA Kernel tasks to run before releasing the CPU to other Windows programs.
- [\[Kernel\]MaxLateTime](#) - The maximum amount of time kernel tasks can run late (in ms).
- [\[Kernel\]MemoryMinimum](#) - Minimum memory limit for warnings (in KB)
- [\[Kernel\]Queue](#) - The number of Kernel queues.
- [\[Kernel\]Retries](#) - Determines the number of Kernel retries before Runtime is terminated.
- [\[Kernel\]Task](#) - The number of Kernel tasks.

- [\[Kernel\]Watchdog](#) - Determines if the Kernel is working.
- [\[Kernel\]WatchdogTime](#) - Determines the number of seconds between watchdog checks.
- [\[Kernel\]WinShutdown](#) - Determines whether Windows can shutdown while Plant SCADA is running.

## See Also

[Parameter Categories](#)

### [Kernel]AlwaysOnTop

Determines if the Kernel window remains on top of all other windows when displayed on a screen.

This parameter is set to 1 when **Always on Top** is selected in the Kernel's **Options** menu.

#### Allowable Values:

- 0 - Kernel window does not display on top of other windows
- 1 - Kernel window displays on top of all other windows

#### Default Value:

0

## See Also

[Kernel Parameters](#)

### [Kernel]BufPoolProtect

#### UNINTENDED EQUIPMENT OPERATION

- Do not use the Kernel for normal Plant SCADA operation. The Kernel is only for diagnostics and debugging purposes.
- Configure your security so that only approved personnel can view or use the Kernel.
- Do not view or use the Kernel unless you are an expert user of Plant SCADA and Cicode, or are under the direct guidance of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

Enables/disables buffer pool debugging.

#### Allowable Values:

- 1 - (to enable debugging mode)

- 0 - (to disable debugging mode)

**Default Value:**

0

**See Also**

[Kernel Parameters](#)

[\[Kernel\]DeltaLateCount](#)

**WARNING****UNINTENDED EQUIPMENT OPERATION**

- Do not use the kernel for normal Plant SCADA operation. The kernel is only for diagnostics and debugging purposes.
- Configure your security so that only approved personnel can view or use the kernel.
- Do not view or use the kernel unless you are an expert user of Plant SCADA and Cicode, or are under the direct guidance of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

Plant SCADA uses a DeltaCheckTask to monitor long running tasks. This parameter specifies the number of times the DeltaCheckTask can run late before an entry is logged to the syslog.dat file. The time used to determine if the task is running late is specified by the parameter [\[Kernel\]DeltaLateTime](#).

**Allowable Values:**

Any value, but within the recommended range of 1 to 20.

**Default Value:**

4

**See Also**

[Kernel Parameters](#)

[\[Kernel\]DeltaLateTime](#)

**WARNING****UNINTENDED EQUIPMENT OPERATION**

- Do not use the kernel for normal Plant SCADA operation. The kernel is only for diagnostics and debugging purposes.
- Configure your security so that only approved personnel can view or use the kernel.
- Do not view or use the kernel unless you are an expert user of Plant SCADA and Cicode, or are under the direct guidance of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

Plant SCADA uses a DeltaCheckTask to monitor long running tasks. This parameter specifies the time (in milliseconds) that is used to determine if the DeltaCheckTask is running late. If this occurs more times than the value specified for [\[Kernel\]DeltaLateCount](#), then an entry will be logged to the syslog.dat file.

If tasks frequently run late, it is likely that the system is overloaded and it will not be acting on values and information at the right time.

## Allowable Values:

Any value.

## Default Value:

250

## See Also

[Kernel Parameters](#)

[\[Kernel\]DeltaSleepTime](#)

## WARNING

### UNINTENDED EQUIPMENT OPERATION

- Do not use the kernel for normal Plant SCADA operation. The kernel is only for diagnostics and debugging purposes.
- Configure your security so that only approved personnel can view or use the kernel.
- Do not view or use the kernel unless you are an expert user of Plant SCADA and Cicode, or are under the direct guidance of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

Plant SCADA uses a DeltaCheckTask to monitor long running tasks. The delta sleep time determines (in milliseconds) how often the DeltaCheckTask runs.

**Note:** Avoid setting this parameter below 250, otherwise there will be too many false warning messages. Also, if this value is too large, then you will not get any warning messages when the tasks are running significantly late, which could overload the system.

**Allowable Values:**

Any value.

**Default Value:**

250

**See Also**

[Kernel Parameters](#)

[\[Kernel\]ErrorBuffers](#)

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

- Do not use the kernel for normal Plant SCADA operation. The kernel is only for diagnostics and debugging purposes.
- Configure your security so that only approved personnel can view or use the kernel.
- Do not view or use the kernel unless you are an expert user of Plant SCADA and Cicode, or are under the direct guidance of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

Determines the maximum number of error buffers available for logging to the syslog.dat file.

When the number of pending messages to process exceeds this count, these messages are not logged any more. Messages lost in this manner can be monitored in the General Kernel Window as the item "Lost Errors".

**Allowable Values:**

0 to 100,000. However setting this value to 0 will mean that no buffers will be available for logging.

**Default Value:**

1000

**See Also**

[Kernel Parameters](#)

[\[Kernel\]ExceptionWatchdog](#)

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

- Do not use the kernel for normal Plant SCADA operation. The kernel is only for diagnostics and debugging purposes.
- Configure your security so that only approved personnel can view or use the kernel.
- Do not view or use the kernel unless you are an expert user of Plant SCADA and Cicode, or are under the direct guidance of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

When set enables a periodic check that determines if the Unhandled exception handler (the Exception Handler) has been reset by a third party dll, and sets it back to the Exception Mailer.

*Allowable Values:*

- 1 - Enable exception handler watchdog
- 0 - disable exception handler watchdog

*Default Value:*

0

**See Also**

[Kernel Parameters](#)

[\[Kernel\]Idle](#)

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

- Do not use the kernel for normal Plant SCADA operation. The kernel is only for diagnostics and debugging purposes.
- Configure your security so that only approved personnel can view or use the kernel.
- Do not view or use the kernel unless you are an expert user of Plant SCADA and Cicode, or are under the direct guidance of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

Determines how many of the Plant SCADA Kernel tasks to run before releasing the CPU to other Windows programs or other non Kernel activities within Plant SCADA. Plant SCADA will release the CPU if it runs out of its own tasks. If you set this parameter too high, you will reduce CPU resources for other programs running at the same time, and may delay responses to user input.

**Allowable Values:**

1 to 50. However it is recommended that you use the default value.

**Default Value:**

15

**See Also**

[Kernel Parameters](#)

**[Kernel]MaxLateTime****⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

- Do not use the kernel for normal Plant SCADA operation. The kernel is only for diagnostics and debugging purposes.
- Configure your security so that only approved personnel can view or use the kernel.
- Do not view or use the kernel unless you are an expert user of Plant SCADA and Cicode, or are under the direct guidance of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

The maximum amount of time kernel tasks can run late (in ms). The number of consecutive times a task is late.

**Allowable Values:**

Any value.

**Default Value:**

250

**See Also**

[Kernel Parameters](#)

**[Kernel]MemoryMinimum****⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

- Do not use the kernel for normal Plant SCADA operation. The kernel is only for diagnostics and debugging purposes.
- Configure your security so that only approved personnel can view or use the kernel.
- Do not view or use the kernel unless you are an expert user of Plant SCADA and Cicode, or are under the direct guidance of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

Minimum memory limit for warnings (in KB)

### Allowable Values:

Any value, but do not set a value less than 90000, or too many false warnings about low memory condition will be recorded in the syslog file. If the value is too high, the system will run out of memory before a warning is recorded.

### Default Value:

90000

### Keyboard Parameters

The Citect.ini file contains the following keyboard parameters:

- [\[Keyboard\]ButtonOnlyLeftClick](#) - Allows only the left mouse button to "push" buttons in Plant SCADA.
- [\[Keyboard\]ButtonRaw](#) - Puts a string (ASCII character code) into the key command line when a button is pressed.
- [\[Keyboard\]EchoPopUp](#) - Determines whether the keyboard input on a graphical object is echoed in a tips popup.
- [\[Keyboard\]LogExtendedDate](#) - Specifies if the extended date format is used in command log formatting.
- [\[Keyboard\]NonPrint](#) - Enables/disables the display of the non-print character (specified in the [\[Keyboard\]NonPrintChar](#) parameter).
- [\[Keyboard\]NonPrintChar](#) - The ASCII character code to display when a key that does not have a displayable character or Key Name is pressed.
- [\[Keyboard\]Type](#) - The keyboard type.

### See Also

[Parameter Categories](#)

### [Keyboard]ButtonOnlyLeftClick

Determines whether only the left mouse button can press a button object. This parameter has a specific purpose relating to events.

When using events, pressing the right mouse button when over a button object will not call the event handler. To allow a right mouse click to trigger an event when over a button, set this parameter to **1**.

**Allowable Values:**

- 0 - (Allow all mouse buttons)
- 1 - (Allow only the left mouse button)

**Default Value:**

0

**See Also**

[Keyboard Parameters](#)

**[Keyboard]ButtonRaw**

Puts a string (ASCII character code) into the key command line when a button is pressed.

**Allowable Values:**

Any ASCII character (specified in decimal)

**Default Value:**

13

**See Also**

[Keyboard Parameters](#)

**[Keyboard]EchoPopUp**

Determines whether the keyboard input on a graphical object is echoed in a tips popup. This allows keyboard feedback local to the input point. Keyboard commands are echoed to the prompt line regardless of the value of this parameter.

**Allowable Values:**

- 0 - (Do not echo to the popup window)
- 1 - (Echo input to the popup window)

**Default Value:**

1

## See Also

[Keyboard Parameters](#)

### [Keyboard]LogExtendedDate

Determines whether the short (dd/mm/yy) or extended (dd/mm/yyyy) date format is used (in syslog.dat command logs) when interpreting the {DATE,n} log format.

#### Allowable Values:

- 0 - (Use short date format)
- 1 - (Use extended date format)

#### Default Value:

1

## See Also

[Keyboard Parameters](#)

### [Keyboard]NonPrint

Enables/disables the display of the non-print character (specified in the [\[Keyboard\]NonPrintChar](#) parameter). If you enable this parameter, the non-print character will be displayed when the key is pressed. If you disable this parameter, the non-print character will not display.

#### Allowable Values:

- 0 - (Enable)
- 1 - (Disable)

#### Default Value:

0

## See Also

[Keyboard Parameters](#)

### [Keyboard]NonPrintChar

The ASCII character code to display when a key that does not have a displayable character or Key Name is pressed.

**Allowable Values:**

0 to 255

**Default Value:**

63 ("?" character)

**See Also**

[Keyboard Parameters](#)

**[Keyboard]Type**

The keyboard type. Plant SCADA will use keys of this type in the project and keys of (default) type 0 for all commands. If the same keys are defined for type 0 and another keyboard type set by this parameter, then the key defined first in the project will execute. Keys of other types are ignored. Type 0 is used for all keyboards.

**Allowable Values:**

0 to 255

**Default Value:**

0

**See Also**

[Keyboard Parameters](#)

**LAN Parameters**

The Citect.ini file contains the following LAN parameters:

- [\[LAN\]AddressScope](#) - Enables the address scope types for IPv6 addresses.
- [\[LAN\]AddressType](#) - Enables support for IPv4 or IPv6 network types.
- [\[LAN\]AllowLegacyConnections](#) - Obsolete in v7.20.
- [\[LAN\]AllowRemoteReload](#) - Enables remote reloading of servers from a client.
- [\[LAN\]BackOffTime](#) - The time that Plant SCADA will back-off trying to send a message if the message pool is full.
- [\[LAN\] Bridge](#) - Obsolete in v7.0.
- [\[LAN\]CancelOnClose](#) - Obsolete in v7.0.
- [\[LAN\]ClientRetryTime](#) - Sets the amount of time between connection attempts by the client.
- [\[LAN\]ConnectionLogging](#) - Provides for additional traces at connection time for Plant SCADA legacy

connections.

- [\[LAN\]Delay](#) - The period (in milliseconds) to wait to optimize a send message - before sending the message.
- [\[LAN\]Disable](#) - Obsolete in v7.0.
- [\[LAN\]EarliestLegacyVersion](#) - Specify the minimum legacy version from which the current version will accept connections.
- [\[LAN\]GroupName](#) - Obsolete in v7.0.
- [\[LAN\]HeartbeatPeriod](#) - Controls how frequently a tran channel sends a heartbeat packet to the other peer.
- [\[LAN\]HeartbeatTimeout](#) - Controls how much idle time on network is accepted prior to dropping the tran connection.
- [\[LAN\]HighWaterMark](#) - Sets the number of messages waiting to be sent on a particular network connection at which the high water mark event will occur.
- [\[LAN\]KeepAliveInterval](#) - Obsolete in v2015.
- [\[LAN\]KeepAliveTime](#) - Obsolete in v2015.
- [\[LAN\]KillPiggyBackAck](#) - Obsolete in v7.0.
- [\[LAN\]LanA](#) - Obsolete in v7.0.
- [\[LAN\]ListenerRetryTime](#) - The amount of time a server will wait between attempts to listen for a connection.
- [\[LAN\]LocalNet](#) - Improves the performance of cluster switching on a client which is also a server.
- [\[LAN\]LowWaterMark](#) - After the high water mark has been reached on a particular network connection, the low water mark represents the number of messages waiting to be sent at which normal operations will resume
- [\[LAN\]NetBIOS](#) - Obsolete in v7.0.
- [\[LAN\]NetTrace](#) - Obsolete in v7.0.
- [\[LAN\]NetTraceBuf](#) - Obsolete in v7.0.
- [\[LAN\]NetTraceErr](#) - Obsolete in v7.0.
- [\[LAN\]NetTraceLog](#) - Obsolete in v7.0.
- [\[LAN\]Node](#) - The name of this Plant SCADA computer.
- [\[LAN\]Poll](#) - Obsolete in v7.0.
- [\[LAN\]ReadOnlyLegacyConnections](#) - Set to allow legacy v7.10 clients to communicate in read-only mode.
- [\[LAN\]ReadPool](#) - The number of receive message buffers used by Plant SCADA.
- [\[LAN\]RemoteTimeOut](#) - Obsolete in v7.0.
- [\[LAN\]Retry](#) - Obsolete in v7.0.
- [\[LAN\]SendTimeout](#) - Obsolete in v7.0.
- [\[LAN\]ServerLoginEnabled](#) - Obsolete in v7.20.
- [\[LAN\]SesRecBuf](#) - Obsolete in v7.0.
- [\[LAN\]SesSendBuf](#) - Obsolete in v7.0.
- [\[LAN\]Sessions](#) - The maximum number of connections across the LAN, i.e. servers x clients.
- [\[LAN\]SocketNoDelay](#) - Switches off the delay on a socket caused by the Nagle algorithm.
- [\[LAN\]TCPIP](#) - Enables the support of TCP/IP protocol.
- [\[LAN\]TimeOut](#) - Obsolete in v7.0.
- [\[LAN\]WaitBufTime](#) - The time Plant SCADA waits for a write message buffer before aborting the session.

- [\[LAN\]WritePool](#) - The maximum number of send message buffers used by Plant SCADA.

## See Also

[Parameter Categories](#)

### [LAN]AddressScope

When using an IPv6 network, this parameter enables the computer to support address scopes that are Global, Link-Local, or both.

IPv6 support can be enabled via the **Network Model** page of the Setup Wizard.

## Allowable Values:

- 0 - (Only Global)
- 1 - (Only Link-Local)
- 2 - (Both Global and Link-Local)

## Default Value:

0

## See Also

[LAN Parameters](#)

[\[LAN\]AddressType](#)

### [LAN]AddressType

This parameter enables support for IPv4, IPv6, or both for network connections between servers and clients. It helps reduce the number of open connections for the computers.

IPv6 support can be enabled via the **Network Model** page of the Setup Wizard.

## Allowable Values:

- 0 - (Only IPv4)
- 1 - (Only IPv6)
- 2 - (Both IPv4 and IPv6)

## Default Value:

0

## See Also

[LAN Parameters](#)

[\[LAN\]AddressScope](#)

### [LAN]AllowRemoteReload

This parameter provides the ability to remotely reload server processes from a client. A valid user needs to be logged in as the client to remotely reload.

## Allowable Values

- 0 - Reload can only be issued locally
- 1 - Reload can be issued locally and remotely

## Default Value:

0

## See Also

[LAN Parameters](#)

### [LAN]BackOffTime

The time that Plant SCADA will back-off trying to send a message if the message pool is full. This back-off time allows the receiver time to process messages already in the queue.

## Allowable Values:

0 to 1000 (milliseconds)

## Default Value:

1

## See Also

[LAN Parameters](#)

### [LAN]ClientRetryTime

Sets the amount of time between connection attempts by a client.

## Allowable Values

Length of time in milliseconds

### Default Value:

5000

## See Also

[LAN Parameters](#)

### [LAN]ConnectionLogging

This setting provides for additional traces at connection time for Plant SCADA legacy connections, i.e. Server to Server connections, CtAPI to Server. Traces also occur at disconnection.

This setting may be useful in diagnosing connection problems.

---

**Note:** Logging is to the Syslog.dat

---

## Allowable Values

- 0 - No additional traces at connection time
- 1 - Enable additional traces at connection time

### Default Value:

0

## See Also

[LAN Parameters](#)

### [LAN]Delay

The period (in milliseconds) to wait to optimize a send message - before sending the message. Plant SCADA will hold back the message for this delay time, so if another message is to be sent, it can be sent in the same network packet. This parameter adds a small delay, but it can reduce network traffic significantly, and so make the total response time faster.

## Allowable Values:

0 to 2000 (milliseconds)

**Default Value:**

10

**See Also**

[LAN Parameters](#)

**[LAN]EarliestLegacyVersion**

Specify the minimum legacy version from which the current version will accept connections.

Connection attempts from processes which are on or above the specified value will be accepted.

Connection attempts from processes which are below the specified value will be denied. The established connection will only be as secure as the earlier of the two connected versions.

The value for this parameter is created using the following formula:

(Product Major Version x 1000) + (Product Minor Version x 10)

For example, for version 8.20, use (8x1000) + (20x10) = 8200

---

**Note:** When using this parameter as part of an online upgrade, only 8100 (and later) is supported. When the online upgrade is complete, you should clear the setting.

**Allowable Values:**

8100 — 8500

**Default Value:**

8500

**See Also**

[LAN Parameters](#)

**[LAN]HeartbeatPeriod**

Heartbeat parameters are used to detect bad tran connections caused by unstable network or equipment failures. The heartbeat parameters do this by exchanging heartbeat messages periodically. For example, a connection between a Plant SCADA client and server may be idle if there are no requests and no tag value updates sent.

The heartbeat packet is a probe designed to elicit a response from the other process to communicate with. If the remote process is reachable and functioning, the remote process acknowledges the heartbeat transmission by returning an acknowledgment packet. If the remote process has stopped, or is unable to respond, this situation will be detected by the local peer by monitoring packets from the remote peer in order to drop the tran channel.

It does not exchange heartbeat messages when there are other valid messages on the channel to avoid unnecessary network data.

This parameter controls how frequently a tran channel sends a heartbeat packet to the other peer.

Lowering the value for HeartbeatPeriod lets the process have less interval between heartbeat packets so that the network problem detection can speed up by configuring shorter [LAN]HeartbeatTimeout value. However, it also increases the network activity on idle connections. Conversely, increasing the value for this parameter will slow down the health checking but decrease the activity on idle connections.

---

**Note:** In order to keep network failures detected in under 5 seconds, the TCPIP socket keep alive, as a parallel mechanism, has been reinstated. This mechanism is very reliable under load as it is monitored by the TCPIP layer itself. The Keep Alive Period and Keep Alive Timeout for the TCPIP socket has been set to the value of the corresponding [LAN] parameters, divided by 5, for faster detection. This means by default the period will be 1 second and the timeout will be 3 seconds, which matches the default of the keep alive in previous versions.

---

## Allowable Values

1 – 2147483647

Length of time in milliseconds. 0 means no heartbeat message will be sent to the other peer.

## Default Value:

5000 (5 seconds)

## See Also

[LAN Parameters](#)

### [LAN]HeartbeatTimeout

Heartbeat parameters are used to detect bad tran connections caused by unstable network or equipment failures. The heartbeat parameters do this by exchanging heartbeat messages periodically. For example, a connection between a Plant SCADA client and a server could be idle for a while if there are no requests and no tag value updates sent. The heartbeat packet is a probe designed to elicit a response from the other process to communicate with. If the remote process is reachable and functioning, the remote process acknowledges the heartbeat transmission by returning an acknowledgment packet. If the remote process has stopped, or is unable to respond, this situation will be detected by the local peer by monitoring packets from the remote peer in order to drop the tran channel.

To avoid unnecessary network data, heartbeat messages will not be exchanged when there are other valid messages on the channel.

This parameter controls how long the network may be idle prior to dropping the tran connection. In lowering the value for HeartbeatTimeout the process may speed up network problem detection. However, it could also lead to drops in connection due to momentary problems. Conversely, increasing the value for this parameter will slow down the health checking but the process will be able to ignore momentary issues.

---

**Note:** In order to keep network failures detected in under 5 seconds, the TCPIP socket keep alive, as a parallel mechanism, has been reinstated. This mechanism is very reliable under load as it is monitored by the TCPIP layer itself. The Keep Alive Period and Keep Alive Timeout for the TCPIP socket has been set to the value of the corresponding [LAN] parameters, divided by 5, for faster detection. This means by default the period will be 1 second and the timeout will be 3 seconds, which matches the default of the keep alive in previous versions.

---

## Allowable Values

1 – 2147483647

Length of time in milliseconds. 0 means no drop will happen.

## Default Value:

15000 (15 seconds)

## See Also

[LAN Parameters](#)

### [LAN]HighWaterMark

Sets the number of messages waiting to be sent on a particular network connection at which the high water mark event will occur. When the high water mark is reached, a hardware alarm will be raised. If this occurs on a connection made to the IO Server, the IO Server will suspend value updates being sent to subscriptions until the low water mark has been reached.

If this hardware alarm occurs irregularly (e.g.if there is a spike of activity in a large system) it may indicate that the value of this parameter needs to be increased for this system.

If this hardware alarm occurs regularly, it may indicate there is a problem with the network or with the performance of the server from which the connection has been made. It can also indicate that more value changes are occurring then the system can deal with. The deadbands of some of the variable tags may need to be increased to reduce the number of value changes in the system, or the sample period of the trends or alarm scan time may need to be increased to reduce the number of polls made to the IODevices.

---

**Note:** If this parameter is set to a value less than or equal to [\[LAN\]LowWaterMark](#) both of these parameters will be ignored and the system will operate at the default values.

---

## Allowable Values

1 to 2147483647

## Default Value

80000

## See Also

[LAN Parameters](#)

### [LAN]LocalNet

Improves the performance of cluster switching on a client which is also a server.

Using the Cicode function ClusterSetName, a client can switch from displaying information from one Plant SCADA server to display information from another Plant SCADA cluster server. If you want to do this on a client which is also a server, set this parameter to 1.

This enables direct communication between client and server, bypassing the network stack, and improving performance on a local connection. With this parameter set to 0, Plant SCADA establishes client/server communication via the network stack, even when the client and server are on the same computer.

## Allowable Values

- 0 Establish communication via network stack
- 1 Establish communication via Plant SCADA local network

## Default Value:

1

## See Also

[LAN Parameters](#)

### [LAN]LowWaterMark

After the high water mark has been reached on a particular network connection, the low water mark represents the number of messages waiting to be sent at which normal operations will resume.

If this occurred on an I/O Server, on returning to the low water mark, the I/O server will send the latest value for tags whose values have changed since the high water mark was reached and then value updates will resume.

**Note:** If this parameter is set to a value greater than or equal to [LAN]HighWaterMark both of these parameters will be ignored and the system will operate at the default values.

## Allowable Values

1 to 2147483647

## Default Value

20000

## See Also

[LAN Parameters](#)

### [LAN]ListenerRetryTime

Specifies the amount of time a server will wait before retrying to start listening on the configured IP Address and TCP Port number.

In a certain cases the configured Plant SCADAServer IP Address and Port Number may not be available for the server to start listening and accepting client connections. For example if the same IP Address and Port Number is already used by another process or the IP Address is not present on any network interface of the machine or if the network card has been unplugged. In these cases, the Plant SCADAServer will start running and in the background it will asynchronously keep trying to start listening and accepting connections on the configured IP Address and Port Number. The interval of time between two attempts to start listening and accepting connections is determined by this parameter.

As soon as the configured IP Address and Port Number are available, the Server will start listening and accepting client connections. It is recommended to configure a Server IP Address and Port Number which are available and not used by another process on the same machine.

## Allowable Values

Length of time in milliseconds

1 - 2147483647

## Default Value:

5000

## See Also

[LAN Parameters](#)

## [LAN]Node

The name of this Plant SCADA computer. Each computer should have a unique name. This name is used by the MsgOpen() function to identify each computer.

If you leave the computer name blank, Plant SCADA sets the computer name to the same name as the Windows Computer Name (as set up in the Network section of the Windows Control Panel).

**Note:** This parameter is modified by the Computer Setup Wizard as well as the Computer Setup Editor.

## Allowable Values:

Any valid computer name

## Default Value:

Unknown

## See Also

[LAN Parameters](#)

## [LAN]ReadOnlyLegacyConnections

Set to allow connections from legacy versions to v7.20 in read-only mode. This parameter is used only if "[LAN]EarlierLegacyVersion" is enabled.

### Allowable Values

- 0 - No read only legacy client connections
- 1 - Read-only legacy client connections are enabled

### Default Value:

0

### See Also

[LAN Parameters](#)

## [LAN]ReadPool

The number of receive message buffers used by Plant SCADA. If you get the error message "Out of buffers" on a server or LAN device, increase this parameter. You might also see the message in the Plant SCADA Kernel or the SYSLOG.DAT file, "Out of buffers lan.read.pool" - if so, increase this parameter.

You should only need to increase this value if you have a large, heavily loaded network system (typically greater than 10 Plant SCADA clients, with greater than 10,000 I/O points). If you have a smaller system and you are getting the above errors, you could have a problem with your LAN hardware or configuration.

### Allowable Values:

16 to 32760

### Default Value:

1024

### See Also

[LAN Parameters](#)

## [LAN]Sessions

The maximum number of connections across the LAN, i.e. servers x clients. If you get an "Out Of Sessions" or "Out of Msg Instance, Increase[LAN]Sessions" error, increase the value of this parameter.

A Plant SCADA client uses 3 sessions for the servers (Alarms, Trends, Reports) + 1 session for each of your I/O Servers, so the default parameter setting is good for Clients.

A Server uses 1 session for each client attached, for each type of server it is. So if a computer is a Alarms, Trends, Reports, and I/O Server and you have 20 clients, the server uses  $4 \times 20 = 80$  sessions. You should also allow 50% extra sessions, because during a redundant changeover you get an extra peak loading. So in the example, allow a total of  $80 + 40 = 120$  sessions.

### Allowable Values:

16 to 4000

### Default Value:

128

### See Also

[LAN Parameters](#)

### [LAN]SocketNoDelay

Switches off the delay on a socket caused by the Nagle algorithm.

A Nagle algorithm is used to buffer packets for up to 200 milliseconds so that they can be combined and sent as a single packet. This results in larger, but less frequent, packet transmission which generally provides more efficient network bandwidth utilization.

### Allowable Values

- 0 - use the Nagle algorithm
- 1 - disable the Nagle algorithm

### Default Value:

1

### See Also

[LAN Parameters](#)

### [LAN]TCPIP

Enables support for TCPIP network connections between Servers and Clients. TCPIP should be enabled for any Station which will connect to any other Station.

### Allowable Values:

- 0 - (Disable TCP/IP protocol)

- 1 - (Enable TCP/IP protocol)

**Default Value:**

0

**See Also**

[LAN Parameters](#)

**[LAN]WaitBufTime**

The time Plant SCADA waits for a write message buffer before aborting the session. Note that this wait is a hard wait - Plant SCADA hangs while it waits for this buffer - so be careful if you use this parameter.

**Allowable Values:**

0 to 30000 (milliseconds)

**Default Value:**

20

**See Also**

[LAN Parameters](#)

**[LAN]WritePool**

The maximum number of send message buffers used by Plant SCADA. If you get the error message "Out of buffers" on a server or LAN device, increase this parameter. You might also see the message in the Plant SCADA Kernel or the SYSLOG.DAT file, "Out of buffers lan.write.pool" - if so, increase this parameter.

You should only need to increase this value if you have a large, heavily loaded network system (typically greater than 10 Plant SCADA clients, with greater than 10,000 I/O points). If you have a smaller system and you are getting the above errors, you could have a problem with your LAN hardware or configuration.

**Allowable Values:**

16 to 32760

**Default Value:**

1024

## See Also

[LAN Parameters](#)

### Language Parameters

Define whether Plant SCADA recognizes differences in case in text marked for automatic language change.

- [\[Language\]CaseSensitive](#) - Determines whether text in the language database is treated as case-sensitive.
- [\[Language\]CharSet](#) - Defines the character set to be used when the LOCAL translation is displayed at runtime.
- [\[Language\]ClientTranslateFile](#) - Determines whether translation of ASCII reports is governed by the client or the Reports Server.
- [\[Language\]CodePage](#) - Determines the codepage to be used when printing database records.
- [\[Language\]DisplayError](#) - Defines whether or not an error message will display when a local translation of a native string cannot be found in the language database.
- [\[Language\]LocalLanguage](#) - Determines the default language used for runtime text items such as alarm descriptions, button text, keyboard/alarm logs, graphic text, Cicode strings and so on.
- [\[Language\]LocalLanguageOnly](#) - Determines whether or not the language drop down list will be displayed on the login form.
- [\[Language\]SuppressWarningUnsupported](#) - Allows suppression of a compiler warning message about unsupported languages.

## See Also

[Parameter Categories](#)

### [Language]CaseSensitive

Determines whether text in the language database is treated as case sensitive. If this value is set to case sensitive, strings that differ only in case will require different local language entries in the language database, and will therefore return a different local translation at runtime.

---

**Note:** This parameter does not apply to Alarm strings. Alarm strings are always case sensitive.

---

#### Allowable Values:

- 0 - (Not case sensitive)
- 1 - (Case sensitive)

#### Default Value:

0

## See Also

[Language Parameters](#)

### [Language]CharSet

Defines the character set to be used when the LOCAL translation is displayed at runtime. If you do not specify this parameter, the runtime text may be garbled (if the local language character set differs from the default character set of the Windows installation).

Definition: Charset: Stands for "character set." A set of characters used in Windows.Charsets refer to the same collections of characters as those defined by Windows code pages.

## Allowable Values:

- 0 - ANSI ASCII
- 1 - System Default Character Set
- 128 - Japanese - Shift JIS
- 129 - Korean - Hangul
- 130 - Korean - Johab
- 134 - Chinese - simplified GB2312
- 136 - Chinese - traditional Big5
- 161 - Greek
- 162 - Turkish
- 163 - Vietnamese
- 177 - Hebrew
- 178 - Arabic
- 186 - Baltic
- 204 - Russian
- 222 - Thai
- 238 - East European

## Default Value:

1

## See Also

[Language Parameters](#)

### [Language]ClientTranslateFile

Specifies whether the Reports Server is used for translating reports containing multi-language text. If the Reports

Server does not translate a report, the client viewing the report must use the LanguageFileTranslate() function to perform translation.

---

**Note:** This parameter is used by the Reports Server. It applies only to reports configured using ASCII devices. Any other logging device will have the report translated into the local language of the Reports Server - regardless of the value of this parameter.

For example, a system has one Reports Server and one client. German is set as the local language on the Reports Server, and French on the client.

If [Language]ClientTranslateFile is set to 0 (zero), when the report is run, the Reports Server will produce the report with German translation.

If [Language]ClientTranslateFile is set to 1 (one), the Reports Server will produce the report untranslated - still containing the @( ) formatting.

To display the report on the client - in French - the LanguageFileTranslate() Cicode function must be used to perform the translation.

## Allowable Values:

- 0 - (Reports Server translates reports)
- 1 - (Reports Server does not translate reports)

## Default Value:

0

## See Also

[Language Parameters](#)

### [Language]CodePage

Defines the codepage to be used when printing database records.

Definition: Code page: An ordered set of characters of a given script in which a numeric index (code-point value) is associated with each character. This term is generally used in the context of code pages defined by Windows and can also be called a "character set" or "charset".

In the newer components of our SCADA software, more particularly the Process Analyst, the displayed texts are managed by using the Unicode standard of specifying characters.

Within the Microsoft OS, conversion facilities are routinely used between coding standards to access Microsoft's own legacy components. Part of the reason is a need for backwards compatibility for older files or programs.

### Background Information

Code pages are a carryover from pre-Unicode days, (Pre 2000) but they are still deeply embedded in many current softwares including our SCADA.

Code Pages 1250 through 1258 are commonly called the ANSI code pages.

The ANSI name is actually a misnomer they are actually Windows code pages. They are the Microsoft implementation of an early ANSI specification. They benefit from providing consistent mapping of identical characters between their languages.

The non proprietary code pages (real ANSI) became ISO 8859-1 through 16.

The frequently mentioned OEM code page usually refers to the Windows OEM Code page CP437 originating from DOS-7 days. It is still used internally in the Windows Operating System, eg..the Win32 Console; a legacy design that primarily supports US English.

The Chinese, Korean and Japanese double byte code pages are also regarded to be Microsoft OEM.

The single byte Vietnamese CP1258 and Thai CP874 code pages are spoken of as being ANSI as well as OEM.

## Allowable Values:

### SBCS (Single Byte Character Set) Codepages

- 1250 Windows Latin II (Central Europe)
- 1251 Windows (Cyrillic)
- 1252 Windows Latin I (ANSI, Western European)
- 1253 Windows (Greek)
- 1254 Windows Latin V (Turkish)
- 1255 Windows (Hebrew)
- 1256 Windows (Arabic)
- 1257 Windows (Baltic)
- 1258 Windows (Vietnam)
- 874 Windows (Thai)

### DBCS (Double Byte Character Set) Codepages

- 932 (Japanese Shift-JIS)
- 936 (Simplified Chinese GBK)
- 949 (Korean)
- 950 (Traditional Chinese Big5)

## Default Value:

The default language CodePage setting is 1252 Latin I.

1252 Latin I (Western European) is also known, correctly as Windows 1252, commonly called ANSI.

It can render US/UK English, French, Danish, German, Italian, Norwegian, Portuguese, Spanish, Swedish, and several others eg. Basque, Galician, Catalan, Malay.

## See Also

[Language Parameters](#)

### [Language]DisplayError

Defines whether or not an error message (#MESS) will display when a local translation of a particular native

string cannot be found in the language database. If you decide not to display the error message, the native string will display at runtime instead.

### Allowable Values:

- 0 - (Display the native text)
- 1 - (Display error message #MESS)

### Default Value:

0

### See Also

[Language Parameters](#)

#### [Language]LocalLanguage

Sets the language database from which the local translations of all native strings in the project will be drawn when the project is run. Native strings are those that are preceded by a @, and enclosed in brackets (e.g. @(Motor Overload)). It determines the language of runtime text items such as alarm descriptions, button text, keyboard/alarm logs, graphic text, Cicode strings etc.

This INI parameter's behaviour has changed from that of 7.20. It is no longer used to switch the language; instead use this parameter to set the default language during startup.

If this parameter is included in the Citect.ini, the language specified needs to be a language defined in the **Languages** view in Plant SCADA Studio's **Setup** activity. If not specified, English will be the default.

Be aware that neutral languages (for example, "French") and region-specific variations (for example, "French (Belgium)") will generate and use their own language database ("French.dbf" and "French(Belgium).dbf"). You cannot refer to a regional variation of a language using just the neutral language name.

Additionally, if a language is not officially supported by Plant SCADA as a native language, but is supported by Windows, before setting it in the [Language]LocalLanguage section or on user login, the language also needs to be added to the Languages view. For instance, if using traditional Chinese, the following string needs to be added: Chinese(Traditional)(Taiwan).

---

**Note:** The **Languages** view should contain every language that will be used at Runtime. If you make any changes to the list of defined languages, you will need to compile your project and restart Runtime.

---

### Allowable Values:

Any string that is defined in the language DBF file which can be recognized by Windows.

### Default Value:

English

---

**Note:** If you change this parameter after or during project configuration, you need to perform an Update Pages

---

---

operation (from the Graphics Builder), followed by a full re-compile of the project.

---

## See Also

[Language Parameters](#)

### [Language]LocalLanguageOnly

Determines whether or not the language drop down list will be displayed on the login form.

#### Allowable Values:

- 0 - language drop-down list displays
- 1 - language drop-down list does not display

#### Default Value:

0

## See Also

[Language Parameters](#)

### [Language]SuppressWarningUnsupported

Allows suppression of the compiler warning message "The specified language is not supported".

#### Allowable Values:

- 0 - The warning message is not suppressed.
- 1 - The warning message is suppressed.

#### Default Value:

0

## See Also

[Language Parameters](#)

### Memory Parameters

The Citect.ini file contains the following memory parameters:

- [\[Memory\]Free](#) - Frees memory for other Windows applications when it is not being used by Plant SCADA.
- [\[Memory\]MinPhyK](#) - Sets the minimum physical memory before Plant SCADA generates the error message "Plant SCADA Runtime low on Physical memory" and the hardware alarm "Low physical memory".
- [\[Memory\]PageLock](#) - Determines whether Plant SCADA locks the memory it uses.
- [\[Memory\]Segment](#) - Controls how Plant SCADA allocates memory from Windows.

## See Also

[Parameter Categories](#)

### [Memory]Free

Frees memory for other Windows applications when it is not being used by Plant SCADA. Plant SCADA reuses memory when it is required, but other Windows applications cannot use memory unless it is free.

#### Allowable Values:

- 0 - (Do not free until shutdown)
- 1 - (Free memory when not in use)

#### Default Value:

1

## See Also

[Memory Parameters](#)

### [Memory]MinPhyK

Sets the minimum physical memory before Plant SCADA generates the error message "Plant SCADA Runtime is low on Physical memory" and the hardware alarm "Low physical memory".

The way Windows calculates the available free memory can be unreliable under some conditions. The error message can display when you do in fact have enough free physical memory, and you might want to disable this error by setting this parameter to 0. However, you should check that you really do have enough free memory to run Plant SCADA before disabling this parameter - running out of memory can cause a severe degradation in system performance.

You should also use an 8 MB persistent swap file to give you some virtual memory. Be aware that if you use temporary memory or a large virtual memory setting, the memory check is unreliable.

#### Allowable Values:

0 (disable) to 300

**Default Value:**

300

**See Also**

[Memory Parameters](#)

**[Memory]PageLock**

Determines whether Plant SCADA locks the memory it uses. Locking memory can cause Windows to abort with a paging error.

**UNINTENDED EQUIPMENT OPERATION**

Do not change the [Memory]PageLock parameter in the Citect.ini file, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Allowable Values:**

- 0 - (Do not lock memory)
- 1 - (Lock memory and do not page to disk)

**Default Value:**

0

**See Also**

[Memory Parameters](#)

**[Memory]Segment**

Controls how Plant SCADA allocates memory from Windows. If you set this parameter to 1, Plant SCADA allocates memory in 64K segments - a faster and more efficient use of memory. If you set this parameter to 0, Plant SCADA allocates many small blocks of memory. Do not disable this parameter unless advised by Technical Support for this product.

**UNINTENDED EQUIPMENT OPERATION**

Do not change the [Memory]Segment parameter in the Citect.ini file, except on the advice of Technical

Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

## Allowable Values:

- 0 - (Allocate as required)
- 1 - (Allocate memory in 64K segments)

## Default Value:

1

## See Also

[Memory Parameters](#)

## MultiMonitor Parameters

The [MultiMonitors] section contains the following parameters:

## Common Parameters

- [\[MultiMonitors\]DisableAutoStart](#) - Disables the MultiMonitor functionally.
- [\[MultiMonitors\]Monitors](#) - Indicates the number of monitors the project will be displayed on.
- [\[MultiMonitors\]ScreenProfile](#) - Sets the arrangement of monitors on a client workstation.
- [\[MultiMonitors\]StartupPage<n>](#) - Determines the pages that appear when starting up a multi monitor setup.
- [\[MultiMonitors\]StartupPage<Name>](#) - Sets the pages that appear when using a particular screen profile.

## Situational Awareness Parameters

- [\[MultiMonitors\]Context<n>](#) - Allows you to share a single context with one or more screens.
- [\[MultiMonitors\]Workspaces](#) - Indicates the number of workspace pages to be shown at startup.

## See Also

[Parameter Categories](#)

### [MultiMonitors]Context<n>

Allows you to share a single context with one or more screens.

**Note:** This parameter is only valid for Situational Awareness projects.

**Allowable Values:**

Any valid context name.

**Default:**

None

The value assigned to the context is comprised of two parts:

- Node name from the navigation hierarchy
- Name of the screen

For example, Context1 = MyPlant.Area1:Primary. This will display details from Area 1 of MyPlant on the primary screen. If you wish to display the same information on a second monitor, you can add Context2 = MyPlant.Area1:Screen2. Both screens will then display the same content, but are independent of each other. You can also choose different views for each monitor by configuring screens to display different content. For example, Context1=MyPlant.Area1:Screen1, Context2=MyPlant.Area2:Screen2 and Context3=MyPlant.Area3:Screen3. In this case, each screen displays content independently.

When you link contexts, only one object can be selected between the two contexts. Linked contexts can be used to display different content for the same object based on the selection. For example, For example, Context1=MyPlant.Area1:Screen1, Screen2. Here, one screen can be used to display the graphics page with a particular equipment from the specified location while the second one can be used to display the Information Pane. The content in the Information pane will be updated for display as and when the selected equipment's state changes.

**See Also**

[MultiMonitor Parameters](#)

**[MultiMonitors]DisableAutoStart**

Used to stop the MultiMonitor functionality from being loaded automatically at startup.

---

**Note:** Use the MultiMonitorStart() Cicode function to load the MultiMonitor function if required

**Allowable Values:**

- False (0)- Enable startup loading of Multimonitor functionality
- True (1)- Disable startup loading of Multimonitor functionality

**Default Value:**

False (0)

## See Also

[MultiMonitor Parameters](#)

### [MultiMonitors]Monitors

Indicates the number of monitors configured for the project.

**Note:** This parameter is ignored if the [\[MultiMonitors\]ScreenProfile](#) parameter is used.

---

## Allowable Values:

1 to 8.

## Default Value:

1

## See Also

[MultiMonitor Parameters](#)

### [MultiMonitors]ScreenProfile

Sets the arrangement of monitors on a client workstation for a project.

## Allowable Values:

Any valid screen profile name

## Default:

None

## See Also

[MultiMonitor Parameters](#)

### [MultiMonitors]StartupPage<Name>

Determines the page that appears on the monitor that corresponds to the screen named "Screen1" in the screen profile.

On start up, Plant SCADA will compare the physical monitors on the workstation to the screens in the screen profile and attempt to map screens to monitors based on the resolution and relative position to the primary monitor/screen. If a physical monitor cannot be found, for example it has failed or been disconnected or the

configuration is incorrect, that screen will be mapped to the primary monitor. So, you may have multiple pages displayed on the primary monitor.

---

**Note:** If you don't specify a startup page for a monitor in the Setup wizard, any startup page setting in the Citect.ini file will be replaced by ><. This overrides the configuration of a monitor set up with a page in the Parameters database.

---

### Allowable Values:

Any valid page name

### Default Value:

No default. However, if no value has been specified for any of the screens, the page specified by the [\[Page\]Startup](#) parameter will be shown on the primary screen only.

### See Also

[MultiMonitor Parameters](#)

## [MultiMonitors]StartupPage<n>

Determines the pages that appear when starting up a multi monitor setup. For example, StartupPagePrimary determines the page that appears on the first monitor at startup, StartupPage1 (the name you have assigned to the parameter) determines what appears on the second monitor, and so on.

### Allowable Values:

Any valid page name

### Default Value:

If left blank, the page specified in parameter [\[Page\]Startup](#).

### See Also

[MultiMonitor Parameters](#)

## [MultiMonitors]Workspaces

Indicates the number of workspace pages that are shown. This parameter is only relevant when using Situational Awareness workspaces.

---

**Note:** If the number specified is incorrect (value too low), the Workspace functionality may not work as expected, or there may be a delay before workspaces are initialized (value too high).

---

**Allowable values:**

Values between 1 to 20

**Default:**

1

**See Also**

[MultiMonitor Parameters](#)

**ODBC Parameters**

The Citect.ini file contains the following ODBC parameter:

- [\[ODBC\]Server](#) - Enables a Plant SCADA ODBC server on the local computer.

**See Also**

[Parameter Categories](#)

**[ODBC]Server**

Enables a Plant SCADA ODBC server on the local computer. This will allow third-party applications that support ODBC to access data directly from Plant SCADA. The ODBC Server is disabled by default. You need to set this parameter to 1 to enable an ODBC server.

For more information, see the topic *Using Plant SCADA as an ODBC Server* in the main Plant SCADA documentation.

**Allowable Values:**

- 0 — (ODBC server not enabled)
- 1 — (ODBC server is enabled)

**Default Value:**

0

**See Also**

[ODBC Parameters](#)

## OID Parameters

The Citect.ini file contains the following OID parameter:

- [OID]Reset - This parameter is obsolete

## See Also

[Parameter Categories](#)

## OpcDaServer Parameters

The Citect.ini file contains the following OPC DA Server parameter:

- [\[OpcDaServer\]AutoStartByClient](#) - Enables or disables the ability to automatically start the OPC DA Server when a client connection occurs.
- [\[OpcDaServer\]RoundToFormat](#) - Specifies if tag values published to an OPC DA Server are rounded.

## See Also

[Parameter Categories](#)

### [OpcDaServer]AutoStartByClient

Allows you to automatically start the OPC DA Server when a client connection occurs.

When this parameter is enabled, a connection request from an OFS client will start Runtime Manager, then start the client and OPC DA Server processes.

When this parameter is disabled, a connection request from an OFS client will start Runtime Manager, but no processes will be launched.

An appropriate log entry will be written to the Runtime Manager log file.

Be aware that an OPC DA Server needs to be properly configured for this parameter to function correctly.

#### Allowable Values:

- 0 - disable OPC DA Server startup on OPC client connection
- 1 - enable OPC DA Server startup on OPC client connection

#### Default Value:

0

## See Also

[OpcDaServer Parameters](#)

## [OpcDaServer]RoundToFormat

Specifies if tag values published to an OPC DA Server are rounded to the format of the variable tag.

For example, if a tag value coming from an I/O device is 3.4999999999999, but the tag format is ##.##, the rounded value will be 3.50.

### Allowable Values:

- 0 - values are not rounded
- 1 - values are rounded

### Default Value:

1

## See Also

[OpcDaServer Parameters](#)

## Page Parameters

The Citect.ini file contains the following page parameters:

- [\[Page\]AddDefaultMenu](#) - Determine whether to add the default menu items to your tabbed menu bar.
- [\[Page\]Alarm](#) - The AN where the configured alarms message is displayed on each graphics page.
- [\[Page\]AlarmPage](#) - The name of the graphics page to display when calling the Cicode function PageAlarm().
- [\[Page\]AllowHScroll](#) - Defines the default behavior for horizontal scrolling.
- [\[Page\]AllowHScrollBar](#) - Defines the default behavior when displaying horizontal scroll bars.
- [\[Page\]AllowVScroll](#) - Defines the default behavior for vertical scrolling.
- [\[Page\]AllowVScrollBar](#) - Defines the default behavior when displaying vertical scroll bars.
- [\[Page\]AnmDelay](#) - When animating with a symbol set, Plant SCADA switches between frames at the frequency specified in AnmDelay.
- [\[Page\]BackgroundColor](#) - Specifies the color used to fill in the background when a page is smaller than the minimum width of a window.
- [\[Page\]BackgroundColour](#) - Obsolete in v7.20. Replaced by [Page]BackgroundColor.
- [\[Page\]BadDitheringColor](#) - Sets the dithering color for graphics elements which are dithered if the value quality is “bad”.
- [\[Page\]BadDitheringDensity](#) - Sets the dithering density for graphics elements which are dithered if the value quality is “bad”.
- [\[Page\]BadText](#) - Text Objects can be displayed as #COM type errors, or as the text overlaid with a dithered pattern if the ‘display value’ expression has “bad” quality.
- [\[Page\]BadTextBackgroundColor](#) - Sets the background color for numeric or text graphics objects to indicate “bad” quality.

- [\[Page\]ComBreak](#) - Obsolete in version 7.20.
- [\[Page\]ComBreakText](#) - Obsolete in version 7.20.
- [\[Page\]CenterStartupPage](#) - Sets the startup page (not the splash screen) to display in the center of the screen.
- [\[Page\]ControlInhibitDitheringColor](#) - Sets the dithering color for graphics elements which are dithered if their values are in ControlInhibit mode.
- [\[Page\]ControlInhibitDitheringDensity](#) - Sets the dithering density for graphics elements which are dithered if their values are in ControlInhibit mode.
- [\[Page\]ControlInhibitTextColor](#) - Sets the background color for numeric or text graphics objects to indicate that the value presented on the objects is in ControlInhibit mode.
- [\[Page\]Date](#) - The AN where the system date is displayed on each graphics page.
- [\[Page\]DefaultQualityFormat](#) - The format of the string representation of quality when a Cicode QUALITY function is used.
- [\[Page\]DefaultTimestampFormat](#) - The format of the string representation of timestamp when a Cicode TIMESTAMP function is used.
- [\[Page\]Delay](#) - This parameter has been superseded by the [\[Page\]ScanTime](#) parameter.
- [\[Page\]DelayRenderAdvancedAnimation](#) - Delays the re-drawing of graphics objects that have been changed by code in a Cicode Object. This delay will continue until the code in all Cicode Objects has been executed.
- [\[Page\]DelayRenderAll](#) - Delays the re-drawing of graphics objects so that all graphics objects on a page are re-drawn at once.
- [\[Page\]DisabledAlarm](#) - The AN where the disabled alarms message is displayed on each graphics page.
- [\[Page\]DisabledGrayTextColor](#) - Sets the color for 'Grayed' option of the 'Disable style' setting on the 'Access'->Disable Tab of the Text Properties Form.
- [\[Page\]DisabledPage](#) - The name of the graphics page to display when calling the Cicode function PageDisabled().
- [\[Page\]DynamicComBreakColour](#) - Obsolete in version 7.20.
- [\[Page\]DynamicComBreakDensity](#) - Obsolete in version 7.20.
- [\[Page\]DynamicSizing](#) - Determines whether pages can be resized at runtime.
- [\[Page\]EnableQualityToolTip](#) - Controls the quality tooltip.
- [\[Page\]ErrorDitheringColor](#) - Sets the dithering color for graphics elements which are dithered if an internal error occurs.
- [\[Page\]ErrorDitheringDensity](#) - Sets the dithering density for graphics elements which are dithered if an internal error occurs.
- [\[Page\]ErrorTextBackgroundColor](#) - Sets the background color for numeric / text graphics objects to indicate an internal error
- [\[Page\]HardwarePage](#) - The name of the graphics page to display when calling the Cicode function PageHardware().
- [\[Page\]HomePage](#) - Sets the page to display when the user clicks the Home page button on the template or calls the Cicode function PageHome()
- [\[Page\]HwAlarm](#) - The AN where the hardware alarms message is displayed on each graphics page.
- [\[Page\]IgnoreValueQuality](#) - Defines the value quality handling by graphic pages.
- [\[Page\]InheritParentScale](#) - Specifies that each page is automatically made the same size as its parent window.

- [\[Page\]KeyEcho](#) - The AN where keyboard commands are echoed.
- [\[Page\]LastAlarm](#) - The AN where the last alarm is displayed.
- [\[Page\]Logo](#) - This sets a symbol to display at the logo area (lower right corner) of the new templates.
- [\[Page\]MaintainAspectRatio](#) - Causes Plant SCADA windows to maintain their aspect ratio when resized.
- [\[Page\]MaximiseOnCreation](#) - Obsolete in version 7.20, use [\[Page\]RelocateNonResizedOnCreation](#) instead.
- [\[Page\]MaxInt](#) - Obsolete in version 7.20.
- [\[Page\]MaxLast](#) - The maximum number of pages that can be placed on the last page stack.
- [\[Page\]MaxList](#) - The maximum number of pages that can be placed on the page list stack. .
- [\[Page\]MaxRecursion](#) - Allows the specified number of recursions on PageGoto, PageDisplay, PageNext, PagePrev, PageCreate, and PageLast functions.
- [\[Page\]MaxStr](#) - Obsolete in version 7.20.
- [\[Page\]MenuDisable](#) - Determines whether the standard menu page is displayed on startup.
- [\[Page\]MenuReloadOnChange](#) - Enables the menu to be reloaded at runtime if list has been updated.
- [\[Page\]MenuShutdown](#) - Determines whether the shutdown button is displayed on the standard menu page.
- [\[Page\]Name](#) - The AN where the Page Name is displayed.
- [\[Page\]OriginAdjust](#) - Adjusts the display of windows that are either partially or completely off screen.
- [\[Page\]OverrideDitheringColor](#) - Sets the dithering color for graphics elements which are dithered if their values are override ("forced").
- [\[Page\]OverrideDitheringDensity](#) - Sets the dithering density for graphics elements which are dithered if an internal error occurs.
- [\[Page\]OverrideTextBackgroundColor](#) - Sets the background color for numeric / text graphics objects to indicate that the value presented on the objects is override ("forced").
- [\[Page\]PagesReloadOnChange](#) - Enables the list of pages to be reloaded at runtime if list has been updated.
- [\[Page\]PrintPage](#) - Sets a custom Cicode function to print the currently displayed page when the user clicks the Print page button on the template or calls the Cicode function PagePrint().
- [\[Page\]ProcessAnalystPage](#) - Sets the page to display when the user calls the Cicode function PageProcessAnalyst() without specifying the page argument.
- [\[Page\]ProcessAnalystPopupPage](#) - Sets the page to pop up when the user calls the Cicode function ProcessAnalystWin() or ProcessAnalystPopup() without specifying the page argument.
- [\[Page\]Prompt](#) - The AN where prompt and error messages are displayed.
- [\[Page\]RangeCheck](#) - Determines if range error messages are displayed.
- [\[Page\]RelocateNonResizedOnCreation](#) - Determines whether windows created with the Cicode function WinNewAt are automatically maximized.
- [\[Page\]ScaleTextToMax](#) - Causes text on pages to have their text scaled to the maximum.
- [\[Page\]ScanTime](#) - Determines how often (in milliseconds) I/O device data is read in order to update the I/O tags on a page.
- [\[Page\]ShowBadText](#) - Text Objects can be displayed as #BAD text, or as the text overlaid with a dithered pattern if the "display value" expression has "bad" quality.
- [\[Page\]ShowErrorText](#) - Text Objects can be displayed as #COM type errors, or as the text overlaid with a dithered pattern if the 'display value' expression has "uncertain" quality
- [\[Page\]ShowUncertainText](#) - Text Objects can be displayed as #UNC text, or as the text overlaid with a

dithered pattern if the "display value" expression has "uncertain" quality.

- [\[Page\]Splash](#) - Specify the name of the page to use for the Splash Screen.
- [\[Page\]SplashTimeout](#) - Milliseconds for the Splash Screen to remain displayed.
- [\[Page\]SplashWinName](#) - Specify the label of the Splash Window for use with the Cicode function WinNumber().
- [\[Page\]Startup](#) - The Page Name of the graphics page to display when the display system starts up.
- [\[Page\]StartUpCancel](#) - Determines whether the Cancel button displays on the Startup message Box.
- [\[Page\]StartupDelay](#) - Milliseconds between when Splash Screen and Start Screen are displayed.
- [\[Page\]StartupHeight](#) - Height of the Start Page on the main display monitor.
- [\[Page\]StartupMode](#) - Specify the window mode of Startup page on main display monitor.
- [\[Page\]StartupWidth](#) - Width of the Start Page on the main display monitor.
- [\[Page\]StartupWinName](#) - Specify the label of the Start Window for use with the Cicode function WinNumber().
- [\[Page\]StartupX](#) - X coordinate of the Start Page on the main display monitor.
- [\[Page\]StartupY](#) - Y coordinate of the Start Page on the main display monitor.
- [\[Page\]SOEPAGE](#) - The name of the graphics page to display when calling the Cicode function PageSOE().
- [\[Page\]SummaryPage](#) - The name of the graphics page to display when calling the Cicode function PageSummary().
- [\[Page\]Time](#) - The AN where the system time is displayed on each graphics page.
- [\[Page\]Tip](#) - The AN where tool tips are displayed on each graphics page.
- [\[Page\]TipHelp](#) - Determines whether tool tips are displayed.
- [\[Page\]TipTimeOut](#) - The time delay between when the mouse pointer stops within an AN area (i.e. over an object) and a tool tip displays (if the object at the AN has text configured for a tool tip).
- [\[Page\]Title](#) - The AN where the Page Title of the graphics page is displayed.
- [\[Page\]UncertainDitheringDensity](#) - Sets the dithering density for graphics elements which are dithered if the value quality is "uncertain".
- [\[Page\]UncertainDitheringColor](#) - Sets the dithering color for graphics elements which are dithered if the value quality is "uncertain".
- [\[Page\]UncertainText](#) - Text Objects can be displayed as #COM type errors, or as the text overlaid with a dithered pattern if the 'display value' expression has "uncertain" quality.
- [\[Page\]UncertainTextBackgroundColor](#) - Sets the background color for numeric or text graphics objects to indicate "uncertain" quality.
- [\[Page\]WaitForValidData](#) - Specifies whether the animation system will attempt to wait for valid data from all subscriptions required to draw a graphics page before it is animated.
- [\[Page\]ValueAbnormalPattern](#) - Displays a diagonal pattern across a graphics object when the corresponding device goes offline, that is, it loses communication.
- [\[Page\]Windows](#) - The maximum number of windows that can be open simultaneously.
- [\[Page\]WinTitle](#) - The format of the window title banner.

## See Also

[Parameter Categories](#)

### [Page]AddDefaultMenu

Determines whether to add the default menu items to your tabbed menu bar.

**Note:** This parameter is only available to pages based on the Tab\_Style templates

The default menu consists of the following tabs:

- Pages - contains buttons to display non-system pages configured in your project.
- Alarms - contains buttons to display the default alarm pages including: Alarm, Disabled, Summary and Hardware pages.
- Trends - contains buttons to display the default Process Analyst pages including: ProcessAnalyst, !ProcessAnalystPopup

Order of default menu items is 100. The items in the default menu are merged with and ordered against your configured menu items at runtime.

## Allowable Values:

- 0 - Do not add default menu items, menu is populated according to what is defined in the menu configuration database
- 1 - Add default menu if nothing is defined in menu configuration form for the generic pages (i.e. menu configuration record with blank page field).
- 2 - Add default menu even if menus are configured

## Default Value:

1

## See Also

[Page Parameters](#)

### [Page]Alarm

**Note:** This parameter is not used for this version of Plant SCADA. It is included for backward compatibility with versions prior to v3.00.

The AN where the configured alarms message is displayed on each graphics page.

## Allowable Values:

0 (Do not display) or 1 to 8192

**Default Value:**

5

**See Also**

[Page Parameters](#)

**[Page]AlarmPage**

The name of the graphics page to display when you call up an alarm page via the Cicode function PageAlarm().

The alarm page is used to display the last occurrence of any configured alarms.

The alarm page is commonly built on the default alarm page template in the style that matches your project but may be any valid page in the project. If the specific page does not exist, a dialog box will appear to alert the user.

**Allowable Values:**

Valid page name

**Default Value:**

Alarm

**See Also**

[Page Parameters](#)

**[Page]AllowHScroll**

This parameter defines the default behavior for horizontal scrolling. When set to 1, scrolling is enabled. When set to 0, scrolling is disabled.

**Allowable Values:**

1 or 0

**Default Value:**

1

**See Also**

[Page Parameters](#)

**[Page]AllowHScrollBar**

This parameter defines the default behavior when displaying horizontal scroll bars. When set to 1, scroll bars are displayed if the window size dictates they are required. When set to 0, scroll bars are hidden.

**Allowable Values:**

1 or 0

**Default Value:**

1

**See Also**

[Page Parameters](#)

**[Page]AllowVScroll**

This parameter defines the default behavior for vertical scrolling. When set to 1, scrolling is enabled. When set to 0, scrolling is disabled.

**Allowable Values:**

1 or 0

**Default Value:**

1

**See Also**

[Page Parameters](#)

**[Page]AllowVScrollBar**

This parameter defines the default behavior when displaying vertical scroll bars. When set to 1, scroll bars are displayed if the window size dictates they are required. When set to 0, scroll bars are hidden.

**Allowable Values:**

1 or 0

**Default Value:**

1

**See Also**[Page Parameters](#)**[Page]AnmDelay**

When animating symbols, Plant SCADA switches between frames at the frequency specified in AnmDelay. See the DspSymAnm() Cicode function for information about animating symbols.

**Allowable Values:**

100 to 10000 (milliseconds)

**Default Value:**

500

**See Also**[Page Parameters](#)**[Page]BackgroundColor**

This parameter specifies the color used to fill in the background when a page being displayed is smaller than the minimum width of a window.

The minimum width for a window is 132 pixels. The minimum page width required to fill this window therefore becomes **132 pixels - 2 \* <border width in pixels>**. In Plant SCADA, the border width of a Window is determined by the function **WinNewAt**, which specifies the window type used via the **Mode** argument. The following table shows the minimum page width supported by each different display mode:

WinNewAt (Mode)	Border size	Minimum page width
0 = Normal window	4	124
4 = No resize	3	126
8 = No icons	3	126
16 = No caption	1	130

If a page you are trying to display is smaller than the relevant width above, it will display left aligned with the remaining space filled by the color specified by this parameter.

**Note:** This parameter should only be used for existing pages that cannot be redrawn. New pages should be made

---

larger than these minimum widths.

---

## Allowable Values:

0x000000 to 0xFFFFFFF

Colors defined as an RGB value. For example:

- 0x000000 - (Black)
- 0x000080 - (Blue)
- 0x008000 - (Green)
- 0x008080 - (Cyan)
- 0x800000 - (Red)
- 0x800080 - (Magenta)
- 0x808000 - (Brown)
- 0xBFBFBF - (Grey)
- 0x7F7F7F - (Dark Grey)
- 0x0000FF - (Light blue)
- 0x00FF00 - (Light green)
- 0x00FFFF - (Light cyan)
- 0xFF0000 - (Light red)
- 0xFF00FF - (Light Magenta)
- 0xFFFF00 - (Yellow)
- 0xFFFFFFFF - (White)

## Default Value:

0xBFBFBF (Grey)

## See Also

[Page Parameters](#)

### [Page]BadDitheringColor

Sets the dithering color for graphics elements which are dithered if the value quality is "bad" if the display expression contains an "unqualified tagname".

Refer to the topic [Tag Extensions](#) for information regarding unqualified tags.

## Allowable Values:

-1 – indication off

0x000000 to 0xFFFFFFF (The RGB color value in hexadecimal)

**Default Value:**

0x000000 (Black)

**See Also**

[Page Parameters](#)

**[Page]BadDitheringDensity**

Sets the dithering density for graphics elements which are dithered if the value quality is "bad".

**Allowable Values:**

- 1 - (Highest Density)
- 2
- 3
- 4 - (Lowest Density)

**Default Value:**

2

**See Also**

[Page Parameters](#)

**[Page]BadText**

Defines the text which appears after "#" character when the 'display value' expression has "bad" quality.  
This type of indication is active only when [\[Page\]ShowBadText](#) = 1 and [\[Page\]IgnoreValueQuality](#) = 0.

**Allowable Values:**

Any string.

**Default Value:**

BAD

**See Also**

[Page Parameters](#)

## [Page]BadTextBackgroundColor

Sets the background color for numeric or text graphics objects to indicate "bad" quality if the display expression contains an "unqualified tagname".

Refer to the topic [Tag Extensions](#) for information regarding unqualified tags.

### Allowable Values:

-1 – indication off

0x000000 to 0xFFFF (The RGB color value in hexadecimal)

### Default Value:

0x800080 - (Magenta)

**Note:** The parameter needs to be set to 2 for this parameter to be observable.

---

### See Also

[Page Parameters](#)

## [Page]CenterStartupPage

Defines if the startup page (not the splash screen) is placed in the center of the screen, otherwise it will display in the top left of the screen.

### Allowable Values:

- 0 - Display startup page in the top left of the screen
- 1- Display startup page in the center of the screen

### Default Value:

0

### See Also

[Page Parameters](#)

## [Page]ControlInhibitDitheringColor

Sets the dithering color for graphics elements which are dithered if their values are in ControlInhibit mode. This type of indication is active only when [\[Page\]IgnoreValueQuality](#) = 0 or 2.

**Allowable Values:**

-1 – indication off  
0x000000 to 0xFFFF (The RGB color value in hexadecimal)

**Default Value:**

0x000000 (Black)

**See Also**

[Page Parameters](#)

**[Page]ControllInhibitDitheringDensity**

Sets the dithering density for graphics elements which are dithered if their values are in ControllInhibit mode. This type of indication is active only when [\[Page\]IgnoreValueQuality](#) = 0 or 2.

**Allowable Values:**

- 1 - (Highest Density)
- 2
- 3
- 4 - (Lowest Density)

**Default Value:**

2

**See Also**

[Page Parameters](#)

**[Page]ControllInhibitTextColor**

Sets the background color for numeric or text graphics objects to indicate that the value presented on the objects is in ControllInhibit mode. This type of indication is active only when [\[Page\]IgnoreValueQuality](#) = 2.

**Allowable Values:**

-1 – indication off  
0x000000 to 0xFFFF (The RGB color value in hexadecimal)

**Default Value:**

0x008080 - (Cyan)

**See Also**

[Page Parameters](#)

**[Page]Date**

---

**Note:** This parameter is not used for this version of Plant SCADA. It is included for backward compatibility with versions prior to v3.00.

---

The AN where the system date is displayed on each graphics page.

**Allowable Values:**

0 (Do not display) or 1 to 8192

**Default Value:**

10

**See Also**

[Page Parameters](#)

**[Page]DefaultQualityFormat**

This parameter defines the format of the string representation of quality when a Cicode QUALITY function is used to initialize quality fields, or to extract a specific quality field to be displayed on graphical pages.

**Allowable Values:**

Any valid "part" parameter value for the function QualityToStr.

- -2: Short representation in the format <General Quality> [-<Quality Substatus>]
- -1: Full representation in the format <General Quality> [Override] [Control Inhibit] – <Quality Substatus>
- 0: <General Quality>
- 1: <Quality Substatus>
- 2: <Quality Limit>
- 3: <Extended Quality Substatus>
- 4: <Quality Override>
- 5: <Control Inhibit>

**Default Value:**

-1

**See Also**

[Page Parameters](#)

**[Page]DefaultTimestampFormat**

This parameter defines the format of the string representation of timestamp when a Cicode TIMESTAMP function is used to initialize timestamp fields, or to extract a specific timestamp field to be displayed on graphical pages.

**Allowable Values:**

Any valid "format" parameter value for the function TimestampToStr.

- 0 – Short time format, hh:mm
- 1 – Long time format, hh:mm:ss
- 2 – Short date format, dd/MM/yyyy
- 3 – Long date format, dddd, dd MMMM yyyy
- 4 – Short date & short time format, dd/MM/yyyy hh:mm
- 5 – Short date & long time format, dd/MM/yyyy hh:mm:ss
- 6 – Long date & short time format, dddd, dd MMMM yyyy hh:mm
- 7 – Long date & long time format, dddd, dd MMMM yyyy hh:mm:ss
- 8 – Month day format, dd MMMM
- 9 – Year month format, MMMM yyyy
- 10 – RFC1123 format, ddd, dd MMM yy hh:mm:ss GMT
- 11 – Sortable date time format, yyyy-MM-ddThh:mm:ss
- 12 – Short universal format, yyyy-MM-dd hh:mm:ss
- 13 – Long universal format, dddd, dd MMMM yyyy hh:mm:ss
- 14 – Long Time & millisecond, hh:mm:ss.fff

**Default Value:**

4

**See Also**

[Page Parameters](#)

## [Page]Delay

This parameter has been superseded by the [\[Page\]ScanTime](#) parameter.

## See Also

[Page Parameters](#)

### [Page]DelayRenderAdvancedAnimation

---

**Note:** If you have not changed the [\[Page\]DelayRenderAll](#) parameter from its default (TRUE), then you should not need to change this parameter.

Delays the re-drawing of graphics objects that have been changed by code in a Cicode Object. This delay will continue until the code in all Cicode Objects has been executed. The associated graphics objects will then be re-drawn together. This delay will occur every time the page is updated (see the [\[Page\]ScanTime](#) parameter).

## Allowable Values:

- 1 (Delay enabled)
- 0 (Delay disabled)

## Default Value:

1

## See Also

[Page Parameters](#)

### [Page]DelayRenderAll

Delays the re-drawing of graphics objects so that all graphics objects on a page are re-drawn at once (Plant SCADA pauses to wait for all underlying Cicode to execute before re-drawing the graphics objects). This delay will occur every time the page is updated. This parameter is intended to enhance page update times (for pages with numerous or complex objects). Be careful not to mistake this delay for inactivity during runtime.

## Allowable Values:

- 1 (Delay enabled - objects re-drawn simultaneously)
- 0 (Delay disabled - objects re-drawn individually)

## Default Value:

1

## See Also

[Page Parameters](#)

### [Page]DisabledAlarm

---

**Note:** This parameter is not used for this version of Plant SCADA. It is included for backward compatibility with versions prior to v3.00.

---

The AN where the disabled alarms message is displayed on each graphics page.

#### Allowable Values:

0 (Do not display) or 1 to 8192

#### Default Value:

7

## See Also

[Page Parameters](#)

### [Page]DisabledGrayTextColor

Sets the color used when 'Grayed' is selected for the **Disable style** setting on the **Access/Disable** tab of the Text Properties dialog.

#### Allowable Values:

0x000000 to 0xFFFFFFF

Colors defined as an RGB value. For example:

- 0x000000 - (Black)
- 0x000080 - (Blue)
- 0x008000 - (Green)
- 0x008080 - (Cyan)
- 0x800000 - (Red)
- 0x800080 - (Magenta)
- 0x808000 - (Brown)
- 0xBFBFBF - (Grey)
- 0x7F7F7F - (Dark Grey)
- 0x0000FF - (Light blue)
- 0x00FF00 - (Light green)

- 0x00FFFF - (Light cyan)
- 0xFF0000 - (Light red)
- 0xFF00FF - (Light Magenta)
- 0xFFFF00 - (Yellow)
- 0xFFFFFFFF - (White)

**Default Value:**

Standard Windows Disabled Grey Text Color

**See Also**

[Page Parameters](#)

**[Page]DisabledPage**

The name of the graphics page to display when you call up a disabled alarm page via the Cicode function PageDisabled.

The disabled alarm page is used to display alarms in the system that have been disabled.

The disabled alarm page is commonly built on the default disabled alarm page template in the style that matches your project but may be any valid page in the project. If the specific page does not exist, a dialog box will appear to alert the user.

**Allowable Values:**

Valid page name

**Default Value:**

Disabled

**See Also**

[Page Parameters](#)

**[Page]DynamicSizing**

Determines whether pages can be resized at runtime. This option overrides the resolution specified for the page.

If dynamic sizing is enabled, you can resize any page by:

- Clicking and dragging on the window frame;
- Maximizing the window;
- Minimizing the window to an icon; or
- Restoring the window to its original state.

You can use the **[Page]InheritParentScale** parameter to specify that each page automatically uses the same scale as its parent. For example, if you increase the size of Page A by 10%, then call Page B, Page B will automatically become 10% larger than it was when it was configured.

Note the following:

- Even if you disable dynamic page resizing, Plant SCADA windows can still be made smaller - if the window is smaller than the page, scroll bars will display to allow you to view the whole page.
- If you have the **[Animator]FullScreen** parameter set, your page will take up the entire screen, and it will have no title bar. In this mode, you cannot resize the window.
- The maximum size of your pages is restricted to that of a full screen Windows application.

## Allowable Values:

- 1 - (Dynamic Resizing ENABLED)
- 0 - (Dynamic Resizing DISABLED)

## Default Value:

1

## See Also

[Page Parameters](#)

## [Page]EnableQualityToolTip

Set by default this parameter controls the quality tooltip that displays the value, quality and timestamp for the current subscription of the tag element or element item.

This feature applies to text / numeric display objects and symbol set objects. The quality information that is displayed is the result of the evaluation of the main expression for the object e.g. for text objects this is the 'display value' expression and will ignore the scale, fill or movement expressions.

The quality information that is displayed is the result of the evaluation of the main expression for the object e.g. for text objects this is the "Display Value" expression and will ignore the scale, fill or movement expressions. The expression has to directly, and in each page, refresh the cycle of reading at least one external tag, ex. "Tag1", "Tag1 + Tag2" or "QualityToStr(Tag1)", but not "10" or "sin(1.0)". Moreover, a reference to the tag cannot refer to the tag's items, so for example "Tag1.v + Tag2.v" is not going to show a tooltip.

When values displayed by text / numeric display objects are not visible because of error codes, such as #COM, their tooltips will include values as well. Tooltips defined in Graphics Builder have higher priority than quality tooltips.

## Allowable Values:

- 0 – Quality tooltip is disabled.
- 1 – Quality tooltip is enabled.

**Default Value:**

1

**See Also**[Page Parameters](#)**[Page]ErrorDitheringColor**

Sets the dithering color for graphics elements which are dithered if an internal error occurs. This type of indication is active only when IgnoreValueQuality = 0.

**Allowable Values:**

- -1 – indication off
- 0x000000 to 0xFFFFFFF (the RGB color value in hexadecimal)

**Default Value:**

0x000000 (Black)

**See Also**[Page Parameters](#)**[Page]ErrorDitheringDensity**

Sets the dithering density for graphics elements which are dithered if an internal error occurs. This type of indication is active only when IgnoreValueQuality= 0.

**Allowable Values**

- 1 - (Highest Density)
- 2
- 3
- 4 - (Lowest Density)

**Default Value:**

2

## See Also

[Page Parameters](#)

### [Page]ErrorTextBackgroundColor

Sets the background color for numeric / text graphics objects to indicate an internal error. The error can be due to several sources such as the Cicode execution system or IO subsystems. In some cases errors are caused in the same way as tag quality, and they are redundant to tag quality. This type of indication is active only when IgnoreValueQuality= 2.

#### Allowable Values:

-1 – indication off  
0x000000 to 0xFFFF (The RGB color value in hexadecimal)

#### Default Value:

0xFF0000 - (Light Red)

## See Also

[Page Parameters](#)

### [Page]HomePage

This sets the page to display when the user clicks the Home page button on the template or calls the Cicode function PageHome().

---

**Note:** If the user creates a page based on the new Tab\_Style templates, the button that displays the home page will be disabled if the page specified by [Page]HomePage does not exist.

---

#### Allowable Values:

The name of any valid page configured in the project

#### Default Value:

NONE

## See Also

[Page Parameters](#)

## [Page]HardwarePage

The name of the graphics page to display when you call up a hardware alarm page via the Cicode function PageHardware().

The hardware alarm page is used to display alarms that are automatically generated by the system to indicate abnormal operation.

The hardware alarm page is commonly built on the default hardware alarm page template in the style that matches your project but may be any valid page in the project. If the specific page does not exist, a dialog box will appear to alert the user.

### Allowable Values:

Valid page name

### Default Value:

Hardware

### See Also

[Page Parameters](#)

## [Page]HwAlarm

---

**Note:** This parameter is not used for this version of Plant SCADA. It is included for backward compatibility with versions prior to v3.00.

The AN where the hardware alarms message is displayed on each graphics page.

### Allowable Values:

0 (Do not display) or 1 to 8192

### Default Value:

6

### See Also

[Page Parameters](#)

## [Page]IgnoreValueQuality

You can use tag elements (such as "Tag1", "Tag1.Field") and tag element items (such as "Tag1.Field.Q") in Cicode expressions. However, by default, when a tag element or an element item is not accessible, or the element quality is not "Good", graphic objects will indicate that state by displaying some alert messages or dithering.

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

If you change the value of this parameter to 1, no dithering or background color will visually identify that an element is not Good or is not accessible, even if the parameters to display such an identifier have been set elsewhere. In such a case the operator may operate the plant inappropriately by relying on incorrect data.

Use the QualityIsOverride() Cicode function or similar method to identify if a tag element has been overridden.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

However, you have the option to disable the default behavior and to display values even when the element quality is not "Good". This option is controlled by the IgnoreValueQuality Cicode task context attribute, which provides equivalent functionality to [Page] ComBreak, which is now obsolete .

*Allowable Values:*

- 0 - The Control Client supports the existing behaviour (#COM) except dithering (dots) will be not shown on text objects when an error is indicated by #<Error Message> (refer to table of error codes below).
  - 1 - The quality of tag subscriptions will be completely ignored. This is equivalent to having previously used the (now obsolete) [Page] ComBreak = 0. The numeric or text objects will display a "bad" quality value and animation will continue. No dithering will be shown.
  - 2 - The text or numeric objects will display "bad" quality values. The background color of the text / numeric objects will change to indicate the quality status. The background colors for QUAL\_BAD and QUAL\_UNCR are defined by [\[Page\]BadTextBackgroundColor](#) and [\[Page\]UncertainTextBackgroundColor](#) Citect.ini parameters.
- If **[Page]IgnoreValueQuality=0** the following short alert messages may be displayed on graphical pages when the Quality of a tag is 'NOT GOOD'. Refer to Cicode and General Errors for more information.

ERROR	ERROR Number	Parameter Set	
<b>ShowUncertainText=0, ShowBadText=0, ShowErrorText=1</b>	>(Default) <b>ShowUncertainText=1, ShowBadText=1, ShowErrorText=1</b>		
Genie not Associated	323	#ASS	#ASS
Divide by zero	273	#DIV/0	#DIV/0
Cicode stack overflow	295	#STACK	#STACK
Out of memory	272	#MEM	#MEM
Format overflow	344	#OVR	#OVR
The unit the tag is on has not been connected to yet	32	#WAIT	#WAIT
Waiting for initial data. Property not ready	423 432	#PEND	#PEND

ERROR	ERROR Number	Parameter Set	
The tag is not known by the server	53	#COM	#COM
Tag not found	424		
Cluster not specified	402		
Cluster not found	403		
Cluster name and tag mismatch	404		
Cluster not connected	405		
No server of type on cluster	418		
No connector	425		
No server could be found	281		
No Error	0	#OK	#BAD/#UNC
Value is out of range	257	#RANGE	#BAD/#UNC
Tag in Last Usable Value	525	#COM	#BAD/#UNC
General software error	256	#COM	#BAD/#UNC
General software error	256	#ERR	#BAD/#UNC

**Default Value:**

0

You can override the IgnoreValueQuality setting for a particular page by using the **Ignore Quality** field on the Page Properties dialog in Graphics Builder.

---

**Note:** The quality of tags referenced by items, ex. Tag1.v or Tag1.Field.t, is GOOD and its timestamps are 0 (INVALID TIMESTAMP). Therefore they give no visual indication of quality, error or change in handling state such as control inhibit or override mode regardless of the setting used for the [Page]IgnoreValueQuality parameter.

**See Also**

[Page Parameters](#)

**[Page]InheritParentScale**

Specifies that each page automatically uses the same scale as its parent window (i.e. the window it was called from). This applies even if the parent window has already been dynamically resized. For example, if you increase the size of Page A by 10%, then call Page B, Page B will automatically become 10% larger than it was when it was configured.

**Allowable Values:**

- 1 (Pages will use the same scale as the parent)
- 0 (Pages will default to the resolution specified for the page)

**Default Value:**

1

**See Also**[Page Parameters](#)**[Page]KeyEcho**

The AN where keyboard commands are echoed. Set to zero (0) to disable.

**Allowable Values:**

0 to 2000

**Default Value:**

1

**See Also**[Page Parameters](#)**[Page]LastAlarm**

---

**Note:** This parameter is not used for this version of Plant SCADA. It is included for backward compatibility only.

The AN where the last alarm is displayed.

**Allowable Values:**

1 to 8192

**Default Value:**

11

## See Also

[Page Parameters](#)

### [Page]Logo

This sets a symbol to display in the logo area of the templates.

Logo size:

- Situation Awareness Templates: less than or equal to 190 x 48 pixels.
- StruxureWare Templates: less than or equal to 230 x 50 pixels.
- Tab Style Projects: less than or equal to 103 x 20 pixels.

## Allowable Values:

Name of the symbol in the format of library.symbol, for example, global.logo

## Default Value:

<None> (The default product logo will be used)

## See Also

[Page Parameters](#)

### [Page]MaintainAspectRatio

This parameter is a boolean, defaulting to 1 (true). When this parameter is set to 1, Plant SCADA windows will maintain their aspect ratios during resizing. When set to 0, windows ignore aspect ratios during resizing, allowing the window to change to the exact required dimensions.

There is also a new page mode which can be specified when you call the Cicode function WinNewAt to create a new window. This new mode will be ignored if [Page]MaintainAspectRatio has been set to 0, every page will not maintain its aspect ratio on resizing. But when [Page]MaintainAspectRatio is set to 1, this new mode is taken into account. In this situation, if 4096 is added to your mode argument passed into WinNewAt, the new window will NOT maintain the aspect ratio during resizing.

## Allowable Values:

0 or 1

## Default Value:

1

## See Also

[Page Parameters](#)

### [Page]MaxInt

The maximum number of page-based integers that can be stored in an array. Page-based variables are stored in an array, local to each display page. See the PageSetInt() Cicode function.

#### Allowable Values:

0 to 100

#### Default Value:

100

## See Also

[Page Parameters](#)

### [Page]MaxLast

The maximum number of pages that can be placed on the last page stack. See the PageLast() Cicode function for information about displaying pages from the last page stack.

#### Allowable Values:

1 to 100

#### Default Value:

10

## See Also

[Page Parameters](#)

### [Page]MaxList

The maximum number of pages that can be placed on the page list stack. See the PageListDisplay() Cicode function for information about displaying pages from the page list stack. When the number of pages in the list reaches the maximum limit, the last page in the list will be replaced with the new page.

**Allowable Values:**

1 to 500

**Default Value:**

25

**See Also**

[Page Parameters](#)

**[Page]MaxRecursion**

Allows the specified number of recursions on PageGoto, PageDisplay, PageNext, PagePrev, PageCreate, and PageLast functions.

**Allowable Values:**

1 to 30

**Default Value:**

5

**See Also**

[Page Parameters](#)

**[Page]MaxStr**

The maximum number of page-based strings that can be stored in an array. Page-based variables are stored in an array, local to each display page. See the PageSetStr() Cicode function.

**Allowable Values:**

0 to 100

**Default Value:**

2

**See Also**

[Page Parameters](#)

**[Page]MenuDisable**

Determines whether the standard menu page is displayed on startup.

**Allowable Values:**

- 0 - Enable menu page
- 1 - Disable menu page

**Default Value:**

0

**See Also**

[Page Parameters](#)

**[Page]MenuReloadOnChange**

This parameter is set by default. Enables the list of menu items to be reloaded at Plant SCADA runtime process if menu has been updated. If set to 0, the menu will not be reloaded until the runtime has been restarted.

**Allowable Values:**

- 0 - Menu will not be reloaded at runtime.
- 1 - Menu will be reloaded at runtime.

**Default Value:**

1

**See Also**

[Page Parameters](#)

**[Page]MenuShutdown**

Determines whether the shutdown button is displayed on the standard menu page.

**Allowable Values:**

- 0 - (Do not display button).
- 1 - (Display shutdown button).

**Default Value:**

1

**See Also**

[Page Parameters](#)

**[Page]Name**

**Note:** This parameter is not used for this version of Plant SCADA. It is included for backward compatibility only.

The AN where the Page Name is displayed.

**Allowable Values:**

0 (Do not display) or 1 to 8192

**Default Value:**

13

**See Also**

[Page Parameters](#)

**[Page]OriginAdjust**

The [Page]OriginAdjust parameter controls the display of windows that are either partially or completely offscreen.

If this flag is set, offscreen windows display at the top left of the screen when restored or maximized.

**Allowable Values:**

- 0 - (Do not adjust window display)
- 1 - (Adjust window display)

**Default Value:**

1

**See Also**

[Page Parameters](#)

## [Page]OverrideDitheringColor

Sets the dithering color for graphics elements which are dithered if their values are override ("forced"). This type of indication is active only when [Page]IgnoreValueQuality = 0 or 2.

### Allowable Values:

- 1 – indication off
- 0x000000 to 0xFFFF (The RGB color value in hexadecimal)

### Default Value:

0x000000 (Black)

### See Also

[Page Parameters](#)

## [Page]OverrideDitheringDensity

Sets the dithering density for graphics elements which are dithered if an internal error occurs. This type of indication is active only when [Page]IgnoreValueQuality = 0 or 2.

### Allowable Values:

- 1 - (Highest Density)
- 2
- 3
- 4 - (Lowest Density)

### Default Value:

2

### See Also

[Page Parameters](#)

## [Page]OverrideTextBackgroundColor

Sets the background color for numeric or text graphics objects to indicate that the value presented on the objects is override ("forced"). This type of indication is active only when [Page]IgnoreValueQuality = 2.

**Allowable Values:**

- -1 – indication off
- 0x000000 to 0xFFFFFFF (The RGB color value in hexadecimal)

**Default Value:**

0xFFFFFFF - (White)

**See Also**

[Page Parameters](#)

**[Page]PagesReloadOnChange**

This parameter is set by default. Enables the list of pages to be reloaded at Plant SCADA runtime process if list has been updated. If set to 0, the list of pages will not be reloaded until the runtime has been restarted.

**Allowable Values:**

- 0 - Page list not reloaded
- 1 - Page list (if updated) reloaded

**Default Value:**

1

**See Also**

[Page Parameters](#)

**[Page]PrintPage**

This sets a custom Cicode function to print the currently displayed page when the user clicks the Print page button on the template or calls the Cicode function PagePrint().

---

**Note:** It is possible to override this setting on a per page basis by using the page environment variable "PrintPage". Refer to 'Using the Tab\_Style Page Templates > Creating a New Project > Using Environment Variables in Tab\_Style Templates' for more information regarding page environment variables.

---

**Note:** This parameter is available only to projects based on Tab\_Style templates.

---

**Allowable Values:**

"?" followed by a valid Cicode function name and comma separated arguments, for example, ?WinPrint LPT1;,0,0,0

**Default Value:**

None

**See Also**

[Page Parameters](#)

**[Page]ProcessAnalystPage**

Sets the page to display when the user calls the Cicode function PageProcessAnalyst() without specifying the page argument. If the specific page does not exist, a dialog box will appear to alert the user.

**Allowable Values:**

The name of any valid page that contains a process analyst

**Default Value:**

ProcessAnalyst

(This page may need to be created in your project.)

**See Also**

[Page Parameters](#)

**[Page]ProcessAnalystPopupPage**

Sets the page to pop up when the user calls the Cicode function ProcessAnalystWin() or ProcessAnalystPopup() without specifying the page argument. If the specific page does not exist, a dialog box will appear to alert the user.

**Allowable Values:**

The name of any valid page that contains a process analyst

**Default Value:**

!ProcessAnalystPopup

(This page may need to be created in your project)

**See Also**

[Page Parameters](#)

### [Page]Prompt

The AN where prompt and error messages are displayed. Set to zero (0) to disable.

See the Prompt() and DspError() Cicode functions for information about displaying prompts and errors.

### Allowable Values:

0 to 2000

### Default Value:

2

### See Also

[Page Parameters](#)

### [Page]RangeCheck

The [Page]RangeCheck parameter determines if range errors are displayed. If this flag is set, the range errors are displayed as per the [\[Page\]IgnoreValueQuality](#), [\[Page\]ShowErrorText](#), [\[Page\]ShowBadText](#), and [\[Page\]ShowUncertainText](#) parameters.

#RANGE will be visible when IgnoreValueQuality=0, ShowErrorText=1, ShowBadText=0, ShowUncertainText=0

### Allowable Values:

- 0 - (Ignore range errors)
- 1 - (Display range errors)

### Default Value:

0

---

**Note:** If this parameter is disabled, the value of the data displayed may be inaccurate.

---

### See Also

[Page Parameters](#)

### [Page]RelocateNonResizedOnCreation

Determines whether windows created with the Cicode function WinNewAt are automatically maximized. By default this is set to 0 to stop windows positioned completely or partially off screen from automatically maximizing and displaying at the top left corner of the screen.

**Allowable Values:**

- 0 (New windows are not automatically maximized)
- 1 (New windows are automatically maximized)

**Default Value:**

0

**See Also**[Page Parameters](#)**[Page]ScaleTextToMax**

If [Page]ScaleTextToMax is set to 0, pages by default will have their text scaled to the minimum of the x and y page scales. If 8192 is added to the mode argument of the WinNewAt Cicode call that created the page, the page will have its text scaled to the maximum of the x and y page scales.

If [Page]ScaleTextToMax is set to 1, pages will have their text scaled to the maximum of the x and y page scales, regardless of the mode used to create the page.

**Allowable Values:**

0 or 1

**Default Value:**

0

**See Also**[Page Parameters](#)**[Page]ScanTime**

---

**Note:** This parameter is modified by the Computer Setup Wizard as well as the Computer Setup Editor. Any value you enter into your project parameters will be overridden by that specified in the Wizard.

---

The Page ScanTime determines how often (in milliseconds) the Animator refreshes a graphics page at runtime. A value of 250 indicates that the Animator will refresh the page 4 times per second.

Under some conditions, you might want to slow the update of your pages to reduce the CPU load on the Client computer. For example, you might want faster response on your main operator computers, while slowing the response time on manager computers.

**Allowable Values:**

1 to 60000 (milliseconds)

**Default Value:**

250

Note the following:

- You can dynamically change this value (for this computer) by calling PageSetInt(-2, <scantime>). You can also find out what the current scan time is, by calling PageGetInt(-2).
- You can set this value (for this computer) using the Computer Setup Wizard.
- You can set the Page ScanTime for individual graphics pages, using the Page Properties (from the File menu in the Graphics Builder).

**See Also**

[Page Parameters](#)

**[Page]ShowBadText**

Text objects can be displayed as #BAD text, or as text overlaid with a dithered pattern if the "display value" expression has "bad" quality.

This setting allows switching between these two modes. This type of indication is active only when [\[Page\]IgnoreValueQuality = 0](#).

**Allowable Values:**

- 0 – Display the result of the "display value" expression overlaid with a dithered pattern if the expression is not in an error condition or the [\[Page\]ShowErrorText](#) parameter is set to 0. If the expression is in error condition, it shows text or a value based on the [\[Page\]ShowErrorText](#) parameter.
- 1 – Display "#" followed by text defined by [\[Page\]BadText](#) (the default value is "BAD").

**Default Value:**

1

**See Also****[Page]ShowErrorText**

Text Objects can be displayed as #COM type errors, or as the text overlaid with a dithered pattern if the "display value" expression has "uncertain" quality.

This setting allows switching between these two modes. This type of indication is active only when

[Page]IgnoreValueQuality = 2.

### Allowable Values:

- 0 – Show the result of the "display value" expression overlaid with a dithered pattern.
- 1 – Show error status as #COM type errors.

### Default Value:

1

### See Also

[\[Page\]IgnoreValueQuality](#)

[Page Parameters](#)

### [Page]ShowUncertainText

Text Objects can be displayed as #UNC text, or as the text overlaid with a dithered pattern if the "display value" expression has "uncertain" quality.

This setting allows switching between these two modes. This type of indication is active only when [Page]IgnoreValueQuality = 2.

### Allowable Values:

- 0 – Show the result of the "display value" expression overlaid with a dithered pattern.
- 1 – Show "#" followed by text defined by [Page] UncertainText (default value: "UNC")

### Default Value:

1

### See Also

[\[Page\]IgnoreValueQuality](#)

[Page Parameters](#)

### [Page]SOEPage

The name of the graphics page to display when you call up an alarm sequence of events (SOE) page via the Cicode function PageSOE().

The SOE page is used to display events that have occurred in the system with entries repeated as required if they occurred multiple times.

The SOE page is commonly built on the default SOE alarm page template in the style that matches your project

but may be any valid page in the project. If the specific page does not exist, a dialog box will be displayed to alert the user.

**Allowable Values:**

Valid page name

**Default Value:**

SOE

**See Also**

[Page Parameters](#)

**[Page]Splash**

Specify the name of the page to use for Splash Screen.

This parameter is not supported in multi monitor mode.

---

**Note:** Adding a splash screen will cause your start window to have a window number of 1 instead of 0. Please consider using the windows name functionality to identify the start window number.

---

**Allowable Values:**

Any valid page name

**Default Value:**

None

**See Also**

[Page Parameters](#)

**[Page]SplashTimeout**

Milliseconds for the Splash Screen to display.

**Allowable Values:**

- 0 - Disable
- 1- 32767 (Milliseconds)

**Default Value:**

5000

**Note:** If [Page]SplashTimeout = 0 the window needs to be closed manually using WinFree(). The following cicode can be used to close the splash window from cicode that runs outside the context of the splash page:  
`WinGoto(WinNumber("SplashWin")); // "SplashWin" needs to match the name defined in  
[Page]SplashWinName WinFree();`

**See Also**

[Page Parameters](#)

**[Page]SplashWinName**

Specify the name of the Splash Window for use with the Cicode function WinNumber().

**Allowable Values:**

Any valid name

**Default Value:**

SplashWin

**See Also**

[Page Parameters](#)

**[Page]Startup**

The Page Name of the graphics page to display when Plant SCADA starts up.

**Note:** This parameter is modified by the Computer Setup Wizard as well as the Computer Setup Editor.

**Allowable Values:**

Any valid Page Name or Page Number.

**Default Value:**

Startup

**See Also**

[Page Parameters](#)

**[Page]StartUpCancel**

This setting determines whether the Cancel button displays on the Startup message Box. The cancel button allows an operator to cancel the startup of Plant SCADA. (With the cancel button disabled, an operator is unable to cancel Plant SCADA as it starts up.)

When set to 0 this setting will also disable the ability for Plant SCADA Runtime Manager to cancel startup for each instance or the whole system.

If this parameter is modified while the Plant SCADA Runtime Manager is running, the changes will not take effect until all instances of Plant SCADA are restarted.

---

**Note:** This parameter is modified by the Computer Setup Wizard as well as the Computer Setup Editor.

---

**Allowable Values:**

- 0 - (Disable display)
- 1 - (Enable display)

**Default Value:**

1

**See Also**

[Page Parameters](#)

**[Page]StartupDelay**

Milliseconds delay before the Startup page is shown. This is to be used in conjunction with the [Page]SplashTimeout parameter to determine the timing of the launching of the splash page and the startup page.

If StartupDelay is negative then the startup page can be called manually by the user using the Cicode function MultiMonitorStart().

If no splash screen is specified then this parameter is ignored.

**Allowable Values:**

-1 - 32767

**Default Value:**

3000

---

**Note:** Setting [Page]StartupDelay to be less than [Page]SplashTimout will cause both the splash page and the startup page to be displayed in two separated windows at the same time momentarily. This will make the window number of the Startup page be 1 instead of 0. If your code depends on the window number of the startup page being 0, you can set StartupDelay to be greater than SplashTimeout so that the splash window and

---

---

the startup window is displayed one after another, and the startup window will end up being allocated window number 0. Alternatively, you can set a window name to your startup page via parameter [\[Page\]StartupWinName](#) (default is StartWin) and retrieve the window number of your startup page via Cicode function WinNumber("<StartupWinName>"). This allows you to find the window number of your startup page regardless of the timing of the startup display sequence.

---

## See Also

[Page Parameters](#)

### [Page]StartupHeight

Height of Startup Page on main display monitor.

#### Allowable Values:

1 - 32767

#### Default Value:

-1

**Note:** If the value is set to be less than 1, for [\[Page\]StartupWidth](#) and [\[Page\]StartupHeight](#) both parameters will be ignored. The window will be displayed in its native dimension or will be reduced in size to fit the dimension of the monitor.

---

## See Also

[Page Parameters](#)

### [Page]StartupMode

Specify the window mode of Startup page on main display monitor. The mode specified in this parameter works in similar fashion as the mode specified in Cicode function WinNewAt. However, some modes used by WinNewAt are not applicable to this parameter.

#### Allowable Values:

Combination of valid window modes. The mode of the window:

- 0 - Normal page
- 4 - No re-size. The window is displayed with thin borders and no maximize/minimize icons. The window cannot be re-sized.
- 8 - No icons. The window is displayed with thin borders and no maximize/minimize or system menu icons. The window cannot be re-sized.
- 16 - No caption. The window is displayed with thin borders, no caption, and no maximize/minimize or system

menu icons. The window cannot be re-sized.

- 64 - Always on top.
- 256 - Display the entire window. This mode commands that no parts of the window will appear off the screen.
- 1024 - Disables dynamic resizing of the new window, overriding the setting of the [Page]DynamicSizing parameter.
- 4096 - Allows the window to be resized without maintaining the current aspect ratio. The aspect ratio defines the relationship between the width and the height of the window, which means this setting allows you to stretch or compress the window to any proportions. This option overrides the setting of the [Page]MaintainAspectRatio parameter.
- 8192 - Text on a page will be resized in proportion with the maximum scale change for a resized window. For example, consider a page that is resized to three times the original width, and half the original height. If this mode is set, the font size of the text on the page will be tripled (in proportion with the maximum scale). This option overrides the setting of the [Page] ScaleTextToMax parameter.
- 16384 - Hide the horizontal scroll bar.
- 32768 - Hide the vertical scroll bar.
- 65536 - Disable horizontal scrolling.
- 131072 - Disable vertical scrolling.

You can select multiple modes by adding modes together (for example, set Mode to 72 to open a window without maximize, minimize, or system menu icons and be always on top).

### Default Value:

0

### See Also

[Page Parameters](#)

### [Page]StartupWidth

Width of Startup Page on main display monitor.

### Allowable Values:

1 - 32767

### Default Value:

-1

**Note:** If the value is set to be less than 1, for [Page]StartupWidth and [Page]StartupHeight both parameters will be ignored. The window will be displayed in its native dimension or will be reduced in size to fit the dimension of the monitor.

## See Also

[Page Parameters](#)

### [Page]StartupWinName

Specify the name of the Startup Window for use with the Cicode function WinNumber().

#### Allowable Values:

Any valid name

#### Default Value:

StartupWin

## See Also

[Page Parameters](#)

### [Page]StartupX

X coordinate of Startup Page on main display monitor.

#### Allowable Values:

-32768 to 32767

#### Default Value:

0

## See Also

[Page Parameters](#)

### [Page]StartupY

Y coordinate of Startup Page on main display monitor.

#### Allowable Values:

-32768 to 32767

**Default Value:**

0

**See Also**

[Page Parameters](#)

**[Page]SummaryPage**

The name of the graphics page to display when you call up an alarm summary page via the Cicode function PageSummary().

The summary alarm page is used to display alarms that have occurred in the system that have yet to be logged with alarms repeated as required if they have occurred multiple times.

The summary alarm page is commonly built on the default summary alarm page template in the style that matches your project but may be any valid page in the project. If the specific page does not exist, a dialog box will appear to alert the user.

**Allowable Values:**

Valid page name

**Default Value:**

Summary

**See Also**

[Page Parameters](#)

**[Page]Time**

---

**Note:** This parameter is not used for this version of Plant SCADA. It is included for backward compatibility only.

The AN where the system time is displayed on each graphics page.

**Allowable Values:**

0 (Do not display) or 1 to 8192

**Default Value:**

9

## See Also

[Page Parameters](#)

### [Page]Tip

**Note:** This parameter is not used for this version of Plant SCADA. It is included for backward compatibility only.

The AN where tool tips are displayed on each graphics page. To control the display of tool tips (on the page), set the [\[Page\]TipHelp](#) parameter.

#### Allowable Values:

0 (Do not display) or 1 to 8192

#### Default Value:

14

## See Also

[Page Parameters](#)

### [Page]TipHelp

Determines whether tool tips are displayed. To control the pause delay of the pop-up windows for tool tips, set the [\[Page\]TipTimeOut](#) parameter.

#### Allowable Values:

- 0 - (Disable)
- 1 - (Enable)

#### Default Value:

1

## See Also

[Page Parameters](#)

### [Page]TipTimeOut

The time delay between when the mouse stops within an AN area and a tool tip displays (if the object at the AN has text configured for a tool tip). If the mouse pointer is within an AN area (over the object) for the Time Out

period, without an event occurring, the tool tip pop-up displays. The operator can then move the mouse from AN to AN, and tool tips display for each AN. If an event other than a mouse movement occurs, or if the mouse is outside an AN area for a period of time, the tool tips boxes do not display.

**Allowable Values:**

200 to 20000 (milliseconds)

**Default Value:**

1000

**See Also**

[Page Parameters](#)

**[Page]Title**

---

**Note:** This parameter is not used for this version of Plant SCADA. It is included for backward compatibility only.

The AN where the Page Title of the graphics page is displayed.

**Allowable Values:**

0 (Do not display) or 1 to 8192

**Default Value:**

12

**See Also**

[Page Parameters](#)

**[Page]UncertainDitheringColor**

Sets the dithering color for graphics elements which are dithered if the value quality is "uncertain" if the display expression contains an "unqualified tagname".

Refer to [Tag Extensions](#) for information regarding unqualified tags.

**Allowable Values:**

-1 – indication off

0x000000 to 0xFFFFFFFF (The RGB color value in hexadecimal)

**Default Value:**

0x000000 (Black)

**See Also**

[Page Parameters](#)

[\[Page\]ValueAbnormalPattern](#)

**[Page]UncertainDitheringDensity**

Sets the dithering density for graphics elements which are dithered if the value quality is "uncertain".

**Allowable Values:**

- 1 - (Highest Density)
- 2
- 3
- 4 - (Lowest Density)

**Default Value:**

2

**See Also**

[Page Parameters](#)

[\[Page\]ValueAbnormalPattern](#)

**[Page]UncertainText**

Defines the text which appears after "#" character when the 'display value' expression has "uncertain" quality.

This type of indication is active only when [\[Page\]ShowUncertainText](#) = 1 and [\[Page\]IgnoreValueQuality](#) = 0.

**Allowable Values:**

Any string.

**Default Value:**

UNC

## See Also

[Page Parameters](#)

### [Page]UncertainTextBackgroundColor

Sets the background color for numeric or text graphics objects to indicate "uncertain" quality if the display expression contains an "unqualified tagname".

#### Allowable Values:

-1 – indication off

0x000000 to 0xFFFF (The RGB color value in hexadecimal)

#### Default Value:

0x800080 - (Magenta)

---

**Note:** The parameter [\[Page\]IgnoreValueQuality](#) needs to be set to 2 for this parameter to be observable.

---

## See Also

[Page Parameters](#)

### [Page]ValueAbnormalPattern

Displays a diagonal line across a graphics object when the corresponding device goes offline, that is, it loses communication. When set to 1, the line appears on the device (for example, equipment) when the communication is lost. The parameter applies to the following bad tag quality conditions as well:

1. Tag Quality in Override mode
2. Tag quality in Override BAD Mode
3. Tag quality in Override Uncertain Mode
4. Tag quality in ControlInhibit Mode

---

**Note:** This parameter can be used in conjunction with existing Page parameters for dithering colors and dithering density.

---

#### Allowable Values:

- 0 - This shows a dithered pattern across the graphic object.
- 1 - Displays a diagonal line across the graphic object.

**Default Value:**

0

**See Also**[Page Parameters](#)[\[Page\]UncertainDitheringDensity](#)[\[Page\]UncertainDitheringColor](#)**[Page]WaitForValidData**

In previous versions of Plant SCADA, the animation system waited for valid data from all subscriptions before drawing the page. If the data took longer than a defined time to arrive, then the page was drawn with "#COM" in place of the missing data items. Plant SCADA now allows you to animate pages immediately, using any available cached values/qualities, and using 0 values (with "bad" quality status and "waiting for initial data" sub-status) for any data items that are not immediately available. As subscription notifications are received, the updated values are used.

**Allowable Values:**

- 0 - The Control Client will animate pages immediately, using the available values.
- 1 - The Control Client will attempt to wait for valid data before animating pages (previous functionality).

**Default Value:**

1

**See Also**[Page Parameters](#)**[Page]Windows**

The maximum number of windows that can be open simultaneously. This parameter sets the maximum number of windows supported by Plant SCADA. You might not be able to open this number of windows - Windows could run out of system resources before you reach this limit.

**Allowable Values:**

1 to 200

**Default Value:**

50

## See Also

[Page Parameters](#)

### [Page]WinTitle

The format of the window title banner. If you use the WinTitle() function, set this parameter to \* (asterisk).

#### Allowable Values:

The following field names: {Name} {Title} {Time} {Date} {Window} or the asterisk ( \* ) character. if you are using the WinTitle() function.

#### Default Value:

{Title,32}

## See Also

[Page Parameters](#)

### Path Parameters

The Citect.ini file contains the following path parameter:

- [\[Path\]<PathName>](#) - Defines a data path.

## See Also

[Parameter Categories](#)

### [Path]<PathName>

Defines a substitution data path in the project's system parameters. You can specify logical data paths (for data storage and retrieval) on your system. You can then use a data path shortcut instead of entering the full path to the data.

For example:

`[path]trenddata=c:\data\mytrends`

In this case, trenddata is defined as the shortcut to the c:\data\mytrends path. This shortcut can be used in Plant SCADA forms. For example, a trend tag's "File Name" field may contain the string:

`"[TRENDATA]:\trend_fast_00001".`

Plant SCADA then expects the trenddata path to be defined in the system parameters or in the INI file. The reserved shortcut names which the system uses can be found in topic Using Path Substitutions.

If one of these reserved path names are used, a "Path not suitable" error is raised on system startup.

---

**Note:** You will need to manually configure the access control list for a folder specified in a path substitution so that it matches the permissions that were applied to the default location during installation. See [Configure Directory Security for Modified Folder Locations](#).

---

### To define (or change a path substitution):

1. Choose **System | Parameters**.
2. In the **Section Name** box, enter **PATH**.
3. In the **Name** property, enter the path substitution string.
4. In the **Value** property, enter the full data path.

## See Also

[Path Parameters](#)

## Privilege Parameters

The Citect.ini file contains the following privilege parameters:

- [\[Privilege\]AckAlarms](#) - Determines the privilege level a user requires to acknowledge alarms.
- [\[Privilege\]DisableAlarms](#) - Determines the privilege level a user requires to disable alarms.
- [\[Privilege>EditUser\]](#) - Determines the privilege level a user requires to edit users using the drop-down menu next to the login user icons on the Tab\_Style template.
- [\[Privilege\]Exclusive](#) - Disables/enables the use of hierarchical privileges.
- [\[Privilege\]Shutdown](#) - Determines the privilege level a user requires to shutdown a project.
- [\[Privilege\]SilenceAlarms](#) - Determines a privilege level a user requires to silence alarms.

## See Also

[Parameter Categories](#)

### [Privilege]AckAlarms

Determines the privilege level a user requires to acknowledge alarms.

---

**Note:** This parameter is available only to projects based on StruxureWare and Tab\_Style templates.

---

### Allowable Values:

0 - 8

### Default Value:

1

## See Also

[Privilege Parameters](#)

### [Privilege]DisableAlarms

Determines the privilege level a user requires to disable alarms.

**Note:** This parameter is available only to projects based on Tab\_Style templates.

---

#### Allowable Values:

0 - 8

#### Default Value:

8

## See Also

[Privilege Parameters](#)

### [Privilege>EditUser

Determines the privilege level a user requires to edit users using the drop-down menu next to the login user icons on the Tab\_Style template.

**Note:** This parameter is available only to projects based on Tab\_Style templates.

---

#### Allowable Values:

0 - 8

#### Default Value:

8

## See Also

[Privilege Parameters](#)

### [Privilege]Exclusive

Disables/enables the use of hierarchical privileges.

If you set this parameter to 1, privileges are exclusive. For example, Privilege 3 means that the operator only has access to Privilege 3 commands.

If you set this parameter to 0, privileges are hierarchical. For example, Privilege 3 means that the operator has access to Privilege 3, 2 and 1 commands.

**Allowable Values:**

- 0 - (Hierarchical)
- 1 - (Not hierarchical)

**Default Value:**

1

**See Also**[Privilege Parameters](#)**[Privilege]Shutdown**

Determines the privilege level a user requires to shutdown a project using the Close window button on the title bar.

**Note:** This parameter is available only to projects based on Tab\_Style templates. It does not stop the user from shutting down Plant SCADA using Cicode functions or using the function OnEvent() to install their own function(s) for handling shutdown confirmation events.

**Allowable Values:**

0 - 8

**Default Value:**

0

**See Also**[Privilege Parameters](#)**[Privilege]SilenceAlarms**

Specifies the privilege level a user is required to have in order to silence the sound of an alarm.

Refer to 'Using the Tab\_Style Page Templates > Creating a New Project > Implementing Audible Alarms' for more information regarding Alarm sounds.

**Note:** This parameter is available only to projects based on Tab\_Style templates.

**Allowable Values:**

0 - 8

**Default Value:**

0

**See Also**[Privilege Parameters](#)**ProcessAnalyst Parameters**

Plant SCADA uses the Cicode functions [Login](#), [UserLogin](#) and [LoginForm](#) to set the preferred language at runtime. To allow the Process Analyst to determine the language it should display, you must map your Plant SCADA language databases to the Process Analyst resource files.

To do this, add a new .ini section called [ProcessAnalyst] to the Citect.ini file on all your Plant SCADA clients and servers, and create a mapping for each language. (Note that this section might already exist in your Citect.ini file.)

The mapping must use this format:

```
[ProcessAnalyst]
```

```
LanguagePath.<dbf>=<ProcessAnalystLanguage>
```

Where <dbf> is the name of a specific Plant SCADA language translation database, and <ProcessAnalystLanguage> is the language code of the resources.dll file containing the equivalent translations.

For example:

```
[ProcessAnalyst]
```

```
LanguagePath.French=fr
```

```
LanguagePath.Chinese=zh-CN
```

```
LanguagePath.German=de
```

Ensure that each of your machines contains the necessary language fonts. Windows provides facilities to add the necessary languages to your machine via the Regional and Language Options dialog box, accessible from the Control Panel. This step is essential if you want to use Asian languages on an English operating system.

**See Also**[Parameter Categories](#)**Protocol Parameters**

The Citect.ini file contains the following protocol parameters:

- [<ProtocolName>]Block - The blocking constant is a trade-off between the time taken to make multiple data requests and the time taken to read more data in a single request.

- [<ProtocolName>]Delay - The period (in milliseconds) to wait between receiving a response and sending the next command.
- [<ProtocolName>]MaxPending - The maximum number of pending commands that the driver holds ready for immediate execution.
- [<ProtocolName>]PollTime - The interrupt or polling service time (in milliseconds). Setting the polling time to 0 puts the driver in interrupt mode.
- [<ProtocolName>]Retry - The number of times to retry a command after a timeout.
- [<ProtocolName>]Timeout - Specifies how many milliseconds to wait for a response before displaying an error message.
- [<ProtocolName>]WatchTime - The frequency (in seconds) that the driver uses to check the communications link to the I/O device.

---

**Note:** The default and allowable values of these parameters are specific to the protocol. To access information about the parameters for a particular driver, see the [The Driver Reference Help](#).

---

## See Also

[Parameter Categories](#)

## Proxi Parameters

- [Proxi]<I/O Server name> - Obsolete in version 7.0.

## See Also

[Parameter Categories](#)

## PubSub Parameters

The Citect.ini file contains the following publish-subscribe parameters:

- [\[PubSub\]CicodeDeviceDelaySwitchInterval](#) - Delays switching to each primary device after an I/O server startup.
- [\[PubSub\]CicodeDeviceDelaySwitchTime](#) - Delays the client from switching tag subscriptions while the primary server is starting.
- [\[PubSub\]LogLevel](#) - Sets the level of logging between the I/O subscription system and the Plant SCADA drivers.
- [\[PubSub\]LogDevice](#) - Selects the device(s) for logging.

## See Also

[Parameter Categories](#)

## [PubSub]CicodeDeviceDelaySwitchInterval

The amount of time (in seconds) to delay the switching for each primary device.

This parameter is set on the target I/O server machine. The I/O server will set its Cicode devices to an 'online' state one at a time using the specified time interval. This will occur after the time specified in [PubSub]CicodeDeviceDelaySwitchTime has expired.

Bringing the devices online one at a time reduces the peak load and allows for performance tuning.

For more information, see Use a Client Tag Subscription Delay for Calculated Variables.

### Allowable values:

0 – 32767

### Default value:

0

### See Also

[PubSub Parameters](#)

## [PubSub]CicodeDeviceDelaySwitchTime

The amount of time (in seconds) to delay a client from switching tag subscriptions while the primary server is starting.

This parameter is set on the target I/O server machine. The I/O server will wait for this delay time before starting and setting its Cicode devices to the 'online' state.

For more information, see Use a Client Tag Subscription Delay for Calculated Variables.

### Allowable values:

0 – 32767

### Default value:

0

When set to the default value (0), the delay is disabled. To enable the delay, set a value of 1 or higher.

### See Also

[\[PubSub\]CicodeDeviceDelaySwitchInterval](#)

[PubSub Parameters](#)

## [PubSub]LogDevice

Determines which devices are logged between the I/O subscription system and the associated Plant SCADA drivers. Messages are logged to the Kernel and syslog.dat.

**Note:** This only occurs on an I/O Server.

### Allowable Values:

Use an asterix "\*" to specify all devices, or use a device name to specify a particular device.(e.g. "PLC\_1234").

### Default Value:

No value, which specifies NO devices.

The parameter [\[PubSub\]LogLevel](#) determines the level of logging used for the specified device(s).

### Example

```
PubSub:(Device IODevDisk ) UNIT ACTIVE change from <none> () Priority -1 to IODevDisk ()  
Priority 1  
PubSub:(Device IODevDisk ) UNIT IODevDisk STATUS change => Offline to Online  
PubSub:(Device IODevDisk ) Update Tag (Force=1): Tag=DiskTag1 RawValue=1  
Timestamp=2010-06-03_16:00.18.225 RawQual=0x00c0 DSError=0 (0x0) Has changed  
PubSub:(Device IODevDisk ) PollRead request : <Block>, Force=0, POINT=A0x00000001  
T0x00000001 RawType 1 Count 5 (DCB=0x07f99a34)
```

**Note:** You can update this parameter within the Citect.ini file while online, as the runtime system will read its value periodically or on demand. For more information, see the topic [Adjust Logging During Runtime](#).

### See Also

[PubSub Parameters](#)

## [PubSub]LogLevel

Sets the degree to which logging is used between the I/O subscription system and the actual Plant SCADA drivers, with respect to I/O requests. Messages are logged to syslog.dat.

Refer to the topic [Log Files](#) in the main help for more information regarding the syslog.dat file.

### Allowable Values:

- 0 - Disable
- 1 - Enable normal logging
- 2 - Enable verbose logging

**Default Value:**

0

This setting impacts the devices specified by the parameter [\[PubSub\]LogDevice](#).

**Note:** You can update this parameter within the Citect.ini file while online, as the runtime system will read its value periodically or on demand. For more information, see the topic [Adjust Logging During Runtime](#).

**See Also**

[PubSub Parameters](#)

**RemoteDB Parameters****[RemoteDB]DefaultComment**

Specifies the default string to be used for the **Comment** field of linked or imported variable tags. If you do not specify a value here, the field will be left blank.

**Allowable Values:**

Any string or blank.

**Default Value:**

No default (the field is left blank).

**See Also**

[RemoteDB Parameters](#)

**Report Parameters**

The Citect.ini file contains the following report parameters:

- [\[Report\]ComBreak](#) - Determines whether reports that are triggered from the I/O devices are run if a communication break exists.
- [\[Report\]Debug](#) - Enables trace logging messages.
- [\[Report\]Disable](#) - Enables/disables the Reports Server.
- [\[Report\]HeartBeat](#) - Determines whether the Primary and Redundant Reports Servers send out heartbeat signals to each other.
- [\[Report\]HeartBeatTime](#) - Determines the period at which heartbeat signals are sent out by the Primary Reports Server. Also determines the period that the Redundant Reports Server will wait for a response (before assuming control of reports) after sending a heartbeat signal to the Primary Reports Server.
- [\[Report\]InhibitEvent](#) - Inhibits event-type reports on startup.
- [\[Report\]Primary](#) - Obsolete in version 7.0.

- [Report]Process - Obsolete in version 7.0.
- [Report]RtfRollOver - Determines whether an RTF report will save to a new file, or append to an existing file.
- [Report]RunStandby - Enables or disables tandem processing of reports.
- [Report]Server - Obsolete in version 7.0.
- [Report]Startup - The report to run when Plant SCADA starts up.
- [Report]TxtRollOver - Determines whether a text report will save to a new file, or append to an existing file.
- [Report]WatchTime - The period at which Plant SCADA checks for reports to run.

## See Also

[Parameter Categories](#)

[Report Process Parameters](#)

### [Report]ComBreak

Determines whether reports that are triggered from the I/O devices are run if a communication error occurs.  
(This parameter only applies to the trigger of the report - not to the data in the report.)

To control the "Com Break" in the actual report you should use the ERR\_FORMAT\_ON and ERR\_FORMAT\_OFF commands.

This parameter can be defined at the finest level of hierarchical granularity  
([Report.Clustername.ServerName]ComBreak). See [Hierarchical Parameters](#) for more information.

## Allowable Values:

- 0 - (Run reports even if there is a communication error associated with this report trigger)
- 1 - (Do not run reports if there is a communication error associated with this report trigger)

## Default Value:

1

## See Also

[Report Parameters](#)

### [Report]Debug

Enables trace logging messages.

When set to "1", entries appear in the appropriate SYSLOG.DAT for the report server process. Report server entries are prefixed by the string "ReportServer:".

**Allowable Values:**

- 0 = Logging is disabled.
- 1 = Logging is enabled.

**Default Value:**

0

**See Also**

[Report Parameters](#)

**[Report]Disable**

Enables/disables the Reports Server.

**Allowable Values:**

- 0 - (Enable)
- 1 - (Disable)

**Default Value:**

0

**See Also**

[Report Parameters](#)

**[Report]HeartBeat**

Determines whether the Reports Servers send out heartbeats to each other.

When enabled on the Primary Reports Server, heartbeat signals are sent to the Redundant Reports Server, informing it that the Primary Reports Server is controlling reports. If the Redundant Reports Server has been controlling reports, it will cease doing so upon receiving this message. The heartbeat signal is sent out every [Report]HeartBeatTime.

When enabled on the Redundant Reports Server, heartbeat signals are sent to the Primary Reports Server to establish its presence (i.e. a response is required). If the Redundant Reports Server does not receive a response from the Primary Reports Server during the [Report]HeartBeatTime, it will assume control of reports.

This parameter can be defined at the finest level of hierarchical granularity (*[Report.Clustername.ServerName]HeartBeat*). See [Hierarchical Parameters](#) for more information.

**Allowable Values:**

- 0 - (Disable)
- 1 - (Enable)

**Default Value:**

1

**See Also**[Report Parameters](#)**[Report]HeartBeatTime**

**On the Primary Reports Server** - The Primary Reports Server will send out a heartbeat signal once each HeartBeatTime.

**On the Redundant Reports Server** - After sending out a heartbeat message to the Primary Reports Server, the Redundant Reports Server will wait this long for a response. If a response is not received during this time, it will assume the Primary Reports Server is down, and will take control of reports. (If a response is received, control of reports will remain with the Primary Reports Server.)

This parameter can be defined at the finest level of hierarchical granularity (*[/Report.Clustername.ServerName]HeartBeatTime*). See [Hierarchical Parameters](#) for more information.

**Allowable Values:**

500 to 60000 (milliseconds)

**Default Value:**

30000

**See Also**[Report Parameters](#)**[Report]InhibitEvent**

Inhibits event-type reports on startup. For example, you might have a report that is triggered off the rising edge of a bit on startup. The Reports Server notices the bit come on, and runs the report. If this parameter is enabled, the Reports Server does not run this report until it has read the I/O devices a second time.

**Note:** This parameter is modified by the Computer Setup Wizard as well as the Computer Setup Editor.

**Allowable Values:**

- 0 - (Do not inhibit)
- 1 - (Inhibit)

**Default Value:**

1

This parameter can be defined at the finest level of hierarchical granularity ([Report.Clustername.ServerName]InhibitEvent). See Hierarchical Parameters for more information.

**See Also**[Report Parameters](#)**[Report]RtfRollOver**

Determines whether an RTF report run using the Report function will save to a new report output file or append to the existing file. If it is saved to a new file, the existing report file is renamed.

**Allowable Values:**

- 0 - (Report information is appended to the report output file)
- 1 - (Report information is saved to a new report output file)

**Default Value:**

0

**See Also**[Report Parameters](#)**[Report]RunStandby**

Enables or disables tandem processing of reports. If this Server is the Standby Reports Server, it can process all reports in tandem with the Primary Server, or it can remain idle until called.

---

**Note:** This parameter is modified by the Computer Setup Wizard as well as the Computer Setup Editor.

**Allowable Values:**

- 0 - (Remain idle until called)
- 1 - (Process in tandem with the Primary Server)

**Default Value:**

1

This parameter can be defined at the finest level of hierarchical granularity (*[Report.Clustername.ServerName]RunStandby*). See [Hierarchical Parameters](#) for more information.

**See Also**

[Report Parameters](#)

**[Report]Startup**

The report to run when Plant SCADA starts up. This parameter is only applicable if this Plant SCADA computer is a Reports Server.

**Note:** This parameter is modified by the Computer Setup Wizard as well as the Computer Setup Editor.

---

**Allowable Values:**

Any configured report.

**Default Value:**

"Startup".

**See Also**

[Report Parameters](#)

**[Report]TxtRollOver**

Determines whether a text report run using the Report function will save to a new report output file or append to the existing file. If it is saved to a new file, the existing report file is renamed.

**Allowable Values:**

- 0 - (Report information is appended to the report output file)
- 1 - (Report information is saved to a new report output file)

**Default Value:**

1

## See Also

[Report Parameters](#)

### [Report]WatchTime

The period at which Plant SCADA checks for reports to run. The shorter the period, the faster the Reports Server checks if a report is due to run. The faster the Reports Server must check for reports to run, the more I/O requests are made (to the I/O Server) for reports that are triggered from the I/O devices, and an increased CPU loading on the Reports Server results. You can slow the period (this parameter) to reduce CPU and I/O Server loading.

Note that, if a report is triggered off a bit, the bit must remain high for at least twice this period so that the Reports Server notices it. For example, if this parameter is set to 1000, a bit should remain on for 2000 msec so that the Reports Server notices that it goes on and off. The exact period depends on how fast the data can be read from the I/O devices. For example, if it takes 2000 msec to read all the data for the report triggers (this is slow), the reports are checked every  $(1000 + 2000) = 3$  seconds.

This parameter can be defined at the finest level of hierarchical granularity (`[Report.Clustername.ServerName]WatchTime`). See [Hierarchical Parameters](#) for more information.

## Allowable Values:

100 to 60000 (milliseconds)

## Default Value:

1000

## See Also

[Report Parameters](#)

### Report Process Parameters

Plant SCADA allows you to specify some parameters for a report server process (see [Hierarchical Parameters](#) in the Plant SCADA documentation).

The following parameters need to be configured for a specific process.

**Note:** The <server name> is the name of the report server as specified in the **Topology** activity.

- `[Report.<ClusterName>.<ServerName>]Clusters` - Sets the clusters this Reports Server process will connect to at startup.
- `[Report.<ClusterName>.<ServerName>]CPU` - Sets the CPU that this Report Server process is assigned to.
- `[Report.<ClusterName>.<ServerName>]Events` - The list of events that this Plant SCADA Report Server process enables.
- `[Report.<ClusterName>.<ServerName>]ShutdownCode` - Determines the Cicode function to run when this Plant SCADA Reports Server process shuts down.

- **[Report.<ClusterName>.<ServerName>]StartupCode** - Determines the Cicode function to run when this Plant SCADA Reports Server process starts up.

The Citect.ini file on any PC that will be connecting to this <cluster name><server name> report server can contain the following parameters:

- **[Report.<ClusterName>.<ServerName>]DisableConnection** - This setting is used to specify if a client should not connect to a server.
- **[Report.<ClusterName>.<ServerName>]Priority** - This setting is used to specify the client priority for the server connection.

## See Also

[Parameter Categories](#)

[Report Parameters](#)

### **[Report.<ClusterName>.<ServerName>]Clusters**

Sets which clusters this Reports Server will connect to at startup.

#### **Allowable Values:**

A comma separated list of configured cluster names.

#### **Default Value:**

If this parameter is blank, the Reports Server will connect to every cluster defined for the project.

This parameter needs to be defined at the finest level of hierarchical granularity (Report.<ClusterName>.<ServerName>Clusters). See [Hierarchical Parameters](#) for more information.

## See Also

[Report Process Parameters](#)

### **[Report.<ClusterName>.<ServerName>]CPU**

This parameter is by Plant SCADA Runtime Manager to determine which CPU(s) the report server process is assigned to. The CPU parameter is configurable for every Plant SCADA process via the **CPU Setup** page in the Computer Setup Wizard (see [CPU Configuration](#)).

This parameter needs to be defined at the finest level of hierarchical granularity (Report.<ClusterName>.<ServerName>CPU). See [Hierarchical Parameters](#) for more information.

CPU numbers are specified in a comma separated list. CPU numbers need to be valid and a subset of the available CPUs on a computer. For example, if there are eight CPUs on a computer, a valid CPU range is 0 to 7.

**Note:** If this parameter is modified while the Plant SCADA Runtime Manager is running, the changes will not take effect until every instance of Plant SCADA is restarted.

## Allowable Values:

A comma separated list in the range 0 to 31 (inclusive) where 0 is the first CPU (for example, "0, 1, 2" or "3, 4, 5").

If no value is entered, the process will run on all available CPUs.

---

**Note:** When a process is set to run on all available CPUs, be aware that performance issues may still occur when your CPU usage is less than 100%. You can detect these issues when your CPU usage for a process is fixed at 100 divided by the number of processors.

---

## Default Value:

No value (the process will run on all CPUs).

---

**Note:** You cannot manually specify CPU assignments on a computer with more than 32 CPUs. Under these circumstances, the Setup Wizard will automatically set this parameter to no value (all CPUs). Any changes you make to this parameter will be overwritten.

---

## See Also

[Report Process Parameters](#)

[\[Client\]CPU](#)

[\[Alarm.<ClusterName>.<ServerName>\]CPU](#)

[\[IOServer.<ClusterName>.<ServerName>\]CPU](#)

[\[Trend.<ClusterName>.<ServerName>\]CPU](#)

## [\[Report.<ClusterName>.<ServerName>\]DisableConnection](#)

This setting is used to specify whether or not the client sub system should connect to the given server. If the Citect.ini on a particular PC has [Type.ClusterName.ServerName]DisableConnection = 1, specified for a particular server, then the client sub system will establish a non-redundant connection to the other server in the redundant pair. If that connection becomes inoperative, the client sub system will not be redirected and will have no connection until the server is restored.

To define connection priority of a particular server use [\[Report.<ClusterName>.<ServerName>\]Priority](#).

## Allowable Values:

- 0 - Allow the client to connect to the server
- 1 - Stop the client connecting to the server

## Default Value:

0

## See Also

[Report Process Parameters](#)

### [Report.<ClusterName>.<ServerName>]Events

The list of events that this Plant SCADA Report Server will enable.

This parameter needs to be defined at the finest level of hierarchical granularity (Report.<ClusterName>.<ServerName>Events). See [Hierarchical Parameters](#) for more information.

---

**Note:** This parameter is modified by the Computer Setup Wizard.

---

## Allowable Values:

List of events (comma separated).

## Default Value:

NONE

---

**Note:** When Plant SCADA is running in single process mode only the events assigned to [Client]Events will enabled. Events specified for particular Plant SCADA components are ignored.

---

**Note:** To set this parameter, we recommend you to enable the required events in the "Events Setup" page of the Computer Setup Wizard (instead of entering the events in the Setup Editor).

---

## See Also

[Report Process Parameters](#)

### [Report.<ClusterName>.<ServerName>]Priority

This setting is used to specify the client sub system's priority for the connection to this specific server. The client sub system will connect to, or switch over to, any available server that has the highest priority (lowest number). If the priorities for multiple servers are set to the same value, the client sub system will only switch on a loss of the currently active connection. This is the default operation to provide the same behavior as in versions of the product prior to v7.20.

To disable (not allow) the client to connect to the server use  
[\[Report.<ClusterName>.<ServerName>\]DisableConnection](#)

Allowable Values:

1 to 32767

## Default Value:

1

## See Also

[Report Process Parameters](#)

### [Report.<ClusterName>.<ServerName>]ShutdownCode

Can be used to specify a Cicode function that runs at shutdown of the Plant SCADA Report Server component. Plant SCADA suspends the shutdown process until the function has finished running. The function needs to complete execution within the time specified by the [\[Code\]ShutdownTime](#) parameter, otherwise Plant SCADA will terminate it.

This parameter needs to be defined at the finest level of hierarchical granularity (`Report .<ClusterName>.<ServerName>ShutdownCode`). See [Hierarchical Parameters](#) for more information.

#### Allowable Values:

Any built-in or user-written Cicode function, 1-31 alpha-numeric characters.

#### Default Value:

NONE

---

**Note:** When Plant SCADA is running in single process mode only the Cicode function assigned to [\[Client\]ShutdownCode](#) will be executed at shutdown. Cicode functions specified for particular Plant SCADA components are ignored.

---

## See Also

[Report Process Parameters](#)

### [Report.<ClusterName>.<ServerName>]StartupCode

Determines the Cicode function to run when the Plant SCADA Reports Server component starts up.

You can only pass constant data to the startup function call. You cannot pass variables or other functions. For example, `MyFunc(1, "str")` is valid, but `MyFunc(PLCTAG, "str")` or `MyFunc(YourFunc(), "str")` is not supported.

This parameter needs to be defined at the finest level of hierarchical granularity (`Report .<ClusterName>.<ServerName>StartupCode`). See [Hierarchical Parameters](#) for more information.

---

**Note:** This parameter is modified by the Computer Setup Wizard.

---

#### Allowable Values:

Any built-in or user-written Cicode function, 1-31 alpha-numeric characters.

#### Default Value:

NONE

---

**Note:** When Plant SCADA is running in single process mode only the Cicode function assigned to [Client]StartupCode will be executed at startup. Cicode functions specified for particular Plant SCADA components are ignored.

---

[Report Process Parameters](#)

### Runtime Manager Parameters

The citect.ini file contains the following Runtime Manager parameters:

- [\[RuntimeManager\]AllowDumpKernel](#) - Enables or disables the Dump Kernel context menu in Runtime Manager.
- [\[RuntimeManager\]AllowReload](#) - Enables or disables the reload option in the Runtime Manager menu.
- [\[RuntimeManager\]AutoRestartTrigger](#) - Specifies how long an instance needs to run before that instance will be automatically restarted if it exits abnormally.
- [\[RuntimeManager\]ExitAfterShutdown](#) - Sets whether the Plant SCADA Runtime Manager exits after all runtime processes are shut down.
- [\[RuntimeManager\]NotRespondingRetries](#) - Specifies the number of retries that the CrashMonitor should wait to detect if an instance of Plant SCADA is not responding.
- [\[RuntimeManager\]Profile](#) - Sets the name of the INI profile to be used. If name does not exist the default citect.ini file will be used.

## See Also

[Parameter Categories](#)

### [RuntimeManager]AllowDumpKernel

Enables or disables the Dump Kernel context menu in Runtime Manager.

#### Allowable Values:

- 0 - (Disables the menu option)
- 1 - (Enables the menu option)

#### Default Value:

1

## See Also

[Runtime Manager Parameters](#)

**[RuntimeManager]AllowReload**

Enables or disables the reload option on the Runtime Manager menu.

**Allowable Values:**

- 0 - (Disables the menu option)
- 1 - (Enables the menu option)

**Default Value:**

1

**See Also**

[Runtime Manager Parameters](#)

**[RuntimeManager]AutoRestartTrigger**

An automatic restart occurs if an instance abnormally exits after the specified trigger time. For example, if set to 3600 seconds (1 hour), and the system exits abnormally after running for 43 minutes, then the automatic restart will not occur. If the system exits abnormally after running for 65 minutes, then the automatic restart will occur.

**Allowable Values:**

- n - the amount of time (in seconds) before an automatic restart occurs following an abnormal exit
- 0 - the instance is restarted automatically following an abnormal exit
- -1 - the instance is not restarted automatically following an abnormal exit

**Default Value:**

3600 seconds (1 hour)

**Note:** If [Runtime]AutoRestartTrigger is less than zero then the minimum value is used, and no auto restart will occur. If  $\geq 0$  then this value is used in seconds. This is the time (from the original Plant SCADA start) before the process will be restarted. If this value is 3600, there is no more than one restart an hour from when the process exited abnormally.

**See Also**

[Runtime Manager Parameters](#)

**[RuntimeManager]ExitAfterShutdown**

Sets whether the Plant SCADA Runtime Manager exits after all runtime processes are shut down.

**Allowable Values:**

- 0 - (Plant SCADA Runtime Manager does not exit)
- 1 - (Plant SCADA Runtime Manager exits)

**Default Value:**

1

**See Also**

[Runtime Manager Parameters](#)

**[RuntimeManager]NotRespondingRetries**

Specifies the number of retries that the CrashMonitor should wait to detect if an instance of Plant SCADA is not responding. One retry is sent by the instance every 30 seconds.

**Allowable Values:**

Minimum: 2

**Default Value:**

3

**See Also**

[Runtime Manager Parameters](#)

**[RuntimeManager]Profile**

Sets the name of the Profile INI file to be used at runtime. If the profile is not found or is blank, the default citect.ini file will be used.

**Allowable Values:**

Name of profile or blank

**Default Value:**

citect.ini file

## See Also

[Runtime Manager Parameters](#)

## Scheduling Parameters

The Citect.ini file contains the following Scheduling parameters:

- [\[Scheduling\]AlwaysExecuteEntryAction](#) - Determines how entry actions are executed by Scheduler.
- [\[Scheduling\]BACnetSchedulePollPeriod](#) - Sets the subscription poll period (rate) for BACnet tags.
- [\[Scheduling\]PersistPath](#) - Sets where the runtime schedule data for the Scheduler is stored.
- [\[Scheduling\]StartDelay](#) - Sets the delay between initialization of the Scheduler's server side components and the start of active schedule processing.

## See Also

[Parameter Categories](#)

### [Scheduling]AlwaysExecuteEntryAction

This parameter determines how entry actions are executed by Scheduler.

When set to true (1), the Scheduler will execute the entry action of all equipment resource states regardless of whether or not their internal states are the same. This ensures backwards compatibility when a piece of equipment remains in the same state but needs to repeatedly perform an action at times configured in the Scheduler.

By default, this parameter is set to false (0), which means only changes that have been made to the selected equipment will take effect. The rest of the equipment states will not be refreshed.

#### Allowable Values:

- 0 – false
- 1 – true.

#### Default Value:

0

## See Also

[Scheduling Parameters](#)

### [Scheduling]BACnetSchedulePollPeriod

Sets the subscription poll period (rate) for BACnet tags. This parameter needs to be set on the report server

machine.

**Allowable Values:**

1 to 3600000 (milliseconds).

**Default Value:**

1000

**See Also**

[Scheduling Parameters](#)

**[Scheduling]PersistPath**

Directs where the configuration data for the Scheduler is stored. Confirm that Windows folder access is set so that path is accessible by the Report Server process.

**Allowable Values:**

- The value is treated as a file path string.

**Default Value:**

The Plant SCADA Data directory

**See Also**

[Scheduling Parameters](#)

**[Scheduling]StartDelay**

This parameter sets the delay from when the Scheduler's server side components are initialized to the point when Scheduler begins processing active schedule entries. This setting is used to allow time to establish the connections to other server processes before the scheduler server executes state actions.

**Note:** A value of [Scheduling]StartDelay=0 indicates no delay resulting in active schedule entries being processed immediately upon Report Server start up.

**Allowable Values:**

- The value is treated as a long number.
- The value units are seconds.

**Default Value:**

10 seconds

**Example**

If the [Scheduling] StartDelay ini parameter is not present in the Plant SCADA ini file, no schedule entries will be processed until 10 seconds after report server start up. If the ini file contains [Scheduling] StartDelay = 5, no schedule entries will be actioned until 5 seconds after the report server start up.

**See Also**

[Scheduling Parameters](#)

**Security Parameters**

The Citect.ini file contains the following Security parameters:

- [\[Security\]AuthenticationLogging](#) -Use this parameter to configure Authentication Event Logging.
- [\[Security\]BlockExec](#) - Can prevent users and groups from running the Exec Cicode function.
- [\[Security>CreateUserByRole](#) - Controls the behavior of the Cicode functions UserCreateForm and UserCreate.
- [\[Security\]DisableDEP](#) - When set will turn off DEP protection for the Plant SCADAruntime.
- [\[Security>DeleteWebContentProfile](#) - Use this parameter to automatically delete the application data associated with users of a Web Content control.

**See Also**

[Parameter Categories](#)

**[Security]AuthenticationLogging**

Use this parameter to configure Authentication Event Logging.

**Allowable Values:**

- 0 - No logging.
- 1 - Log only unsuccessful login attempts.
- 2 - Log every login and logout event.

**Default Value:**

1

**See Also**

[Security Parameters](#)

**[Security]BlockExec**

Can be used to prevent users and groups from running the Exec Cicode function. If the parameter is left blank, it defaults to 1. This parameter is set to 0 for the Example project. This is used in conjunction with the Allow Exec user role permission. A user can run the Exec Cicode function only if this parameter is set to 0 **and** the Allow Exec user role is set to TRUE. For more information about the role, refer to the Plant SCADA online help.

**Allowable Values:**

- 0 - Running Exec is allowed for users or groups with the Allow Exec permission set to TRUE.
- 1 - Running Exec is not allowed.

**Default Value:**

1

**See Also**[Security Parameters](#)**[Security]CreateUserByRole**

This parameter controls the behavior of the Cicode function [UserCreate](#). It determines if a created Plant SCADA user is of a specified Type or assigned to a specified Role.

---

**Note:** This parameter was designed to support the function UserCreate, which is now deprecated. If you use the function [UserCreateByRole](#) instead, you may not need to use this parameter.

---

**Allowable Values:**

- 0 - UserCreate will create a user of a specified type.
- 1 - UserCreate will create a user assigned to a specified role.

**Default Value:**

0

**See Also**[Security Parameters](#)**[Security]DisableDEP**

When set will turn off DEP protection for the Plant SCADA runtime.

**Allowable Values:**

- 0 -DEP is enabled.
- 1 - DEP is disabled.

**Default Value:**

0

**See Also**[Security Parameters](#)**[Security]DeleteWebContentProfile**

Use this parameter to automatically delete the application data associated with users of a Web Content control.

When a Web Content control is displayed, any user-specific data (such as cookies, storage and browsing history) is stored in the profile folder for the current Windows user (for example, C:\Users\<Windows User Name>). The following sub-directory is used:

\AppData\Local\AVEVA Plant SCADA\WebContent\Profiles\<User>\

Where <User> is the name of the user that is currently logged in to Plant SCADA runtime.

If this parameter is set to 1, the <User> folder will be deleted when:

- The user logs out.
- Switching to a different user account occurs.
- If the runtime application is closed.

**Allowable Values:**

- 0 -User's data is not deleted.
- 1 - User's data is deleted.

**Default Value:**

0

**See Also**[Security Parameters](#)

## Server Parameters

- [Server]Name - Obsolete in version 7.0.
- [\[Server\]AutoLoginMode](#) - Determines the auto login method the server will use when establishing a connection to other servers.

## See Also

[Parameter Categories](#)

### [Server]AutoLoginMode

Determines which auto login method the server will use when establishing a connection to other servers.

#### Allowable Values:

- 0 – Auto login is disabled
- 1 –Default server user (full areas and privileges)
- 2 - Specific User (from Computer Setup Wizard)

#### Default Value:

1

## See Also

[Server Parameters](#)

## Shutdown Parameters

The Citect.ini file contains the following shutdown parameters:

- [\[Shutdown\]NetworkIgnore](#) - Determines whether this computer responds to any network shutdown calls.
- [\[Shutdown\]NetworkStart](#) - Enables network shutdown and restart from this computer.
- [\[Shutdown\]Phase](#) - The shutdown phase for this computer.

## See Also

[Parameter Categories](#)

### [Shutdown]NetworkIgnore

Determines whether this computer responds to any network shutdown calls.

This parameter applies to shutdown calls from a remote client and needs to be configured on the server

machine. If using this parameter you need to enable the parameter [Shutdown]NetworkRestart on the remote client.

**Note:** Set this parameter to 0 for all the computers that will send or accept a shutdown command.

---

### Allowable Values:

- 0 - (Allow network shutdown).
- 1 - (Ignore network shutdown).

### Default Value:

1

### See Also

[Shutdown Parameters](#)

### [Shutdown]NetworkStart

Enables network shutdown and restart from this computer.

### Allowable Values:

- 0 - (Do not allow network shutdown and restart)
- 1 - (Allow network shutdown and restart)

### Default Value:

0

### See Also

[Shutdown Parameters](#)

### [Shutdown]Phase

The shutdown phase for this computer. This parameter only comes into effect when [Shutdown]NetworkIgnore is set to 0 and a client receives a shutdown request message from a server. Phase 2 clients receive a shutdown request when the first phase 1 client has reconnected to the server.

### Allowable Values:

- 1 - (Shutdown in first phase)
- 2 - (Shutdown in second phase)

## Default Value:

1

## See Also

[Shutdown Parameters](#)

## SPC Parameters

The Citect.ini file contains the following parameters:

- [\[SPC\]AlarmBufferSize](#) - Specifies the number of subgroups used in SPC Alarm calculations.
- [\[SPC\]XFreak](#) - The number of data points required to set the SPC XFreak type alarm
- [\[SPC\]PartialSubgroup](#) - Enables masking of subgroups from being included in calculations.
- [\[SPC\]RAboveUCL](#) - Sets the number of consecutive data points required to set the RAboveUCL SPC alarm.
- [\[SPC\]RBelowLCL](#) - Sets the number of consecutive data points required to set the RBelowLCL SPC alarm.
- [\[SPC\]ROutsideCL](#) - Sets the number of consecutive data points required to set the ROutsideCL SPC alarm.
- [\[SPC\]XAboveUCL](#) - Sets the number of consecutive data points required to set the XAboveUCL SPC alarm.
- [\[SPC\]XBelowLCL](#) - Sets the number of consecutive data points required to set the XBelowLCL SPC alarm.
- [\[SPC\]XDownTrend](#) - Sets the number of consecutive data points required to set the XDownTrend SPC alarm.
- [\[SPC\]XErratic](#) - Sets the number of consecutive data points required to set the XErratic SPC alarm.
- [\[SPC\]XGradualDown](#) - Sets the number of consecutive data points required to set the XGradualDown SPC alarm.
- [\[SPC\]XGradualUp](#) - Sets the number of consecutive data points required to set the XGradualUp SPC alarm.
- [\[SPC\]XMixture](#) - Sets the number of consecutive data points required to set the XMixture SPC alarm.
- [\[SPC\]XOutsideCL](#) - Sets the number of consecutive data points required to set the XOutsideCL SPC alarm.
- [\[SPC\]XOutsideWL](#) - Sets the number of consecutive data points required to set the XOutsideWL SPC alarm.
- [\[SPC\]XStratification](#) - Sets the number of consecutive data points required to set the XStratification SPC alarm.
- [\[SPC\]XUptrend](#) - Sets the number of consecutive data points required to set the XUptrend SPC alarm.

## See Also

[Parameter Categories](#)

### [SPC]AlarmBufferSize

Specifies the number of subgroups used in SPC Alarm calculations.

**Note:** You may find it useful to make the **AlarmBufferSize** the same as number of subgroups displayed on your SPC charts, so that any SPC alarms directly correlate with those charts.

The following shows the number of subgroups displayed on the standard SPC templates for the given

resolutions:

VGA - 39

SVGA - 52

XGA - 58

SXGA - 76

### Allowable Values:

1 to 200

### Default Value:

39 (standard VGA template)

### See Also

[SPC Parameters](#)

## [SPC]PartialSubgroup

### Allowable Values:

- 0 - (Incomplete subgroups will NOT be included in SPC calculations)
- 1 - (Incomplete subgroups will be included in SPC calculations)

### Default Value:

0

Enables masking of subgroups from being included in calculations if the subgroup data is incomplete. Subgroups that are not complete will have an effect on the accuracy of SPC calculations. The magnitude of this effect is relative to the number of subgroups on screen.

### See Also

[SPC Parameters](#)

## [SPC]RAboveUCL

Sets the number of consecutive data points required to set the RAboveUCL SPC alarm. The alarm is triggered when consecutive subgroup range values are above the upper control limit (UCL).

### Allowable Values:

1 to 20

**Default Value:**

3

**See Also**[SPC Parameters](#)**[SPC]RBelowLCL**

Sets the number of consecutive data points required to set the RBelowLCL SPC alarm. The alarm is triggered when consecutive subgroup range values are below the lower control limit (LCL).

**Allowable Values:**

1 to 20

**Default Value:**

3

**See Also**[SPC Parameters](#)**[SPC]ROutsideCL**

Sets the number of consecutive data points required to set the ROutsideCL SPC alarm. The alarm is triggered when consecutive subgroup range values are outside the control limits (UCL and LCL).

**Allowable Values:**

1 to 20

**Default Value:**

3

**See Also**[SPC Parameters](#)**[SPC]XAboveUCL**

Sets the number of consecutive data points required to set the XAboveUCL SPC alarm. The alarm is triggered

when consecutive subgroup mean values are above the upper control limit (UCL).

**Allowable Values:**

1 to 20

**Default Value:**

3

**See Also**

[SPC Parameters](#)

**[SPC]XBelowLCL**

Sets the number of consecutive data points required to set the XBelowLCL SPC alarm. The alarm is triggered when consecutive subgroup mean values are below the lower control limit (LCL).

**Allowable Values:**

1 to 20

**Default Value:**

3

**See Also**

[SPC Parameters](#)

**[SPC]XDownTrend**

Sets the number of consecutive data points required to set the XDownTrend SPC alarm. The alarm is triggered when consecutive subgroup mean values are gradually descending.

**Allowable Values:**

1 to 20

**Default Value:**

5

## See Also

[SPC Parameters](#)

### [SPC]XErratic

Sets the number of consecutive data points required to set the XErratic SPC alarm. The alarm is triggered when consecutive subgroup mean values are erratic in behaviour.

#### Allowable Values:

1 to 20

#### Default Value:

3

## See Also

[SPC Parameters](#)

### [SPC]XFreak

The number of consecutive data points required to set the SPC XFreak type alarm.

#### Allowable Values:

1 to 10

#### Default Value:

1

## See Also

[SPC Parameters](#)

### [SPC]XGradualDown

Sets the number of consecutive data points required to set the XGradualDown SPC alarm. The alarm is triggered when consecutive subgroup mean values are below the centre line (CL).

#### Allowable Values:

1 to 20

**Default Value:**

8

**See Also**

[SPC Parameters](#)

**[SPC]XGradualUp**

Sets the number of consecutive data points required to set the XGradualUp SPC alarm. The alarm is triggered when consecutive subgroup mean values are above the centre line (CL).

**Allowable Values:**

1 to 20

**Default Value:**

8

**See Also**

[SPC Parameters](#)

**[SPC]XMixture**

Sets the number of consecutive data points required to set the XMixture SPC alarm. The alarm is triggered when consecutive subgroup mean values are both above and below the centre line (CL).

**Allowable Values:**

1 to 20

**Default Value:**

8

**See Also**

[SPC Parameters](#)

**[SPC]XOutsideCL**

Sets the number of consecutive data points required to set the XOutsideCL SPC alarm. The alarm is triggered

when consecutive subgroup mean values are outside the control limits (UCL and LCL).

**Allowable Values:**

1 to 20

**Default Value:**

3

**See Also**

[SPC Parameters](#)

**[SPC]XOutsideWL**

Sets the number of consecutive data points required to set the XOutsideWL SPC alarm. The alarm is triggered when consecutive subgroup mean values are outside the alarm limits.

**Allowable Values:**

1 to 20

**Default Value:**

5

**See Also**

[SPC Parameters](#)

**[SPC]XStratification**

Sets the number of consecutive data points required to set the XStratification SPC alarm. The alarm is triggered when consecutive subgroup mean values are constant.

**Allowable Values:**

1 to 20

**Default Value:**

15

## See Also

[SPC Parameters](#)

### [SPC]XUptrend

Sets the number of consecutive data points required to set the XUptrend SPC alarm. The alarm is triggered when consecutive subgroup mean values are gradually ascending.

#### Allowable Values:

1 to 20

#### Default Value:

5

## See Also

[SPC Parameters](#)

### SQL Parameters

The Citect.ini file contains the following SQL parameters:

- [\[SQL\]DefaultTimestampFormat](#) - Sets the formatting pattern being used by SQLGetField function for converting database date/time values to strings
- [\[SQL\]MaxConnections](#) - Defines the maximum number of DB connection objects.
- [\[SQL\]MaxRecordsets](#) - Defines the maximum number of disconnected recordsets in the system.
- [\[SQL\]QueryTimeout](#) - Sets the timeout period for SQL queries globally.
- [\[SQL\]TextColWidth](#) - Sets the column width for text columns returned from SQL queries.

## See Also

[Parameter Categories](#)

### [SQL]DefaultTimestampFormat

Sets the formatting pattern being used by SQLGetField function for converting database date/time values to strings.

Please note that only main date/time data types are affected by this parameter. For SQL Server it works for DateTime and SmallDateTime, while for MS Access it works for Date/Time type. If it is necessary to use the parameter for converting other parameters, please use conversion macros to main types in your SQL queries. For example in T-SQL, the conversion may use CONVERT macro: SELECT CONVERT(DateTime, MyDateColumn) FROM MyTable.

**Allowable Values:**

Any valid "format" parameter value for the function TimestampToStr.  
0 - Short time format, hh:mm  
1 - Long time format, hh:mm:ss  
2 - Short date format, dd/MM/yyyy  
3 - Long date format, dddd, dd MMMM yyyy.  
4 - Short date & short time format, dd/MM/yyyy hh:mm  
5 - Short date & long time format, dd/MM/yyyy hh:mm:ss  
6 - Long date & short time format, dddd, dd MMMM yyyy hh:mm  
7 - Long date & long time format, dddd, dd MMMM yyyy hh:mm:ss  
8 - Month day format, dd MMMM  
9 - Year month format, MMMM yyyy  
10 - RFC1123 format, ddd, dd MMM yyyy hh:mm:ss GMT  
11 - Sortable date time format, yyyy-MM-ddThh:mm:ss  
12 - Short universal format, yyyy-MM-dd hh:mm:ss  
13 - Long universal format, dddd, dd MMMM yyyy hh:mm:ss

**Default Value:**

11

**See Also**[SQL Parameters](#)**[SQL]MaxConnections**

Defines the maximum number of DB connection objects. Note that the number includes connections which are not opened. If the current number of connections is equal or greater than this parameter then new DB connection objects cannot be created and respective functions return invalid handles. A hardware alarm is generated in this case and an appropriate log is written to TraceLog.

**Allowable Values:**

0 (Unlimited), 0 .. n

**Default Value:**

10

## See Also

[SQL Parameters](#)

### [SQL]MaxRecordsets

Defines the maximum number of disconnected recordsets in the system. If the current number of recordsets is equal or greater than this parameter then new recordsets cannot be created and respective functions return invalid handles. A SCADA hardware alarm is generated in such case and an appropriate log is written to TraceLog

#### Allowable Values:

0 (Unlimited), 0 .. n

#### Default Value:

30

## See Also

### [SQL]QueryTimeout

Sets the timeout period for SQL queries globally. This is the period of time that Plant SCADA will wait for an SQL query to be processed before terminating the query.

A query value of zero (0) seconds has special meaning: Plant SCADA will wait indefinitely for the query to be processed.

#### Allowable Values:

From 0 to 14400 (4 hours)

#### Default Value:

30

## See Also

[SQL Parameters](#)

### [SQL]TextColWidth

Sets the maximum number of text characters retrieved from a database record. This parameter only needs to be set if the SQL query returns text columns longer than 256 characters.

**Allowable Values:**

1 to 255 (characters)

**Default Value:**

255

**See Also****Time Parameters**

**Trend Parameters**

The Citect.ini file contains the following trend parameters:

- [\[Trend\]AbortStartupOnError](#) - If set and the history file properties of any Trend tag have been modified, restart of the Trend Server will not occur because the history files can not be reloaded.
- [\[Trend\]AcquisitionTimeout](#) - stops a trend server from infinitely acquiring a valid data sample from a disconnected I/O device
- [\[Trend\]AllFiles](#) - Indicates whether trend history files should be created at startup or created when needed.
- [\[Trend\]BlockByIODevice](#) - Obsolete in version 7.0.
- [\[Trend\]BytesReadBeforeSleep](#) - Controls the amount of data read from the trend archive before the trend server has to sleep.
- [\[Trend\]BytesWrittenBeforeSleep](#) - Specifies how many bytes of trend data are written to file by the TrendWriteTask before it sleeps.
- [\[Trend\]CacheSize0](#) - Determines the number of samples that can be stored in the cache of a trend with sample period < 50ms.
- [\[Trend\]CacheSize1](#) - Determines the number of samples that can be stored in the cache of a trend with sample period >= 50ms and < 250ms.

- [\[Trend\]CacheSize2](#) - Determines the number of samples that can be stored in the cache of a trend with sample period >= 250ms and < 1 second.
- [\[Trend\]CacheSize3](#) - Determines the number of samples that can be stored in the cache of a trend with sample period >= 1 second and < 5 seconds.
- [\[Trend\]CacheSize4](#) - Determines the number of samples that can be stored in the cache of a trend with sample period >= 5 seconds and < 10 seconds.
- [\[Trend\]CacheSize5](#) - Determines the number of samples that can be stored in the cache of a trend with sample period >= 10 seconds and < 20 seconds.
- - Determines the number of samples that can be stored in the cache of a trend with sample period >= 20 seconds and < 50 seconds.
- [\[Trend\]CacheSize7](#) - Determines the number of samples that can be stored in the cache of a trend with sample period >= 50 seconds < 100 seconds.
- [\[Trend\]CacheSize8](#) - Determines the number of samples that can be stored in the cache of a trend with sample period >= 100 seconds.
- [\[Trend\]ClientRequestTime](#) - The delay (in milliseconds) after real-time trend data is requested from the Trends Server before the next data is requested.
- [\[Trend\]CopyFilesMessage](#) - Determines whether the redundant Trends Server displays an alert message if it cannot find any trend files.
- [\[Trend\]CPU](#) - Obsolete in version 7.0.
- [\[Trend\]CursorColor](#) - Allows the cursor color to be specified.
- [\[Trend\]CursorColour](#) - Obsolete in version 7.20 (replaced by [\[Trend\]CursorColor](#)).
- [\[Trend\]DeleteIfIncompatible](#) - Deletes incompatible history files automatically.
- [\[Trend\]Disable](#) - Enables/disables the Trends Server.
- [\[Trend\]EnableBackfill](#) - Allows trend backfill to be disabled.
- [\[Trend\]FileCreationWriteSize](#) - Controls the rate at which trend files are initialised (whether created at startup or runtime).
- [\[Trend\]FileNameType](#) - Specifies whether your trend file names will be long or short.
- [\[Trend\]FilterViewByPrivilege](#) - Determines if the results from a trend browse will be filtered according to privilege.
- [\[Trend\]GapFillMode](#) - Determines which method is used to fill gaps in a trend file and graph caused by missing trend samples.
- [\[Trend\]GapFillSamples](#) - Determines whether gaps in a trend graph caused by missing samples are filled (determined by the number of samples missed).
- [\[Trend\]GapFillTime](#) - Determines whether gaps in a trend graph caused by missing samples are filled (determined by the duration of the gap).
- [\[Trend\]InhibitEvent](#) - Inhibits event trends on startup.
- [\[Trend\]InstantTrendIdleTime](#) - Set this parameter to specify the maximum number of seconds that an unused instant trend will be retained.
- [\[Trend\]InstantTrendSamples](#) - Set this parameter to determine the maximum number of samples that will be retained for an individual instant trend.
- [\[Trend\]MaxBackfillsAtOnce](#) - Determines the number of trend to be requested for backfill at a time.
- [\[Trend\]MaxRdnSamples](#) - Determines the maximum samples to be requested for a trend at a time.

- [\[Trend\]MaxRequestLength](#) - Determines the maximum number of trend sample requests allowed per trend.
- [\[Trend\]MaxSetTableQue](#) - Determines the maximum number of SetTrendTable requests on the primary trend server to be transferred to the standby server.
- [\[Trend\]MaxSetTableStnbyPending](#) - Controls the maximum number of pending SetTrendTable requests to the standby trend server.
- [\[Trend\]MissedSamplesAlarmTime](#) - Controls the amount of trend data that can be missed before a hardware alarm is triggered.
- [\[Trend\]Process](#) - Obsolete in version 7.0.
- [\[Trend\]RangeCheck](#) - Checks for invalid trend sample values.
- [\[Trend\]ReadWatchTime](#) - Determines how long the trend server will wait (in milliseconds) between each file read of trend samples.
- [\[Trend\]Redundancy](#) - Obsolete in version 7.0.
- [\[Trend\]ReloadBackOffTime](#) - Back-off time configured to control the pace of the reload on an Trend server.
- [\[Trend\]Server](#) - Obsolete in version 7.0.
- [\[Trend>ShowCacheSizes](#) - Determines whether the currently set values and sample period ranges for parameters [Trend]CacheSize0 . . . [Trend]CacheSize8 are displayed in the Plant SCADA Kernel.
- [\[Trend\]StaggerRequestSubgroups](#) - Obsolete in version 7.0.
- [\[Trend\]TrendDebug](#) - Used to debug the trend system during commissioning.
- [\[Trend\]WatchTime](#) - The delay (in milliseconds) after data is returned from the I/O device before data is requested for the next trend acquisition cycle.
- [\[Trend\]WriteWatchTime](#) - The trend write task writes out trend data to disk, and then sleeps for the time specified in this parameter (before writing the next trend file).

## See Also

[Parameter Categories](#)

[Trend Process Parameters](#)

### [Trend]AbortStartupOnError

When set the trend server will abort the startup if it finds a history file that does not match the required format.

---

**Note:** The configuration can be returned to its previous state so that the history file will match the required format. Alternatively, the invalid files may be backed up and deleted so that new files can be created on the next restart.

---

### Allowable Values:

- 0 - Start the trend server but with trends that have miss-matched history file configuration disabled.
- 1 - Abort the trend server startup if any trends have miss-matched history file configuration.

### Default Value:

0

## See Also

[Trend Parameters](#)

### [Trend]AcquisitionTimeout

Sets a timeout to stop a trend server waiting indefinitely for a valid data sample from an I/O device while the connection to the I/O server is lost or the device is offline.

On each sample collection, the gap between current time and the last sample request time is checked. If this gap is greater or equal to the value set for this parameter, and the sample data is invalid, a gap fill action is requested (i.e. synchronization will be performed). This implementation is designed to avoid large gaps in trend history when the connection to an I/O device is lost.

#### Allowable Values:

0 to 65536 (seconds)

#### Default Value:

300 (seconds)

## See Also

[Trend Parameters](#)

### [Trend]AllFiles

Indicates whether all trend history files should be created at startup or created when needed. By default, Plant SCADA creates all trend history files at startup, so that the required disk space is allocated at the same time, without fragmentation. (Because files are created at startup, you know the total disk requirements.) Creating history files at startup happens only once - the first time Plant SCADA starts up.

On large systems with many trends, the first startup could take considerable time. If you change the default of this parameter, history files are created whenever needed, reducing the first time startup delay. However, if a disk space shortage occurs while Plant SCADA is running, data loss will occur because new history files cannot be created.

#### Allowable Values:

- 0 - (Create a file when needed)
- 1 - (Create all files at startup)

#### Default Value:

1

## See Also

[Trend Parameters](#)

### [Trend]BlockByIODevice

**Note:** This parameter is obsolete. From version 7.0, trend data from a device is no longer blocked by the Trend Server, but instead is blocked by the I/O device. Trend tags are automatically updated with trend data.

Setting this parameter to 1 commands that if I/O problems (e.g. with hardware, the I/O device, or the communications link) resulted in gaps for one trend tag, other trend tags were unaffected.

Leaving this parameter set to 0 meant that one trend tag with gaps could cause gaps for **all** trend tags.

## Allowable Values:

- 0 - Gaps caused for one trend tag will cause gaps for all trend tags
- 1 - Gaps caused for one trend tag will leave other trend tags unaffected

## Default Value:

1

## See Also

### [Trend]BytesReadBeforeSleep

Increasing the value of this parameter allows more data to be read from the trend archive before the trend server has to sleep. This may improve the read performance of trend requests on the trend server.

**Note:** Increasing this value may also increase the CPU usage on the trend server.

## Allowable Values:

1 to 2147483647

## Default Value:

65536

## See Also

[Trend Parameters](#)

### [Trend]BytesWrittenBeforeSleep

This parameter specifies how many bytes of trend data are written to file by the TrendWriteTask, before it sleeps

for the amount of time specified by the WriteWatchTime parameter.

## **WARNING**

### **UNINTENDED EQUIPMENT OPERATION**

Do not change the [Trend]BytesWrittenBeforeSleep parameter in the Citect.ini file, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

### **Allowable Values:**

1 to 1000000 (bytes)

### **Default Value:**

65536

### **See Also**

[Trend Parameters](#)

### **[Trend]CacheSize0**

Determines the number of samples that can be stored in the cache of trends with sample period < 50ms.

### **Allowable Values:**

Any integer between 1 and 65536 inclusive (trend samples)

### **Default Value:**

8188

If your sample period is  $\geq$  50ms, Plant SCADA uses a different parameter to set the number of samples the cache can store. See the following table:

[Trend]Parameter	Sample Period	Default Value (No. of samples)
[Trend]CacheSize0	< 50 ms	8188
[Trend]CacheSize1	$\geq$ 50 ms and < 250 ms	2044
[Trend]CacheSize2	$\geq$ 250 ms and < 1 second	1020
[Trend]CacheSize3	$\geq$ 1 second and < 5 seconds	764
[Trend]CacheSize4	$\geq$ 5 seconds and < 10 seconds	508

[Trend]Parameter	Sample Period	Default Value (No. of samples)
[Trend]CacheSize5	>= 10 seconds and < 20 seconds	380
[Trend]CacheSize6	>= 20 seconds and < 50 seconds	252
[Trend]CacheSize7	>= 50 seconds and < 100 seconds	192
[Trend]CacheSize8	>= 100 seconds	128

## See Also

[Trend Parameters](#)

### [Trend]CacheSize1

Determines the number of samples that can be stored in the cache of trends with sample period >= 50ms and < 250ms.

#### Allowable Values:

Any integer between 1 and 65536 inclusive (trend samples)

#### Default Value:

2044

If your sample period is < 50 ms or >= 250ms, Plant SCADA uses a different parameter to set the number of samples the cache can store. See the following table:

[Trend]Parameter	Sample Period	Default Value (No. of samples)
[Trend]CacheSize0	< 50 ms	8188
[Trend]CacheSize1	>= 50 ms and < 250 ms	2044
[Trend]CacheSize2	>= 250 ms and < 1 second	1020
[Trend]CacheSize3	>= 1 second and < 5 seconds	764
[Trend]CacheSize4	>= 5 seconds and < 10 seconds	508
[Trend]CacheSize5	>= 10 seconds and < 20 seconds	380
[Trend]CacheSize6	>= 20 seconds and < 50 seconds	252
[Trend]CacheSize7	>= 50 seconds and < 100 seconds	192
[Trend]CacheSize8	>= 100 seconds	128

## See Also

[Trend Parameters](#)

### [Trend]CacheSize2

Determines the number of samples that can be stored in the cache of trends with sample period  $\geq 250\text{ms}$  and  $< 1\text{ second}$ .

#### Allowable Values:

Any integer between 1 and 65536 inclusive (trend samples)

#### Default Value:

1020

If your sample period is  $<250\text{ ms}$  or  $\geq 1\text{ second}$ , Plant SCADA uses a different parameter to set the number of samples the cache can store. See the following table:

[Trend]Parameter	Sample Period	Default Value (No. of samples)
[Trend]CacheSize0	< 50 ms	8188
[Trend]CacheSize1	$\geq 50\text{ ms}$ and $< 250\text{ ms}$	2044
[Trend]CacheSize2	$\geq 250\text{ ms}$ and $< 1\text{ second}$	1020
[Trend]CacheSize3	$\geq 1\text{ second}$ and $< 5\text{ seconds}$	764
[Trend]CacheSize4	$\geq 5\text{ seconds}$ and $< 10\text{ seconds}$	508
[Trend]CacheSize5	$\geq 10\text{ seconds}$ and $< 20\text{ seconds}$	380
[Trend]CacheSize6	$\geq 20\text{ seconds}$ and $< 50\text{ seconds}$	252
[Trend]CacheSize7	$\geq 50\text{ seconds}$ and $< 100\text{ seconds}$	192
[Trend]CacheSize8	$\geq 100\text{ seconds}$	128

## See Also

[Trend Parameters](#)

### [Trend]CacheSize3

Determines the number of samples that can be stored in the cache of trends with sample period  $\geq 1\text{ second}$  and  $< 5\text{ seconds}$ .

**Allowable Values:**

Any integer between 1 and 65536 inclusive (trend samples)

**Default Value:**

764

If your sample period is <1 second or  $\geq$  5 seconds, Plant SCADA uses a different parameter to set the number of samples the cache can store. See the following table:

[Trend]Parameter	Sample Period	(No. of samples)
[Trend]CacheSize0	< 50 ms	8188
[Trend]CacheSize1	$\geq$ 50 ms and < 250 ms	2044
[Trend]CacheSize2	$\geq$ 250 ms and < 1 second	1020
[Trend]CacheSize3	$\geq$ 1 second and < 5 seconds	764
[Trend]CacheSize4	$\geq$ 5 seconds and < 10 seconds	508
[Trend]CacheSize5	$\geq$ 10 seconds and < 20 seconds	380
[Trend]CacheSize6	$\geq$ 20 seconds and < 50 seconds	252
[Trend]CacheSize7	$\geq$ 50 seconds and < 100 seconds	192
[Trend]CacheSize8	$\geq$ 100 seconds	128

**See Also**

[Trend Parameters](#)

**[Trend]CacheSize4**

Determines the number of samples that can be stored in the cache of trends with sample period  $\geq$  5 seconds and < 10 seconds.

**Allowable Values:**

Any integer between 1 and 65536 inclusive (trend samples)

**Default Value:**

508

If your sample period is <5 seconds or  $\geq$  10 seconds, Plant SCADA uses a different parameter to set the number of samples the cache can store. See the following table:

[Trend]Parameter	Sample Period	Default Value (No. of samples)
[Trend]CacheSize0	< 50 ms	8188
[Trend]CacheSize1	>= 50 ms and < 250 ms	2044
[Trend]CacheSize2	>= 250 ms and < 1 second	1020
[Trend]CacheSize3	>= 1 second and < 5 seconds	764
[Trend]CacheSize4	>= 5 seconds and < 10 seconds	508
[Trend]CacheSize5	>= 10 seconds and < 20 seconds	380
[Trend]CacheSize6	>= 20 seconds and < 50 seconds	252
[Trend]CacheSize7	>= 50 seconds and < 100 seconds	192
[Trend]CacheSize8	>= 100 seconds	128

## See Also

[Trend Parameters](#)

### [Trend]CacheSize5

Determines the number of samples that can be stored in the cache of trends with sample period >= 10 seconds and < 20 seconds.

#### Allowable Values:

Any integer between 1 and 65536 inclusive (trend samples)

#### Default Value:

380

If your sample period is < 10 seconds or >= 20 seconds, Plant SCADA uses a different parameter to set the number of samples the cache can store. See the following table:

[Trend]Parameter	Sample Period	Default Value (No. of samples)
[Trend]CacheSize0	< 50 ms	8188
[Trend]CacheSize1	>= 50 ms and < 250 ms	2044
[Trend]CacheSize2	>= 250 ms and < 1 second	1020
[Trend]CacheSize3	>= 1 second and < 5 seconds	764

[Trend]Parameter	Sample Period	Default Value (No. of samples)
[Trend]CacheSize4	>= 5 seconds and < 10 seconds	508
[Trend]CacheSize5	>= 10 seconds and < 20 seconds	380
[Trend]CacheSize6	>= 20 seconds and < 50 seconds	252
[Trend]CacheSize7	>= 50 seconds and < 100 seconds	192
[Trend]CacheSize8	>= 100 seconds	128

## See Also

[Trend Parameters](#)

### [Trend]CacheSize6

Determines the number of samples that can be stored in the cache of trends with sample period >= 20 seconds and < 50 seconds

#### Allowable Values:

Any integer between 1 and 65536 inclusive (trend samples)

#### Default Value:

252

If your sample period is < 20 seconds or >= 50 seconds, Plant SCADA uses a different parameter to set the number of samples the cache can store. See the following table:

[Trend]Parameter	Sample Period	Default Value (No. of samples)
[Trend]CacheSize0	< 50 ms	8188
[Trend]CacheSize1	>= 50 ms and < 250 ms	2044
[Trend]CacheSize2	>= 250 ms and < 1 second	1020
[Trend]CacheSize3	>= 1 second and < 5 seconds	764
[Trend]CacheSize4	>= 5 seconds and < 10 seconds	508
[Trend]CacheSize5	>= 10 seconds and < 20 seconds	380
[Trend]CacheSize6	>= 20 seconds and < 50 seconds	252
[Trend]CacheSize7	>= 50 seconds and < 100 seconds	192

[Trend]Parameter	Sample Period	Default Value (No. of samples)
[Trend]CacheSize8	>= 100 seconds	128

## See Also

[Trend Parameters](#)

### [Trend]CacheSize7

Determines the number of samples that can be stored in the cache of trends with sample period >= 50 seconds and < 100 seconds.

#### Allowable Values:

Any integer between 1 and 65536 inclusive (trend samples)

#### Default Value:

192

If your sample period is <50 seconds or >= 100 seconds, Plant SCADA uses a different parameter to set the number of samples the cache can store. See the following table:

[Trend]Parameter	Sample Period	(No. of samples)
[Trend]CacheSize0	< 50 ms	8188
[Trend]CacheSize1	>= 50 ms and < 250 ms	2044
[Trend]CacheSize2	>= 250 ms and < 1 second	1020
[Trend]CacheSize3	>= 1 second and < 5 seconds	764
[Trend]CacheSize4	>= 5 seconds and < 10 seconds	508
[Trend]CacheSize5	>= 10 seconds and < 20 seconds	380
[Trend]CacheSize6	>= 20 seconds and < 50 seconds	252
[Trend]CacheSize7	>= 50 seconds and < 100 seconds	192
[Trend]CacheSize8	>= 100 seconds	128

## See Also

[Trend Parameters](#)

**[Trend]CacheSize8**

Determines the number of samples that can be stored in the cache of trends with sample period >= 100 seconds.

**Allowable Values:**

Any integer between 1 and 65536 inclusive (trend samples)

**Default Value:**

128

If your sample period is < 100 seconds, Plant SCADA uses a different parameter to set the number of samples the cache can store. See the following table:

[Trend]Parameter	Sample Period	Default Value (No. of samples)
[Trend]CacheSize0	< 50 ms	8188
[Trend]CacheSize1	>= 50 ms and < 250 ms	2044
[Trend]CacheSize2	>= 250 ms and < 1 second	1020
[Trend]CacheSize3	>= 1 second and < 5 seconds	764
[Trend]CacheSize4	>= 5 seconds and < 10 seconds	508
[Trend]CacheSize5	>= 10 seconds and < 20 seconds	380
[Trend]CacheSize6	>= 20 seconds and < 50 seconds	252
[Trend]CacheSize7	>= 50 seconds and < 100 seconds	192
[Trend]CacheSize8	>= 100 seconds	128

**See Also**

[Trend Parameters](#)

**[Trend]ClientRequestTime**

The interval between client requests for trend data from the Trends Server. For instance, if you set this value to 500ms, any trends with a display period of 300ms will only be updated with new data every 500ms. You can set this parameter to any value, but the lower the value, the more frequent the requests to the Trends Server, and this will cause an increased CPU load.

**Allowable Values:**

1 to 60000 (milliseconds)

**Default Value:**

250

**See Also**[Trend Parameters](#)**[Trend]CopyFilesMessage**

Determines whether the redundant Trends Server displays an alert message if it cannot find any trend files. Such an error might be reported when the redundant Trends Server starts up for the first time, or if files have been deleted.

If the projects being run by both Trends Servers are not identical, the redundant copy may not succeed, displaying an alert message. For example, if trend tags are missing or in a different order.

**Allowable Values:**

- 0 - (Do not display alert message)
- 1 - (Display alert message)

**Default Value:**

1

**See Also****[Trend]CursorColor**

Specifies the trend cursor color.

**Allowable Values:**

0x000000 to 0xFFFFF

Color defined as an RGB value, for example:

- 0x000000 - (Black)
- 0x000080 - (Blue)
- 0x008000 - (Green)
- 0x008080 - (Cyan)
- 0x800000 - (Red)
- 0x800080 - (Magenta)
- 0x808000 - (Brown)

- 0xBFBFBF - (Grey)
- 0x7F7F7F - (Dark Grey)
- 0x0000FF - (Light blue)
- 0x00FF00 - (Light green)
- 0x00FFFF - (Light cyan)
- 0xFF0000 - (Light red)
- 0xFF00FF - (Light Magenta)
- 0xFFFF00 - (Yellow)
- 0xFFFFFFFF - (White)

**Default Value:**

0x000000 (Black)

**See Also**

[Trend Parameters](#)

**[Trend]DeleteIfIncompatible**

Causes automatic deletion of incompatible history files at start-up.

**Allowable Values:**

- 0 - (No file deletion. Plant SCADA shuts down.)
- 1 - (Incompatible history files are automatically deleted. Plant SCADA logs a message to the SYSLOG.DAT file and continues.)

**Default Value:**

0

**See Also**

[Trend Parameters](#)

**[Trend]Disable**

Enables/disables the Trends Server.

**Allowable Values:**

- 0 - (Enable)

- 1 - (Disable)

**Default Value:**

0

**See Also**

[Trend Parameters](#)

**[Trend]EnableBackfill**

Allows users to disable trend backfill at startup and server re-connection.

**Allowable Values:**

- 0 - (Disable)
- 1 - (Enable)

**Default Value:**

1

**See Also**

[Trend Parameters](#)

**[Trend]FileCreationWriteSize**

Controls the rate at which trend files are initialised (whether created at startup or runtime). Optimal performance is achieved with values of 327680 bytes or lower. File writes larger than this may be batched in chunks of 65536 bytes, reducing the performance benefit. Environmental factors may also alter this threshold.

**Allowable Values:**

1 to 2147483647

**Default Value:**

16384

**See Also**

[Trend Parameters](#)

## [Trend]FileNameType

Specifies whether your trend file names will be long or short. There are three options: Compatible file names, Long file names, and Short file names.

- Compatible File Names - All new trend files will have long file names if supported by the operating system. Existing short file names will be unaffected. The trend system will check for short file names, so Plant SCADA startup may take longer.
- Long File Names - All new and existing trend files will be assigned long file names. Existing short file names will not be deleted, but the trend system will be unable to use them.
- Short File Names - All new and existing trend files will be assigned short file names. Existing long file names will not be deleted, but the trend system will be unable to use them.

### Allowable Values:

- 0 - (Compatible file names)
- 1 - (Long file names)
- 2 - (Short file names)

### Default Value:

0

### See Also

[Trend Parameters](#)

## [Trend]FilterViewByPrivilege

The setting applied to this parameter effects any any trend browse or data request performed by the cicode functions TrnBrowseOpen, TrnGetTable, TrnEventGetTable or TrnEventGetTableMS, or through CTAPI using CtFindFirst for the tables TrnQuery and CTAPITrend.

When this parameter is set to 0 on the trend server, the set of records returned from the browse will not be filtered by privilege. When this parameter is set to 1, the set of records returned from the browse will be filtered by privilege. The privilege and area of the current logged in user who initiated the browse will be checked against that configured in the privilege and area fields of each trend in the trend forms in Plant SCADA Studio, and the trend will only be included if the user met that level of access.

### Allowable Values:

- 0 - browse sessions not filtered by privilege
- 1 - browse sessions filtered by privilege

**Default Value:**

0

**See Also**

[Trend Parameters](#)

**[Trend]GapFillMode**

Determines the method used to fill gaps in a trend file and graph caused by missing trend samples. You can choose either the Step or Ratio method.

If you choose Step, Plant SCADA will fill the gap with a sample of the same value as the last real sample.

If you choose Ratio, Plant SCADA will fill the gap with a sample which is calculated using the ratio of sample times and values immediately before and after the gap. The gap in the trend graph will then be filled with a straight line.

**Note:** For gaps to be filled, you must also set the parameter [Trend]GapFillTime or [Trend]GapFillSamples.

If you want to fill gaps left by missing trend samples on the trend graph only (and not in the trend's file), you must use TrnSetDisplayMode() instead of this parameter.

**Allowable Values:**

- 0 - Step
- 1 - Ratio

**Default Value:**

0

**See Also**

[Trend Parameters](#)

**[Trend]GapFillSamples**

Determines how Plant SCADA processes missing trend samples (i.e. gaps in the trend file and graph). If the number of missing samples is less than the value you enter here, the gap will be filled. Gaps larger than or equal to this value will not be filled.

If you enter 0, no gaps will be filled - the gaps will actually appear on your trend graphs.

**Note:** To use time (instead of samples) to determine which gaps will be filled, set this parameter to -1.

[Trend]GapFillTime will then be used. If you set it to any value greater than or equal to 0, [Trend]GapFillTime will be ignored.

The method used to fill the gap is specified by the [Trend]GapFillMode parameter.

To fill gaps left by missing trend samples on the trend graph only (and not in the trend's file), you must use

TrnSetDisplayMode() instead of this parameter.

### Allowable Values:

-1 to 1000000

### Default Value:

-1

### See Also

[Trend Parameters](#)

## [Trend]GapFillTime

Determines how Plant SCADA processes missing trend samples (i.e. gaps in the trend file and graph). Any gaps equal to or shorter than the time you enter here will be filled with values calculated by Plant SCADA. If you enter 0, no gaps will be filled - the gaps will actually appear on your trend graphs.

---

**Note:** To use samples (instead of time) to determine which gaps will be filled, set [Trend]GapFillSamples to a value greater than or equal to 0, [Trend]GapFillTime will then be ignored.

The method used to fill the gap is specified by the [Trend]GapFillMode parameter.

To fill gaps left by missing trend samples on the trend graph only (and not in the trend's file), use TrnSetDisplayMode() instead of this parameter.

### Allowable Values:

0 to 60000 (milliseconds)

### Default Value:

10000

### See Also

[Trend Parameters](#)

## [Trend]InhibitEvent

Inhibits event trends on startup. For example, you might have a trend that is triggered off the rising edge of a bit on startup. The Trends Server notices the bit come on, and displays the trend. If this parameter is enabled, the Trends Server does not display this trend until it has read the I/O devices a second time.

---

**Note:** This parameter is modified by the Computer Setup Wizard as well as the Computer Setup Editor.

**Allowable Values:**

- 0 - (Do not disable)
- 1 - (Disable)

**Default Value:**

1

**See Also**[Trend Parameters](#)**[Trend]InstantTrendIdleTime**

Set this parameter to specify the number of seconds that data will be held in the cache for an instant trend without client display requests. If no requests for the data occur for this period of time, the cached data will be cleared and the instant trend will need to restart the cache for the next client display request.

---

**Note:** Increasing this value may increase the memory usage of the display client, which may impact performance.

---

**Allowable Values:**

0 to 1000000 (seconds).

**Default Value:**

600

**See Also**[Trend Parameters](#)**[Trend]InstantTrendSamples**

Set this parameter to determine the maximum number of samples that will be retained for an individual instant trend. When the limit is reached, the oldest samples are discarded.

---

**Note:** Increasing this value may increase the memory usage of the display client, which may impact performance.

---

**Allowable Values:**

0 to 1000000.

**Default Value:**

6000

**See Also**

[Trend Parameters](#)

**[Trend]MaxBackfillsAtOnce**

Limits the number of trends that can be requested for backfill at a time. Useful for restricting the CPU and network traffic for trend backfilling upon startup or network recapture.

**UNINTENDED EQUIPMENT OPERATION**

Do not change the [Trend]MaxBackfillsAtOnce parameter in the Citect.ini file, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Allowable Values:**

1 to 32000

**Default Value:**

5

**See Also**

[Trend Parameters](#)

**[Trend]MaxRdnSamples**

Determines the maximum number of samples in a single redundancy backfilling request for a particular trend. Increasing the value of this parameter will cause trend redundancy requests to be larger which may speed up trend redundancy backfilling, but at the potential cost of making the trend server less responsive to display client requests during redundancy synchronisation. Decreasing the value of this parameter will cause trend redundancy requests to be smaller, potentially allowing display client trend requests to be responded to faster during redundancy synchronisation, but this may slow down trend redundancy synchronisation.

**Allowable Values:**

1 to 32767

**Default Value:**

500

**See Also**

[Trend Parameters](#)

**[Trend]MaxRequestLength**

The maximum size of a trend request measured in the number of samples that a trend server will accept from clients. This parameter protects the trend server from being overloaded by requests that are too large.

Decreasing this parameter will cause smaller trend requests to be rejected, increasing its value will let the trend server process large requests which could reduce the responsiveness of the trend server to smaller requests.

**Note:** Trend redundancy backfilling requests from the peer trend server are never rejected, regardless of what setting is applied to this parameter. In order to control the size of trend redundancy requests, use the parameter [\[Trend\]MaxRdnSamples](#).

**Allowable Values:**

1 to 100000000

**Default Value:**

4000

**See Also**

[Trend Parameters](#)

**[Trend]MaxSetTableQue**

The maximum number of SetTrendTable requests on the primary trend server allowed when these have to be transferred to the standby server.

**Note:** When [Trend]TrendDebug is on you will get a syslog message: "SET TABLE Que size too big. Abandoning request for trend: xxxx" when the queue hits the high water mark on the primary trend server.

**Allowable Values:**

1000 to 32000

**Default Value:**

32000

## See Also

[Trend Parameters](#)

### [Trend]MaxSetTableStnbyPending

Controls the maximum number of pending SetTrendTable requests to the standby trend server. It is the primary trend server which uses this INI parameter.

This has been done so that the standby trend server does not receive too many requests.

---

**Note:** When [trend]TrendDebug logging is on you will get a syslog message: "SET TABLE Standby server update has reached 100 max pending high water mark" when the queue hits the high water mark on the primary trend server.

---

## Allowable Values:

1 to 32000

## Default Value:

100

## See Also

[Trend Parameters](#)

### [Trend]MissedSamplesAlarmTime

Controls the amount of trend data that can be missed before a hardware alarm is triggered. A value of 0 disables the alarm. If the value is > 0, an alarm will be raised if a gap occurs which is larger than this value.

## Allowable Values:

0 to 60000 (milliseconds)

## Default Value:

5000 (milliseconds)

## See Also

[Trend Parameters](#)

### [Trend]RangeCheck

Plant SCADA checks for trend values that have fallen outside their full scale and zero scale range. The RangeCheck parameter allows you to specify the action that Plant SCADA should take when such values are detected.

#### Allowable Values:

- 0 - (Clamp values to limits)
- 1 - (Invalidate values - <NA> is displayed)
- 2 - (Clamp values to limits for Scaled [2-byte] storage method.  
Leave values outside the range for Floating Point [8-byte] storage method)
- 3 - (Invalidate values for Scaled [2-byte] storage method. Leave values outside the range for Floating Point [8-byte] storage method)

#### Default Value:

1

#### See Also

### [Trend]ReadWatchTime

Determines how long the trend server will wait (in milliseconds) between each read of trend samples.

Setting this parameter to 0 (zero) causes the read thread to give up the rest of its current CPU time slice.

If this value is -1, there will be no delay between reads. You should avoid setting this parameter to -1 if you have many clients. In extreme cases of many clients doing many trend read requests, it may be necessary to increase the value of ReadWatchTime so that the main Plant SCADA thread still gets all its work done.

#### **WARNING**

##### **UNINTENDED EQUIPMENT OPERATION**

Do not change the [Trend]ReadWatchTime parameter in the Citect.ini file, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

#### Allowable Values:

-1 to 60 000 (milliseconds)

#### Default Value:

1

## See Also

[Trend Parameters](#)

### [Trend]ReloadBackOffTime

Adding or updating trend records too quickly could potentially put pressure to the server disk, causing delays to server responsiveness or trend sample collection.

A back-off time can be configured to control the pace of the reload on a trend server. The back-off time represents the minimal number of milliseconds for which the system will wait after adding or updating a trend record. The system will not attempt to reload another trend record before this back-off time is out.

This configuration value is read at the beginning of each server reload.

#### Allowable Values:

- 0 ~ 2147483647 (milliseconds)

#### Default Value:

1 (millisecond)

## See Also

[Trend Parameters](#)

### [Trend]ShowCacheSizes

Determines whether the currently set values and sample period ranges for [Trend] parameters CacheSize0..CacheSize8 are displayed in the Plant SCADA Kernel.

#### Allowable Values:

- 0 - (Information is not displayed)
- 1 - (Information is displayed)

Default Value:

0

## See Also

[Trend Parameters](#)

## [Trend]TrendDebug

Used to diagnose the trend system during commissioning. Options values are:

- 1 - Logs the client, server, and redundancy message types and also the samples being written in the trend server from normal acquisition, to syslog.dat.
- 2 - Logs detailed information about the currently active backfill process, to syslog.dat. This will include the redundant samples written to the archive.
- 4 - Logs detailed information for the TrendSetTable functions, to syslog.dat.
- 8 - Logs the summary information only of the currently active backfill process, to syslog.dat.
- 16 - Logs the client trend data, to syslog.dat.

These settings can be added together to have combinations of logging levels. For example:

```
[Trend]
TrendDebug=6 ! 4 + 2
```

This will log the detailed backfill process and TrendSetTable functions.

### Allowable Values:

0 to 31

### Default Value:

0

**Note:** You can update this parameter within the Citect.ini file while online, as the runtime system will read its value periodically or on demand. For more information, search the Plant SCADA Help for the topic *Adjusting Logging During Runtime*.

### See Also

[Trend Parameters](#)

## [Trend]WatchTime

The interval between Trends Server requests for data from the I/O devices. This parameter is ignored if you have a trend in your system that requests data at a higher rate - the Trends Server will request data as often as the trends in your system demand. For instance, if you set this value to 500ms, and a trend in your system has a sampling period of 300ms, the Trends Server will cater for this sampling period.

**Note:** The parameter value is not altered when the interval is automatically set for fast trends.

You can set this parameter to any value, but the lower the value, the more frequent the requests to the I/O devices, and this will cause an increased CPU load.

### Allowable Values:

100 to 60000 (milliseconds)

**Default Value:**

500

**See Also**

[Trend Parameters](#)

**[Trend]WriteWatchTime**

**WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not change the [Trend]WriteWatchTime parameter in the Citect.ini file, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

There are two uses for this parameter. The trend write task writes out trend data to disk, and then sleeps for the time specified in this parameter (before writing the next trend file). This small delay stops the trend write task from using too much CPU time when it is writing out a large number of files. If this parameter is set to 0, no delay occurs and the trend data is written to disk as fast as possible.

In addition, this parameter is used to define how long a trend will sleep for after the parameter, BytesWrittenBeforeSleep, has determined how long data will be written to disk.

**Allowable Values:**

0 to 60000 (milliseconds)

**Default Value:**

40

**See Also**

[Trend Parameters](#)

**Trend Process Parameters**

Plant SCADA allows you to specify some parameters for a trend server process (see [Hierarchical Parameters](#) in the Plant SCADA documentation).

The following parameters need to be configured for a specific process.

**Note:** The <server name> is the name of the trend server as specified in the **Topology** activity.

- [\[Trend.<ClusterName>.<ServerName>\]Clusters](#) - Sets the clusters this Trends Server process will connect to

at startup.

- [\[Trend.<ClusterName>.<ServerName>\]CPU](#) - Sets the CPU that the Trend Server process is assigned to.
- [\[Trend.<ClusterName>.<ServerName>\]Events](#) - The list of events that this Plant SCADA Trend Server process enables.
- [\[Trend.<ClusterName>.<ServerName>\]ShutdownCode](#) - Determines the Cicode function to run when Plant SCADA Trend Server process shuts down.
- [\[Trend.<ClusterName>.<ServerName>\]StartupCode](#) - Determines the Cicode function to run when Plant SCADA Trend Server process starts up.

The Citect.ini file on any PC that will be connecting to this <cluster name><server name> trend server can contain the following parameters:

- [\[Trend.<ClusterName>.<ServerName>\]DisableConnection](#) - This setting is used to specify if a client should not connect to a server.
- [\[Trend.<ClusterName>.<ServerName>\]Priority](#) - This setting is used to specify the client priority for the server connection.

## See Also

[Parameter Categories](#)

[Trend Parameters](#)

### [Trend.<ClusterName>.<ServerName>]Clusters

Sets which clusters this Trends Server will connect to at startup.

#### Allowable Values:

A comma separated list of configured cluster names.

#### Default Value:

If this parameter is blank, the Trend Server will connect to every cluster defined for the project.

This parameter needs to be defined at the finest level of hierarchical granularity (Trend.<ClusterName>.<ServerName>Clusters). See [Hierarchical Parameters](#) for more information.

## See Also

[Trend Process Parameters](#)

### [Trend.<ClusterName>.<ServerName>]CPU

This parameter is by Plant SCADA Runtime Manager to determine which CPU(s) the trend server process is assigned to. The CPU parameter is configurable for every Plant SCADA process via the **CPU Setup** page in the Computer Setup Wizard (see [CPU Configuration](#)).

This parameter needs to be defined at the finest level of hierarchical granularity (Trend.<ClusterName>.<ServerName>CPU). See [Hierarchical Parameters](#) for more information.

CPU numbers are specified in a comma separated list. CPU numbers need to be valid and a subset of the available CPUs on a computer. For example, if there are eight CPUs on a computer, a valid CPU range is 0 to 7.

**Note:** If this parameter is modified while the Plant SCADA Runtime Manager is running, the changes will not take effect until every instance of Plant SCADA is restarted.

## Allowable Values:

A comma separated list in the range 0 to 31 (inclusive) where 0 is the first CPU (for example, "0, 1, 2" or "3, 4, 5").

If no value is entered, the process will run on all available CPUs.

**Note:** When a process is set to run on all available CPUs, be aware that performance issues may still occur when your CPU usage is less than 100%. You can detect these issues when your CPU usage for a process is fixed at 100 divided by the number of processors.

## Default Value:

No value (the process will run on all CPUs).

**Note:** You cannot manually specify CPU assignments on a computer with more than 32 CPUs. Under these circumstances, the Setup Wizard will automatically set this parameter to no value (all CPUs). Any changes you make to this parameter will be overwritten.

## See Also

[Trend Process Parameters](#)

[\[Client\]CPU](#)

[\[Alarm.<ClusterName>.<ServerName>\]CPU](#)

[\[IOServer.<ClusterName>.<ServerName>\]CPU](#)

[\[Report.<ClusterName>.<ServerName>\]CPU](#)

## [Trend.<ClusterName>.<ServerName>]DisableConnection

This setting is used to specify whether or not the client sub system should connect to the given server. If the Citect.ini on a particular pc has [Type.ClusterName.ServerName]DisableConnection = 1, specified for a particular server, then the client sub system will establish a non-redundant connection to the other server in the redundant pair. If that connection becomes inoperative, the client sub system will not be redirected and will have no connection until the server is restored.

To define connection priority of a particular server use [\[Trend.<ClusterName>.<ServerName>\]Priority](#)

## Allowable Values:

- 0 - Allow the client to connect to the server
- 1 - Stop the client connecting to the server

**Default Value:**

0

**See Also**[Trend Process Parameters](#)**[Trend.<ClusterName>.<ServerName>]Events**

The list of events that this Plant SCADA Trend Server will enable.

This parameter must be defined at the finest level of hierarchical granularity (Trend.<ClusterName>.<Server>Events). See [Hierarchical Parameters](#) for more information.

---

**Note:** This parameter is modified by the Computer Setup Wizard.

---

**Allowable Values:**

List of events (comma separated).

**Default Value:**

NONE

---

**Note:** When Plant SCADA is running in single process mode only the events assigned to [\[Client\]Events](#) will be enabled. Events specified for particular Plant SCADA components are ignored.

---

**See Also**[Trend Process Parameters](#)**[Trend.<ClusterName>.<ServerName>]Priority**

This setting is used to specify the client sub system's priority for the connection to this specific server. The client sub system will connect to, or switch over to, any available server that has the highest priority (lowest number). If the priorities for multiple servers are set to the same value, the client sub system will only switch on a loss of the currently active connection. This is the default operation to provide the same behavior as in versions of the product prior to v7.20.

To disable (not allow) the client to connect to the server use

[\[Trend.<ClusterName>.<ServerName>\]DisableConnection](#)

**Allowable Values:**

1 to 32767

**Default Value:**

1

**See Also**

[Trend Process Parameters](#)

**[Trend.<ClusterName>.<ServerName>]ShutdownCode**

Can be used to specify a Cicode function that runs at shutdown of the Plant SCADA Trend Server component. Plant SCADA suspends the shutdown process until the function has finished running. The function needs to complete execution within the time specified by the [\[Code\]ShutdownTime](#) parameter, otherwise Plant SCADA will terminate it.

This parameter needs to be defined at the finest level of hierarchical granularity (Trend.<ClusterName>.<ServerName>ShutdownCode). See [Hierarchical Parameters](#) for more information.

---

**Note:** This parameter is modified by the Computer Setup Wizard.

**Allowable Values:**

Any built-in or user-written Cicode function, 1-31 alpha-numeric characters.

**Default Value:**

NONE

---

**Note:** When Plant SCADA is running in single process mode only the Cicode function assigned to [\[Client\]ShutdownCode](#) will be executed at shutdown. Cicode functions specified for particular Plant SCADA components are ignored.

**See Also**

[Trend Process Parameters](#)

**[Trend.<ClusterName>.<ServerName>]StartupCode**

Determines the Cicode function to run when the Plant SCADA Trend Server component starts up.

You can only pass constant data to the startup function call. You cannot pass variables or other functions. For example, MyFunc(1, "str") is valid, but MyFunc(PLCTAG, "str") or MyFunc(YourFunc(), "str") is not supported.

This parameter needs to be defined at the finest level of hierarchical granularity (Trend.<ClusterName>.<ServerName>StartupCode). See [Hierarchical Parameters](#) for more information.

---

**Note:** This parameter is modified by the Computer Setup Wizard.

**Allowable Values:**

Any built-in or user-written Cicode function, 1-31 alpha-numeric characters.

**Default Value:**

NONE

---

**Note:** When Plant SCADA is running in single process mode only the Cicode function assigned to [Client]StartupCode will be executed at startup. Cicode functions specified for particular Plant SCADA components are ignored.

---

**See Also**

[Trend Process Parameters](#)

**Win Parameters**

The Citect.ini file contains the following Win parameters:

- [\[Win\]AltEsc](#) - Determines whether the Windows key command [Alt]+[Esc] can be used in the runtime system (to cycle through open applications).
- [\[Win\]AltSpace](#) - Determines whether the Windows key command [Alt]+[Space] can be used in the runtime system (to display the control menu).
- [\[Win\]AltTab](#) - Determines whether the Windows key command [Alt]+[Tab] can be used in the runtime system (to cycle through open applications).
- [\[Win\]CtrlEsc](#) - Obsolete in version 7.10.
- [\[Win\]Configure](#) - Determines whether the Project Editor and Graphics Builder options are displayed on the control menu of the Plant SCADA runtime system.
- [\[Win\]ScreenSaver](#) - Determines whether the Windows screen saver is active when Plant SCADA is running.
- [\[Win>ShowAbout](#) - Determines if the Parameter to control whether the about box is added to the ALT-SPACE menu of the Plant SCADA runtime system.

**See Also**

[Parameter Categories](#)

**[Win]AltEsc**

Determines whether the Windows key command [Alt]+[Esc] can be used in the runtime system (to cycle through open applications).

---

**Note:** This parameter is modified by the Computer Setup Wizard as well as the Computer Setup Editor.

---

**Allowable Values:**

- 0 - (Ignore the [Alt] [Esc] key)
- 1 - (Cycle through open applications)

**Default Value:**

1

**See Also**[Win Parameters](#)**[Win]AltSpace**

Determines whether the Windows key command [Alt]+[Space] can be used in the runtime system (to display the control menu).

---

**Note:** This parameter is modified by the Computer Setup Wizard as well as the Computer Setup Editor.

---

**Allowable Values:**

- 0 - (Ignore the [Alt] [Space] key)
- 1 - (Display the control menu)

**Default Value:**

1

**See Also**[Win Parameters](#)**[Win]AltTab**

Determines whether the Windows key command [Alt]+[Tab] can be used in the runtime system (to cycle through open applications).

---

**Note:** This parameter is modified by the Computer Setup Wizard as well as the Computer Setup Editor.

---

**Allowable Values:**

- 0 - (Ignore the [Alt] [Tab] key)
- 1 - (Cycle through open applications)

**Default Value:**

1

**See Also**[Win Parameters](#)**[Win]Configure**

Determines whether the **Graphics Builder** options are displayed on the control menu of the Plant SCADA runtime system.

---

**Note:** This parameter is modified by the Computer Setup Wizard as well as the Computer Setup Editor.

---

**Allowable Values:**

- 0 - (Do not display control menu options)
- 1 - (Display options)

**Default Value:**

1

**See Also**[Win Parameters](#)**[Win]ScreenSaver**

Determines whether the Windows screen saver is active when Plant SCADA is running. The screen saver changes the image on the screen to a random image (if it is not changed within a certain period).

---

**Note:** This parameter is modified by the Computer Setup Wizard as well as the Computer Setup Editor.

---

**Allowable Values:**

- 0 - (Screen saver disabled)
- 1 - (Screen saver enabled)

**Default Value:**

1

## See Also

[Win Parameters](#)

### [Win]ShowAbout

Determines if the Parameter to control whether the About box is added to the ALT-SPACE menu of the Plant SCADA runtime system.

**Note:** This parameter is modified by the Computer Setup Wizard as well as the Computer Setup Editor.

## Allowable Values:

- 0 - (About is not listed in the ALT-SPACE menu.)
- 1 - (About is listed in the ALT-SPACE menu.)

## Default Value:

0

## See Also

[Win Parameters](#)

## Workspace Parameters

The [Workspace] section contains the following parameters:

- [\[Workspace\]AlarmSortOrder](#) - Defines a customized sort order for the default alarms pages in a Situational Awareness project.
- [\[Workspace\]EquipmentNavigationModelFilter](#) - Filters the equipment model loaded by the workspace.
- [\[Workspace\]InfoZoneAlarms.IncludeReferences](#) - Determines if alarms from referenced equipment are included in the Alarms page on the Information Zone.
- [\[Workspace\]InfoZoneTrends](#) - Determines the pens that will be displayed in the Information Zone of the workspace based on the equipment items configured.
- [\[Workspace\]InfoZoneTrends.Type](#) - Determines the pens that will be displayed in the Information Zone of the workspace based on the equipment types configured in the Equipment Editor.
- [\[Workspace\]NumberOfTopPriorities](#) - Determines how many alarm priorities are included in the alarm counts presented on an alarm page tree view and the Navigation Zone.

## See Also

[Situational Awareness Parameters](#)

[Parameter Categories](#)

## [Workspace]AlarmSortOrder

Defines a customized sort order for the following alarm lists in a Situational Awareness project:

- Active Alarms page
- Alarms panel in the Information Zone
- Top 5 alarms pop-up for the HD1080 workspace
- Alarm Summary panel for the UHD4K workspace
- Shelved Alarms page.

To specify a sort order, use the following syntax:

{*KeyName,SortDirection*} {*KeyName,SortDirection*}

*KeyName* specifies the name of the pre-defined order-by key to be used. The valid options are a subset of the alarm display fields:

- Tag
- Name
- Category
- Priority
- Area
- Equipment
- Priv
- Time
- State.

*SortDirection* (optional) indicates whether the sort will be ascending or descending. Valid options are:

- 0 = Descending (default)
- 1 = Ascending

### Allowable Values:

Any valid sort order string.

### Default Value:

Empty string.

If the above parameter is not defined, the alarm list will be sorted according to the current setting for the alarm server's **Highest Priority Order** field ("Priority, Alarm State" or "Alarm State, Priority").

### Examples

Sort by **Tag** ascending, and **Time** descending:

```
[Workspace]AlarmSortOrder={Tag,1}{Time}
```

Sort by **Time** ascending and **Tag** descending:

```
[Workspace]AlarmSortOrder={Time,1}{Tag,0}
```

Sort by **Equipment** ascending and **Tag** descending:

```
[Workspace]AlarmSortOrder={Equipment,1}{Tag,0}
```

## See Also

[Workspace Parameters](#)

### [Workspace]EquipmentNavigationModelFilter

Use this parameter to filter the equipment model loaded by the workspace. For example the equipment tree on the trend page, and alarm pages. It is also used as part of the workspace auto-fill functionality.

#### Allowable Values:

Any valid filter.

An empty string indicates that all records will be returned. Where a fieldname is not specified in the filter, it is assumed to be equipment name. For example, the filter "AAA" is equivalent to "name=AAA".

The following regular expressions are supported: \*expr, expr\*, and \*expr\*. To specify an exclusion filtering condition, use the NOT keyword after the = operator.

See the topic **EquipBrowseOpen** in the Cicode Reference for list of Fields.

#### Default Value:

Empty string.

#### Examples

Filter by Drive01:

```
[Workspace]EquipmentNavigationModelFilter=PlantA.Pump1.Drive01
```

Filter by Pump1:

```
[Workspace]EquipmentNavigationModelFilter=PlantA.Pump1
```

Filter by Pump1 and subequipment:

```
[Workspace]EquipmentNavigationModelFilter=PlantA.Pump1.*
```

Filter by Cluster1 and all sub equipment in PlantA:

```
[Workspace]EquipmentNavigationModelFilter = Cluster=Cluster1; Name=PlantA.*
```

Filter by Cluster1 and Pump1 and Pump2:

```
[Workspace]EquipmentNavigationModelFilter = Cluster=Cluster1;  
Name=PlantA.Pump1,PlantA.Pump2
```

Filter by Cluster2 and all subquipment in PlantC:

```
[Workspace]EquipmentNavigationModelFilter = Cluster=Cluster2; Name=PlantC.*
```

## See Also

[Workspace Parameters](#)

### [Workspace]InfoZoneAlarms.IncludeReferences

Determines if alarms from referenced equipment are included in the Information Zone **Alarms** tab on the Situational Awareness Operator Dashboard. This is a client-side setting and will affect all equipment.

#### Allowable Values:

- 0 = Alarms from referenced equipment are not included
- 1 = Alarms from referenced equipment are included

#### Default Value:

1

## See Also

[Workspace Parameters](#)

### [Workspace]InfoZoneTrends

Determines the pens that will be displayed in the Information Zone of the workspace based on the equipment items configured. The value of this parameter is a comma-separated list of equipment item names. Up to five equipment items can be configured. Pens will be displayed in the order in which the equipment items are defined by this parameter.

---

**Note:** A warning is logged to syslog.dat if there are any invalid or duplicate items, that is, a value does not correspond to an item with a trend tag.

---

#### Allowable Values:

Any valid equipment items with a trend tag configured.

#### Default Value:

PV,OP, FB,SP

## See Also

[Workspace Parameters](#)

### [Workspace]InfoZoneTrends.Type

Determines the pens that will be displayed in the Information Zone of the workspace based on the equipment types configured in the Equipment Editor. The value of this parameter is a comma-separated list of equipment item names. Up to five equipment items can be configured. Pens will be displayed in the order in which the equipment items are defined by this parameter.

**Note:** A warning is logged to syslog.dat if there are any invalid or duplicate items, that is, a value does not correspond to an item with a trend tag.

#### Allowable Values:

Any valid equipment items with a trend tag configured.

#### Default Values:

Equipment Type	Default Value
InfoZoneTrends.FeederGate	PV,OP,FB,Height
InfoZoneTrends.TargetMeter	PV,PVTarget,OP,FB,SP
InfoZoneTrends.WindCompass	WindPV,WindPVAvg,WindSpeed,WindSpeedAvg

#### Example

InfoZoneTrends.Drive=PV,SP,FB

#### See Also

[Workspace Parameters](#)

### [Workspace]NumberOfTopPriorities

Determines how many alarm priorities are included in the alarm counts presented in the following locations:

- The Tree View on alarm and trend pages
- The tabs and buttons in the Navigation Zone.

Specifically, you can use this parameter to include the top four alarm priorities rather than just the top three. This setting only applies to projects based on the Situational Awareness Starter project.

#### Allowable Values:

3 or 4

**Default Value:**

3

For more information on how to implement a fourth alarm priority, see the topic *Configure Display Properties for a Fourth Alarm Priority* in the main Plant SCADA help.

**See Also**[Workspace Parameters](#)

## Logging Parameters

These parameters can be used to gather runtime information about your Plant SCADA system. Before making adjustments to these parameters, you need to understand the concepts and processes described in the Monitoring Runtime chapter in the Plant SCADA help.

Similarly, the section on I/O Devices includes information that explains how to log drivers (see [Troubleshooting Device Communications](#)).

Plant SCADA includes the following logging parameters.

Parameter	Description
[Alarm]EnableErrorLogging	Enables or disables the logging of operational errors.
[Alarm]EnableStateLogging	Enables or disables the logging of major alarm system state changes.
[Code]DebugMessage	Enables the DebugMsg Cicode function, and controls the logging functionality of the Assert function.
[Code]EnableErrorLogging	Enables or disables the logging of issues with the ErrSet() Cicode function and related functions.
[Debug]ArchiveFiles	Enables or disables the archiving of the tracelog.dat log file once the maximum size specified by [Debug]MaximumFileSize is reached.
[Debug]CategoryFilter	Allows you to filter logging messages sent to tracelog.dat by component category. <sup>1</sup>
[Debug]CategoryFilterMode	Enables logging of categories declared by [Debug]CategoryFilter. <sup>1</sup>
[Debug]DriverTrace	Enables the Kernel's Driver Trace utility. <sup>1</sup>
[Debug]EnableLogging	Enables or disables logging to the tracelog.dat file. <sup>1</sup>
[Debug]LogDirect	Indicates whether to log directly to a log file or via the Kernel logging system.

Parameter	Description
[Debug]MaximumFileSize	Sets the maximum size for tracelog.dat log file, in kilobytes.
[Debug]Priority	Allows you to filter messages logged to the tracelog.dat file according to their priority. <sup>1</sup>
[Debug]SeverityFilter	Allows you to filter messages logged to the tracelog.dat file according to their severity. <sup>1</sup>
[Debug]SeverityFilterMode	Enables logging of severities declared by the [Debug]SeverityFilter value. <sup>1</sup>
[Debug]SysLogArchive	Enable the creation of syslog.dat archive files. <sup>1,2</sup>
[Debug]SysLogSize	Sets the maximum size of the syslog.dat file. <sup>1</sup>
[Debug]SysErrDsp	Allows you to disable many system error logs and popup boxes.
[Dial]Debug	Enables or disables scheduled I/O device debugging.
[Dial]DebugLevel	Allows you to set the trace level for scheduled I/O device debugging. <sup>2</sup>
[General]Verbose	Enables a startup dialog box which shows the opening runtime databases and other information. <sup>1</sup>
[General]VerboseToSysLog	Sends additional startup information generated by [General]Verbose to syslog.dat. <sup>1</sup>
[Kernel]ErrorBuffers	Determines the maximum number of error buffers available for logging to the syslog.dat file.
[Trend]TrendDebug	Used to determine problems with the trend system during commissioning. <sup>2</sup>

1. You can adjust these parameters during runtime using the SetLogging() Cicode function.
2. You can update this parameter within the Citect.ini file while online, as the runtime system will read its value periodically or on demand.

For more information on 1 and 2, search the Plant SCADA Help for the topic *Adjusting Logging During Runtime*.

[Advanced Logging Parameters](#)

## Advanced Logging Parameters

The following parameters are recommended only for advanced users.

Parameter	Description
[CtAPI]EventLogging	Enables logging of the communications between CtAPI clients and Plant SCADA.
[Debug]DebugAllTrans	Allows TRAN session logging to be turned on or off. <sup>1</sup>
[Debug]EnableReloadLogging	Enables additional debugging output for server reloads. <sup>2</sup>
[Debug]LogShutdown	Logs the shutdown function addresses to syslog.dat. This INI is only needed if [Debug]ShutDownProtect is active. <sup>1</sup>
[General]ShowDriverError	Determines whether an error dialog displays when an internal driver error occurs. <sup>2</sup>
[IOServer]RedundancyDebug	Enables I/O device redundancy debugging. <sup>1</sup>
[IPC]EventLogging	Enables logging of the communications between processes.
[Keyboard]LogExtendedDate	Determines the date format is used in command logs.
[LAN]ConnectionLogging	Provides legacy component connection logging to the syslog.dat.
[PubSub]LogLevel	Sets the logging level between the I/O subscription system and the Plant SCADA drivers. <sup>2</sup>
[PubSub]LogDevice	Selects the device(s) logged between the I/O subscription system and the Plant SCADA drivers. <sup>2</sup>

1. You can adjust these parameters during runtime using the SetLogging() function.
2. You can update this parameter within the Citect.ini file while online, as the runtime system will read its value periodically or on demand.

For more information on 1 and 2, search the Plant SCADA Help for the topic *Adjusting Logging During Runtime*.

[Logging Parameters](#)

## Template Parameters

These parameters can be used to manage the configuration of the templates in pre-configured projects.

The following Plant SCADA template projects include parameters that you can modify:

- [Tab\\_Style Template Parameters](#)
- [Situational Awareness Parameters](#)

### Tab\_Style Template Parameters

Below are the sections that describe the Tab\_Style Template parameters recognized by Plant SCADA.

Section
<a href="#">Alarm Parameters</a>
<a href="#">Alarm Heading Parameters</a>
<a href="#">Format Parameters</a>
<a href="#">Page Parameters</a>
<a href="#">Privilege Parameters</a>
<a href="#">[TabAlarm.Custom] Parameters</a>
<a href="#">[Tabmenu.Custom] Parameters</a>

#### Alarm Parameters

The Tab\_Style Templates will recognize the following alarm parameters:

- [\[Alarm\]BackgroundColorMode](#) - Sets the background color mode of the alarm list and alarm banner on the Tab\_Style templates.
- [\[Alarm\]LastAlarmCategories](#) - Determines which alarms are displayed on the alarms toolbar, based on category.
- [\[Alarm\]LastAlarmDisplayMode](#) - Determines whether the last alarm is displayed by category or priority.
- [\[Alarm\]LastAlarmFmt](#) - Specifies the format of the last alarm as displayed on the included templates.
- [\[Alarm\]LastAlarmPriorities](#) - Determines which alarms are displayed on the alarms toolbar, based on priority.
- [\[Alarm\]LastAlarmType](#) - Determines which alarms are displayed in the alarms toolbar, based on type.
- [\[Alarm\]Sound<n>](#) - Determines the .wav file that is used when an alarm sounds, based on the priority of the alarm <n>.
- [\[Alarm\]Sound<n>Interval](#) - Determines the interval of time between an alarm sound, based on the priority of the alarm <n>.
- [\[Alarm\]SoundSilenceTimeoutOnAck](#) - Determines the timeout period in seconds for silencing alarm after the user acknowledges any alarms using the Tab\_Style templates.

- [\[Alarm\]HeadingFont](#) - Determines the text font used for column headings displayed on the alarm templates.

## Alarm Heading Parameters

The Tab\_Style Templates will recognize the following [AlarmHeading] parameters:

- [\[AlarmHeading\]AlarmField](#) - Specifies alternative names for the standard alarm field names for display in the column heading of the new Tab\_Style alarm template.

## Format Parameters

The Tab\_Style Templates will recognize the following [Format] parameters:

- [\[Format\]FormatName](#) - Define a display format under a specified name.

## Page Parameters

The Tab\_Style Templates will recognize the following page parameters:

- [\[Page\]AddDefaultMenu](#) - Determine whether to add the default menu items to your tabbed menu bar.
- [\[Page\]AlarmPage](#) - The name of the graphics page to display when calling the Cicode function PageAlarm().
- [\[Page\]DisabledPage](#) - The name of the graphics page to display when calling the Cicode function PageDisabled().
- [\[Page\]HardwarePage](#) - The name of the graphics page to display when calling the Cicode function PageHardware().
- [\[Page\]HomePage](#) - Sets the page to display when the user clicks the Home page button on the template or calls the Cicode function PageHome()
- [\[Page\]Logo](#) - This sets a symbol to display at the logo area (lower right corner) of the new templates.
- [\[Page\]PrintPage](#) - Sets a custom Cicode function to print the currently displayed page when the user clicks the Print page button on the template or calls the Cicode function PagePrint().
- [\[Page\]ProcessAnalystPage](#) - Sets the page to display when the user calls the Cicode function PageProcessAnalyst() without specifying the page argument.
- [\[Page\]ProcessAnalystPopupPage](#) - Sets the page to pop up when the user calls the Cicode function ProcessAnalystWin() or ProcessAnalystPopup() without specifying the page argument.
- [\[Page\]SummaryPage](#) - The name of the graphics page to display when calling the Cicode function PageSummary().

## Privilege Parameters

The Tab\_Style Templates will recognize the following [Privilege] parameters:

- [\[Privilege\]AckAlarms](#) - Determines the privilege level a user requires to acknowledge alarms.
- [\[Privilege\]DisableAlarms](#) - Determines the privilege level a user requires to disable alarms.
- [\[Privilege>EditUser](#) - Determines the privilege level a user requires to edit users using the drop-down menu next to the login user icons on the Tab\_Style template.

- [\[Privilege\]Shutdown](#) - Determines the privilege level a user requires to shutdown a project.
- [\[Privilege\]SilenceAlarms](#) - Determines a privilege level a user requires to silence alarms.

### [TabAlarm.Custom] Parameters

The [TabAlarm.Custom] section contains the following parameters:

- [\[TabAlarm.Custom\]Function.AlarmGetDsp](#) - Define display format under a specified name.
- [\[TabAlarm.Custom\]Function.Row.ShowContextMenu](#) - Define display format under a specified name.
- [\[TabAlarm.Custom\]Function.Row.ShowHWContextMenu](#) - Define display format under a specified name.

## [TabAlarm.Custom]Function.AlarmGetDsp

Sets your own function to return the value of the specified alarm field on the tab style alarm templates. If specified, your function, instead of the default one, will be called to return the value for the requested alarm field.

**Note:** This parameter is available only to projects based on the Tab\_Style templates.

### Allowable Values:

Name of user defined function which conforms to the following specification:

### Syntax

<function>(INT *listID*, INT *recordAN*, STRING *field*)

- *listID*: ID of the alarm list
- *recordAN*: Animation Number (AN) of the alarm record
- *field*: Name of the alarm field being requested

### Default Value:

None

### Return Value:

Value of the alarm field

### Example

```
[TabAlarm.Custom]
Function.AlarmGetDsp = MyAlarmValue
STRING FUNCTION MyAlarmValue(INT listID, INT recordAN, STRING field)
    // return a textual description for priority
```

```
IF (field = "Priority") THEN
    SELECT CASE AlarmGetDsp(recordAN, field)
    CASE "1"
        RETURN "Critical";
    CASE "2"
        RETURN "Major";
    CASE ELSE
        RETURN "Minor";
    END SELECT
ELSE
    RETURN AlarmGetDsp(recordAN, field);
END
END
```

## See Also

[\[TabAlarm.Custom\] Parameters](#)

# [TabAlarm.Custom]Function.Row.ShowContextMenu

Sets your own function to show the context menu to response to the right-clicking of an alarm on the tab style alarm templates.

**Note:** This parameter is available only to projects based on the Tab\_Style templates.

## Allowable Values:

Name of user defined function which conforms to the following specification:

## Syntax

```
<function>(INT listID, INT rowID)  
listID: ID of the alarm list  
rowID: Row number (starting from 0) of the clicked alarm
```

## Default Value:

None

## Return Value:

0 if run successfully or error code otherwise

### Example

```
[TabAlarm.Custom]
Function.Row.ShowContextMenu =
.
INT FUNCTION MyAlarmContextMenu(INT listID, INT rowID)
```

```
// Get AN of the alarm list
INT listAN = TabAlarm_GetAN(listID);
INT selection;
// Show menu
DspPopupMenu(0, "Show Details");
DspPopupMenu(0, "Acknowledge");
selection = DspPopupMenu();
// Run selected command
SELECT CASE selection
CASE 1
    RETURN TabAlarm_Row_ShowInfo(listID, rowID);
CASE 2
    IF TabAlarm_GetAckPriv() THEN
        RETURN AlarmAckRec(AlarmGetDsp(listAN + rowID, "RecNo"));
    ELSE
        Message("Error", ErrMsg(276), 16);
        RETURN 276; // no privilege for operation
    END
END SELECT
RETURN 0;
END
```

## See Also

[\[TabAlarm.Custom\] Parameters](#)

# [TabAlarm.Custom]Function.Row.ShowHWContextMen

Sets your own function to show the context menu to response to the right-clicking of an alarm on the tab style hardware alarm template.

---

**Note:** This parameter is available only to projects based on the Tab\_Style templates.

---

## Allowable Values:

Name of user defined function which conforms to the following specification:

## Syntax

<function>(INT *recordAN*)  
*recordAN*: Animation Number (AN) of the alarm record

## Default Value:

None

**Return Value:**

0 if run successfully or error code otherwise

**Example**

```
[TabAlarm.Custom]
Function.Row.ShowHWContextMenu = MyHardwareContextMenu

INT FUNCTION MyHardwareContextMenu(INT recordAN)
    INT selection;

    // Show menu
    DspPopupMenu(0, "Acknowledge");
    selection = DspPopupMenu();

    // Run selected command
    SELECT CASE selection
    CASE 1
        IF TabAlarm_GetAckPriv() THEN
            KeySetCursor(recordAN);
            RETURN AlarmAck(0, 0);
        ELSE
            Message("Error", ErrMsg(276), 16);
            RETURN 276; // no privilege for operation
        END
    END SELECT

    RETURN 0;
END
```

**See Also**

[\[TabAlarm.Custom\] Parameters](#)

**[Tabmenu.Custom] Parameters**

The [Tabmenu.Custom] section contains the following parameters:

- [\[Tabmenu.Custom\]Font.Disabled](#) - Define display format under a specified name.
- [\[Tabmenu.Custom\]Font.Normal](#) - Define display format under a specified name.
- [\[Tabmenu.Custom\]Function.CreateDefaultMenu](#) - Define display format under a specified name.

## [Tabmenu.Custom]Font.Disabled

Sets a user defined font for the text displayed on the tab menu when an item is disabled.

**Note:** This parameter is available only to projects based on the Tab\_Style templates.

**Allowable Values:**

Name of user defined font

**Default Value:**

None (When not specified, the Arial, 10pt font in grey-blue color is used)

**See Also**

[\[Tabmenu.Custom\] Parameters](#)

## [Tabmenu.Custom]Font.Normal

Sets a user defined font for the text displayed on the tab menu when an item is in normal state.

**Note:** This parameter is available only to projects based on the Tab\_Style templates.

**Allowable Values:**

Name of user defined font

**Default Value:**

None (When not specified, the Arial, 10pt font in dark-blue color is used)

**See Also**

[\[Tabmenu.Custom\] Parameters](#)

## [Tabmenu.Custom]Function.CreateDefaultMenu

Sets your own function to create the default menu for the tab style templates.

**Note:** This parameter is available only to projects based on the Tab\_Style templates.

This parameter is used to replace the built-in default menu and is effective only if the Menu Configuration form is blank. If there are items defined in the Menu Configuration form, the menu will be displayed according to the contents of the form.

Note that the INI parameter [Page]AddDefaultMenu determines items to be displayed on the tabbed menu bar. The default value of this parameter is 1 where the menu is populated as described earlier. However, if [Page]AddDefaultMenu=0 and a [Tabmenu.Custom]Function.CreateDefaultMenu is specified, the menu is populated based on the contents of the Menu Configuration settings, not the Cicode defined in [Tabmenu.Custom]Function.CreateDefaultMenu.

Setting [Page]AddDefaultMenu=2 and specifying a Cicode function in

[Tabmenu.Custom]Function.CreateDefaultMenu, will result in merging items defined in Menu Configuration form to items populated via Cicode function.

## Allowable Values:

Name of user defined function which conforms to the following specification:

## Syntax

<function>(INT *winNo*)

*winNo*: The window number of the window where the menu is displayed

## Default Value:

None

## Return Value:

The menu node handle for the current window

### Example

```
[Tabmenu.Custom]
Function.CreateDefaultMenu = MyDefaultMenu

INT FUNCTION MyDefaultMenu(INT winNo)
    INT winNode = MenuGetWindowNode(winNo);
    INT tabNode, childNode;

    // Add Pages tab
    tabNode = Tabmenu_AddChild(winNode, "Pages");
    IF (tabNode >= 0) THEN
        // Populate predefined pages
        Tabmenu_AddChild(tabNode, "Page 1", "PageDisplay", "^^Page1^^");
        Tabmenu_AddChild(tabNode, "Page 2", "PageDisplay", "^^Page2^^");
        Tabmenu_AddChild(tabNode, "Page 3", "PageDisplay", "^^Page3^^");
    END

    // Add Alarms tab
    tabNode = Tabmenu_AddChild(winNode, "Alarms");
    IF (tabNode >= 0) THEN
        // Populate alarm pages
        Tabmenu_AddChild(tabNode, "Active Alarms", "PageAlarm", "");
        Tabmenu_AddChild(tabNode, "Alarm Summary", "PageSummary", "");
        Tabmenu_AddChild(tabNode, "Disabled Alarms", "PageDisabled", "");
        Tabmenu_AddChild(tabNode, "Hardware Alarms", "PageHardware", "");
    END

    // Add Trends tab
    tabNode = Tabmenu_AddChild(winNode, "Trends");
    IF (tabNode >= 0) THEN
        // Populate trend pages
        Tabmenu_AddChild(tabNode, "Trends", "PageProcessAnalyst", "^^^,^^");
    END
```

```
    Tabmenu_AddChild(tabNode, "Trend Pop-up", "ProcessAnalystPopup", "^\"^");
END

// Add Tools tab
tabNode = Tabmenu_AddChild(winNode, "Tools");
IF (tabNode >= 0) THEN
    // Populate administrative pages / commands
    Tabmenu_AddChild(tabNode, "Log", "PageFile", "^"[DATA]:OperLog.txt^");
    childNode = Tabmenu_AddChild(tabNode, "Exit", "ShutdownForm", "");
    MenuNodeSetProperty(childNode, 2, 8); // set privilege to 8
END

RETURN winNode;
END
```

## Situational Awareness Parameters

Below are the sections that contain the Situational Awareness Include parameters recognized by Plant SCADA.

- [\[Format\] Parameters](#)
- [\[MultiMonitors\] Parameters](#)
- [\[SA\\_Library.Meter\] Parameters](#)
- [\[Workspace\] Parameters](#)

## See Also

- [Template Parameters](#)

### Format Parameters

The Tab\_Style Templates will recognize the following [Format] parameters:

- [\[Format\]FormatName](#) - Define a display format under a specified name.

### [MultiMonitors] Parameters

- [\[MultiMonitors\]Context<n>](#) - Allows you to share a single context with one or more screens.
- [\[MultiMonitors\]Workspaces](#) - Indicates the number of workspace pages to be shown at startup.

## See Also

- [Template Parameters](#)

## [SA\_Library.Meter] Parameters

The [SA\_Library.Meter] parameters allow you to define and display a range of PLC alarm limits. Where standard analog alarm limits are limited to four states, there is no limit on the number of PLC alarm limits that can be defined and displayed.

The [SA\_Library.Meter] section comprises the following parameters:

- [\[SA\\_Library.Meter\]UseDefaultPLCLimits](#)
- [\[SA\\_Library.Meter\]PLCLimitNames](#)
- [\[SA\\_Library.Meter\]PLCLimitLabels](#)
- [\[SA\\_Library.Meter\]DefaultPLCLimits](#)

## See Also

[Situational Awareness Parameters](#)

## [SA\_Library.Meter]UseDefaultPLCLimits

Allows you to use PLC alarm limits for faceplates.

### Allowable Values:

TRUE, FALSE.

### Default:

None

When set to TRUE, the system will display the defined PLC alarm limits. Otherwise, it will use the standard analog alarm limits for display on faceplates.

## See Also

[\[SA\\_Library.Meter\]PLCLimitNames](#)

[\[SA\\_Library.Meter\]PLCLimitLabels](#)

[\[SA\\_Library.Meter\]DefaultPLCLimits](#)

## [SA\_Library.Meter]PLCLimitNames

Names for PLC alarm limits. This is a comma-separated list of values. For example, Limit1, Limit2, Limit3 and so on. You should specify all possible limits that may be used by equipment in the project. There is no limit on the number of PLC alarm limits that you can define.

**Note:** Each limit should correspond to an Item Name, and may also be associated with a piece of equipment

---

through a tag. For example, if the equipment is Meter1 and the PLC alarm limit is Limit1, you could have a tag Meter1.Limit1.

---

PLC alarm limits are applicable to the entire project.

**Allowable Values:**

Any valid limit names.

**Default:**

None

**See Also**

[\[SA\\_Library.Meter\]UseDefaultPLCLimits](#)

[\[SA\\_Library.Meter\]PLCLimitLabels](#)

[\[SA\\_Library.Meter\]DefaultPLCLimits](#)

## [SA\_Library.Meter]PLCLimitLabels

Display labels that correspond to each PLC alarm limit defined. This is a comma-separated list of values. For example, L1, L2, L3 and so on. You should define one label for each limit defined. It is recommended that the label not be more than 2 to 3 characters long so that the entire label is visible on the faceplates.

---

**Note:** The order of the PLC limit labels needs to match the order of the PLC limit names.

---

**Allowable Values:**

Any valid names.

**Default:**

None

**See Also**

[\[SA\\_Library.Meter\]UseDefaultPLCLimits](#)

[\[SA\\_Library.Meter\]PLCLimitNames](#)

[\[SA\\_Library.Meter\]DefaultPLCLimits](#)

## [SA\_Library.Meter]DefaultPLCLimits

A number that determines the order in which to use the defined PLC alarm limits. 0 corresponds to the lowest

PLC alarm limit defined, while the largest number corresponds to the highest limit defined. Note that if you have defined limits as Limit1, Limit2 and Limit3:

- 0 will correspond to Limit1
- 1 will correspond to Limit2
- 2 will correspond to Limit3

In the example above, you cannot specify "3" or "4" or any other number as one of the values for the DefaultPLCLimit. The values can only be 0,1 and/or 2.

This is a comma-separated list of values.

For example, if your list contains the values 0,1,4,5,3 and the limits you have defined are Limit1, Limit2, Limit3, Limit4, Limit5 and Limit6, the order will be:

DefaultPLCLimit	PLCLimitNames
0	Limit1
1	Limit2
4	Limit5
5	Limit6
3	Limit4

It is possible to override the limits set up at a project level, and apply these limits to an individual piece of equipment. This can be done in the **System Model** activity | **Runtime Parameters** view.

To associate PLC alarm limits with a piece of equipment:

- Define the **[SA\_Library.Meter]PLCLimitNames** to use.
- In Plant SCADA Studio, navigate to **System Model** activity | **Equipment**. Select **Runtime Parameters** from the dropdown menu.
- For each equipment, in the **Name** property, type PLCLimits.
- In the **Value** property, specify your comma-separated list of default PLC limits, that is the order in which the defined PLC alarm limits need to be used.

---

**Note:** Setting the **Value** property to \* reverses the setting of the UseDefaultPLCLimits parameter. Therefore, if the UseDefaultPLCLimits parameter is set to TRUE, it will be reversed and applied as if it were set to FALSE. In this example, analog alarm limits will apply. If UseDefaultPLCLimits is FALSE, setting the value of the runtime parameter to \* will cause the associated equipment to use the default PLC limits defined at the project level.

---

- Set the **IsTag** property to FALSE so that the PLC limit labels are displayed on the meter faceplates.
- Click **Save**.

## Allowable Values:

Any whole number.

**Default:**

None

**See Also**

[\[SA\\_Library.Meter\]UseDefaultPLCLimits](#)  
[\[SA\\_Library.Meter\]PLCLimitNames](#)  
[\[SA\\_Library.Meter\]PLCLimitLabels](#)

**[Workspace] Parameters**

The [Workspace] section contains the following parameters:

- [\[Workspace\]AlarmSortOrder](#) - Defines a customized sort order for the default alarms pages in a Situational Awareness project.
- [\[Workspace\]EquipmentNavigationModelFilter](#) - Filters the equipment model loaded by the workspace.
- [\[Workspace\]InfoZoneAlarms.IncludeReferences](#) - Determines if alarms from referenced equipment are included in the Alarms page on the Information Zone.
- [\[Workspace\]InfoZoneTrends](#) - Determines the pens that will be displayed in the Information Zone of the workspace based on the equipment items configured.
- [\[Workspace\]InfoZoneTrends.Type](#) - Determines the pens that will be displayed in the Information Zone of the workspace based on the equipment types configured in the Equipment Editor.
- [\[Workspace\]NumberOfTopPriorities](#) - Determines how many alarm priorities are included in the alarm counts presented on an alarm page tree view and the Navigation Zone.

**See Also**

[Situational Awareness Parameters](#)

## VBA Programming Reference

VBA is a Visual Basic for Applications (VBA) and VBScript-compatible Basic scripting language. Plant SCADA has embedded support for VBA.

---

**Note:** VBA is not supported on a 64-bit process, such as an alarm server operating in Extended Memory mode. If a call to VBA code occurs from a 64-bit process, an error code will be returned, a hardware alarm will be raised and the Cicode thread will stop.

---

VBA has the following features:

- VBA code is multithreaded and fully scheduled within the Plant SCADA Kernel.
- VBA uses the same well proven engine that Cicode uses and can be used wherever Cicode is used.
- VBA has a small footprint of under 400K.
- VBA code is directly callable from Plant SCADA Command and Expression fields.

- VBA code is callable from Cicode and vice versa.
- VBA code provides native support for ActiveX objects, Plant SCADA Variable Tags and Alarm Tags.
- VBA makes ActiveX object manipulating easier. It allows direct interaction with the object models from 3rd party applications such as Word, Excel, etc.

---

**Note:** You may notice slight differences between VBA and VBA in other applications; this is normal as each application has a different object model.

---

The Cicode Editor has been upgraded to fully support VBA. Supported features include:

- Integrated Cicode and VBA compiler
- Integrated Cicode and VBA source code editor
- Integrated Cicode and VBA debugger

This section contains information on the VBA programming language and describes the following:

- [Integrating VBA into a Project](#)
- [Understanding VBA Language Basics](#)
- [VBA Function Reference](#)
- [ASCII/ANSI Character Code Listings](#)

---

**Note:** For information regarding methods you can use to extend Plant SCADA that do not require VBA, see the topic [Extensibility](#).

---

## Integrating VBA into a Project

You can integrate VBA into your Plant SCADA project in two ways:

- [Using VBA in Command or Expression Fields](#)
- Store user-defined VBA script in a separate [VBA Files](#).

In either case, all procedures within a VBA script can access (read and write) any Plant SCADA variable tag in the same way Cicode can access Plant SCADA tags.

### Access Cicode Tags with VBA

VBA can use your Plant SCADA project variable tag and alarm tag variables in the same way as could Cicode (except for syntax differences). Both programming languages refer to a project's variable tags by using the name of the tags as defined in the project.

For instance, in the following example, two variable tags in your Plant SCADA project may be named **B1\_PUMP\_101\_SP** and **B1\_PUMP\_101\_PV** respectively, representing the Set Point and Process Variable values of Pump 101. These variable tag names can be used within a VBA statement (just as you would use any other variable in VBA). Both values can be read-from and written-to directly using VBA:

```
' set pump speed to 500 rpm
B1_PUMP_101_SP = 500
' calculate pump speed error
Dim varPumpSpeedError
```

```
varPumpSpeedError = B1_PUMP_101_PV - B1_PUMP_101_SP
```

You should note that VBA does not recognize Plant SCADA variable tags that are named with an initial digit (0-9).

To access such tags using VBA, you must precede the tag name with a case-insensitive string containing the letters 'V', 'B,' and the underscore character (VB\_) as in the following example:

```
Plant SCADA Tag Name: "123Pump"  
CitectVBA reference "VB_123Pump"
```

For details of using tags that have a number as their first digit in your project, consider using the [\[General\]TagStartDigit](#) Citect.ini parameter.

## Access Plant SCADA Array Values with VBA

To access Plant SCADA Array Values in VBA use the following format:

```
<TagName>.<Index>(<indexNumber>)
```

Where:

- <TagName> = The name of the array
- <Index> = The function that retrieves the values located at the specified <indexNumber>
- <indexNumber> = Position of the array to read/write the value.

### Example

In this example, an array is declared with name "sampleArray" in Plant SCADA Studio with 10 elements.

- To read the value at index 2 from sampleArray use the following syntax:

```
sampleArray.Index(2)
```

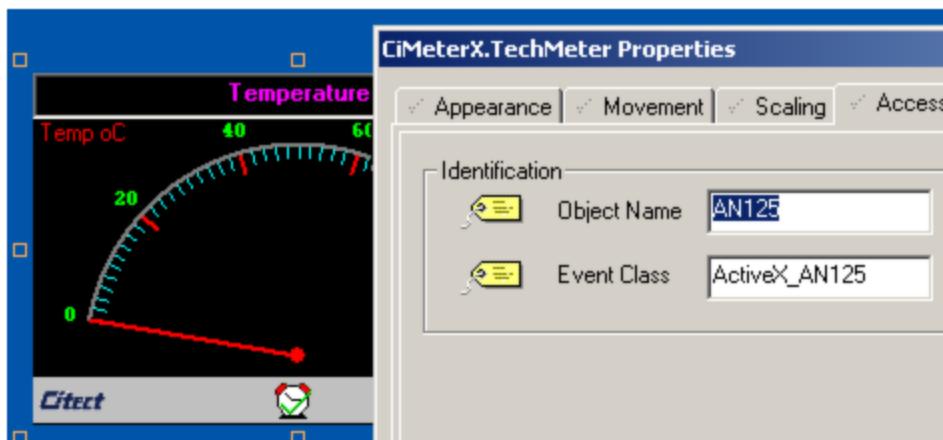

- To write to the value at index 3 in sampleArray use the following syntax:

```
sampleArray.Index(3) = 4
```

## Access ActiveX Objects with VBA

ActiveX objects which have been added to a graphics page in your Plant SCADA project can be referred to in VBA by constructing a unique reference name using the page name, the underscore character, the letters 'AN', and the animation number of the object.

This reference name is called the Event Class name in Plant SCADA. To view the reference name, double-click the ActiveX object, select the **Access** tab, then click the **Identification** tab.

### Example

In this example, the reference name for the Temperature meter object would be referred to in VBA as ActiveX\_AN125.

All object properties can be accessed and manipulated using VBA in the same way that object properties can be manipulated using Cicode.

## Using VBA in Command or Expression Fields

Plant SCADA expects that all code contained within a Plant SCADA Command or Expression field to be Cicode by default. When using VBA code script directly in a Plant SCADA Command or Expression field within Plant SCADA, you must precede the VBA script with the keyword **CiVBA**, as shown here:

```
CiVBA
TestTag_1 = TestTag_1 + 1
```

This is known as the language override command. When the Plant SCADA compiler reads the keyword CiVBA, it knows to handle that code (within the same Plant SCADA Command or Expression field) as VBA script, and compiles it as such. No such override command is required to use Cicode.

The CiVBA language override statement must be placed first in the Plant SCADA Command or Expression field if you want to use VBA script code instead of Cicode in that Plant SCADA Command or Expression field.

---

**Note:** You must use either Cicode or VBA in a Plant SCADA Command or Expression field. You cannot change or swap between the two programming languages (within the same Plant SCADA Command or Expression field) once you've started using one or the other.

---

You can, however, call a single Cicode function from within VBA script if you wrap the Cicode call within special VBA functions **CicodeCallOpen()** and **CicodeCallReturn()**.

## Calling Cicode from VBA

Calling a Cicode function from VBA is accomplished by two VBA functions: **CicodeCallOpen()** and **CicodeCallReturn()**.

To call a given Cicode function, use the **CicodeCallOpen** function which will create and execute a Cicode thread that runs the function. For multitasking purposes, a separate function **CicodeCallReturn** is used to obtain the return-value of the completed Cicode function most recently called by the **CicodeCallOpen** function.

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not nest the CicodeCallOpen and CicodeCallReturn functions. Nesting these functions can lead to unintended equipment operation when your program is run.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

The return value is initialized when control is returned to the Plant SCADA kernel. This occurs only after completion of the line of VBA code containing CicodeCallOpen. For details on multithreading in VBA, see [Multithread Considerations with VBA](#).

To call a given Cicode function or subroutine from VBA, use the CicodeCallOpen function. Upon return from CicodeCallOpen, you can call the CicodeCallReturn function to obtain the return value of the Cicode function called.

The CicodeCallOpen function is a VBA function used to call a Cicode function from VBA. It is used to initiate and execute a call to the Cicode function and returns an integer value representing the success or the type of error encountered by the CicodeCallOpen function.

```
<ReturnValue> = CicodeCallOpen(<FunctName>, <ArgList>)
```

Where:

- <ReturnValue> represents the return value of:
  - 0 if CicodeCallOpen function was successful
  - 1 for CicodeCallOpen function general error
  - 2 for specified Cicode function not found
  - 3 for incorrect number of arguments for specified Cicode function passed in <ArgList>.
- <FunctName> is a string representing the name of the Cicode function being called. The function name should be enclosed in double quotes.
- <ArgList> represents a variable length comma separated argument list of all the arguments to be passed to the Cicode function being opened (dependant upon which Cicode function is being called and the arguments that Cicode function requires). The argument list should not be enclosed within brackets, although when using variable names as arguments, those variable arguments within the list need to be individually enclosed within brackets to force the passing of the variable to Cicode by value.

The CicodeCallReturn function is a VBA function used to obtain the return value of the most recently completed Cicode function opened with the VBA CicodeCallOpen function.

```
<ReturnValue> = CicodeCallReturn()
```

Where:

- <ReturnValue> represents the return value of the Cicode function specified in the most recent call of the CicodeCallOpen function. Note that the return data type of CicodeCallReturn will depend upon the return data type of the Cicode function called in the most recent call of the CicodeCallOpen function.

No arguments are passed to the CicodeCallReturn function, as it can only return the result of the most recent return-value for the Cicode function called by the VBA CicodeCallOpen function.

**Note:** In the following example, a VBA variable is enclosed in brackets to force the passing of the variable by

---

value. See [Passing Variables Byref and Byval](#).

## VBA

```
' declare modular variant variable to store function results
Dim vntRet as Variant
Function TestCicode() As Integer
    ' declare local variables
    Dim intRet As Integer
    Dim strReply as String
    Dim intMaxScale as Integer
    ' copy current tag value to variable
    ' uses the project variable tag named MAX_SCALE
    intMaxScale = MAX_SCALE
    ' call Cicode function
    ' for example: TrnSetScale( AN, Pen, Percent, Scale)
    intRet = CicodeCallOpen( "TrnSetScale", 53, -1, 100, (IntMaxScale) )
    ' Note the syntax used:
    '- brackets around the VBA function argument list
    '(Only necessary when the VBA function is preceded by an equals (=) sign .)
    '- double quotes around the Cicode function name
    '- no brackets around the Cicode function argument list
    '- brackets around individual variable arguments
    ' test results
    If intRet = 0 Then
        '
        ' insert code for successful completion here
        '

        vntRet = CicodeCallReturn()
        strReply = "CicodeCallOpen Function successfully called"
    Else
        '
        ' insert code for unsuccessful completion here
        '

        Select Case intRet
        Case = 1
            ' assign return comment for this case
            strReply = "CicodeCallOpen Function call general error"

        Case = 2
            ' assign return comment for this case
            strReply = "Cicode Function not found"
        Case = 3
            ' assign return comment for this case
            strReply = "Wrong number of arguments " _
            & "in Cicode CallOpen function call"
        Case Else
            ' assign return comment for this case
            strReply = "Unknown error"
        End Select
    End If
    ' display return comment for your information
    MsgBox strReply
    ' assign return value for this function
    TestCicode = intRet
End Function
```

Alternatively, to call a single VBA function (from within the Plant SCADA Command or Expression field) after you

have already used Cicode in that field, you can wrap the VBA within three nested special Cicode functions: VbCallOpen(), VbCallRun() and VbCallReturn().

## Calling VBA from Cicode

Three new Cicode functions allow VBA code to be called from within Cicode script, and be pre-emptively multitasked by Plant SCADA. These calls VbCallOpen(), VbCallRun(), and VbCallReturn() can be nested to implement the entire function set with a single line of Cicode.

**Note:** When using the CiVBA language override in a Command field, the compiler constructs the nested call for you. The same mechanism is used even though it is not self evident. For details, see .

For information on multithreading in VBA, see [Multithread Considerations with VBA](#).

To call a given VBA function or subroutine from Cicode, use the VbCallOpen function. This returns a handle which can then be used to execute the call by passing it to the VbCallRun function. Upon return from VbCallRun, you can call the VbCallReturn function to get the return value of the VBA function called.

The Cicode VbCallOpen() function is used to initiate a call to the VBA function or subroutine, and returns a handle to the open function.

```
<ReturnValue> = VbCallOpen(<FunctName>, <ArgList>)
```

Where:

- <ReturnValue> represents the handle to the opened function.
- <FunctName> represents the name of the VBA function or subroutine being called.
- <ArgList> represents a comma separated list of arguments to pass to the opened VBA function or subroutine named in <FunctName>.

The Cicode VbCallRun() function is used to execute the VBA function or subroutine (previously opened with the Cicode VbCallOpen function), and requires the handle returned from the VbCallOpen function call. The VbCallRun function provides an opportunity for the opened VBA function to complete and return a value in the multi-threaded Plant SCADA environment. It passes its argument value (of OBJECT data type) through as its return value upon completion.

```
<ReturnValue> = VbCallRun(<CallHandle>)
```

Where:

- <ReturnValue> represents the handle to the opened VBA function passed through for the <CallHandle> argument.
- <CallHandle> represents the handle to the previously opened VBA function as returned by the Cicode VbCallOpenfunction.

The Cicode VbCallReturn() function is used to obtain the return value of the completed VBA function (previously opened with the Cicode VbCallOpen function), and requires the handle returned from the VbCallRun function call.

```
<ReturnValue> = VbCallReturn(<CallHandle>)
```

Where:

- <ReturnValue> represents the value returned by the completed VBA function (which was previously opened by the Cicode VbCallOpen function). The data type of the return value is dependent upon the data type of

the return value for the VBA function opened.

- <CallHandle> represents the handle to the previously opened VBA function as returned by the Cicode VbCallRun function.

## Example

```
FUNCTION
TestCitectVBA()
INT iRet;
STRING sMsg = "Hello";
INT iVal = 123;
iRet = VbCallReturn(VbCallRun(VbCallOpen("CiVBATest", iVal)));
Message("TestCitectVBA Function", "CiVBATest = " + IntToStr(iRet), 0);
END
```

## Example

```
Function CiVBATest(Value As Integer) As Integer
CiVBATest = Value * 2
End Function
```

[Multithread Considerations with VBA](#)

## Multithread Considerations with VBA

Cicode is pre-empted and executed on an instruction-by-instruction basis. This means that execution of a simple unnested Cicode thread can only switch to another thread after the current Cicode instruction has completed execution.

VBA code is pre-empted and executed on a line-by-line basis (as opposed to an instruction-by-instruction basis), and pre-empting can only occur after the current line has completed execution.

Each line of VBA script is handled as a separate thread in Plant SCADA. Therefore multiple procedures placed on one line may not complete before another subsequent thread is processed in a multithreading environment. This could cause unpredictable results and consequences, including data invalidation and corruption.

### UNINTENDED EQUIPMENT OPERATION

- Create your VBA program so that every code statement is positioned on a unique line.
- Do not group more than one code statement on a single line in your program. Grouping VBA statements on a single line can cause data corruption during multithreaded execution.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

If, for example, you were reading or setting some variable or point in a multi-statement thread, and further processing that data in a later thread, that data might become invalid or incorrect. For this reason, you should separate every statement onto separate lines in VBA.

For example, it is better to write:

```
A = Motor1.speed() + Motor4.speed() + Motor5.speed()
```

as

```
A = Motor1.speed()  
A = A + Motor4.speed()  
A = A + Motor5.speed()
```

in situations where the method `speed()` may take a long time to execute.

In the first example above, the VBA thread executes for three times longer before it can be pre-empted than in the latter example.

---

**Note:** This does not apply to Cicode because the Cicode engine can pre-empt aggregated code.

---

- [DLLs and APIs](#)
- [OLE Services](#)

- [File Input/Output with VBA](#)

## VBA Files

VBA code scripts can be saved to file, can include comments, statements, various representations of numbers, can handle many different data types, and can have multiple and nested control structures. However, VBA is primarily provided with Plant SCADA to interact with ActiveX objects.

VBA files are ASCII text files stored in ANSI format with a BAS extension (*filename.BAS*), and are known as file modules.

VBA file modules can be viewed and edited in any text editor program. They can be used in Plant SCADA, but must be saved as 'text with linebreaks' with a '.BAS' file extension or Plant SCADA will not be able to open the file.

## Cicode Editor

The Cicode Editor is VBA aware and designed to help you create, edit, test, and debug VBA file modules in your Plant SCADA project.

The Cicode Editor has features suitable for use with VBA file modules including:

- Ability to create, open, edit, and save VBA file modules
- Customizable coloration of VBA code syntax structure
- Recognition of predefined keywords with tooltip prompting and auto-completion functionality
- Fully integrated debugging of VBA file modules
- Separate VB Watch window for viewing runtime VBA variable values

A sample VBA file module named Sample.Bas is included in the User\Example subfolder on the drive on which you installed Plant SCADA. This module explains most of the VBA functionality.

VBA file modules will never be compiled into standalone Windows executable files; instead, they're included with the compiled Plant SCADA. As a result, they don't require a Main procedure to be declared. Therefore, VBA file modules are structured to contain only their header information, modular constant and variable declarations, then procedures (subroutines, and functions).

VBA file modules are automatically included with a Plant SCADA project if they are stored in the same file folder as your project. When saving a VBA file module to disk, save it to your project folder.

## Scope of VBA

The scope of an object determines which portions of your code scripts can use that object.

---

**Note:** The use of **Global**, **Public**, and **Private** keywords has no effect on scope in VBA.

---

### Procedural (Local) Level Scope

Variables and constants declared (using the Dim, Static, or Const statements) within a VBA procedure (subroutine or function) have local scope to only that within the procedure. This means that procedural level variables and constants cannot be referenced (accessed and used) from anywhere outside of that procedure.

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not use the Global, Public, or Private keywords in your VBA procedures. Using these keywords in procedures can lead to unintended equipment operation when your program is run.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

Procedural level variables declared using the Dim statement do not retain their assigned values when dereferenced. Procedural level variables declared using the Static statement, however, do retain their assigned values between references, even after that procedure moves out of scope.

## Modular level scope

Constants declared (using the Const statement) and variables declared (using the Static statement) at the modular level (outside any procedure) in a VBA file have modular scope to all procedures within that same VBA module (file). This means that modular constants and static variables can only be referenced from a procedure located within the same file module, and cannot be referenced from outside of that file module. This has no effect in VBA, even if declared using the Global keyword.

Modular level constants and static variables retain their assigned values for the entire runtime of the project.

## Global Level Scope

Variables declared (using the Dim, Global, or Public statements) at the modular level (outside any procedure) in a VBA module (file), have global scope within the Plant SCADA project. This means that modular VBA variables (except statics) can be referenced from both inside and outside of their file module.

Global level variables can be used directly within Plant SCADA command or expression fields.

Procedures (subroutines or functions) declared within a VBA file module, like global variables, have global scope within a Plant SCADA project. They can be referenced or called from any VBA module, as well as from any Plant SCADA command or expression field.

Equally important, all Plant SCADA variable tags, alarm tags, and ActiveX objects are accessible to all VBA file modules (and their procedures) within that project, in the same manner as they have always been accessible to project Cicode files. For information about referencing Plant SCADA project tags using VBA, see [Integrating VBA into a Project](#).

Global level variables will also retain their assigned values between subsequent references, behaving somewhat similarly to the values stored in Plant SCADA tags. In this regard, Global and Public statements are redundant at the modular (global) level in VBA, as they perform the exact same duty as the Dim statement.

**Note:** If an array is declared with an explicit data type using the Public or Dim keyword at global level, it will result in the error message "Sub or Function not defined". See the example below for more information.

## Example

```
Dim myVarAr(5) As Integer //Results in Error
Dim myVarAr(5) //No Error

Dim daysOfWeek(5) As String //Results in Error
```

```
Dim Intvar(5) As Long //Results in Error
Public myArray(5) //No Error
Public myArray2(5) As Integer //Results in Error

Sub TArrayIn()
Dim myVarAr(5) As Integer //No Error
Dim Intvar(5) As Long //No Error
Dim daysOfWeek(5) As String //No Error

Intvar(1)=1
Print Intvar(1)

daysOfWeek(1)= "Naresh"
Print daysOfWeek(1)

myVarAr(2) = 1
Print myVarAr(2)
myArray(1)=3
Print myArray(1)

myArray2(1)=4
Print myArray2(1)

End Sub
```

[Multithread Considerations with VBA](#)

[VBA Files](#)

## VBA Statements

A statement in VBA is an unbroken sequence of syntactically correct code script containing at least one VBA keyword instruction. A single statement in VBA is one complete segment of code script that instructs Plant SCADA to do something.

In VBA there is no statement terminator. As in other BASIC programming languages, the end of the line containing the statement is treated as the statement terminator by default.

Most often, a statement consists of a single line of VBA script. However, more than one statement can be placed on one line of VBA script, provided each statement is separated by a colon character (:); for example:

```
Pump234.AddPoint( 25, 100): Pump234.AddPoint( 0, 75)
```

This is equivalent in VBA to:

```
Pump234.AddPoint( 25, 100)
Pump234.AddPoint( 0, 75)
```

Using complex multi-statement lines of VBA script is not recommended in Plant SCADA. Multithreading should be considered when using more than one statement per line in VBA. For details, see [Multithread Considerations with VBA](#).

## Comments

Comments are non-executed sections of code that are ignored by the VBA compiler. Comments allow programmers to describe the purpose of a section of code to facilitate code maintenance.

As in other BASIC programming languages, both the apostrophe character ( ' ), and the keyword REM are recognized as the start of a comment in VBA. All characters following an apostrophe or the keyword REM are ignored by the VBA compiler until it reaches the end of the line. Line continuation characters do not work inside comments.

REM, like all other keywords and most names in VBA, is not case sensitive.

```
' This whole line is a comment
rem This whole line is a comment
Rem This whole line is a comment
REM This whole line is a comment
```

Both types of comments can be used on their own separate line, or the apostrophe character can be used to start a comment at the end of a statement on the same line as a statement.

```
Pump234.AddPoint( 25, 100 ' Add point to pump 234
```

Everything placed on the same line after an apostrophe is treated by VBA as a comment. If you want to place a comment on the same line as a statement, the comment must be placed last after all statements on that line. Comments cannot be placed between multiple statements on the same line.

Not every line of code requires a comment. In fact, VBA should contain understandable naming structures and be laid out in such a manner as to make comments unnecessary. However, where a complex function, equation, or logic structure is not readily understandable by viewing the code, it is good practice to include a pertinent comment to make the code more understandable when viewed in isolation.

## See Also

[VBA Files](#)

## Header Information

You should include header information with every file you create or edit. Data such as the file name, author name, creation date, update date, editing history, and the like should be included to form the header information. Each function or subroutine should include a brief comment describing the purpose or function of the procedure.

### VBA file header example

```
' FILE IDENTIFICATION
' VBA example named VBA.bas
' Created by Plant SCADA Documentation Team
' Created in April 2001
```

## See Also

[VBA Files](#)

## Labels

Labels can be used to divide a large VBA function or subroutine into logical sub-sections of code script. Labels are often used in association with the GoTo statement. All of the VBA script following the label and extending through to another label, or to the end of the function or subroutine containing the label, is regarded as belonging to that label. Or more appropriately, the label is said to identify, or be attached to, that particular section of VBA script.

Labels must begin with a letter, be no longer than 40 characters, and cannot be a reserved word. Labels must terminate with the colon character (:). Label names can only contain the letters 'A' to 'Z' and 'a' to 'z', the underscore '\_' character, and the digits '0' to '9'. Label names cannot contain the space character.

Label names (once declared), become a keyword in VBA. Like most keywords in VBA, label names are not case sensitive. For example, all of the following label examples are treated identically in VBA:

```
label1:  
Label1:  
LABEL1:
```

**Note:** Labels as used in VBA are not the same as labels used in Plant SCADA.

---

## See Also

[VBA Files](#)

## VBA Line Continuation Character

The underscore is the line continuation character in VBA. There must be a space before and after the line continuation character. Line continuation characters do not work inside comments.

The following sample code statements are treated identically in VBA:

```
Pump234.AddPoint _( 25, 100)  
Pump234.AddPoint( 25, 100)
```

Strings cannot be separated between lines using the line-break character in VBA, unless the strings are properly enclosed within double quotes on each line, and appended together as per the following example:

```
Dim strSample as String  
strSample = "This sentence on the first line in my code. " _  
& "This sentence is on the second line in my code. " _  
& "Yet all would display on the same line " _  
& "if the display were wide enough."
```

## See Also

[VBA Files](#)

## Naming

Function, subroutine, variable, constant, and label naming in VBA must begin with a letter, be no longer than 40 characters, and cannot be a reserved word. Name field are not case-sensitive and can only contain the letters 'A' to 'Z' and 'a' to 'z', the underscore '\_' character, and the digits '0' to '9'. Names cannot contain the space

character. You cannot use the name of a VBA predefined function as a name. For a list of predefined functions, see .

Function, subroutine, variable, constant, and label object names (once declared), become a keyword in VBA. Like most keywords in VBA, these names are not case sensitive. For example, all of the following examples are treated identically in VBA:

```
pump234.addpoint(25, 100)  
Pump234.AddPoint(25, 100)  
PUMP234.ADDPOINT(25, 100)
```

When naming in VBA, make the name an appropriately descriptive term that is easily recognizable. For example:

```
X.addpoint(25, 100)
```

This does not make as much sense as:

```
Pump234.AddPoint(25, 100)
```

Combining upper- and lowercase letters between words in the name is an acceptable common programming practice, and aids in readability.

Identically named objects cannot be declared more than once per Plant SCADA project, even though they may exist in different VBA code file modules. However, if an object declared locally within a procedure has the same name as an object declared in a module, VBA will reference the local procedure scope object instead of the modular scope object.

[Scope of VBA](#)

[VBA Files](#)

[Integrating VBA into a Project](#)

## Option Statements

VBA supports the use of file scope Option statements which determine the default behaviour of some VBA functions. For instance, the Option Explicit statement causes the VBA compiler to produce compile errors whenever it encounters the use of previously undeclared variables. The Option Compare statement sets the default comparison method for string comparisons. The Option Base statement sets the default base number for VBA variable arrays to either zero or one.

clare all option statements in VBA at the beginning of your VBA code files.

### Option Explicit Statement

As in other BASIC programming languages, VBA supports the declaration of variables both implicitly and explicitly. An unfortunate consequence of implicit variable declaration is the possible misspelling of the variable name in subsequent code writing, with unreliable program behaviour and unpredictable consequences.

To minimize implicit declaration, and to foster good, consistent programming standards, use the option explicit statement at the beginning of all your VBA files:

```
Option Explicit
```

This causes the VBA compiler to produce a compile error whenever it encounters an undeclared variable. This can be useful in locating and identifying variable name typing errors in your VBA code at compile time, thus

trapping and minimizing the likelihood of runtime errors caused by such mistakes.

## Option Compare Statement

The Option Compare statement determines how strings are compared within a VBA file, and like other Option statements in VBA, should be declared at the beginning of your VBA code files.

When strings are compared using VBA functions such as StrComp() or InStr(), VBA determines whether they contain equivalent characters and how they differ if they do not match.

---

**Note:** When comparing strings, VBA compares the ANSI values of each character in the strings. For example, the character capital 'A' has the ANSI value of 65, and the character lowercase 'a' has the ANSI value of 97. For a listing of ANSI character values, see [ASCII/ANSI Character Code Listings](#).

---

You can use the Option Compare statement to specify the default case-sensitivity behavior for VBA functions when making string comparisons.

The Option Compare statement in VBA has two settings:

- **Option Compare Binary:** String comparisons are case-sensitive, and this is the default string-comparison setting.
- **Option Compare Text:** String comparisons are case-insensitive.

## Option Base Statement

The Option Base statement determines the default base number for the indexing of variable arrays created within a VBA file, and like other Option statements in VBA, should be declared at the beginning of your VBA code files.

There are two settings for the Option Base statement in VBA:

- **Option Base 0:** Variable arrays are indexed from number zero, and this is the default setting.
- **Option Base 1:** Variable arrays are indexed from number one.

For an example of using the Option Base statement, see [Fixed Size Arrays](#).

## VBA Data Types

VBA uses ten predefined data types:

Variable	Char	Type Declaration	Size	Value Range
Byte		Dim bytVar As Byte	1 byte (8 bits)	0 to 255
Boolean		Dim binVar As Boolean	2 bytes	True or False

Variable	Char	Type Declaration	Size	Value Range
String	\$	Dim strVar As String	10 bytes + 1 byte per character	0 to 65,535 characters
Integer	%	Dim intVar As Integer	2 bytes	-32,768 to 32,767
Long Integer	&	Dim lngVar As Long	4 bytes	-2,147,483,648 to 2,147,483,647
Single precision	!	Dim sglVar As Single	4 bytes	3.4E-38 to 3.4E+38
Double Precision	#	Dim dblVar As Double	8 bytes	1.79D-308 to 1.79D+308
Variant		Dim vntVar As Any	16 bytes	Same ranges as data types stored
Object		Dim objVar As Object	4 bytes	Any OLE Object reference
Date/Time		Dim dtmVar As Date	8 bytes	Jan 1, 100 to Dec 31, 9999

**Note:** VBA does not support user-defined data types.

## See Also

[Numeric Data Types](#)

[Numbers](#)

[Variables](#)

[VBA Function Reference](#)

## Constants

Your VBA code may contain frequently recurring constant values like Pi, or may contain numbers that are difficult to remember or have no obvious meaning. You can make your VBA code much easier to read and maintain using constants to represent those values.

Unlike variables, constants can't be changed once your Plant SCADA project is compiled and running. Constants are either symbolic or intrinsic:

- Symbolic or user-defined constants are declared by using the `const` statement.
- Intrinsic constants are provided in object libraries of ActiveX objects and you cannot use them in VBA: they cause compile errors as there is no way to provide early-binding to the object type library.

You can create a constant in VBA named `Pi`, assign it the numeric value once in your code, then refer to it by using the constant name, as shown here:

```
'modular level constant declaration
Const Pi = 3.1415926
Function CircleArea(Byval Radius)
    ' calculate and return area of circle
    ' using radius passed in as argument
    CircleArea = Pi * (Radius * Radius)
End Function
Function CircleCircumference(Byval Radius)
    ' calculate and return circumference of circle
    ' using radius passed in as argument
    CircleCircumference = Pi * Radius * 2
End Function
```

These VBA functions would be called from a Plant SCADA command or expression field like this:

```
CivBA
TestTag_1 = CircleArea(TestTag_1)
```

or

```
CivBA
TestTag_1 = CircleCircumference(TestTag_1)
```

[Declaration of Constants](#)  
[Passing Variables Byref and Byval](#)  
[Integrating VBA into a Project](#)  
[Intrinsic Constants](#)  
[Scope of VBA](#)  
[VBA Function Reference](#)

## Declaration of Constants

VBA constants can only be declared and referenced within VBA file modules. VBA modular constants have modular scope and cannot be referenced (accessed and used) from outside their VBA module (file).

**Note:** VBA constants cannot be used directly in Plant SCADA command or expression fields.

Once declared within a VBA module, VBA constants can be referenced and used in any procedure within the same code module. A constant declared outside a procedure has modular scope to all procedures within that same VBA module (file). See [Scope of VBA](#). Constants declared in a Sub or Function procedure have local scope only within that procedure.

VBA constants are declared with the Const statement in the following format.

```
Const <ConstantName> [ As <DataType> ] = <expression>
```

Where:

- Const is the required constant declaration statement BASIC keyword
- <ConstantName> represents the required name of the constant being declared
- <DataType> represents the optional VBA data type of the constant being declared
- <expression> represents the required value being assigned to the constant

---

**Note:** Do not include the brackets from the explanation in the actual code statement.

---

If no data type is declared, VBA automatically assigns one of the following data types to the constant:

- Long (if it is a long or integer).
- Double (if a decimal place is present).
- String (if it contains quote marks).

Constant statements can only be declared and assigned using simple expressions. Constants cannot be assigned values from variables, user-defined functions, intrinsic VBA functions (such as Chr), or from any expression that involves an operator. A constant needs to be defined before it can be used.

## Example

```
' Correct declaration examples
Const Seven = 7

' long assignment
Const Pi = 3.14159

' double assignment
Const Lab = "Laboratory"

' string assignment
' Incorrect declaration examples. Note that the following declarations demonstrate
incorrect assignments because each contains an operator
Const conPi = 4 * Atn(1)
' will cause a VBA compile error
Const conDegToRad = (conPi / 180)
' will cause a VBA compile error
```

For an example of using constants in VBA, see [Constants](#).

---

**Note:** The use of Global, Public, and Private keywords has no effect on scope in VBA.

---

## Intrinsic Constants

VBA has no predefined intrinsic (built-in and declared) constants, however, does provide limited support for intrinsic constants provided in object libraries of ActiveX objects when the object they refer to is loaded using the predefined VBA CreateObject() function.

## See Also

[Declaration of Constants](#)

[Constants](#)

## Variables

Variables are used in VBA to temporarily store data values. Variables let you assign a descriptive name to the data you are working with. You can create a variable once only in your code, and reference (refer to) it thereafter as many times as you like, by using its name in your code in place of the data value. Unlike constants, the value that a variable holds can be changed during the runtime of the project.

All variables declared within a VBA procedure (subroutine or function) have local scope to that procedure only. Procedural level variables declared using the `Dim` statement do not retain their assigned values when dereferenced. Procedural level variables declared using the `Static` statement, however, retain their assigned values between references, even after that procedure moves out of scope.

VBA code used within a Plant SCADA command or expression field is treated as if the command or expression is a separate VBA procedure. Variables declared within such a command procedure have procedural scope and lifetime, as described above.

Variables declared using the `static` statement at the modular level (outside any procedure) in a VBA file, have modular scope to all procedures within that same VBA module (file). Modular level `static` variables retain their assigned values for the entire runtime of the project.

Variables declared (using the `dim`,`global`,or `public` statements) at the modular level (outside any procedure) in a VBA file do, however, have global scope within the Plant SCADA project.

---

**Note:** Global and public statements are redundant at the modular (global) level in VBA, as they perform the exact same duty as the `dim` statement.

## See Also

[Variant Declaration](#)

[Variable Initialization Values](#)

## Variable Declaration

In VBA, variables are declared (dimensioned) with the `dim` statement in the following format.

`Dim <VariableName> [ As <DataType> ]`

Where:

- `Dim` is the required Variable declaration statement BASIC keyword
- `<VariableName>` represents the required name of the variable being declared (dimensioned)
- `<DataType>` represents the optional VBA data type of the variable being declared

In the variable declaration statement:

- Every placeholder shown inside arrow brackets (`<placeholder>`) should be replaced in any actual code with

the value of the item that it describes. The arrow brackets and the word they contain should not be included in the statement, and are shown here only for your information.

- Statements shown between square brackets ( [ ] ) are optional. The square brackets should not be included in the statement, and are shown here only for your information.

If no data type is declared, the data type is Variant by default. To declare a variable other than a Variant, the variable declaration needs to be immediately followed by As <datatype> (where <datatype> represents one of the 10 data types), or appended by a type declaration character such as a \$, %, &, !, or # for string, integer, long, single, or double data types respectively. For example:

```
Dim intVar As Integer
Dim dblVar As Double
Dim vntVar ' as variant by default
Dim strName$, Age% ' multiple declarations on one line
```

Be aware that multiple declarations in the same statement require individual data type assignment if you want them be other than the variant type. In the following example, only the first variable is not a variant. For example:

```
Dim strName As String, vntAge, vntAddress
```

The same statement with data type assignment for every variable would look like the following example:

```
Dim strName As String, intAge As Integer, strAddress As String
```

[Variant Declaration](#)

[Arrays of Variables](#)

[VBA Function Reference](#)

## Variable Initialization Values

VBA variables are initialized when first declared. Numeric variables are initialized to 0 (zero). Variable-length strings are initialized to zero-length strings (""). Fixed length strings are filled with zeros. Variant variables are initialized to Empty.

To be sure of the contents of a variable, a valid value needs to be assigned to it before it is used as an operand in a VBA statement. For details, see [Assignment Operator](#).

---

**Note:** Only implicitly declared variables can be assigned an initial value in the declaration. However, as explicit declaration is preferred practice in VBA, explicit variables need to be declared before they can be assigned a value.

---

Every call to a procedure will reinitialize the value of all objects (except static variables) declared within that procedure.

---

**Note:** In VBA, use a static variable, a modular variable, or a Plant SCADA tag to store variable values between procedures. For details, see [Scope of VBA](#).

---

Objects (including variables) declared in VBA are only initialized when referenced by a running piece of code, and

are removed from memory when all references are closed.

In the Plant SCADA multithreaded environment, VBA remains active in memory only so long as a procedure is being processed. At the completion of a VBA procedure, all objects no longer referenced by that procedure are removed from memory. For details, see [Multithread Considerations with VBA](#).

[Variant Declaration](#)

[Arrays of Variables](#)

## Arrays of Variables

Arrays of variables allow you to group like variables together, somewhat similar to the grouping of like items in fields of a database. An array is an ordered group of variables of the same name, containing values of the same data type. Individual member elements of the array are identified by a separate index number. Arrays in VBA start their indexing sequence by default at zero. This default base value can be changed in a VBA file module by using the option base statement.

VBA supports single and multi-dimension arrays of variables. VBA creates single dimension arrays by default. Multi-dimension arrays must be specifically declared.

VBA allocates memory space for each element of the array. To minimize the amount of memory used storing arrays, and to minimize the time required to access array data, arrays should not be declared any larger than required.

All elements in an array must be of the same data type. VBA supports arrays of bytes, booleans, longs, integers, singles, doubles, strings, and variants. For details about VBA data types, see [VBA Data Types](#).

Arrays declared in a sub or function procedure have local scope only within that procedure. An array declared outside a procedure has modular (global) scope to all procedures within the project.

---

**Note:** VBA arrays cannot be used directly in Plant SCADA command or expression fields. Also, VBA does not support user-defined data types.

---

Arrays declared (using the dim statement within procedures) do not retain their values between procedure calls in VBA.

## Variable Array Declaration

Arrays of variables are declared within a VBA file module, function, or subroutine, using the dim statement with parentheses positioned after the array name, in the following syntax:

Dim <ArrayName>( [<Subscripts>] ) [As <DataType>]

Where:

- dim is the required variable declaration statement BASIC keyword.
- <ArrayName> represents the required name of the array being declared (dimensioned).
- ( ) are the required parentheses to hold the array subscript range (dimensions).
- <Subscripts> represents the optional subscript ranges and dimensions for the array.
- As is the optional As statement keyword declaring the array data type.
- <DataType> represents the optional VBA data type declaration for the array.

In the variable array declaration statement:

- Every placeholder shown inside arrow brackets (<placeholder>) should be replaced in any actual code with the value of the item that it describes. The arrow brackets and the word they contain should not be included in the statement, and are shown here only for your information.
- Statements shown between square brackets ( [ ] ) are optional. The square brackets should not be included in the statement, and are shown here only for your information.

[Multi-Dimensional Arrays](#)

[Dynamic Size Arrays](#)

[Array Subscripts](#)

[Arrays of Variables](#)

[Dim](#)

## Array Subscripts

Arrays can be declared with default or defined boundaries known as bounds. Unless specifically defined in the array declaration statement, default lower bound settings are used. The default lower bound is zero, unless set by the module option base statement setting.

VBA does not have an arbitrary upper bound on array dimensions. The upper bound of the array dimension must be defined before the array can be used. All bound values must be whole integers.

Subscripts are contained within one set of parentheses positioned immediately after the array name in the array declaration statement.

Subscripts are used to specify the bounds of each dimension of an array when the array is declared. If a single value is used, for instance (5), this represents the upper bound for that dimension of the array. If a range is specified, for instance (1 to 9), this specifies both the lower and upper bounds for that dimension of the array. If more than one subscript is used, for instance ( 5, 1 To 9), each subscript must be separated by a comma, and each subscript represents a separate dimension of the array.

The syntax of an array subscript range consists of a numeric value range separated by the to clause:

(<LowerBound> To <UpperBound>)

Where:

- ( ) are the required parentheses to hold an array subscript range (dimensions).
- <LowerBound> represents the lower bound of the subscript range for the array dimension.
- To is the clause linking the lower and upper bounds of the subscript range.
- <UpperBound> represents the upper bound of the subscript range for the array dimension.

## See Also

[Fixed Size Arrays](#)

[Multi-Dimensional Arrays](#)

[Dynamic Size Arrays](#)

[Arrays of Variables](#)

[Dim](#)

### Fixed Size Arrays

To declare a fixed size array, the array name must be followed by the upper bound subscript enclosed within parentheses. The upper bound must be an integer.

```
Dim ArrayName(10) As Integer  
Dim Sum(20) As Double
```

Unless specifically defined in the array declaration statement, default lower bound settings are used. The default lower bound is zero, unless set by the module option base statement setting. For details, see [Array Subscripts](#).

The first declaration in the previous example creates an array with 11 elements, with index numbers running from 0 to 10. The second creates an array with 21 elements (if base 0). One way to specify the lower bound is to provide it explicitly (as an integer in the range -32,768 to 32,767) using the To clause within the subscript:

```
Dim intCounters (1 To13) As Integer  
Dim strSums (100 To126) As String
```

In the preceding example, the index numbers of intCounters run from 1-13, and the index numbers of strSums run from 100-126.

**Note:** An array in VBA must be declared before it can be referenced.

Loops often provide an efficient way to manipulate arrays. For example, the following for loop initializes all elements in the array to 5:

```
Dim int As IntegerDim Counters(1 To 20) As Integer  
For int = 1 To 20  
Counters(int) = 5  
Next int
```

Arrays declared (using the dim statement within procedures) do not retain their values between procedure calls in VBA.

## See Also

[Multi-Dimensional Arrays](#)

[Dynamic Size Arrays](#)

[Arrays of Variables](#)

[Array Subscripts](#)

## Option Statements

### Multi-Dimensional Arrays

VBA supports multi-dimensional arrays, declared using multiple subscripts. Each subscript must be separated by a comma, and each subscript represents a separate dimension of the array.

The following example declares a two-dimensional array.

```
Dim dblMat(20, 20) As Double
```

Unless specifically defined in the array declaration statement, default lower bound settings are used. The default lower bound is zero, unless set by the module option base statement setting. For more information on bounds, see "Array Subscripts in VBA."

Reusing the previous example, either or both dimensions can be declared with explicit lower bounds.

```
Dim dblMat(1 To 10, 1 To 10) As Double
```

Arrays can be more than two dimensional. This declaration creates an array that has three dimensions with sizes 6 elements by 4 elements by 3 elements, using base 0:

```
Dim ArrTest(5, 3, 2)
```

You can efficiently process a multi-dimensional array with the use of for loops. In the following statements the elements in a multi-dimensional array are set to a value.

```
Dim L As Integer, J As Integer
Dim TestArray(1 To 10, 1 to 10) As Double
For L = 1 to 10
For J = 1 to 10
TestArray(L,J) = I * 10 + J
Next J
Next L
```

Arrays declared (using the dim statement within procedures,) do not retain their values between procedure calls in VBA.

[Array Subscripts](#)

[Option Statements](#)

[Fixed Size Arrays](#)

### Dynamic Size Arrays

To declare a dynamic sized array, the array must first be declared using the dim statement with an empty pair of parentheses following the array name. For example:

```
Dim ArrayName( ) As Integer
```

Once declared as dynamic in this manner, the array can then ONLY be resized within a function or subroutine using the redim statement.

```
ReDim ArrayName(20) As Integer
```

---

**Note:** You cannot resize an array whose size was predefined in its initial declaration.

In the above examples, the first declaration creates an array with 0 elements. The second recreates the array to contain 21 elements, with index numbers running from 0 to 20, unless the option base statement has been set previously in the code module (file), in which case the array will contain 20 elements with index numbering ranging from 1 to 21.

Unless specifically defined in the array declaration statement, default lower bound settings are used. The default lower bound is zero, unless set by the module option base statement setting. For more information on bounds, see "Array Subscripts in VBA."

Redim erases all values the array may have held. To preserve the contents of the array when resizing, precede the Redim statement with the preserve keyword.

```
Preserve ReDim ArrayName(20) As Integer
```

Redimensioning an array to a smaller value, will erase any values it may have contained in the removed portions.

Arrays declared (using the dim statement within procedures,) do not retain their values between procedure calls in VBA.

[Option Statements](#)

[Fixed Size Arrays](#)

## Variant Declaration

As is the case with Visual Basic, when a variable is introduced in VBA, it is not necessary to declare it first (see for an exception to this rule). When a variable is used but not declared, it is implicitly created as a variant data type. Variants can also be declared explicitly using As Variant. Both of the following example declarations are treated identically in VBA:

```
Dim vntVar ' implicit variant declaration
Dim vntVar As Variant ' explicit variant declaration
```

The IsEmpty( ) function can be used to find out if a variant variable has been previously assigned a value.

## Variant Data Types and Coercion

The variant data type is capable of storing numbers, strings, dates, and times. When using a variant, you do not have to explicitly convert a variable from one data type to another. This data type conversion is handled automatically, and is termed data type coercion.

```
' declares variant variable
Dim vntVar
' assign numeric 10 to variant
vntVar = 10
' add numeric 8 to numeric variant value
vntVar = vntVar + 8
' convert variant to string value and concatenates strings
vntVar = "F" & vntVar
```

```
' print string "F18"  
print vntVar
```

Numeric characters inside quotes ("567") will be stored and treated as a string in a variant data type variable. If this string (containing numeric characters) is subsequently used in a numeric operation, it will be coerced into a numeric data type and treated as a number in the operation. Conversely, numeric characters stored as a number data type in a variant variable, and subsequently used in an operation with a string, will be coerced into a string data type, and treated as a string value in the operation.

**Note:** To determine the type of a variant variable, use the function `VarType( )`, which returns a value that corresponds to the explicit data types. See [VarType](#) for return values.

## Numbers in Variants

When storing numbers in variant variables, the data type used is the most compact type possible. For example, if you first assign a whole number to the variant it will be stored as an integer or long. If you assign a number with a fractional component, it is stored as a single or double.

For doing numeric operations on a variant variable, it is sometimes necessary to determine if the value stored is a valid numeric, thus avoiding an error. This can be done with the `IsNumeric( )` function.

[Numbers](#)

[VBA Function Reference](#)

## Numbers

VBA supports three representations of numbers: decimal, octal, and hexadecimal.

To indicate the use of octal (base 8) or hexadecimal (base 16) numbers, prefix the number with &O or &H respectively. If no prefix is included with a number, it is treated as decimal (base 10). For example:

```
Dim vntVar as Variant  
vntVar = 12345 ' assign decimal value  
vntVar = &o12345 ' assign octal value  
vntVar = &h12345 ' assign hexadecimal value
```

Most numbers used in VBA formulas are decimal numbers. Decimal numbers consist of integral values (known as integers) positioned to the left of the decimal point, and fractional values (known as fractions) positioned to the right of the decimal point. If the decimal point is omitted, the number is treated as an integer (whole number with no fraction).

When using numbers in VBA, consideration needs to be given to the data type of the variables that hold and store the numbers, as well as to the behaviour of VBA when dealing with numbers. For details, see [Numeric Data Types](#), [Floating Point Calculation Rules](#), and [Rounding Numbers](#).

## See Also

[Variant Declaration](#)  
[Strings](#)  
[Variables](#)  
[Constants](#)  
[VBA Data Types](#)  
[VBA Function Reference](#)

## Numeric Data Types

Numbers are expressed in VBA in decimal format by default, and can be stored in variables of different numeric data types—integer, long, single, double, and variant—providing different levels of numeric accuracy.

- **Integer** (Integer data type) variables can only store whole number values (no decimal or fraction values) within the range -32,000 to +32,000. If you use a number outside this range, the long integer (Long data type) can store whole number values in the range -2.1 million to +2.1 million.
- **Floating point** numbers contain both integer and fractional values with a floating decimal point. VBA provides both single precision (Single data type) and Double Precision (Double data type) variables for handling floating-point numbers.
- **Single-precision** variables can store floating-point numbers within the range of approximately 3.4E-38 to 3.4E+38, with 7 significant digits and occupying 4 bytes of memory.
- **Double-precision** variables can store floating-point numbers within the range of approximately 1.79D-308 to 1.79D+308, with 15 significant digits and occupying 8 bytes of memory.

For an explanation of exponential notation, see [Exponential Notation](#).

The principal differences between single and double data types, are the significance they can represent, the storage they require, and their range. Double data type variables have a smaller range, but hold more precision and occupy more memory than single data type variables.

If precision is less of a concern than storage, consider using single for floating-point variables. Conversely, if precision is the most important criterion, use double.

Variant (variant data type) variables in VBA can store numbers by storing them as integer, long, single, or double data types within the variant structure. See [Variant Declaration](#).

## See Also

[Numbers](#)

## Exponential Notation

VBA can handle very large numbers, up to a value of 1.7976931486232 raised to the power of 308, (1.7 308). To represent very large numbers such as these, exponential notation is used.

Commonly, exponential notation uses the letter 'E' in the number, followed by the sign of the number (+ or -), and then the exponential value (power) of the number. VBA uses the letter 'E' for Single data type exponential

values, and the letter 'D' for Double data type exponential values. The maximum size number for a double precision data type, as quoted above, would be represented using exponential notation as 1.7976931486232D+308, or abbreviated to 1.79D+308.

You can use exponential notation in your VBA calculations, so long as the data types of all the variables in the calculation are capable of storing floating point values; i.e.: Single, Double or Variant.

For details about precision, accuracy, and rounding issues with using floating point variables in VBA, see [Numeric Data Types](#), [Floating Point Calculation Rules](#), and [Rounding Numbers](#).

## See Also

[Numbers](#)

## Floating Point Calculation Rules

Often precision, rounding, and accuracy in floating-point calculations can generate unexpected results. To avoid this situation, follow these rules:

- In a calculation involving both single and double precision, the result will not usually be any more accurate than single precision. If double precision is required, be certain all terms in the calculation, including constants, are specified in double precision.
- Never assume that a simple numeric value is accurately represented in the computer. Most floating-point values can't be precisely represented as a finite binary value. For example .1 is .0001100110011... in binary (it repeats forever), so it can't be represented with complete accuracy on a computer using binary arithmetic, which includes all PCs.
- Never assume that the result is accurate to the last decimal place. There are always small differences between the "true" answer and what can be calculated with the finite precision of any floating point processing unit.
- Never compare two floating-point values to see if they are equal or not-equal. This is a corollary to rule three. There are almost always going to be small differences between numbers that "should" be equal. Instead, always check to see if the numbers are nearly equal. That is, check to see if the difference between them is very small or insignificant.

[Date and Time Handling](#)

## Rounding Numbers

Rounding occurs when you convert a number of greater precision into a number of lesser precision. For instance, when converting a floating-point number (single precision, double precision, or variant data types) into an integer or long data type number. The possible ways of numeric rounding are discussed below.

## Rounding Down

The simplest form of rounding is truncation. Any digits after the desired precision are ignored and dropped. The VBA Fix() function is an example of truncation. For example, Fix(3.5) is 3, and Fix(-3.5) is -3.

The Int() function rounds down to the highest integer less than the value. Both Int() and Fix() act the same way with positive numbers (truncating), but give different results for negative numbers: Int(-3.5) gives -4.

The Fix() function is an example of symmetric rounding because it affects the magnitude (absolute value) of positive and negative numbers in the same way. The Int() function is an example of asymmetric rounding because it affects the magnitude of positive and negative numbers differently.

## Rounding Up

VBA does not have a specific round-up function. However, for negative numbers, both Fix() and Int() can be used to round upward, in different ways:

- Fix() rounds towards 0 (up in the absolute sense, but down in terms of absolute magnitude). For example: Fix(-3.5) is -3.5.
- Int() rounds away from 0 (up in terms of absolute magnitude, but down in the absolute sense). For example: Int(-3.5) is -4.

## Arithmetic Rounding

When continually rounding in one direction (down or up), the resulting number is not necessarily the closest to the original number. For example, if you round 1.9 down to 1, the difference is a lot larger than if you round it up to 2. It is easy to see that numbers from 1.6 to 2.4 should be rounded to 2. However, what about 1.5, which is equidistant between 1 and 2? By mathematical convention, the half-way number is rounded up.

To implement rounding half-way numbers in a symmetric fashion, -.5 is rounded down to -1, or in an asymmetric fashion, where -.5 is rounded up to 0.

VBA does not have a function for arithmetic rounding.

## Banker's Rounding

When you add rounded values together, always rounding .5 in the same direction results in a bias that grows with the more numbers you add together. One way to minimize the bias is with banker's rounding.

Banker's rounding rounds .5 up sometimes and down sometimes. The convention is to round to the nearest even number, so that both 1.5 and 2.5 round to 2, and 3.5 and 4.5 both round to 4. Banker's rounding is symmetric.

In VBA, the CByte(), CInt(), CLng(), CCur(), and Round() numeric functions perform banker's rounding.

## Random Rounding

Even banker's rounding can bias totals. You can take an extra step to remove bias by rounding .5 up or down in a truly random fashion. This way, even if the data is deliberately biased, bias might be minimized. However, using random rounding with randomly distributed data might result in a larger bias than banker's rounding. Random rounding could result in two different totals on the same data.

VBA does not have a function for random rounding.

## Alternate Rounding

Alternate rounding is rounding between .5 up and .5 down on successive calls. VBA does not have a function for alternate rounding.

## See Also

[Numbers](#)

## Date and Time Handling

VBA has several pre-defined date and time functions that return date/time values. There are three functions enabling you to determine the current date and time set in Windows. The Now function, Date function, and Time function check your system clock and return all or part of the current setting.

To retrieve the date portion of a date/time value, use the pre-defined DateValue function. This function takes in either a string or a date value and returns only the date portion.

Using DateValue, you can compare the date portion of a date variable to a specific date value, like this:

```
If DateValue(dtmSomeDate) = #5/14/70# Then
    ' You know the date portion of dtmSomeDate is 5/14/70
End If
```

If you need just the time portion of a date variable, use the TimeValue function. Using this function, you could write code that checks the time portion of a date variable against a particular time, like this:

```
If TimeValue(dtmSomeDate) > #1:00 PM# Then
    ' You know the date variable contained a date portion
    ' with a time after 1:00 PM.
End If
```

You can perform arithmetic or mathematics (math) on date/time values because VBA stores dates internally as serial values. Adding or subtracting integers adds or subtracts days, while adding or subtracting fractions adds or subtracts time. Therefore, adding 20 to a date value in VBA adds 20 days, while subtracting 1/24 subtracts one hour. For example, to get tomorrow's date, you could just add 1 to today's date, like this:

```
dtmTomorrow = Date() + 1
```

Date is a built-in VBA function that returns the date portion (the integer part) of the current date and time retrieved from the Windows operating system. Adding 1 to that value returns a date that represents the next day.

The same mechanism works for subtracting two dates. Although VBA supplies the DateDiff function for finding the interval spanned by two date/time values, if you just need to know the number of days between the two dates, you can simply subtract one from the other.

## See Also

[Date and Time Functions](#)  
[Date Constants](#)  
[Formatting Date Values](#)  
[VBA Function Reference](#)

## Date Constants

You can use date/time literals in VBA code by enclosing them with the hash sign (#), in the same way you enclose string literals with double quotation marks (""). This is commonly known as declaring date constants.

For example, #2/6/10# represents the Australian date value of 2nd June, 2010 if the short date setting for the locale was set to d/MM/yyyy. The same date constant would represent the American date value of February 6, 2010 if the short date setting for the locale was set to MM/d/yyyy. See [Formatting Date Values](#).

**Note:** The system locale settings are determined using Regional Settings in Windows Control Panel.

Similarly, you can compare a date/time value with a complete date/time literal:

```
If SomeDate > #3/6/99 1:20pm# Then
```

If you don't include a time in a date/time literal, VBA sets the time part of the value to midnight (the start of the day). If you don't include a date in a date/time literal, VBA sets the date part of the value to December 30, 1899.

VBA accepts a wide variety of date and time formats in literals. These are all valid date/time values:

```
SomeDate = #3-6-93 13:20#
SomeDate = #March 27, 1993 1:20am#
SomeDate = #Apr-2-93#
SomeDate = #4 April 1993#
```

In the same way that you can use the IsNumeric function to determine if a Variant variable contains a value that can be considered a valid numeric value, you can use the IsDate function to determine if a variant contains a value that can be considered a valid date/time value. You can then use the CDate function to convert the value into a date/time value.

For example, the following code tests the Text property of a text box with IsDate. If the property contains text that can be considered a valid date, VBA converts the text into a date and computes the days left until the end of the year:

```
Dim SomeDate, daysleft
If IsDate(Text1.Text) Then
    SomeDate = CDate(Text1.Text)
    daysleft = DateSerial(Year(SomeDate)) + _
    1, 1, 1) - SomeDate
    Text2.Text = daysleft & " days left in the year."
Else
    MsgBox Text1.Text & " is not a valid date."
End If
```

## See Also

[Date and Time Functions](#)  
[Formatting Date Values](#)  
[VBA Function Reference](#)  
[Date and Time Handling](#)

## Formatting Date Values

Date values in VBA can be formatted and displayed as strings containing any combination of the following lists of values, all of which are case-sensitive.

Most VBA date and time functions are locale-aware and recognize the order for day, month, and year according

to the short date format in the Regional Settings section of Windows Control Panel.

**Note:** Always use long date format whenever possible. Also, please ensure that you enter and display dates in an unambiguous format. For example, dates in short date format might be misinterpreted in queries if the year or the day of the month are 12 or less (for example, 3/11/10). Dates in medium date format display only the first few characters of the month name, which can create ambiguity or an undesirable appearance.

## Text

All strings should be surrounded by single quotes, and any single quotes should be entered as four single quotes in a row:

Value	Example
it'''s	it's
'Today is 'M/dd/yy' and it'''s 'h:mm	Today is 01/22/99 and it's 8:18

## Day

The day can be displayed in one of four formats using a lowercase "d".

Value	Meaning	Example
d	Day of the month as digits without leading zeros for single digit days.	5
dd	Day of the month as digits with leading zeros for single digit days.	05
ddd	Day of the week as a three letter abbreviation.	Mon
dddd	Day of the week as its full name.	Monday

## Month

The month can be displayed in one of four formats using capital "M". The letter "M" must be uppercase to distinguish months from minutes.

Value	Meaning	Example
M	Month as digits without leading zeros for single digit months.	1
MM	Month as digits with leading zeros for single digit months.	01
MMM	Month as a three letter abbreviation.	Jan

Value	Meaning	Example
MMMM	Month as its full name.	January

## Year

The year can be displayed in one of three formats using lowercase "y".

Value	Meaning	Example
y	Year represented only by the last digit, if the year is less than 10. Years greater than 10 will be given the value of yy.	9
yy	Year represented only by the last two digits.	09
yyyy	Year represented by the full 4 digits.	1909

## Period/Era

The period/era string can be displayed in a single format using the letter "g". The letter "g" must be lowercase. If you include the gg in a date string that does not have any associated Era string, the gg is ignored.

Value	Meaning
(Null)	Gregorian dates are used. Does nothing if Gregorian is value of iCalendarType
gg	Period/era string. This is used by Windows to calculate the year when an optional calendar is selected. See iCalendarType for optional Calendars.

## Time

The time can be displayed in one of many formats using the letter "h" or "H" to denote hours, the letter "m" to denote minutes, the letter "s" to denote seconds and the letter "t" to denote the time marker. The lowercase "h" denotes the 12 hour clock and uppercase "H" denotes the 24 hour clock. The "m" must be lowercase to denote minutes as opposed to Months. The "s" for seconds and "t" for the time marker string must also be lowercase.

Value	Meaning	Example
h	Hours without leading zeros for single digit hours (12 hour clock).	1
hh	Hours with leading zeros for single	01

Value	Meaning	Example
	digit hours (12 hour clock).	
H	Hours without leading zeros for single digit hours (24 hour clock).	1
HH	Hours with leading zeros for single digit hours (24 hour clock).	01
m	Minutes without leading zeros for single digit minutes.	9
mm	Minutes with leading zeros for single digit minutes.	09
s	Seconds without leading zeros for single digit seconds.	5
ss	Seconds with leading zeros for single digit seconds.	05
t	One character time marker string. This will be the first letter of the values in the AM symbol or PM symbol boxes in Regional Options	A
tt	Multi-character time marker string. This will be values in the AM symbol or PM symbol boxes in Regional Options	AM

[Date and Time Data Constraints](#)

## Date and Time Data Constraints

VBA has several constraints on date and time values based upon the Gregorian Calendar:

- The value of the month field must be between 1 and 12, inclusive.
- The value of the day field must be in the range from 1 through the number of days in the month. The number of days in the month is determined from the values of the year and months fields and can be 28, 29, 30, or 31. (The number of days in the month can also depend on whether it is a leap year.)
- The value of the hour field must be between 0 and 23, inclusive.
- The value of the minute field must be between 0 and 59, inclusive.

- For the trailing seconds field of interval data types, the value of the seconds field must be between 0 and  $59.9(n)$ , inclusive, where  $n$  is the number of digits in the fractional seconds precision.
- For the trailing seconds field of datetime data types, the value of the seconds field must be between 0 and  $61.9(n)$ , inclusive, where  $n$  specifies the number of "9" digits and the value of  $n$  is the fractional seconds precision. (The range of seconds allows as many as two leap seconds to maintain synchronisation of sidereal time.)

[Date Data Type Structure](#)  
[Dates in Databases Using Different Calendars](#)

## Date Data Type Structure

The date data type structure in VBA is a junction of two very different methods of data storage. It is formed from the serial concatenation of a date-value followed by a time-value, separated by a floating point, and stored in an 8-byte floating-point date data type value.

- The integer (whole) portion of the value represents the number of days elapsed since December 30, 1899.
- The remainder (fractional) portion of the value represents the elapsed portion of the day since midnight.

The integer (date-value) portion (to the left of the floating point) and the remainder (time-value) portion (to the right of the floating point) must be handled differently as they are structured very differently. VBA has a number of pre-defined date and time functions to convert between the internal floating-point date data type format and visibly recognizable dates and times.

---

**Note:** Dates in VBA are based upon the Gregorian Calendar.

For example, the date and time of 5/22/97 at 3:00 p.m. would be stored in VBA as 35572.625 representing the 35572 days since 12/30/1899, and 3:00 p.m. as 625/1000 of a full day.

---

**Note:** Don't confuse Date data types used in VBA with date and time values used in Windows, DLLs, Plant SCADA, or in Cicode. For instance, Plant SCADA stores time/date-related variables as a single integer representing the number of seconds since 01/01/1970.

---

## Date-values

A date-value in VBA is a count of the number of days from December 30, 1899. December 31, 1899 has the date-value of 1, and the 1st January 1900 is 2. December 30, 1899 has the date value of zero. Negative date-values represent dates prior to December 30, 1899.

A date-value in VBA can actually range from January 1, 0100, to December 31, 9999 inclusive, which is a integer value ranging from -657434 up to +2958465 respectively. Using values outside this range will cause compiler errors in VBA.

The pre-defined VBA Year, Month, and Day functions calculate and return the appropriate year, month or day value (as an integer) from a date-value.

## Time-values

A time-value in VBA represents the fractional time of day since the previous midnight. Unlike a date-value which is simply a count of the number of days, the time-value is a decimal fraction of a day.

As every day invariably consists of 24 hours, or 1440 minutes, or 86,400 seconds, the time of day can be readily determined from a time-value using simple math. An hour has the time-value of one twenty-fourth of one day (0.0416'), one minute has the time-value of 0.000694', and a second has the time-value of 0.000011574'0'7'. Midday has the time-value of 0.50. 1AM has the time-value of 0.0416'. 1PM has the time value of 0.5416'.

The pre-defined VBA Hour function, Minute function, and Second function calculates and returns the appropriate hour, minute or second value (as an integer) from a time-value.

[Dates in Databases Using Different Calendars](#)

[Date and Time Data Constraints](#)

## Dates in Databases Using Different Calendars

If you use an existing database with date references of a different calendar type than your current operation system locality settings, VBA could report a variety of errors or perform in an unexpected manner at runtime. For example, if you have used Hijri Calendar dates in your database, a syntax error message will occur if VBA makes reference to Gregorian dates that are invalid Hijri dates (for example, the 31st of any month will produce a syntax error because no Hijri month has 31 days).

### UNINTENDED EQUIPMENT OPERATION

Always confirm that calendar types in existing databases are compatible with the locality (regional and language) options of the operating system.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

To avoid problems of this sort, all date references in an external database should be based on the Gregorian Calendar, or the database tables can be exported to text files before use in Plant SCADA. Dates in Microsoft Access database tables exported as text files are always stored as Gregorian values. If the database calendar is set to Hijri for example, automatic Hijri to Gregorian conversion is performed during the export process.

You can't set a database calendar programmatically using VBA.

---

**Note:** When you want to use characters for Baltic, Central European, Cyrillic, Greek, Turkish, and Asian languages, or right-to-left languages (Arabic, Hebrew, Farsi, and Urdu) the operating system would need to have the corresponding language version of Windows, or have installed system support for that language.

---

## Operators

Variables can be manipulated in VBA using assignment, arithmetic, relational, and logical operators.

- The assignment operator is used to assign a value to a variable or constant (that equals this).
- Arithmetic operators are used to mathematically manipulate numeric variables and numbers (addition, subtraction, multiplication, division, etc.).
- Relational Operators are used to compare the relationship between variables (less than, greater than, not equal to, etc.).
- Logical operators are used to perform digital logic operations on variables ( AND, OR, NOT, etc.).

When using multiple operators in a VBA statement, you need to ensure the proper execution of your code by observing order of precedence rules.

The string concatenation operator is used to join strings together.

## See Also

[Constants](#)

[Variables](#)

[Numbers](#)

[Strings](#)

[Date and Time Handling](#)

[VBA Function Reference](#)

## Assignment Operator

The VBA assignment operator uses the equals character ( = ) in a VBA statement. The variable named to the left side of the assignment operator is assigned the operand value from the right side of the assignment operator, as shown here:

```
' declares integer variable named X
Dim X As Integer
' declares integer variable named Y
Dim Y as Integer
X = 123 ' assigns numeric value 123 to variable X
Y = X ' assigns value of variable X to variable Y
```

Only one variable can be assigned at any one time with the assignment operator.

There must be a space on either side of the assignment operator, or the equals character may be confused with either the variable name or the value being assigned, and a compile error may occur.

Unless the variable is a variant data type, the value being assigned must be the same data type as the variable receiving the assigned value. For instance, if you assign a text string into a long data type variable, you'll cause an

error to occur.

The variable must be previously declared before being assigned a value. The value of a variable can be changed any number of times in a later statements, as in the following VBA example:

```
' declare integer variable named X
' and assign an initial numeric value of 123 to it
Dim X = 123 As Integer
' <statement>
' <statement>
' <statement>
' reassign X to store the numeric value 456
X = 456
' <statement>
' <statement>
' <statement>
' reassign X to store the numeric value 789
X = 789
```

## See Also

[Operators](#)

### Arithmetical (Math) Operators

VBA arithmetic operators are used in VBA statements to mathematically manipulate numeric variables and numbers. The resultant is often assigned to a third variable using the assignment operator.

The arithmetic operation as determined by the arithmetic operator is performed between the values of the operands (variables or numbers positioned immediately on either side of the arithmetic operator).

Operator	Function	Usage
$^$	Exponentiation	$X = Y ^ 2$
$-$	Negation	$X = - 2$
$*$	Multiplication	$X = 2 * 3$
$/$	Division	$X = 10 / 2$
Mod	Modulo	$X = Y \text{ MOD } Z$
$+$	Addition	$X = 2 + 3$
$-$	Addition	$X = 6 - 4$

## See Also

[Operators](#)

## Relational Operators

VBA Relational Operators are used in VBA statements to compare the relationship between operands (values positioned immediately on either side of the Relational Operator). The boolean result is either True or False.

Operator	Function	Usage
<	Less than	X < Y
<=	Less than or equal to	X <= Y
=	Equals	X = Y
>=	Greater than or equal to	X >= Y
>	Greater than	X > Y
<>	Not equal to	X <> Y

## See Also

[Operators](#)

## Logical Operators

Logical (boolean) operators are used to perform digital logic operations on variables. All logical operations result in either a boolean True or False.

Operator	Function	Usage
Not	logical negation	if not X
And	logical And	If (X> Y) And (X < Z)
Or	logical Or	If (X = Y) Or (X = Z)

## See Also

[Operators](#)

## Operator Precedence

The operator precedence in VBA runs like this:

Operator	Description	Order
( )	Parenthesis	Highest
^	Exponentiation	

Operator	Description	Order
-	Unary minus	
/, *	division/multiplication	
Mod	Modulo	
+, -, &	addition, subtraction, concatenation	
=, <>, <, >, <=, >=	Relational	
Not	Logical negation	
And	Logical conjunction	
Or	logical disjunction	
Xor	logical exclusion	
Eqv	logical equivalence	
Imp	logical implication	Lowest

## See Also

[Operators](#)

## Strings

Strings can be stored in variables of string and variant. When using variant strings, be aware of type coercion in VBA. Strings can be compared with each other in VBA to determine whether they contain the same characters or not. Strings can be joined together to create longer strings in VBA using the concatenation operator.

Strings can be searched using the:

- [InStr](#) function, which returns the character position of the first occurrence of a string within another;
- [Left](#), [Left\\$\(\)](#) function or [Right\(\)](#) function which return a copy of the left or right most characters of a string respectively; and
- [Mid\(\)](#) function, which returns the copy of a substring from within another string.

To determine the length of a string, use the [Len\(\)](#) function which returns a Long variable containing the number of characters in the string.

String characters can be converted to ASCII values using the [Asc\(\)](#) function, and ASCII values can be converted to their string characters using the [Chr\(\)](#) function.

String characters can be converted to all lowercase or all uppercase using the [LCase\(\)](#) Function or the [UCase\(\)](#) Function respectively.

Leading or trailing spaces can be stripped off strings using the [LTrim\(\)](#) function or the [RTrim\(\)](#) function respectively.

Strings can be created consisting of a specified number of spaces or characters using the [Space\(\)](#) function or the [String\(\)](#) function respectively.

For syntax details of using string functions, see [String Functions](#).

[Operators](#)

[Numbers](#)

[Control Structures](#)

## String Comparisons

VBA compares ANSI values of characters when comparing strings. For example, the character capital 'A' has the ANSI value of 65, and the character lowercase 'a' has the ANSI value of 97. For a listing of ANSI characters values, see [ASCII/ANSI Character Code Listings](#).

You can use VBA relational operators (less than, greater than, equal to, not equal to, and so on) to compare string variables. All relational operators return either `true` or `false`.

With comparisons made using relational operators, the result depends on the option `compare string-comparison` option setting of the VBA file. Consider the following example:

`"vba" > "VBA"`

If the file Option string-comparison setting is `Option Compare Binary` (or not set at all), the comparison returns `true`. VBA compares the binary (ANSI) values for each corresponding position in the string until it finds two that differ. In this example, the lowercase letter "v" corresponds to the ANSI value 118, while the uppercase letter "V" corresponds to the ANSI value 86. Because 118 is greater than 86, the comparison returns `true`.

If the file Option string-comparison setting is `Option Compare Text`, `"vba" > "VBA"` returns `false`, because the strings are equivalent apart from case.

The built-in VBA `StrComp()` Function returns a variant containing a value representing the result of the comparison of two strings. It has an optional third argument `Comp` which can override the file Option string-comparison setting.

## See Also

[Option Statements](#)

[Strings](#)

## String Concatenation

To concatenate strings in VBA, use the ampersand ( `&` ) concatenation operator between the strings. Multiple concatenations can occur in the same VBA statement.

```
Dim strFirstName As String
Dim strLastName As String
Dim strFullName As String
```

```
Const strSpaceChar = " "
' note the space character between the quotes
strFirstName = "Colin"
strLastName = "Ramsden"
strFullName = strFirstName &strSpaceChar &strLastName
' concatenates string values
```

The & concatenation operator does not perform arithmetic, and will convert variable data types to strings for concatenation. For instance, if a variant string and a variant number are concatenated, the result is a string. For more details of variant data types, see [Variant Declaration](#) and [VBA Data Types](#).

[Control Structures](#)

## Control Structures

VBA provides conditional control functionality, which can be used to conditionally perform VBA statements or blocks of statements dependant upon the result of the condition tested. This is known as logical decision making.

The logical decision-making control structures available in VBA consist of three conditional looping or repetitive statements (Do Statement, While Statement, and For Statement), and two conditional flow control sequence statements (Select Case Statement, and variations of the If Statement). In addition, VBA provides one unconditional branching GoTo Statement.

---

**Note:** In the control structure syntax examples, every placeholder shown inside arrow brackets ( <placeholder> ) should be replaced in any actual code with the value of the item that it describes. The arrow brackets and the word they contain should not be included in the statement, and are shown here only for your information. Also, statements shown between square brackets ( [ ] ) are optional. The square brackets should not be included in the statement, and are shown here only for your information.

[Select Case Statement](#)  
[End Statement](#)  
[Exit Statement](#)  
[OnError Statement](#)  
[Stop Statement](#)  
[With Statement](#)

[VBA Function Reference](#)

## GoTo Statement

The GoTo conditional statement branches unconditionally and without return to the label specified in the GoTo statement. The label must be located in the same subroutine or function as the Goto statement.

```
<statement/s>
If <condition> then GoTo Label1
Else GoTo Label2
End If
Label1:
<statement/s>
GoTo Label3
Label2:
<statement/s>
GoTo Label3
Label3:
<statement/s>
```

In this example, VBA tests the If condition, and jumps to the part of the script that begins with the label "Label1:" if the condition was true, or jumps to the part of the script that begins with the label "Label2:" if the condition was false. This could be anywhere in the same subroutine or function.

## See Also

[Control Structures](#)

## Do Statement

The Do...Loop conditional statement allows you to execute a block of statements an indefinite number of times. The variations of the Do...Loop are Do While, Do Until, Do Loop While, and Do Loop Until.

```
Do While|Until <condition>
    <statement/s>
Loop

Do Until <condition>
    <statement/s>
Loop

Do
    <statement/s>
Loop While <condition>

Do
    <statement/s>
Loop Until <condition>
```

Do While and Do Until check the condition before entering the loop, thus the block of statements inside the loop are only executed when those conditions are met. Do Loop While and Do Loop Until check the condition after having executed the block of statements so that the block of statements is executed at least once.

Any Do statement can be exited using the Exit Do statement.

## See Also

[Control Structures](#)

### While Statement

The While...Wend loop conditional statement is similar to the Do While loop statement. The condition is checked before executing the block of statements comprising the loop.

```
While <condition>
    <statement/s>
Wend
```

## See Also

[Control Structures](#)

### For Statement

The For...Next loop conditional statement repeats its block of statements a set number of times as determined by the values used with the To clause.

```
For <CounterName> = <BeginValue> To <EndValue> [Step <StepValue>]
    <statement/s>
Next
```

The counter variable is increased or decreased (by the value stated in the optional Step parameter), with each reiteration of the loop. The counter default is to increment by one if the Step parameter is omitted.

## See Also

[Control Structures](#)

### If Statement

The If statement in VBA tests an initial condition and then either performs or omits to perform the statements it contains, dependant upon the logical result of the test condition. The condition can be a comparison or an expression, and must logically evaluate to either True or False. The If statement has both single line and multiple line syntax structure.

The single line syntax uses the If <TestCondition> Then <StatementToPerformIfTrue> structure, however, can only perform a single statement if and only if the test condition result is True. No 'End If' statement is required:

```
If <Condition> Then <Statement>
```

If the result of the If test condition was True, the program flow continues into and performs the statement following the Then statement, until it reaches the end of the line.

To perform a single statement conditionally upon a False result, use the NOT logical operator:

```
If NOT <Condition> Then <Statement>
```

To perform multiple statements, use the multiple line syntax structure which ends with the 'End If' statement:

```
If <Condition> Then
```

```
' Then statement block
' perform only if true
<Statement/s>
End If
```

If the result of the If test condition was True, the program flow continues into the Then statement block, and performs the statements following the Then statement, until it reaches the End If statement.

If the result of the If test condition was False, the program flow jumps over the Then statement block, which in this case exits the If structure (without performing any statements other than the initial test condition).

The multiple line If structure can perform different blocks of statements dependant upon EITHER a True OR a False result to the test condition, through the use of the Else statement block:

```
If <Condition> Then
' Then statement block
' perform only if true
<Statement/s>
Else
' Else statement block
' perform only if false
<Statement/s>
End If
```

If the result of the If test condition was True, the program flow performs the Then block statements, until it reaches the Else statement. It then jumps over the Else statement block and exits the If structure (without performing any of the Else statement block statements).

If the result of the If test condition was False, the program flow jumps over the Then statement block (without performing any of those statements) to the Else statement to perform the statements in the Else statement block until it reaches the End If statement.

Further test conditions can be placed into an If structure through the use of the optional Else If <Condition> statement block. ElseIf statement blocks can only be positioned within an If structure before the Else statement block.

```
If <Condition> Then
' Then statement block
' perform only if true
<Statement/s>
ElseIf <Condition>
' Else If statement block
' perform only if true
<Statement/s>
Else
' Else statement block
' perform only if false
<Statement/s>
End If
```

The ElseIf test condition is only evaluated after the initial If structure test condition results in False.

If the result of the ElseIf test condition was True, the statements within the ElseIf statement block are performed. The program flow then jumps over the Else statement block and exits the If structure (without performing any of the Else statement block statements).

If the result of the ElseIf test condition was False, the program flow jumps over the ElseIf statement block (without performing any of those statements) to the Else statement to perform the statements in the Else statement block until it reaches the End If statement.

There is no apparent limit to the number of Else If statement blocks that any one If structure can hold, however,

the Select Case Statement structure handles multiple condition result alternatives much more efficiently.

## See Also

[Control Structures](#)

### Select Case Statement

The Select Case statement tests the same variable for many different conditions. The test value provided with the initial Select Case statement is logically tested against the Case test condition.

The Select Case structure can perform different blocks of statements dependant upon whichever Case statement test condition (if more than one) first results as True, through the use of the Case statement block:

```
Select Case <TestValue>
Case <Condition>
  ' Case statement block
  ' perform only if case true
<Statement/s>
Case Else
  ' Else statement block
  ' perform only if all cases false
<Statement/s>
End Select
```

If the result of the Case test condition was True, the program flow performs the statements contained within that Case statement block, and will then exit the Select Case structure (without performing any of the Else statement block statements).

If the result of the Case test condition was False, the program flow jumps over the Case statement block (without performing any of those statements) to the Case Else statement to perform the statements in the Else statement block until it reaches the End Select statement.

Further test conditions can be placed into a Select Case structure through the optional use of further Case statement blocks. Case statement blocks can only be positioned within a Select Case structure before the Case Else statement block.

```
Select Case <TestValue>
Case <Condition>
  ' Case statement block
  ' perform only if case true
<Statement/s>
Case <Condition>
  ' Case statement block
  ' perform only if case true
<Statement/s>
Case Else
  ' Else statement block
  ' perform only if all cases false
<Statement/s>
End Select
```

Each Case statement block is evaluated in order until the test condition of one results as True. The program flow performs the statements contained within that Case statement block, and will then exit the Select Case structure (without performing any other statements).

The statements of ONLY one Case statement block are ever performed, unless all result in False and there is no

Case Else block declared, in which case no Case statement blocks are performed at all.

The following example may help clarify the logic testing being performed in a Select Case structure. Lets say that we have a variable named (intDayOfWeek) containing an integer (ranging from 1 to 7) representing the day of the week, and we wished to display that value as a string (named strDayOfWeek) containing the name of the day of the week, assuming in this example, that Sunday is the first day of the week (1). The Select Case structure would look like this:

```
Dim strDayOfWeek As String
Select Case intDayOfWeek
Case = 1
StrDayOfWeek = "Sunday"
Case = 2
StrDayOfWeek = "Monday"
Case = 3
StrDayOfWeek = "Tuesday"
Case = 4
StrDayOfWeek = "Wednesday"
Case = 5
StrDayOfWeek = "Thursday"
Case = 6
StrDayOfWeek = "Friday"
Case = 7
StrDayOfWeek = "Saturday"
Case Else
StrDayOfWeek = "Invalid"
End Select
```

The Select Case structure tends to be easier to read, understand, and follow and should be used in place of a complicated multi-nested If...ElseIf structure.

## See Also

[Control Structures](#)

## End Statement

The End statement Ends a block of statements such as a Sub procedure or Function.

```
End[{Function | If | Sub}]
```

## Example

```
Dim Var1 as String
Var1 = "hello"
' Calling Test
Test Var1
MsgBox Var1

Sub Test(wvar1 as string)
MsgBox wvar1
wvar1 = "goodbye"
End
End Sub
```

## See Also

[Control Structures](#)

## Exit Statement

Exits a loop or procedure

```
Exit {Do | For | Function | Sub }
```

## Example

```
' This sample shows Do ... Loop with Exit Do to get out.  
Dim Value, Msg ' Declare variables  
Do  
Value = InputBox("Enter a value from 5 to 10.")  
If Value >= 5 And Value <= 10 Then ' Check range  
Exit Do ' Exit Do...Loop  
Else  
Beep ' Beep if not in range  
End If  
Loop
```

## See Also

[Control Structures](#)

## OnError Statement

VBA's error-handling routine and specifies the line label of the error-handling routine. The line parameter refers to a label. That label needs to be present in the code or an error is generated.

## Syntax

```
On Error {GoTo line | Resume Next | GoTo 0}
```

## Example

```
On Error GoTo errHandler  
Dim x as object  
x.draw ' Object not set  
..  
Exit Sub  
errHandler:  
Print Err.Number, Err.Description  
Resume Next
```

## See Also

[Control Structures](#)

### Stop Statement

Ends execution of the program. The Stop statement can be placed anywhere in your code.

## Example

```
Dim x,y,z
For x = 1 to 5
For y = 1 to 5
For z = 1 to 5
Print "Looping",z,y,x
Next z
Next y
Stop
Next x
```

## See Also

[Control Structures](#)

### With Statement

The With Statement is not supported in VBA. When performing a series of commands on an object, you must explicitly refer to the name of the object with each command.

## See Also

[Control Structures](#)

## Subroutines and Functions

Commonly used sequences of VBA statements can be grouped together into functions and subroutines, so that they can be keyed in once, and used many times in many places, by 'calling' the name of the subroutine or function in code.

A subroutine or function is a group or list of sequential statements that VBA can perform (execute) in the logical order that they exist within the subroutine or function from top to bottom in the order they are listed within the function or subroutine.

If the group of statements returns a value, it must be declared as a function. If it does not return a value, it must be declared as a subroutine. A subroutine or function is called by placing the name of the subroutine or function in a code statement where you want the action of the subroutine or function to occur.

**Note:** Subroutines and functions can contain statements that call other subroutines or functions (to perform, before returning to the following statements within the calling subroutine or function).

Both subroutines and functions can similarly be passed values as arguments when they are called:

- Arguments are passed to **subroutines** in VBA code following the subroutine name and separated by space characters.
- Arguments are passed to **functions** enclosed within parentheses in VBA code, similarly following the subroutine name and separated by space characters.

**Note:** Plant SCADA tag values must be declared by value when passed as argument values to a VBA procedure from within a Plant SCADA command or expression field (see [Passing Variables Byref and Byval](#)).

## See Also

[Subroutines](#)  
[Functions](#)  
[Arguments](#)

## Subroutines

A VBA subroutine starts with the SUB statement and finishes with the END SUB statement. All other statements that lie between the SUB and END SUB statements, will be executed by the subroutine, when called to do so.

In the following subroutine syntax example:

- Every placeholder shown inside arrow brackets (**<placeholder>**) should be replaced in any actual code with the value of the item that it describes. The arrow brackets and the word they contain should not be included in the statement, and are shown here only for your information.
- Statements shown between square brackets ([ ]) are optional. The square brackets should not be included in the statement, and are shown here only for your information.

In VBA, Subroutines are created with the SUB statement in the following format.

```
Sub <SubName> ( [ Byval ] [ <Argument/s> ] [ <As Data Type> ] )
<statement>
<statement>
<statement>
End Sub
```

Where:

- **[Byval]** is the optional parameter for the argument;
- **Sub** is the required subroutine statement basic keyword
- **<SubName>** represents the required name of the subroutine being created
- **<Argument/s>** represents the optional argument/s of the subroutine
- **<statement>** represents the executable VBA script statement/s
- **End Sub** is the subroutine terminating statement

The name given to the subroutine immediately follows the SUB keyword, and is used to identify the subroutine to VBA. This name is referred to when the subroutine is called upon (called) to be executed (perform the statements it contains) by some other procedure in VBA.

Subroutine names can contain the letters 'A' to 'Z' and 'a' to 'z', the underscore '\_' and digits '0' to '9'. The subroutine name must begin with a letter, be no longer than 40 characters, cannot contain the space character, and cannot be a reserved word. Subroutine names (once declared), become a keyword in VBA. Like most keywords in VBA, these names are not case sensitive.

The subroutine name always ends with a pair of parentheses ( ) which may or may not contain one or more arguments required by (necessary for use in) the subroutine . Multiple arguments if used, are separated by commas ( , ). See [Arguments](#) for more details and argument syntax.

All the lines located between the SUB and the END SUB statements, contain the statements that will be executed when the subroutine is called in VBA. These statements will be executed one at a time in logical order from top to bottom within the subroutine.

[Subroutines and Functions](#)

[Functions](#)

[Arguments](#)

## Functions

A VBA function starts with the FUNCTION statement and finishes with the END FUNCTION statement. All other statements that lie between the FUNCTION and END FUNCTION statements, will be executed by the function, when called to do so.

In the following function syntax example:

- Every placeholder shown inside arrow brackets ( <placeholder>) should be replaced in any actual code with the value of the item that it describes. The arrow brackets and the word they contain should not be included in the statement, and are shown here only for your information.
- Statements shown between square brackets ( [ ] ) are optional. The square brackets should not be included in the statement, and are shown here only for your information.

A typical VBA function is structured like in the following example:

```
Function <FunctionName> ( [ ByVal ] [ <Argument/s> ] ) [ As <ReturnDataType> ]
<statement>
<statement>
<statement>
[ <FunctionName> = <value> ]
End Function
```

Where:

- **Function** is the required function statement basic keyword
- **[ ByVal ]** is the optional parameter for the argument;
- **<FunctionName>** represents the required name of the function being created
- **<Argument/s>** represents the optional argument/s of the function
- **<ReturnDataType>** represents the optional return data type of the function
- **<statement>** represents the executable VBA script statement/s

- **= <value>** represents the optional assignment of the return value for the function
- **End Function** is the function terminating statement

The name given to the function, immediately follows the FUNCTION keyword, and is used to identify the function to VBA. This name is referred to when the function is called upon (called) to be executed (perform the statements it contains) by some other procedure in VBA.

Function names can contain the letters 'A' to 'Z' and 'a' to 'z', the underscore '\_' and digits '0' to '9'. The function name must begin with a letter, be no longer than 40 characters, cannot contain the space character, and cannot be a reserved word. Function names (once declared), become a keyword in VBA. Like most keywords in VBA, these names are not case sensitive.

The function name always ends with a pair of parentheses ( ) which may or may not contain one or more arguments required by (necessary for use in) the function. Multiple arguments if used, are separated by commas ( , ). See the section titled 'Arguments in VBA' for more details and argument syntax.

All the lines located between the FUNCTION and the END FUNCTION statements, contain the statements that will be executed when the function is called in VBA. These statements will be executed one at a time in logical order from top to bottom within the function.

The return value of the function is optionally assigned within the function in a statement using the function name. This value is often used within the calling procedure to determine the status of the function. Commonly, this value may be a Boolean True or False to indicate the successful completion or not of the function.

[Subroutines and Functions](#)  
[Arguments](#)  
[Subroutines](#)  
[Accessing Functions in DLLs](#)

## Arguments

Arguments are used in VBA to pass values into subroutines and functions when they are being called. Arguments are positioned between parentheses '( )' immediately after the subroutine or function name in the subroutine or function declaration. If no arguments are required for the subroutine or function, the parentheses must be included and left empty in the declaration.

Arguments are optional in the sense that subroutines and functions do not require them. However, if arguments are to be used in a subroutine or function, the arguments must first be declared with the subroutine or function declaration, before they can be used. If declared, they must be used whenever the subroutine or function is called.

VBA does NOT support named arguments so all arguments must be used in declaration order. If omitted, strings default to an empty string (""), and numeric values default to zero (0). Boolean values in VBA are represented with -1 for TRUE, and 0 for FALSE.

Multiple arguments must be separated by a comma ( , ) placed between the arguments. The number of arguments that can be used in any single subroutine or function is not stated, (but likely limited to something like 255). If you are declaring a subroutine or function with that many arguments, you should probably split your subroutine or function into smaller separate logical routines with less arguments for each routine. If an argument is omitted, its place must be declared by the use of a comma in the call.

If you want to use the value in a Plant SCADA tag as an argument to a function or subroutine, you must assign the value of the tag to a VBA variable, and then pass the variable as the argument. You cannot pass a Plant SCADA tag name as an argument to a function or subroutine.

Each argument declaration in a subroutine or function must be structured using the proper VBA argument syntax as described below.

VBA argument structure syntax in the declaration of functions or subroutines is as follows:

( [ Byval ] <Argument/s> [ As <DataType> ] )

Where:

- [ **Byval** ] is the optional parameter for the argument.
- <Argument/s> represents the argument/s required by the function or subroutine.
- [ As <DataType> ] represents the optional data type declaration of the argument.

The optional 'Byval' parameter specifies that the variable is passed by value instead of by reference (see the section titled 'Passing Variables Byref and Byval with VBA').

---

**Note:** Plant SCADA tag values MUST be declared by value when passed as argument values to a VBA procedure from within a Plant SCADA command or expression field. This is best done by declaring a variable, assigning it the tag value, then passing the variable by value.

The function or subroutine name always ends with a pair of parentheses ( ) which may or may not contain one or more arguments required by (necessary for use in) the function or subroutine. Multiple arguments if used, are separated by commas ( , ).

The optional 'As <DataType>' parameter is used to specify the data type of the argument variable. The argument data types must be individually declared, or will be of Variant data type by default. Valid data types for arguments in VBA are: String, Integer, Double, Long, and Variant (see the section titled 'VBA\_Data\_Types' for descriptions of data types in VBA).

## Example

```
' Arguments are declared with the function or subroutine
' The function is called from the subroutine highlighted below
Function longArea(Byval longLength As Long, _
Byval longWidth As Long) As Long
    ' multiplies arguments and
    ' assigns result to return value
longArea = longLength * longWidth
End Function
Sub FindArea
    ' declare long variables X Y and Z
Dim longX As Long
Dim longY As Long
Dim longZ As Long

    ' assign numeric value 12 to variable X
X = 12
    ' assign numeric value 34 to variable Y
Y = 34

    ' call function named longArea,
    ' passing in values of X and Y variables
```

```
' as arguments
'store result in variable Z
Z = longArea(X, Y)
' copy result Z to tag
TestTag_1 = Z
End Sub
```

Granted, that's not likely the way you'd actually calculate an area given two fixed values in a subroutine that calls a function. You could just as easily do the calculation within the subroutine. However, this example does demonstrate the passing of values from a subroutine to a function, and the retrieval of a return value from the function back to the calling subroutine.

Note in the previous example, that the argument names ('longLength' and 'longWidth') are only used within the function in which they were declared. The values they represented were passed in with the call to the function in the statement line:

```
Z = longArea(X, Y)
```

The values of the variables 'X' and 'Y' were passed into the function 'longArea' and were handled within the function as its argument names 'longLength' and 'longWidth'. The result was returned and stored in the variable named 'Z'.

## DLLs and APIs

Dynamic Linked Libraries (DLLs) are files that contain functions which can be called from any application running under Microsoft Windows. At run time, a function in a DLL is dynamically linked into an application that calls it. No matter how many applications call a function in a DLL, that function exists in only a single file on the computer, and the DLL is loaded only once in memory.

An application programming interface (API) is a set of functions you can use to work with a component, application, or the operating system. Typically an API consists of one or more DLLs that provide some specific functionality.

For example, the Windows API includes the DLLs that make up the Windows Operating System (OS). Every Windows application interacts with the Windows API directly or indirectly. The Windows API is provided so that all applications running under Windows can behave in a consistent manner.

---

**Note:** Plant SCADA itself provides an API for external access to Plant SCADA I/O variable tags via a DLL interface.

APIs are traditionally written for C and C++ programmers who are building Windows applications, however, the functions in a DLL can also be called by other programming languages, including VBA. Because most DLLs are written and documented primarily for C/C++ programmers, calling a DLL function may differ somewhat from calling a VBA function. In order to work with an API, you need to understand how to pass arguments from VBA to a DLL function. See [Passing Arguments to DLL Functions from VBA](#).

## See Also

[Passing Variables Byref and ByVal](#)

[VBA Function Reference](#)

## Accessing Functions in DLLs

To be able to call and use an external DLL function using VBA, you must have previously provided VBA with details about the function being called. VBA requires information like the name of the function, where that function is located, what arguments it expects, and what type of data it returns. VBA uses the Declare statement to detail that information.

The Declare statement must be positioned in the VBA file in your project above and before any code that calls that declared function of the DLL.

### Declare Statement Structure

The Declare statement consists of the required Declare keyword, followed by the required Function statement, the required Lib statement, the optional Alias statement, the optional Argument statement(s) contained within braces, and the optional return data type statement.

---

**Note:** The use of the OPTIONAL components of the **Declare** statement syntax indicates that they may not be required in all DLL functions. It is not up to you whether you can optionally use them or not. If included in a DLL function, they **MUST** be used when declaring that function to VBA.

---

The Declare statement in VBA details the name, file location, arguments, intrinsic constants, and type definitions that the DLL function requires. Here's an example of the Declare statement for the Windows API GetTempPathA function, which returns the path to the Windows system temporary folder:

```
Declare Function GetTempPathA Lib "kernel32" _
(Byval nBufferLength As Long, _
Byval lpBuffer As String) As Long
```

The Declare keyword indicates to VBA that you intend to call a function belonging to an external DLL. The Declare keyword must be used first in the declaration statement.

## Declare - Function Statement

The Function statement consists of the Function keyword, followed by the name that you will use when calling this function from VBA.

## Declare - Lib Statement

The Lib statement specifies which DLL contains the function you wish to use. The Lib statement consists of the Lib keyword, followed by the name of the DLL contained within string double quotes. Some commonly used DLLs in the Windows API for example, are Kernel32.dll - which performs low level OS functions like memory management and resource handling, the User32.dll - which performs Windows message handling, timers, menus and communication functions, and the GDI32.dll - which performs the graphics display and font management functions.

# Declare - Alias Statement

In the previous Declare statement example, the name of the declared function in VBA is the same as the name of the actual function within the DLL. This does not necessarily have to be the case. There are some instances where the name of the function in the DLL is incompatible with the naming structure of VBA, and cannot be used as a declared function name in VBA. An example would be those DLL function names that start with an underscore.

To overcome such incompatibilities, the VBA Declare statement supports the use of an alias name for the DLL function, through the use of the optional Alias statement . The Alias statement consists of the Alias keyword, followed by the actual name of the DLL function contained within string double quotes. The Alias statement must be positioned within the Declare statement between the Lib statement and the Argument statement.

Here's an example of the Declare statement for the Windows API GetTempPathA function as used above, however, this time using the optional Alias statement:

```
Declare Function GetWinTempPath Lib "kernel32" _  
    (Byval nBufferLength As Long, _ Alias "GetTempPathA" _  
    Byval lpBuffer As String) As Long
```

In this example, the name of the API function in the DLL is GetTempPathA, and the name by which you would call this function from VBA is GetWinTempPath. Note that the actual name of the DLL function appears contained within string double quotes positioned after the Alias keyword. This instructs VBA to use the alias function name when calling the DLL.

Because an alias allows you to name a declared DLL function anything you want in VBA, you can make the function name conform to your own naming standards.

---

**Note:** DLL functions are case sensitive; VBA function names are not. When declaring DLL functions in VBA, be careful to accurately remain case sensitive in the declaration.

---

[Functions](#)

[Passing Variables Byref and Byval](#)

[Passing Arguments to DLL Functions from VBA](#)

[DLLs and APIs](#)

## Passing Variables Byref and Byval

Passing an argument by reference (using the Byref parameter) passes a pointer to the memory location of that argument. A pointer is just a memory address that indicates where the value is stored. If the procedure modifies that argument's value, it modifies the source of that argument, so when execution returns to the calling procedure, the source contains the modified value.

Passing an argument to a function by value (using the Byval parameter), on the other hand, passes a copy of the value as the argument. This prevents that function from modifying the source of the argument. When execution returns to the calling procedure, the source contains the same value it did before the function was called.

The **Byref** parameter is the default in VBA and does not need to be used explicitly within VBA. **Byref** gives other subroutines and functions permission to make changes to the source of the values that are passed in **Byref**. The keyword **Byval** denies this permission so the argument source cannot be altered.

There are two possible methods for indicating to VBA that you wish to pass an argument by value:

- When declaring the argument in the subroutine or function declaration statement, by using the **Byval** keyword placed immediately before the argument name. This forces the subroutine or function to use a copy of the argument passed in and not modify the source. For example, the following function TestPassArg has declared its first argument intVal as being requested **Byval**.

```
Function TestPassArg(ByvalintVal As Integer, varVal, strVal as String)
```

- When passing an argument to a subroutine or function, by enclosing the individual argument within parentheses. Only the value of the argument, and not its address in memory, is passed to the subroutine or function, so that the source of the argument is not modified. For example, only the variable var3 is passed by value to the subroutine TestPassArg (because only that argument is enclosed within parentheses in the subroutine call).

```
TestPassArg var1, var2,(var3)
```

- In the next example, the parameter iVar is passed by value to the function TestFunction. Since arguments passed to functions must be enclosed in parentheses, an extra pair is used to force the argument to be passed by value.

```
TestFunction((iVar))
```

---

**Note:**

- Plant SCADA does not support passing by reference, so Plant SCADA tag values need to be declared by value when passed as arguments to a VBA procedure from within a Plant SCADA command or expression field. This is best done by declaring the variable, assigning it the tag value, then passing the variable by value. (See the example below.)
  - Passing arrays to functions is not supported.
- 

## Example

Suppose you had a variable tag of integer type named "iTag1" and you need to pass it to a function. From within a VBA script, or Plant SCADA command or expression field, you would use the following code example to pass the variable tag value to a function named TagArgumentTest:

```
CivBA
Dim iVar1 as Integer
iVar1 = iTag1
TagArgumentTest(iVar1)
```

---

**Note:** CivBA does not support passing by reference, so VBA variables passed to CivBA functions using the CivBAFunctionCallOpen function must be enclosed in brackets to force the passing of those variables by value.

---

## See Also

[Passing Arguments to DLL Functions from VBA](#)  
[DLLs and APIs](#)  
[Arguments](#)

## Passing Arguments to DLL Functions from VBA

Many arguments to DLL functions are passed by value. By default, arguments in VBA are passed by reference, so

It's important that you include the `Byval` keyword in the function definition when the DLL function requires that an argument be passed by value. See [Passing Variables Byref and Byval](#).

**Note:** Although the `Byval` keyword appears in front of some arguments of type `String`, strings are always passed to Windows API functions by reference, therefore any DLL function can always modify a string source directly.

DLL functions don't return strings in the same way that VBA functions do. Because strings are always passed to DLL functions by reference, the DLL function can modify the value of the string argument. Rather than returning a string as the return value for the function, as you would probably do in VBA, a DLL function returns a string into an argument of type `String` that was passed to the function. The actual return value for the function is often a long integer specifying the number of bytes that were written into the string argument.

To call a DLL function that writes to a `String` variable, you need to take additional steps to format the string properly. First of all, the `String` variable must be a null-terminated string. A null-terminated string ends in a special null character. Secondly, a DLL function can't change the size of a string once it has been created.

Therefore, you need to make sure that the string that you pass to a function is large enough to hold the entire return value, and that it terminates with a Null character. When you pass a string to a DLL function, you'll usually need to specify the size of the string that you've passed in another argument. Windows keeps track of the length of the string so that it doesn't overwrite any memory that the string is using.

**Note:** It's only necessary to pass in a null-terminated string and its size if you're returning a string from a function. If the function does not return a string into a string argument, but instead takes a string that provides information to the function, you can simply pass in a normal VBA `String` variable.

A `Nullstring` is a string of value 0 [no Character code]; note that this is not the same as an empty string ("").

[Arguments](#)

[Passing Variables Byref and Byval](#)

## OLE Services

OLE (Object Linking and Embedding) services is the term used to generally describe the integrated use of separate software components (applications) working together to provide custom software solutions based upon the Microsoft Component Object Model (COM) architecture.

**Note:** When considering the use of OLE services, you should be aware that there are different uses of OLE which have developed over the years and which may be confused with one another. Examples of different OLE services include: object linking, object embedding, visual editing, drag-and-drop, ActiveX Controls, OLE Automation, OLE DB, OLE Messaging, and OLE Networking services. See [OLE Terminology](#).

Plant SCADA supports linked and embedded OLE objects in its graphics pages with the use of ActiveX Controls. See [Accessing ActiveX Objects with VBA](#) in the topic [Integrating VBA into a Project](#).

Plant SCADA can use VBA to perform as an OLE Automation controller. See [OLE Automation Objects](#). Plant SCADA can also exchange data with other applications using other data transfer technologies.

## OLE Terminology

OLE superceded the Dynamic Data Exchange protocol. Network DDE was introduced to afford the same data

transfer facility between Windows applications connected across the same network. Plant SCADA supports both DDE and Network DDE connectivity.

## OLE Linking and Embedding

The differences between linked objects and embedded objects which may affect you, concern where the data is stored, and how it is updated after you place it in the destination file. With linked OLE objects, the source of the OLE object data remains in the original data file of the application that was used to create it, and only a copy of the data is ever displayed in the destination document. The data is updated only when the source file is modified. Embedded OLE objects duplicate and store a local copy of the source file data within the destination document data file, and are not linked to the source file. That is, the data copy in the destination file does not change when you modify the source file.

With both linked and embedded OLE objects, when the OLE object in the destination document is double-clicked, the original application (that was used to create the data) of the OLE object is launched to permit editing of the data using that source program's editor. Linked OLE objects store their data back in the original source data files, while embedded OLE objects store their data in the destination program data files.

## OLE Automation

'OLE Automation' was developed to permit the (remote) control of other applications on the same computer. Applications which expose their functionality using OLE Automation are known as OLE Automation servers, and could be automated by code running in a completely separate application, known as OLE Automation clients or controllers.

OLE Automation servers exposed their functionality through structured object models, which are listings of the internal functions, methods and properties of the application object. All Microsoft Office applications are OLE Automation servers to some extent, and can be subsequently controlled by any OLE Automation compliant controller, using the appropriate syntax to manipulate and control the relevant application object model.

Not all applications that support OLE services support OLE Automation. For example, many products support drag-and-drop, and object linking and embedding, but do not support OLE Automation. Linking and embedding allow the user to access the object, whereas OLE Automation allows one application to control another application, possibly with minimal or no user interaction.

## See Also

[OLE Services](#)

## OLE Automation Objects

VBA supports the referencing and control of OLE Automation objects of external applications, permitting you to use the properties, methods and events of those objects from within Plant SCADA.

To access an OLE Automation object using VBA, you must first declare an object variable in your VBA code, then assign an OLE Automation reference to the variable. See Declaration of OLE Automation objects in VBA, and Assigning references to OLE Automation objects in VBA.

Objects declared in a VBA Sub or Function procedure are local to that procedure, and their lifetime ends along with the end of the procedure. An object declared outside a procedure has modular scope to all procedures within the same VBA file module and lasts for the lifetime of the variable that retains the reference to the object.

All object references must be deleted when they are no longer required, to release the memory they were using. When considering the use of OLE Automation, you should be aware that there are different uses of OLE which have developed over the years and which may be confused with one another.

## See Also

[OLE Services](#)

### Declaration of OLE Automation Objects

VBA objects can only be declared and referenced within VBA file modules. VBA modular objects have modular scope and cannot be referenced (accessed and used) from outside their VBA module (file).

---

**Note:** VBA objects cannot be used directly in Plant SCADA command or expression fields.

Once declared within a VBA module, VBA objects can be referenced and used in any procedure within the same code module. An object declared outside of a procedure has modular scope to all procedures within that same VBA module (file). Objects declared within a Sub or Function procedure have local scope only within that procedure.

The object variable must be declared before it can be assigned an object reference. Object variables are declared by the Dim Statement with the As Object VBA data type using the following syntax:

Dim <VariableName> As Object

Where:

- Dim is the required Variable declaration statement BASIC keyword
- <VariableName> represents the required name of the variable being declared (dimensioned)
- As Object declares the variable as a VBA 'object' data type

---

**Note:** The placeholder shown inside arrow brackets (<placeholder>) should be replaced in any actual code with the value of the item that it describes. The arrow brackets and the word they contain should not be included in the statement, and are shown here only for your information.

For example:

```
' create local variables to store object references
Dim objExcelApp As Object
Dim objWordApp As Object
```

Once declared, you can then assign an OLE Automation reference to the object variable in VBA.

## See Also

[Deleting OLE Automation Objects](#)

[Using OLE Automation Objects](#)

### Assigning References to OLE Automation Objects

An OLE Automation object MUST be defined before it can be used. Once defined (see Declaration of OLE Automation objects in VBA), you assign an OLE Automation reference to the object variable in VBA using the VBA

CreateObject function within a VBA Set statement in the following syntax:

```
Set <objVarName> = CreateObject(<objClassName>)
```

Where:

- Set is the required reference assignment statement keyword
- <objVarName> represents the required name of the variable receiving the reference
- CreateObject() function creates the object of the class type specified in the argument
- <objClassName> represents the required name of the class providing the object

The object class name passed as the argument to the CreateObject function usually consists of the fully qualified class name of the object being created, for example "Word.Application" or "Excel.Application".

## Example

```
' create variable to store object reference
Dim objExcelApp As Object
' create the app object and assign the reference
Set objExcelApp = CreateObject("Excel.Application")
' or
' create variable to store object reference
Dim objWordApp As Object
' create the app object and assign the reference
Set objWordApp = CreateObject("Word.Application")
```

Once assigned, you can then use that object variable in your VBA code to manipulate the referenced object model. See [Using OLE Automation Objects](#).

Dependant objects (which cannot be created independantly) can be "drilled-down" to and subsequently assigned from existing (externally creatable) independant object s, by using a method of the higher level object. See Understanding object models in OLE Automation.

For examples of independant objects, Microsoft Excel provides the "Excel.Application", "Excel.Sheet ", and "Excel.Chart" externally creatable objects amongst others, (two of which are demonstrated in OLE Automation example using the Microsoft Excel object), and Microsoft Word provides the "Word.Application", "Word.Document", and "Word.Picture" externally creatable objects amongst others (and is demonstrated in OLE Automation example using the Microsoft Word object).

## See Also

[OLE Automation Objects](#)

### Using OLE Automation Objects

The trick with successfully using OLE Automation is determining what you can and can't do with it. In theory, you can do anything the OLE Automation server application can do. However, in practice, not every OLE Automation server application exposes all of its functionality through its OLE Automation interface.

You have to be able to use the native programming language of the OLE Automation server application in your code. You also need to know about the limitations imposed by the Plant SCADA operating environment, and its implementation of the VBA programming language.

VBA does not support early binding of OLE Automation objects, as there is no mechanism for providing a reference to the object type library (like you can do in Microsoft Visual Studio) until runtime. So, VBA compile errors can occur with valid VBA code which may work well in other VBA supporting applications. Most ported VBA code will require some modification to compile and perform as expected in VBA. For example, VBA does not support the use of "With" statements concerning properties or methods of an object, yet does support the use of "For Each" statements with objects in a collection.

VBA does not support the use of named arguments using the ":=" named argument operator (colon followed by an equal sign). Nor does it support the use of missing arguments using placeholder commas, however, VBA does support the use of the "empty" keyword in place of missing arguments.

VBA does not support the passing of SCADA variable tags by reference, however, the tag value can be copied to a VBA variable, and it can be passed by value. See [Passing Variables Byref and Byval with VBA](#).

To help manage these considerations, you should know how to access the object model of the OLE Automation server applications. VBA does not support the use of application-defined object types nor intrinsic constants due to late-binding of the object model. VBA supports only 10 data-types, so be aware of the possibility of data being lost due to rounding when converting between different data types. See [Rounding Numbers in VBA](#).

To make full use of the OLE Automation object models, you should make yourself familiar with Object related terms. See [Understanding object models in OLE Automation](#).

## See Also

[OLE Automation Objects](#)

### Accessing the Object Model of OLE Automation Server Applications

During the development stage of your project, to access the object model of any OLE Automation server applications, you must have a copy of the appropriate application program installed on the computer you are developing the OLE Automation controller with.

Equally, during Plant SCADA runtime, there must be a copy of the appropriate application program installed on the computer you are running the OLE Automation controller from. If, for example, you were calling the code which creates the object from say a button on a graphics page on a Plant SCADA Client machine, the appropriate application program must be installed on every Client machine with access to that graphics page, for the code to work (if called) on that Client machine.

All of the Microsoft Office suite of products support the VBA language in some manner, and export an OLE Automation object type library which you can view and use. See [How to view an OLE Automation object type library from a Microsoft Office product](#).

Also, the VB programming IDE within Visual Studio can be referenced to load the appropriate type library as required. See [How to view an OLE Automation object type library in VB](#).

Both these suites provide an object browser which you can use to explore the object models. You use the structure of the object model to access, manipulate and control the OLE Automation object using VBA. See [Understanding object models in OLE Automation](#).

## See Also

[OLE Automation Objects](#)

## Understanding Object Models in OLE Automation

Objects are the fundamental building blocks of OLE Automation, and object models are a roadmap to the object structure. OLE Automation using VBA involves creating and modifying the objects provided by other applications (external to the Plant SCADA application). For instance, every element of Microsoft Word ( documents, tables, paragraphs, bookmarks, fields and so on) can be represented by an object in VBA using OLE automation with the Word object model.

### What are objects and collections?

An object represents an element of the OLE Automation application. A collection is an object that contains several other objects, usually of the same type. For example, all the bookmark objects in a document are contained in a single Bookmarks collection object of the Word application. Using appropriate properties and methods, OLE Automation permits the modification of a single object or an entire collection of objects.

### What is a property?

A property is an attribute of an object or an aspect of its behavior. For example, properties of a Word document include its name, its content, and its save status, as well as whether change tracking is turned on. To change the characteristics of any referenced object, you change the values of its properties.

To set the value of a property, follow the reference to an object with a period, the property name, an equal sign, and the new property value. The following example turns on change tracking in the Word document named "MyDoc.doc."

```
objWordApp.Documents("MyDoc.doc").TrackRevisions = True
```

In this example, Documents refers to the collection of open documents, and the name "MyDoc.doc" identifies a single document in the collection. The TrackRevisions property is set for that single document.

You can also return information about an object by returning the value of one of its properties. The following example returns the name of the active Word document.

```
docName = objWordApp.ActiveDocument.Name
```

In this example, ActiveDocument refers to the document in the active window in Word. The name of that document is assigned to the variable "docName".

---

**Note:** Some properties cannot be set. The Help topic for each property indicates whether you can set that property (read-write), only read the property (read-only), or only write the property (write-only). Also the Object Browser in the Visual Basic Editor displays the read-write status at the bottom of the browser window when the property is selected.

---

### What is a method?

A method is an action that an object can perform. For example, just as a Word document can be printed, the Document object has a PrintOut method. Methods often have arguments that qualify how the action is performed. The following example prints the first three pages of the active Word document.

```
objWordApp.ActiveDocument.PrintOut From:=1, To:=3
```

In most cases, methods are actions and properties are qualities. Using a method causes something to happen to an object, while using a property returns information about the object or it causes a quality about the object to change.

## Returning an object

Most objects return a single object from the collection. For example, the Documents collection contains the currently open Word documents. You use the Documents property of the Application object (the object at the top of the Word object hierarchy) to return the Documents collection.

After you've accessed the collection, you can return a single object by using an index value in parentheses (this is similar to how you work with VBA arrays). The index value can be either a number or a name.

The following example uses the Documents property to access the Document collection. The index number is used to return the first document in the Documents collection. The Close method is then applied to the Document object to close the first document in the Documents collection.

```
objWordApp.Documents(1).Close
```

The following example uses a name (specified as a string) to identify a Document object within the Documents collection.

```
objWordApp.Documents("Sales.doc").Close
```

Collection objects often have methods and properties which you can use to modify the entire collection of objects. The Documents object has a Save method that saves all the documents in the collection. The following example saves the open documents by applying the Save method.

```
objWordApp.Documents.Save
```

The Document object also has a Save method available for saving a single document. The following example saves the document named Report.doc.

```
objWordApp.Documents("Report.doc").Save
```

To return an object that is further down in the Word object hierarchy, you must "drill down" to it by using properties and methods to return objects.

To see how this is done, in Word, open the Visual Basic Editor and click Object Browser on the View menu. Click Application in the Classes list on the left. Then click ActiveDocument from the list of members on the right. The text at bottom of the Object Browser indicates that ActiveDocument is a read-only property that returns a Document object. Click Document at the bottom of the Object Browser; the Document object is automatically selected in the Classes list, and the Members list displays the members of the Document object. Scroll through the list of members until you find Close. Click the Close method. The text at the bottom of the Object Browser window shows the syntax for the method. For more information about the method, press F1 or click the Help button to jump to the Close method Help topic.

Given this information, you can write the following instruction to close the active document.

```
objWordApp.ActiveDocument.Close SaveChanges:=wdSaveChanges
```

The following example maximizes the active document window.

```
objWordApp.ActiveDocument.ActiveWindow.WindowState = wdWindowStateMaximize
```

The ActiveWindow property returns a Window object that represents the active window. The WindowState property is set to the maximize constant (wdWindowStateMaximize).

The following example creates a new document and displays the Save As dialog box so that a name can be provided for the document.

```
objWordApp.Documents.Add.Save
```

The Documents property returns the Documents collection. The Add method creates a new document and returns a Document object. The Save method is then applied to the Document object.

As you can see, you use methods or properties to drill down to an object. That is, you return an object by

applying a method or property to an object above it in the object hierarchy. After you return the object you want, you can apply the methods and control the properties of that object.

## Using the Microsoft Word Object Model

You should use the associated online help documentation that came with the object application to obtain details of the object model. The help is quite easy to use. Each of the classes and collections can be clicked to jump to its page.

In VBA, you must use the full Application object qualifier when referencing the properties and methods of the object. For example, you must use the full syntax "Application.ActiveDocument.PrintOut", instead of "ActiveDocument.PrintOut".

## OLE Automation Example Using the Microsoft Word Object

All commands in Word are directed to the active document, which may be changed in code. It is recommended to use named arguments, as the argument sequences are recorded incorrectly in some documentation, including the type library and what the recorder writes to macros.

```
Sub runWord()
    ' demonstrating the use of OLE Automation
    ' to manipulate Word

    ' create local variables
    Dim objWordApp As Object
    ' create the app object and assign the reference
    Set objWordApp = CreateObject("Word.Application")

    ' manipulate the app object
    ' insert appropriate VBA code here to manipulate Word object

    ' close Word
    objWordApp.Quit

    ' delete the object
    Set objWordApp= Nothing

End Sub
```

### Deleting OLE Automation Objects

All object references must be deleted when they are no longer required, to release the memory they were using.

You delete an OLE Automation reference to the object variable in VBA using the VBA Nothing keyword within a VBA Set statement in the following syntax:

Set <objVarName> = Nothing

Where:

- Set is the required reference assignment/release statement keyword.
- <objVarName> represents the required name of the variable holding the reference.
- Nothing is the keyword used to release the object reference.

When several object variables refer to the same object, they also refer to the memory and system resources associated with the object. These resources are released only after all of them have been set to Nothing, either explicitly using Set, or implicitly after the last object variable set to Nothing goes out of scope.

## Example

```
' Word example
' create variable to store object reference
Dim objWord as Object
' create object and assign reference to variable
Set objWord = CreateObject( "Word.Document" )
' insert appropriate VBA code here to manipulate Word object
' release reference
Set objWord = Nothing
' Excel example
' create local variables
Dim objExcelApp As Object
Dim objExcelCht As Object
' create the app object and assign the reference
Set objExcelApp = CreateObject("Excel.Application")
' create a chart and assign the reference
Set objExcelCht = objExcelApp.Charts.Add()
' insert appropriate VBA code here to manipulate Excel objects
' delete the objects
Set objExcelApp = Nothing
Set objExcelCht = Nothing
```

## File Input/Output with VBA

VBA supports full sequential and binary file Input/Output (I/O).

Files stored on disk, can contain text (ASCII) characters or binary (ones and zeros) digits. All VBA files that contain VBA code are stored as text files. However, you can use VBA to store and retrieve files in either format, using VBA file I/O functions and statements.

The File I/O functions predefined in VBA are:

ChDir, ChDrive, Close, CurDir, Dir, EOF, FileCopy, FileLen,  
FreeFile, Get #, GetAttr, Input #, Kill, Line Input #, Loc, LOF,  
MkDir, RmDir, Name, Open, Print #, Put, Seek, SetAttr, Write #.

For details of all predefined VBA functions, see [VBA Function Reference](#).

## VBA Function Reference

VBA includes the following function categories.

Array Functions	File I/O Functions
Conditional Statements	Math/Trigonometry Functions
Conversion Functions	Miscellaneous Functions
Declarations	Procedural Statements
Date and Time Functions	String Functions

## Array Functions

VBA array functions are provided to allow you to declare, resize, initialize, populate, and erase arrays and their elements.

The array functions predefined in VBA are:

Dim	Allocates storage for, and declares the data type of, variables and arrays in a module.
Erase	Reinitializes the elements of a fixed array.
Lbound	Returns the smallest available subscript for the dimension of the indicated array.
Option Base	Declares the default lower bound for array subscripts.
ReDim	Used to size or resize a dynamic array that has already been declared using the Dim statement with empty parentheses.
Ubound	Returns the value of the largest usable subscript for

	the specified dimension of an array.
--	--------------------------------------

## Dim

The Dim statement allocates storage for, and declares the data type of, variables and arrays in a module.

The To clause in the array subscript range of a Dim statement provides a more flexible way to control the lower bound of an array. If you don't explicitly set the lower bound with a To clause, the [Option Base](#) setting (if used) comes into affect, or defaults to zero (if not used).

## Syntax

**Dim** *VariableName*[(*Subscripts*)] [As *DataType*]

*VariableName*:

The name of the variable or array being declared (dimensioned).

*Subscripts*:

The optional subscript range (dimensions) for an array in parentheses.

*DataType*:

The optional data type declaration for the variable or array.

## Related Functions

[Const](#) | [ReDim](#) | [Static](#)

## Example

```
Dim bytVar As Byte
Dim binVar As Boolean
Dim strVar As String
Dim intVar As Integer
Dim lngVar As Long
Dim sngVar As Single
Dim dblVar As Double
Dim vntVar As Variant
Dim objVar As Object
Dim dtmVar As Date

Dim daysOfWeek() As String ' declares an array variable to hold strings

Dim monthsOfYear(12) As Date ' declares an array variable to hold 12 strings
Dim users(,) As String ' declares a two dimensional array to hold strings
Dim usernames(5,5) As String ' declares a two dimensional 5 x 5 array to hold strings

Dim MyArray(1 To 10, 5 To 15, 10 To 20) ' declares the three dimensional array
MyArray and specifies the upper and lower bounds of each dimension
```

## Erase

Reinitializes the elements of a fixed array specified in the *ArrayList* parameter.

## Syntax

**Erase**(*ArrayList*)

*ArrayList*:

A comma delimited list of valid variable array names.

## Related Functions

[Dim](#) | [ReDim](#)

## Example

```
Option Base 1
Dim Num(10) As Integer ' Integer array.
Dim StrVarArray(10) As String ' Variable-string array.
Dim StrFixArray(10) As String * 10 ' Fixed-string array.
Dim VarArray(10) As Variant ' Variant array.
Dim DynamicArray() As Integer ' Dynamic array.
ReDim DynamicArray(10) ' Allocate storage space.
Erase Num ' Each element set to 0.
Erase StrVarArray ' Each element set to zero-length string ("").
Erase StrFixArray ' Each element set to 0.
Erase VarArray ' Each element set to Empty.
Erase DynamicArray ' Free memory used by array.
Erase StrVarArray,StrFixArray,VarArray ' Reset three arrays at the same time.
```

## Lbound

Determines the value of the lower bound for the dimension of the array specified in the arguments.

*Lbound* expects the required argument *ArrayName* to be a valid variable array name. The optional argument *ArrayDimension* must be a whole long number indicating which dimension's lower bound is to be returned. Use 1 for the first dimension, 2 for the second, and so on.

## Syntax

**Lbound**(*ArrayName*, *ArrayDimension*)

*ArrayName*:

The name of the array.

*ArrayDimension*:

The dimension of the array for which you want to the lower bound. If *ArrayDimension* is omitted, 1 is assumed.

## Return Value

Returns a number of Long data type.

## Related Functions

[Ubound](#)

## Example

```
Dim Lower
Dim MyArray(1 To 10, 5 To 15, 10 To 20) ' Declare array variables.
Dim AnyArray(10)
Lower = LBound(MyArray, 1) ' Returns 1.
Lower = LBound(MyArray, 2) ' Returns 5.
Lower = LBound(AnyArray) ' Returns 1.
```

## Option Base

Declares the default lower bound for array subscripts.

The Option Base statement is optional. If used, it can appear only once in a VBA file, and must be used before you declare the dimensions of any arrays.

The To clause in the array subscript range of a [Dim](#) statement provides a more flexible way to control the lower bound of an array. If you don't explicitly set the lower bound with a To clause, the Option Base setting (if used) comes into affect, or defaults to zero (if not used).

## Syntax

### Option Base Num

*Num:*

An Integer or expression representing a valid numeric value. The value of the 'number' parameter must be either 0 or 1. The default is 0.

## Related Functions

[Dim | ReDim](#)

## Example

The example below uses the Option Base statement to override the default base array subscript value of 0.

```
' Module level statement
Option Base 1

' Create the array
Dim Arr(20)
' Declare message variables
```

```
Dim Msg As String
Dim NL as String
' Define newline
NL = Chr(10) & Chr(13)
' Create message
Msg = "The lower bound is " & LBound(Arr) & "."
Msg = Msg & NL & "The upper bound is " & UBound(Arr) & "."
' Display message
MsgBox Msg
```

## ReDim

Used to size or resize a dynamic array that has already been declared using the [Dim](#) statement with empty parentheses.

Use the ReDim statement to change the number of elements in an array, but not to change the number of dimensions in an array or the type of the elements in the array.

## Syntax

**ReDim** *VariableName*(*Subscripts*)

*VariableName*:

The name of the variable or array being redimensioned.

*Subscripts*:

An Integer or expression representing a valid To numeric value range when declaring the dimensions of an variable array. Up to 60 multiple dimensions may be declared.

The subscripts argument uses the following syntax:

[lower To] upper [, [lower To] upper] . . .

When not explicitly stated in **lower**, the **lower** bound of an array is controlled by the [Option Base](#) statement. The lower bound is zero if no Option Base statement is present in the VBA file.

## Related Functions

[Dim](#) | [Const](#) | [Static](#)

## Example

```
Dim TestArray() As Integer
Dim I
ReDim TestArray(10)
For I = 1 To 10
    TestArray(I) = I + 10
    Print TestArray(I)
Next I
```

## Ubound

Determines the value of the largest subscript for the *ArrayDimension* of the *ArrayName* provided in the

argument. Ubound expects the required argument *ArrayName* to be a valid variable array name.

The optional argument *ArrayDimension* must be a whole long number indicating which dimension's lower bound is to be returned. Use 1 for the first dimension, 2 for the second, and so on. If *ArrayDimension* is omitted, 1 is assumed.

## Syntax

**Ubound(*ArrayName*, *ArrayDimension*)**

*ArrayName*:

A string or expression that can represent a valid variable array name.

*ArrayDimension*:

A numeric value or expression that can represent a valid long data type value.

## Return Value

Returns a number of Long data type.

## Related Functions

[Lbound](#)

## Example

```
Dim Upper
Dim MyArray(1 To 10, 5 To 15, 10 To 20) ' Declare array variables.
Dim AnyArray(10)
Upper = UBound(MyArray, 1) ' Returns 10.
Upper = UBound(MyArray, 3) ' Returns 20.
Upper = UBound(AnyArray) ' Returns 10.
```

## Conditional Statements

<a href="#">Do Loop</a>	Allows you to execute a block of statements an indefinite number of times.
<a href="#">End Function</a>	Ends a block of statements such as a Sub procedure or function.
<a href="#">Exit</a>	Exits a loop or procedure.
<a href="#">For</a>	Repeats its block of statements a set number of times as determined by the values used with the To clause.
<a href="#">GoTo</a>	Branches unconditionally and without return to the label specified in the GoTo statement.

If	Tests an initial condition and then either performs or omits to perform the statements it contains, dependant upon the logical result of the test condition.
OnError Statement	VBA's error-handling routine and specifies the line label of the error-handling routine.
Select	Tests the same variable for many different conditions.
Stop	Ends execution of the program.
While...Wend	Similar to the Do While loop statement.
With	Not supported in VBA.

## Do Loop

The Do...Loop conditional statement allows you to execute a block of statements an indefinite number of times. The variations of the Do...Loop are Do...While, Do...Until, Do...Loop While, and Do...Loop Until.

```
Do While <condition>
    <statement/s>
Loop
Do Until <condition>
    <statement/s>
Loop
Do
    <statement/s>
Loop While <condition>
Do
    <statement/s>
Loop Until <condition>
```

Do...While and Do...Until check the condition before entering the loop, thus the block of statements inside the loop are only executed when those conditions are met. Do...Loop While and Do...Loop Until check the condition after having executed the block of statements so that the block of statements is executed at least once.

Any Do statement can be exited using the [Exit](#) statement.

## End Function

The End Function statement ends a program or a block of statements within a function. A VBA function starts with the FUNCTION statement and finishes with the END FUNCTION statement. All other statements that lie between the FUNCTION and END FUNCTION statements will be executed by the function when called to do so.

## Syntax

**End {Function | Sub | If}**

## Related Functions

[Call](#) | [Sub](#) | [End Sub](#) | [Exit](#)

## Example

```
Function GetColor2( c% ) As Long
    GetColor2 = c% * 25
    If c% > 2 Then
        GetColor2 = 255 ' 0x0000FF - Red
    End If
    If c% > 5 Then
        GetColor2 = 65280 ' 0x00FF00 - Green
    End If
    If c% > 8 Then
        GetColor2 = 16711680 ' 0xFF0000 - Blue
    End If
End Function
Sub TestColor2
    Dim I as integer
    For I = 1 to 10
        Print GetColor2(I)
    Next I
End Sub
```

## Exit

Exits a loop or procedure.

## Syntax

**Exit {Do | For | Function | Sub}**

## Example

```
' This sample shows Do ... Loop with Exit Do to get out.
Dim Value, Msg ' Declare variables
Do
    Value = InputBox("Enter a value from 5 to 10.")
    If Value >= 5 And Value <= 10 Then ' Check range
        Exit Do ' Exit Do...Loop
    Else
        Beep ' Beep if not in range
    End If
Loop
```

## For

Repeats its block of statements a set number of times as determined by the values used with the To clause.

## Example

```
For <CounterName> = <BeginValue> To <EndValue> [Step <StepValue>]  
    <statement/s>  
Next
```

## GoTo

The GoTo conditional statement branches unconditionally and without return to the label specified in the GoTo statement. The label must be located in the same subroutine or function as the GoTo statement.

## Example

```
<statement/s>  
If <condition> then  
    GoTo Label1  
Else  
    GoTo Label2  
End If  
  
Label1:  
<statement/s>  
GoTo Label3  
  
Label2:  
<statement/s>  
GoTo Label3  
  
Label3:  
<statement/s>
```

In this example, VBA tests the If condition, and jumps to the part of the script that begins with the label "Label1:" if the condition was true, or jumps to the part of the script that begins with the label "Label2:" if the condition was false. This could be anywhere in the same subroutine or function.

## If

Tests an initial condition and then either performs or omits to perform the statements it contains, dependant upon the logical result of the test condition. The condition can be a comparison or an expression, and must logically evaluate to either True or False. The If statement has both single line and multiple line syntax structure.

The single line syntax uses the If <TestCondition> Then <StatementToPerformIfTrue> structure, however, can only perform a single statement if and only if the test condition result is True. No 'End If' statement is required:

## Example

If<Condition>Then<Statement>

If the result of the If test condition was True, the program flow continues into and performs the statement following the Then statement, until it reaches the end of the line.

To perform a single statement conditionally upon a False result, use the NOT logical operator:

```
If NOT <Condition> Then <Statement>
```

To perform multiple statements, use the multiple line syntax structure which ends with the 'End If' statement:

```
If <Condition> Then
    ' Then statement block
    ' perform only if true
    <Statement/s>
End If
```

If the result of the If test condition was True, the program flow continues into the Then statement block, and performs the statements following the Then statement, until it reaches the End If statement.

If the result of the If test condition was False, the program flow jumps over the Then statement block, which in this case exits the If structure (without performing any statements other than the initial test condition).

The mutiple line If structure can perform different blocks of statements dependant upon EITHER a True OR a False result to the test condition, through the use of the Else statement block:

```
If <Condition> Then
    ' Then statement block
    ' perform only if true
    <Statement/s>
Else
    ' Else statement block
    ' perform only if false
    <Statement/s>
End If
```

If the result of the If test condition was True, the program flow performs the Then block statements, until it reaches the Else statement. It then jumps over the Else statement block and exits the If structure (without performing any of the Else statement block statements).

Further test conditions can be placed into an If structure through the use of the optional Else If <Condition> statement block. Elseif statement blocks can only be positioned within an If structure before the Else statement block. If the result of the If test condition was False, the program flow jumps over the Then statement block (without performing any of those statements) to the Else statement to perform the statements in the Else statement block until it reaches the End If statement.

```
If <Condition> Then
    ' Then statement block
    ' perform only if true
    <Statement/s>
ElseIf <Condition>
    ' Else If statement block
    ' perform only if true
    <Statement/s>
Else
    ' Else statement block
    ' perform only if false
    <Statement/s>
End If
```

The Elseif test condition is only evaluated after the initial If structure test condition results in False.

If the result of the Elseif test condition was True, the statements within the Elseif statement block are performed. The program flow then jumps over the Else statement block and exits the If structure (without performing any of the Else statement block statements).

If the result of the Elseif test condition was False, the program flow jumps over the Elseif statement block (without performing any of those statements) to the Else statement to perform the statements in the Else

statement block until it reaches the End If statement.

There is no apparent limit to the number of Else If statement blocks that any one If structure can hold, however, the Select Case Statement structure handles multiple condition result alternatives much more efficiently.

## OnError

VBA's error-handling routine and specifies the line label of the error-handling routine. The line parameter refers to a label. That label needs to be present in the code or an error is generated.

## Syntax

```
On Error { GoTo line | Resume Next | GoTo 0}
```

## Example

```
On Error GoTo errHandler
Dim x as object
x.draw ' Object not set
..
Exit Sub
errHandler:
Print Err.Number, Err.Description
Resume Next
```

## Select

The Select Case statement tests the same variable for many different conditions. The test value provided with the initial Select Case statement is logically tested against the Case test condition.

The Select Case structure can perform different blocks of statements dependant upon whichever Case statement test condition (if more than one) first results as True, through the use of the Case statement block:

```
Select Case <TestValue>
Case <Condition>
    ' Case statement block
    ' perform only if case true
    <Statement/s>
Case Else
    ' Else statement block
    ' perform only if all cases false
    <Statement/s>
End Select
```

If the result of the Case test condition was True, the program flow performs the statements contained within that Case statement block, and will then exit the Select Case structure (without performing any of the Else statement block statements).

If the result of the Case test condition was False, the program flow jumps over the Case statement block (without performing any of those statements) to the Case Else statement to perform the statements in the Else statement block until it reaches the End Select statement.

Further test conditions can be placed into a Select Case structure through the optional use of further Case statement blocks. Case statement blocks can only be positioned within a Select Case structure before the Case

Else statement block.

```
Select Case <TestValue>
Case <Condition>
    ' Case statement block
    ' perform only if case true
    <Statement/s>
Case <Condition>
    ' Case statement block
    ' perform only if case true
    <Statement/s>
Case Else
    ' Else statement block
    ' perform only if all cases false
    <Statement/s>
End Select
```

Each Case statement block is evaluated in order until the test condition of one results as True. The program flow performs the statements contained within that Case statement block, and will then exit the Select Case structure (without performing any other statements).

The statements of ONLY one Case statement block are ever performed, unless all result in False and there is no Case Else block declared, in which case no Case statement blocks are performed at all.

The following example may help clarify the logic testing being performed in a Select Case structure. Let's say that we have a variable named (intDayOfWeek) containing an integer (ranging from 1 to 7) representing the day of the week, and we wished to display that value as a string (named strDayOfWeek) containing the name of the day of the week, assuming in this example, that Sunday is the first day of the week (1). The Select Case structure would look like this:

```
Dim strDayOfWeek As String
Select Case intDayOfWeek
Case = 1
    StrDayOfWeek = "Sunday"
Case = 2
    StrDayOfWeek = "Monday"
Case = 3
    StrDayOfWeek = "Tuesday"
Case = 4
    StrDayOfWeek = "Wednesday"
Case = 5
    StrDayOfWeek = "Thursday"
Case = 6
    StrDayOfWeek = "Friday"
Case = 7
    StrDayOfWeek = "Saturday"
Case Else
    StrDayOfWeek = "Invalid"
End Select
```

The Select Case structure tends to be easier to read, understand, and follow and should be used in place of a complicated multi-nested If...ElseIf structure.

## Stop

Ends execution of the program. The Stop statement can be placed anywhere in your code.

## Example

```
Dim x,y,z
For x = 1 to 5
    For y = 1 to 5
        For z = 1 to 5
            Print "Looping",z,y,x
        Next z
    Next y
    Stop
Next x
```

## While...Wend

The While...Wend loop conditional statement is similar to the Do While loop statement. The condition is checked before executing the block of statements comprising the loop.

## Example

```
While <condition>
    <statement/s>
Wend
```

## With

---

**Note:** The With statement is not supported in VBA.

---

When performing a series of commands on an object, you must explicitly refer to the name of the object with each command.

## Conversion Functions

VBA conversion functions are provided to assist with data manipulation and calculation in your formulas. Conversion functions can be used in VBA statements, and will (like all other functions), return a value to the caller.

### ASCII Character Code Conversion

Plant SCADA uses the following character code conversion functions:

Asc	Returns the numeric ASCII value of a string.
Chr	Returns the string ASCII value of a number.

#### Asc

Converts a text string character to its numeric ASCII code value. The Asc function expects the argument *Str* to be a valid string expression. If *Str* contains no characters, a runtime error occurs. The Asc function performs the

opposite of the [Chr](#) function, which converts a number into its string character ASCII code value.

## Syntax

**Asc(*Str*)**

*Str*:

A string or expression that can represent a valid text value.

## Return Value

Returns the numeric ASCII code value of the first character in *Str* provided in the argument.

## Related Functions

[Chr](#)

## Example

```
Dim vntVar ' declare result holder variable
vntVar = Asc("A")' returns 65
vntVar = Asc("Z")' returns 90
vntVar = Asc("a")' returns 97
vntVar = Asc("z")' returns 122
vntVar = Asc("Apple")' returns 65
vntVar = Asc("Zoe")' returns 90
```

## Chr

Converts a number into its string character ASCII code value.

The Chr function expects the argument *Num* to be a valid numeric integer (whole positive number within the range 0 to 255 inclusive). If *Chr* contains no number, a runtime error occurs.

**Note:** Values 8, 9, 10, and 13 convert to backspace, tab, linefeed, and carriage return characters respectively.

The Chr function performs the opposite of the [Asc](#) function, which converts a text string character to its numeric ASCII code value.

## Syntax

**Chr(*Num*)**

*Num*:

An integer or expression representing a valid numeric value.

## Return Value

Returns a single character string representing the ASCII character code value of the number *Num* provided in the argument.

## Related Functions

[Asc](#)

## Example

```
Dim vntVar ' declare result holder variable
vntVar = Chr(65) ' returns "A"
vntVar = Chr(97) ' returns "a"
vntVar = Chr(90) ' returns "Z"
vntVar = Chr(122) ' returns "z"
```

## Date Conversion

Plant SCADA uses the following date conversion functions:

<a href="#">CDate</a>	Converts an expression to a variant of date data type.
<a href="#">CDbl</a>	Converts an expression to a double data type.
<a href="#">Clnt</a>	Converts an expression to a integer data type.
<a href="#">CLng</a>	Converts an expression to a long data type.
<a href="#">CSng</a>	Converts an expression to a single data type.
<a href="#">CStr</a>	Converts an expression to a string data type.
<a href="#">CVar</a>	Converts an expression to a variant data type.

### CDate

Converts any valid date expression to a Date data type.

The CDate function expects the argument Date to be a date expression (limited to numbers or strings in any combination) that can represent a date from January 1, 100 through December 31, 9999.

## Syntax

**CDate(Date)**

*Date:*

A string or expression that can represent a date value. This includes any combination of date literals, numbers that look like dates, strings that look like dates, and dates from functions.

## Return Value

Returns the value of the expression Date provided in the argument as a variant with a vartype of 7 (date data type).

## Related Functions

[CDbl](#) | [CInt](#) | [CLng](#) | [CSng](#) | [CStr](#) | [CVar](#)

## Example

```
Dim MybDate, MDate, MTime, MSTime
' Define date.
MybDate = "May 29, 1959"
' Convert to Date data type.
MDate = CDate(MybDate)
' Define time.
MTime = "10:32:27 PM"
' Convert to Date data type.
MSTime = CDate(MTime)
```

## CDbl

Converts expressions to a double data type.

## Syntax

**CDbl(***Exp***)**

*Exp*:

A valid string, number or Variant containing a value recognizable as a string or a number.

## Return Value

Returns the value of the expression *Exp* provided in the argument as a double data type.

## Related Functions

[CDate](#) | [CInt](#) | [CLng](#) | [CSng](#) | [CStr](#) | [CVar](#)

## Example

```
Dim x as integer
Dim z as double
z = CDbl(x)'Converts the integer value of x to a double value in z
```

## CInt

Converts expressions to an integer data type.

## Syntax

**CInt(Exp)**

*Exp:*

A valid string, number or Variant containing a value recognizable as a string or number.

## Return Value

Returns the value of the expression *Exp* provided in the argument as an integer data type.

## Related Functions

[CDate](#) | [CDbl](#) | [CLng](#) | [CSng](#) | [CStr](#) | [CVar](#)

## Example

```
Dim x as integer
Dim y as long
x = CInt(y) 'Converts the long value of y to an integer value in x
```

## CLng

Converts expressions to a long data type.

## Syntax

**CLng(Exp)**

*Exp:*

A valid string, number or Variant containing a value recognizable as a string or number.

## Return Value

Returns the value of the expression *Exp* provided in the argument as a long data type.

## Related Functions

[CDate](#) | [CDbl](#) | [CInt](#) | [CSng](#) | [CStr](#) | [CVar](#)

## Example

```
Dim x as integer
Dim y as long
y = CLng(x) 'Converts the integer value of x to an long value in y
```

## CSng

Converts expressions to a single data type.

### Syntax

**CSng(*Exp*)**

*Exp*:

A valid string, number or Variant containing a value recognizable as a string or number.

### Return Value

Returns the value of the expression *Exp* provided in the argument as a single data type.

### Related Functions

[CDate](#) | [CDbl](#) | [CInt](#) | [CLng](#) | [CStr](#) | [CVar](#)

## Example

```
Dim x as integer
Dim s as single
s = CSng(x) 'Converts the integer value of x to a single value in s
```

## CStr

Converts expressions to a string data type.

### Syntax

**CStr(*Exp*)**

*Exp*:

A valid string, number or Variant containing a value recognizable as a string or number.

### Return Value

Returns the value of the expression *Exp* provided in the argument as a string data type.

### Related Functions

[CDate](#) | [CDbl](#) | [CInt](#) | [CLng](#) | [CStr](#) | [CVar](#) | [CSng](#)

## Example

```
Dim x as integer
```

```
Dim t as string
t = CStr(x) 'Converts the integer value of x to a string value in t
```

## CVar

Converts expressions to a variant data type.

## Syntax

**CVar(Exp)**

*Exp:*

A valid string, number or Variant containing a value recognizable as a string or number.

## Return Value

Returns the value of the expression (*Exp*) provided in the argument as a variant data type.

## Related Functions

[CDate](#) | [CDbl](#) | [CInt](#) | [CLng](#) | [CSng](#) | [CStr](#)

## Example

```
Dim x as integer
Dim v as variant
v = CVar(x) 'Converts the integer value of x to a variant value in v
```

## Date and Time Formatting/Conversion

Plant SCADA uses the following formatting/conversion functions:

<a href="#">DateSerial</a>	Constructs a date value.
<a href="#">TimeSerial</a>	Constructs an time value.

## DateSerial

Constructs a date value from the given Year, Month, and Day arguments passed to the function. The DateSerial function expects all three parameters to be valid. Date values in VBA are evaluated using the Gregorian Calendar.

## Syntax

**DateSerial(year,month,day)**

*year, month, day:*

The year, month and day as integers.

## Return Value

Returns a Variant (of date data type) containing a date value corresponding to the Year, Month and Day values that were passed in to the function.

## Related Functions

[TimeSerial](#)

## Example

```
Dim varMyBDate
varMyBDate = DateSerial(1958, 7, 08)
' constructs and stores date value.
```

## TimeSerial

Constructs a time value serially from the given Hrs, Mins, and Secs arguments passed to the function. The TimeSerial Function expects all three arguments to be valid.

## Syntax

**TimeSerial(*hours,minutes,seconds*)**

*hours, minutes, seconds:*

The hours, minutes and seconds to be converted to serial form as integers.

## Return Value

Returns a Variant (of date data type) containing a time value corresponding to the Hrs, Mins, and Secs values that were passed in to the function.

## Related Functions

[DateSerial](#)

## Example

```
Dim varMyTime
varMyTime = TimeSerial(14, 35, 17)
' stores time as 2:35:17 PM
```

## Number and String Conversion

Plant SCADA uses the following functions for converting and formatting numbers and strings:

<a href="#">Format</a>	Formats a string, number, or variant to the format expression (fmt ).
<a href="#">Hex</a>	Converts a value to a string representing the hex value.
<a href="#">Oct</a>	Converts a value to a string representing the octal value.
<a href="#">Str</a>	Converts a value to a string containing numeric characters.
<a href="#">Val</a>	Converts a string containing numeric characters to a numeric value.

## Format

Formats a string, number, or variant to the format expression *fmt*. The Format function expects the argument *Exp* to be a valid expression to be formatted.

The Format function expects the argument *fmt* to be a string of characters that specify how the expression is to be displayed, or the name of a commonly used format that has been predefined in VBA. Do not mix different type format expressions in a single *fmt* parameter.

If the *fmt* parameter is omitted or is zero-length and the expression parameter is a numeric, Format[\$] provides the same functionality as the Str[\$] function by converting the numeric value to the appropriate return data type. Positive numbers convert to strings using Format[\$] lack the leading space reserved for displaying the sign of the value, whereas those converted using Str[\$] retain the leading space.

To format numbers, you can use the commonly used formats that have been predefined in VBA, or you can create user-defined formats with standard characters that have special meaning when used in a format expression.

## Syntax

**Format(*Exp* [,*fmt*])**

*Exp*:

A valid string, number or Variant containing a value recognizable as a string or number.

## Return Value

Returns a formatted string.

### Predefined numeric format names

- *General* - Display the number as is, with no thousand Separators
- *Fixed* - Display at least one digit to the left and two digits to the right of the decimal separator.
- *Standard* - Display number with thousand separator, if appropriate; display two digits to the right of the decimal separator.

- *Percent* - Display number multiplied by 100 with a percent sign (%) appended to the right' display two digits to the right of the decimal separator.
- *Scientific* - Use standard scientific notation.
- *True/False* - Display False if number is 0, otherwise display True.

### User-defined number formats

- *Null string* - Display the number with no formatting.
- *0* - Digit placeholder.

### Display a digit or a zero

If the number being formatted has fewer digits than there are zeros (on either side of the decimal) in the format expression, leading or trailing zeros are displayed. If the number has more digits to the right of the decimal separator than there are zeros to the right of the decimal separator in the format expression, the number is rounded to as many decimal places as there are zeros. If the number has more digits to left of the decimal separator than there are zeros to the left of the decimal separator in the format expression, the extra digits are displayed without modification.

- **Digit placeholder(#)**. Displays a digit or nothing. If there is a digit in the expression being formatted in the position where the # appears in the format string, displays it; otherwise, nothing is displayed.
- **Decimal placeholder(.)**. The decimal placeholder determines how many digits are displayed to the left and right of the decimal separator.
- **Percentage placeholder.(%)** The percent character (%) is inserted in the position where it appears in the format string. The expression is multiplied by 100.
- **Thousand separator(,)**. The thousand separator separates thousands from hundreds within a number that has four or more places to the left of the decimal separator. Use of this separator as specified in the format statement contains a comma surrounded by digit placeholders(0 or #). Two adjacent commas or a comma immediately to the left of the decimal separator (whether or not a decimal is specified) means "scale the number by dividing it by 1000, rounding as needed."
- **Scientific format(E-E+e-e+)**. If the format expression contains at least one digit placeholder (0 or #) to the right of E-,E+,e- or e+, the number is displayed in scientific formatted E or e inserted between the number and its exponent. The number of digit placeholders to the right determines the number of digits in the exponent. Use E- or e- to place a minus sign next to negative exponents. Use E+ or e+ to place a plus sign next to positive exponents.
- **Time separator(:)**. The actual character used as the time separator depends on the Time Format specified in the International section of the Control Panel.
- **Date separator(/)**. The actual character used as the date separator in the formatted out depends on Date Format specified in the International section of the Control Panel.
- Display a literal character (- + \$ ( )). To display a character other than one of those listed, precede it with a backslash (\).
- Display the next character in the format string (\). The backslash itself isn't displayed. To display a backslash, use two backslashes (\\\).

---

**Note:** Examples of characters that can't be displayed as literal characters are the date- and time- formatting characters (a,c,d,h,m,n,p,q,s,t,w,y, and /:), the numeric formatting characters(#,0,%,E,e,comma, and period), and the string- formatting characters (@,&,<,>, and !).

---

- Display the string inside the double quotation marks ("String"). To include a string in fmt from within VBA, you need to use the ANSI code for a double quotation mark Chr(34) to enclose the text.
- Display the next character as the fill character (\*). Any empty space in a field is filled with the character following the asterisk.

Unless the *fmt* argument contains one of the predefined formats, a format expression for numbers can have from one to four sections separated by semicolons.

If you use	The result is
One section	The format expression applies to all values.
Two	The first section applies to positive values, the second to negative sections values.
Three	The first section applies to positive values, the second to negative sections values, and the third to zeros.
Four	The first section applies to positive values, the second to negative section values, the third to zeros, and the fourth to Null values.

The following example has two sections: the first defines the format for positive values and zeros; the second section defines the format for negative values.

"\$#,##0; (\$#,##0)"

If you include semicolons with nothing between them, the missing section is printed using the format of the positive value. For example, the following format displays positive and negative values using the format in the first section and displays "Zero" if the value is zero.

"\$#,##0; ;\Z\ e\r\o"

Some sample format expressions for numbers are shown below. (These examples assume the Country is set to United States in the International section of the Control Panel.) The first column contains the format strings. The other columns contain the output the results if the formatted data has the value given in the column headings.

Format (fmt)	Positive 3	Negative 3	Decimal .3	Null
Null string	3	-3	0.3	
0	3	-3	1	
0.00	3.00	-3.00	0.30	
#,##0	3	-3	1	
#,##0.00;;Nil	3.00	-3.00	0.30	Nil
\$#,##0;(\$#,##0)	\$3	(\$3)	\$1	
\$#,##0.00;(\$#,##0.0)	\$3.00	(\$3.00)	\$0.30	

<b>Format (fmt)</b>	<b>Positive 3</b>	<b>Negative 3</b>	<b>Decimal .3</b>	<b>Null</b>
0%	300%	-300%	30%	
0.00%	300.00%	-300.00%	30.00%	
0.00E+00	3.00E+00	-3.00E+00	3.00E-01	
0.00E-00	3.00E00	-3.00E00	3.00E-01	

Numbers can also be used to represent date and time information. You can format date and time serial numbers using date and time formats or number formats because date/time serial numbers are stored as floating-point values.

To format dates and times, you can use either the commonly used format that have been predefined or create user-defined time formats using standard meaning of each:

General	Display a date and/or time. for real numbers, display a date and time.(e.g. 4/3/93 03:34 PM); If there is no fractional part, display only a date (e.g. 4/3/93); if there is no integer part, display time only (e.g. 03:34 PM).
Long Date	Display a Long Date, as defined in the International section of the Control Panel.
Medium	Display a date in the same form as the Short Date, as defined in the international section of the Control Panel, except spell out the month abbreviation.
Short Date	Display a Short Date, as defined in the International section of the Control Panel.
Long Time	Display a Long Time, as defined in the International section of the Control panel. Long Time includes hours, minutes, seconds.
Medium	Display time in 12-hour format using hours and minuets and the Time AM/PM designator.
Short Time	Display a time using the 24-hour format (e.g. 17:45)
c	Display the date as dddd and display the time as tttt. in the order.
d	Display the day as a number without a leading zero (1-31).
dd	Display the day as a number with a leading zero (01-31).
ddd	Display the day as an abbreviation (Sun-Sat).

ddddd	Display a date serial number as a complete date (including day , month, and year).
w	Display the day of the week as a number (1- 7 ).
ww	Display the week of the year as a number (1-53).
m	Display the month as a number without a leading zero (1-12). If m immediately follows h or hh, the minute rather than the month is displayed.
mm	Display the month as a number with a leading zero (01-12). If mm immediately follows h or hh, the minute rather than the month is displayed.
mmm	Display the month as an abbreviation (Jan-Dec).
mmmm	Display the month as a full month name (January-December).
q	display the quarter of the year as a number (1-4).
y	Display the day of the year as a number (1-366).
yy	Display the day of the year as a two-digit number (00-99)
yyyy	Display the day of the year as a four-digit number (100-9999).
h	Display the hour as a number without leading zeros (0-23).
hh	Display the hour as a number with leading zeros (00-23).
n	Display the minute as a number without leading zeros (0-59).
nn	Display the minute as a number with leading zeros (00-59).
s	Display the second as a number without leading zeros (0-59).
ss	Display the second as a number with leading zeros (00-59).
tttt	Display a time serial number as a complete time (including hour, minute, and second) formatted using the time separator defined by the Time Format in the

	International section of the Control Panel. A leading zero is displayed if the Leading Zero option is selected and the time is before 10:00 A.M. or P.M. The default time format is h:mm:ss.
AM/PM	Use the 12-hour clock and display an uppercase AM/PM
am/pm	Use the 12-hour clock display a lowercase am/pm
A/P	Use the 12-hour clock display a uppercase A/P
a/p	Use the 12-hour clock display a lowercase a/p
AMPM	Use the 12-hour clock and display the contents of the 11:59 string(s1159) in the WIN.INI file with any hour before noon; display the contents of the 2359 string (s2359) with any hour between noon and 11:59 PM. AMPM can be either uppercase or lowercase, but the case of the string displayed matches the string as it exists in the WIN.INI file. The default format is AM/PM.
m/d/yy	2/26/65
d-mmmm-yy	26-February-65
d-mmmm	26 February
mmmm-yy	February 65
hh:nn	AM/PM 06:45 PM
h:nn:ss a/p	6:45:15 p
h:nn:ss	18:45:15
m/d/yy/h:nn	2/26/65 18:45

Strings can also be formatted with Format[\$]. A format expression for strings can have one section or two sections separated by a semicolon.

If you use	The result is
One section only	The format applies to all string data.
Two sections	The first section applies to string data, the second to Null values and zero-length strings.

The following characters can be used to create a format expression for strings:

@	Character placeholder. Displays a character or a space.
---	---

	Placeholders are filled from right to left unless there is an !character in the format string.
&	Character placeholder. Display a character or nothing.
<	Force lowercase.
>	Force uppercase.
!	Force placeholders to fill from left to right instead of right to left.

## Example

```
' Format Function Example
' This example shows various uses of the Format function to format values
' using both named and user-defined formats. For the date separator (/),
' time separator (:), and AM/ PM literal, the actual formatted output
' displayed by your system depends on the locale settings on which the code
' is running. When times and dates are displayed in the development
' environment, the short time and short date formats of the code locale
' are used. When displayed by running code, the short time and short date
' formats of the system locale are used, which may differ from the code
' locale. For this example, English/United States is assumed.

' MyTime and MyDate are displayed in the development environment using
' current system short time and short date settings.
MyTime = "08:04:23 PM"
MyDate = "03/03/95"
MyDate = "January 27, 1993"
MsgBox Now
MsgBox MyTime
MsgBox Second( MyTime ) & " Seconds"
MsgBox Minute( MyTime ) & " Minutes"
MsgBox Hour( MyTime ) & " Hours"
MsgBox Day( MyDate ) & " Days"
MsgBox Month( MyDate ) & " Months"
MsgBox Year( MyDate ) & " Years"
' Returns current system time in the system-defined long time format.
MsgBox Format(Time, "Short Time")
MyStr = Format(Time, "Long Time")
' Returns current system date in the system-defined long date format.
MsgBox Format(Date, "Short Date")
MsgBox Format(Date, "Long Date")
MyStr Format(MyTime, "h:n:s") ' Returns "17:4:23".
MyStr Format(MyTime, "hh:nn:ss")' Returns "20:04:22 ".
MyStr Format(MyDate, "dddd, mmm d yyyy")' Returns "Wednesday, Jan 27 1993".
' If format is not supplied, a string is returned.
MsgBox Format(23) ' Returns "23".
```

```
' User-defined formats.  
MsgBox Format(5459.4, "##,##0.00") ' Returns "5,459.40".  
MsgBox Format(334.9, "####0.00") ' Returns "334.90".  
MsgBox Format(5, "0.00%") ' Returns "500.00%".  
MsgBox Format("HELLO", "<") ' Returns "hello".  
MsgBox Format("This is it", ">") ' Returns "THIS IS IT".
```

## Hex

Converts a numeric value to a text string representing the hexadecimal value of the number.

The Hex function expects the argument *Num* to be a valid numeric value. It is rounded to nearest whole number before evaluation.

## Syntax

**Hex(*Num*)**

*Num*:

An Integer or expression representing a valid numeric value.

## Return Value

Returns a text string containing the hexadecimal value of the numeric *Num* value provided in the argument.

## Related Functions

[Format](#) | [Oct](#) | [Str](#) | [Val](#)

## Example

```
Dim MyHex as String  
MyHex = Hex(5) 'returns "5"  
MyHex = Hex(10) 'returns "A"  
MyHex = Hex(459) 'returns "1CB"
```

## Oct

Converts a numeric value to a text string representing the octal value of the number.

The Oct function expects the argument *Num* to be a valid numeric value. It is rounded to nearest whole number before evaluation.

## Syntax

**Oct(*Num*)**

*Num*:

An Integer or expression representing a valid numeric value.

## Return Value

Returns a text string containing the octal value of the numeric *Num* value provided in the argument.

## Related Functions

[Format](#) | [Hex](#) | [Str](#) | [Val](#)

## Example

```
Dim MyOct as String
MyOct = Oct(4) 'returns "4"
MyOct = Oct(8) 'returns "10"
MyOct = Oct(459) 'returns "713"
```

## Str

Converts a numeric value to a text string containing numeric characters. The Str function expects the argument *Num* to be a valid numeric value.

The Str function is often used to prepare a numerical value for display as a string in a caption, label, string field, or string expression.

The Str function performs the opposite of the Val function, which converts a text string containing numeric characters to a numeric value.

---

**Note:** Please remember the data type coercion considerations with variant data types. See Variants.

---

## Syntax

**Str(*Num*)**

*Num*:

An Integer or expression representing a valid numeric value.

## Return Value

Returns a string containing the numeric character representation of the numeric *Num* value provided in the argument.

The Str function reserves the first return string character for the sign of *Num*. If *Num* is positive, a leading space is used and the plus sign is implied.

## Related Functions

[Format](#) | [Hex](#) | [Oct](#) | [Val](#)

## Example

```
Dim vntVar ' declare result holder variable
```

```
vntVar = Str() ' returns " "
vntVar = Str(65) ' returns " 65"
vntVar = Str(97.578) ' returns " 97.578"
vntVar = Str(-97.578) ' returns "-97.578"
```

## Val

Converts a text string containing numeric characters to a numeric value. The Val function expects the argument *Str* to be a valid string expression. The Val function stops reading the string when it reaches a non numeric character.

Symbols such as dollar signs and commas are not recognized; however, radix prefixes for octal (&O) and hexadecimal (&H) are. Blanks, tabs and line feeds are stripped out from the return.

The Val function performs the opposite of the Str function, which converts a numeric value to a text string containing numeric characters.

## Syntax

**Val(*Str*)**

*Str*:

A string or expression that can represent a valid text value.

## Return Value

Returns the numeric value of a string of characters extracted from the *Str* provided in the argument.

## Related Functions

[Format](#) | [Hex](#) | [Oct](#) | [Str](#)

## Example

```
Dim vntVar ' declare result holder variable
vntVar = Val("65") ' returns 65
vntVar = Val("90 Main St.") ' returns 90
vntVar = Val("12+34+56") ' returns 12
vntVar = Val(" 12 34 56 ") ' returns 123456
vntVar = Val("&0FF") ' returns
vntVar = Val("Zoe") ' returns 0
```

## Declarations

VBA declarations allow you to manipulate and control variables and constants. The Declaration functions and statements predefined in VBA are:

<a href="#">CreateObject</a> function	Creates an OLE Automation object reference
<a href="#">Const</a> statement	Assigns a symbolic name to a constant value.
<a href="#">Declare</a> statement	Declare references to external procedures in a DLL.
<a href="#">Dim</a> statement	Allocates storage for, and declares the data type of, variables and arrays.
<a href="#">IsDate</a>	Determines if a Variant parameter can be converted to a date.
<a href="#">IsEmpty</a>	Determines if a Variant parameter has been initialized.
<a href="#">IsNull</a>	Determines if a Variant contains NULL.
<a href="#">IsNumeric</a>	Determines if a Variant can be converted to a numeric data type.
<a href="#">Nothing</a> keyword	Releases an OLE Automation object reference from a variable of object type.
<a href="#">Option Base</a> statement	Declares the default lower bound for array subscripts.
<a href="#">Option Compare</a> statement	Determines the default string comparison method. Forces explicit declaration of all variables.
<a href="#">ReDim</a> statement	Used to size or resize a dynamic array.
<a href="#">Set</a> statement	Assigns an OLE Automation object reference to a variable of object type.
<a href="#">Static</a> statement	Allocates storage for, and declares the data type of, variables and arrays.
<a href="#">VarType</a>	Indicates the data type used within the Variant.

## CreateObject

Creates a new OLE Automation object and assigns a reference to the object.

## Syntax

Set *objVarName* = CreateObject(*objClassName*)

*objVarName*:

The required name of the variable receiving the reference.

*objClassName*:

The required class name of the object to be created.

The object variable *objVarName* must be declared before it can be set to reference an OLE Automation object.

## Related Functions

[Dim](#) | [Set](#)

## Example

```
' create variable to store object reference
Dim objWord as Object
' create object and assign reference to variable
Set objWord = CreateObject( "Word.Document" )
' insert appropriate VBA code here to manipulate Word object
' release reference
Set objWord = Nothing.
```

## Const

Assigns a symbolic name to a constant value using the following syntax:

```
Const VarName [As DataType] = Expression
```

A constant must be defined before it is used. Unlike variables, constants are assigned values when initialized and retain that same value during the life of the constant.

Constant statements can only be declared and assigned using simple expressions. Constants can NOT be assigned values from variables, user-defined functions, intrinsic VBA functions (such as Chr), or from any expression that involves an operator.

Constants declared in a Sub or Function procedure are local to that procedure. A constant declared outside a procedure has modular scope to all procedures within the same VBA file module. See Scope of VBA.

Constants can be used anywhere in your VBA code where you could use a VBA expression.

If you use Const outside a procedure its scope becomes global.

A type declaration character may also be used. However if none is used, VBA will automatically assign one of the following data types to the constant: long (if it is a long or integer); Double (if a decimal place is present); or String (if it is a string).

## Syntax

**Const**(*VarName*, *Exp*)

*VarName*:

A string representing a valid variable name.

*Exp*:

A valid string, number or Variant containing a value recognizable as a string or number.

## Related Functions

[Dim](#) | [ReDim](#) | [Static](#)

## Example

```
' Correct declaration examples
' long assignment
Const Seven = 7
' double assignment
Const Pi = 3.14159
' string assignment
Const Lab = "Laboratory"

' Incorrect declaration examples
' NOTE that the following declarations demonstrate incorrect
assignments
' because each contains an operator
Const conPi = 4 * Atn(1)
' will cause a VBA compile error
Const conDegToRad = (conPi / 180)
' will cause a VBA compile error
```

## Declare

The Declare statement is used at module (file) level to declare references to external procedures in a dynamic-link library (DLL).

## Syntax

**Declare Function**<FunctionName> Lib "<LibName>" [Alias "<AliasName>"] [(<ArgList>)] [As <ReturnType>]

*FunctionName*:

The required name of the function being declared.

*LibName*:

The required DLL filename containing the function being called.

*AliasName*:

The optional function name within the DLL being called.

*ArgList*:

The optional argument/s of the function.

*ReturnType*:

The optional return data type.

## Related Functions

[Dim](#)

## Example

```
Declare Function GetWinTempPath Lib "kernel32" _
Alias "GetTempPathA" _
(ByVal nBufferLength As Long, _
```

```
ByVal lpBuffer As String) As Long
```

## Dim

The Dim statement allocates storage for, and declares the data type of, variables and arrays in a module.

The To clause in the array subscript range of a Dim statement provides a more flexible way to control the lower bound of an array. If you don't explicitly set the lower bound with a To clause, the [Option Base](#) setting (if used) comes into affect, or defaults to zero (if not used).

## Syntax

**Dim** *VariableName*[(*Subscripts*)] [As *DataType*]

*VariableName*:

The name of the variable or array being declared (dimensioned).

*Subscripts*:

The optional subscript range (dimensions) for an array in parentheses.

*DataType*:

The optional data type declaration for the variable or array.

## Related Functions

[Const](#) | [ReDim](#) | [Static](#)

## Example

```
Dim bytVar As Byte
Dim binVar As Boolean
Dim strVar As String
Dim intVar As Integer
Dim lngVar As Long
Dim sngVar As Single
Dim dblVar As Double
Dim vntVar As Variant
Dim objVar As Object
Dim dtmVar As Date

Dim daysOfWeek() As String ' declares an array variable to hold strings

Dim monthsOfYear(12) As Date ' declares an array variable to hold 12 strings
Dim users(,) As String ' declares a two dimensional array to hold strings
Dim usernames(5,5) As String ' declares a two dimensional 5 x 5 array to hold strings

Dim MyArray(1 To 10, 5 To 15, 10 To 20) ' declares the three dimensional array
MyArray and specifies the upper and lower bounds of each dimension
```

## IsDate

Determines if an expression can be converted to a date.

The required *Date* argument is a Variant containing a date expression or string expression recognizable as a date or time value.

## Syntax

**IsDate(*Date*)**

*Date*:

A string or expression that can represent a date value. This includes any combination of date literals, numbers that look like dates, strings that look like dates, and dates from functions.

## Return Value

Returns a Boolean True or False.

## Related Functions

[IsEmpty](#) | [IsNull](#) | [IsNumeric](#) | [VarType](#)

## Example

```
Dim x As String
Dim MArray As Integer, MCheck
MArray = 345
x = "January 1, 1987"
MCheck = IsDate(MArray)
MChekk = IsDate(x)
MArray1 = CStr(MArray)
MCheck1 = CStr(MCheck)
Print MArray1 & " is a date " & Chr(10) & MCheck
Print x & " is a date" & Chr(10) & MChekk
```

## IsEmpty

Determines if a variant parameter has been initialised.

The required *Exp* argument is a variant containing a numeric or string expression. However, because **IsEmpty** is used to determine if individual variables are initialised, the *Exp* argument is most often a single variable name.

**IsEmpty** returns **True** if the variable is un-initialised, or is explicitly set to **Empty**; otherwise, it returns **False**. **False** is returned if *Exp* contains more than one variable.

**Note:** **IsEmpty** only returns meaningful information for variants.

## Syntax

**IsEmpty(*Exp*)**

*Exp*

A valid string, number or Variant containing a value recognizable as a string or number.

## Related Functions

Returns a Boolean **True** or **False**.

## Related Functions

[IsDate](#) | [IsNull](#) | [IsNumeric](#) | [VarType](#)

## Example

```
Dim x ' Empty
x = 5 ' Not Empty - Long
x = Empty ' Empty
y = x ' Both Empty
MsgBox "x" & " IsEmpty: " & IsEmpty(x)
```

## IsNull

Determines if a Variant contains **Null**.

**IsNull** returns **True** if expression is **Null**; otherwise, **IsNull** returns **False**. If *Exp* consists of more than one variable, **Null** in any constituent variable causes **True** to be returned for the entire expression.

The **Null** value indicates that the Variant contains no valid data. **Null** is not the same as **Empty**, which indicates that a variable has not yet been initialized. It is also not the same as a zero-length string (" "), which is sometimes referred to as a null string.

---

**Note:** Use the **IsNull** function to determine whether *VarName* contains a **Null** value. Expressions that you might expect to evaluate to **True** under some circumstances, such as If *Var* = **Null** and If *Var* <> **Null**, are always **False**. This is because any expression containing a **Null** is itself **Null** and, therefore, **False**.

---

## Syntax

**IsNull**(*Exp*)

*Exp*

A valid string, number or Variant containing a value recognizable as a string or number.

## Return Value

Returns a Boolean **True** or **False**.

## Related Functions

[IsDate](#) | [IsEmpty](#) | [IsNumeric](#) | [VarType](#)

## Example

```
Dim MyVar, MyCheck
MyCheck = IsNull(MyVar) ' Returns False.

MyVar = ""
MyCheck = IsNull(MyVar) ' Returns False.

MyVar = Null
MyCheck = IsNull(MyVar) ' Returns True.
```

## IsNumeric

Determines if a variant can be evaluated as a number.

The required *Exp* argument is a variant containing a numeric expression or string expression that can be evaluated as a number.

IsNumeric returns **False** if *Exp* is a date expression.

## Syntax

**IsNumeric(*Exp*)**

*Exp*

A valid string, number or Variant containing a value recognizable as a string or number.

## Return Value

Returns a Boolean **True** or **False**.

## Related Functions

[IsDate](#) | [IsEmpty](#) | [IsNull](#) | [VarType](#)

## Example

```
Dim TestVar ' Declare variable.
TestVar = InputBox("Please enter a number, letter, or symbol.")
If IsNumeric(TestVar) Then ' Evaluate variable.
    MsgBox "Entered data is numeric." ' Message if number.
Else
    MsgBox "Entered data is not numeric." ' Message if not.
End If
```

## Nothing

Releases an OLE Automation object reference from a variable of object type. The Nothing keyword is used in a Set statement.

In the following declaration syntax example, each placeholder shown inside arrow brackets ( <placeholder> )

should be replaced in any actual code with the value of the item that it describes. The arrow brackets and the word they contain should not be included in the statement, and are shown here only for your information.

## Syntax

**Set** *objVarName* = **Nothing**

*objVarName*:

The required name of the variable receiving the reference.

The **nothing** keyword should be used when you are finished with an object, to clear any variables that reference the object, so the object can be released from memory.

## Related Functions

[CreateObject](#) | [Function](#) | [Set](#)

## Example

```
' create variable to store object reference
Dim objWord as Object
' create object and assign reference to variable
Set objWord = CreateObject( "Word.Document" )
' insert appropriate VBA code here to manipulate Word object
' release reference
Set objWord = Nothing
```

## Option Base

Declares the default lower bound for array subscripts.

The Option Base statement is optional. If used, it can appear only once in a VBA file, and must be used before you declare the dimensions of any arrays.

The To clause in the array subscript range of a **Dim** statement provides a more flexible way to control the lower bound of an array. If you don't explicitly set the lower bound with a To clause, the Option Base setting (if used) comes into affect, or defaults to zero (if not used).

## Syntax

**Option Base** *Num*

*Num*:

An Integer or expression representing a valid numeric value. The value of the 'number' parameter must be either 0 or 1. The default is 0.

## Related Functions

[Dim](#) | [ReDim](#)

## Example

The example below uses the Option Base statement to override the default base array subscript value of 0.

```
' Module level statement
Option Base 1

' Create the array
Dim Arr(20)
' Declare message variables
Dim Msg As String
Dim NL as String
' Define newline
NL = Chr(10) & Chr(13)
' Create message
Msg = "The lower bound is " & LBound(Arr) & "."
Msg = Msg & NL & "The upper bound is " & UBound(Arr) & "."
' Display message
MsgBox Msg
```

## Option Compare

Determines how strings are compared within a VBA module. The optional Option Compare statement if used, must be placed at the top of the VBA file along with any other Option declarations.

If an Option Compare statement is not included, the default text comparison method is Binary.

## Syntax

**Option Compare {Binary | Text}**

## Related Functions

[InStr](#) | [StrComp](#)

## Example

```
Option Compare Binary
Dim vntResult as Variant
vntResult = StrComp("VBA rules!", "vba Rules!")
' returns 1 (strings unequal)
```

## Example

```
Option Compare Text
Dim vntResult as Variant
vntResult = StrComp("VBA rules!", "vba Rules!")
' returns 0 (strings equal)
```

## ReDim

Used to size or resize a dynamic array that has already been declared using the [Dim](#) statement with empty parentheses.

Use the ReDim statement to change the number of elements in an array, but not to change the number of dimensions in an array or the type of the elements in the array.

## Syntax

**ReDim** *VariableName(Subscripts)*

*VariableName*:

The name of the variable or array being redimensioned.

*Subscripts*:

An Integer or expression representing a valid To numeric value range when declaring the dimensions of an variable array. Up to 60 multiple dimensions may be declared.

The subscripts argument uses the following syntax:

[lower To] upper [, [lower To] upper] . . .

When not explicitly stated in **lower**, the **lower** bound of an array is controlled by the [Option Base](#) statement. The lower bound is zero if no Option Base statement is present in the VBA file.

## Related Functions

[Dim](#) | [Const](#) | [Static](#)

## Example

```
Dim TestArray() As Integer
Dim I
ReDim TestArray(10)
For I = 1 To 10
    TestArray(I) = I + 10
    Print TestArray(I)
Next I
```

## Set

Assigns an OLE Automation object reference to a variable of object type.

## Syntax

**Set** *objVarName* = [CreateObject](#)(*objClassName*) | [Nothing](#)

*objVarName*:

The required name of the variable receiving the reference.

*objClassName*:

The required class name of the object to be created.

Use the **Nothing** keyword to release the object reference.

The object variable *objVarName* must be declared before it can be set to reference an OLE Automation object.

## Related Functions

[CreateObject](#) | [Nothing](#)

## Example

```
' create variable to store object reference
Dim objWord as Object
' create object and assign reference to variable
Set objWord = CreateObject( "Word.Document" )
' insert appropriate VBA code here to manipulate Word object
' release reference
Set objWord = Nothing
```

## Static

The Static statement allocates storage for-and declares the data type of-variables and arrays that will retain their values between subsequent references. Static variables are more commonly used within procedures (subroutines and functions), and have local scope.

## Syntax

**Static** *VariableName*[(*Subscripts*)] [As *DataType*]

*VariableName*:

The required name of the variable being declared (dimensioned).

*Subscripts*:

The optional subscript range for an array.

*DataType*:

The optional VBA data type declaration for the variable.

## Related Functions

[Const](#) | [Dim](#) | [ReDim](#)

## Example

```
Static bytVar As Byte
Static binVar As Boolean
Static strVar As String
Static intVar As Integer
Static lngVar As Long
Static sngVar As Single
```

```
Static dblVar As Double
Static vntVar As Variant
Static objVar As Object
Static dtmVar As Date
Static udtVar As <UserDefinedTypeName>
```

## VarType

Determines the data type of a Variant variable.

The required VarName argument is a Variant containing any variable (except user-defined type).

## Syntax

**VarType(VarName)**

*VarName:*

A string representing a valid variable name.

## Return Value

These are the return values:

- 0 - Empty
- 1 - Null
- 2 - Integer
- 3 - Long
- 4 - Single
- 5 - Double
- 6 - Not Applicable
- 7 - Date/Time
- 8 - String

## Related Functions

[IsDate](#) | [IsEmpty](#) | [IsNull](#) | [IsNumeric](#)

## Example

```
Dim IntVar, StrVar, DateVar, MyCheck
' Initialize variables.
IntVar = 459
StrVar = "Hello World"
DateVar = #2/12/69#
MyCheck = VarType(IntVar) ' Returns 2.
MyCheck = VarType(DateVar) ' Returns 7.
MyCheck = VarType(StrVar) ' Returns 8.
```

## Date and Time Functions

VBA date and time functions let you make use of your computer's system time and date.

The date and time functions predefined in VBA are:

<a href="#">Date function</a>	Determines the current system date according to the setting of the computer's system time.
<a href="#">Date Statement</a>	Sets the current system date.
<a href="#">DateSerial function</a>	Constructs a date value.
<a href="#">DateValue function</a>	Calculates a date.
<a href="#">Day function</a>	Calculates the day.
<a href="#">Hour function</a>	Extracts the hours value from an expression (Time ).
<a href="#">Minute function</a>	Extracts the minutes value from an expression (Time ).
<a href="#">Month function</a>	Calculates the month.
<a href="#">Now function</a>	Determines the current date and time according to the setting of the computer's system date and time.
<a href="#">Second function</a>	Extracts the seconds value from an expression (Time ).
<a href="#">Time function</a>	Determines the current time according to the setting of the computer's system time.
<a href="#">Time (statement)</a>	Sets the current system time.
<a href="#">Timer event</a>	Used to track elapsed time.
<a href="#">TimeSerial function</a>	Constructs an time value.
<a href="#">TimeValue function</a>	Calculates a time.
<a href="#">WeekDay function</a>	Calculates the weekday value of a date.
<a href="#">Year function</a>	Calculates the year.

### Date

Gets the current date in string format.

Time/Date functions can only be used with dates between 1980 and 2035. You should check that the date you are using is valid with Cicode similar to the following:

```
IF StrToDate(Arg1) > 0 THEN
...
ELSE
...

```

END

## Syntax

**Date([Format])**

*Format:*

The format required:

2 - Short date format, dd/mm/yy

3 - Long date format, day month year

9 - Extended date format, dd/mm/yyyy

If omitted, the default Format is 2. All of these formats follow the Regional Settings found in the Windows Control Panel.

## Return Value

The current date (in string format).

## Related Functions

[Time](#)

## Example

```
/* If the current system date is 3rd November 1991 and the Windows date format is
dd/mm/yy; */
str = Date();
! Sets str to "3/11/91".
str = Date(2);
! Sets str to "3/11/91".
str = Date(3);
! Sets str to "3rd November 1991".
```

## See Also

[Date and Time Functions](#)

## Date Statement

Sets the current system date.

The DateValue literal is displayed in short date format using the locale settings of your development system. To view the locale settings for your system, in Windows, select Start, Settings, Control Panel, Regional Options, Date. For example: in Australia, the short date format is represented as d/MM/yyyy.

## Syntax

**Date** = *dateVariable*

*dateVariable*:

You must enclose a Date literal within number signs (# #), for example #31/5/1993#.

## Related Functions

[Time \(statement\)](#)

## Example

```
Dim varVBAReleaseDate
varVBAReleaseDate = #01/07/2001#
Date = varVBAReleaseDate
' sets system date to VBA Release Date
```

## DateValue

Calculates a date from the given date argument passed to the function. Date values in VBA are evaluated using the Gregorian Calendar. The DateValue function expects the argument value (*Date*) to be a string or any expression that can represent a date.

## Syntax

**DateValue**(*Date*)

*Date*:

A string or expression that can represent a date value. This includes any combination of date literals, numbers that look like dates, strings that look like dates, and dates from functions.

## Return Value

Returns a variant (of date data type) corresponding to the string date expression that was passed in.

## Related Functions

[TimeValue](#)

## Example

```
Dim varMyBDate
varMyBDate = DateValue("1958/07/08")
' stores date value.
```

## Day

Calculates the day from the given date argument passed to the function using the Gregorian Calendar.

## Syntax

**Day(*Date*)**

*Date*:

A string or expression that can represent a date value. This includes any combination of date literals, numbers that look like dates, strings that look like dates, and dates from functions.

## Return Value

Returns a variant date corresponding to the date expression that was passed in.

## Related Functions

[Date](#) | [Year](#) | [Month](#) | [WeekDay](#)

## Example

```
Dim varMyBDate, varMyDay
varMyBDate = #July 8, 1958#
varMyDay = Day(varMyBDate)
' stores 8 for day value.
```

## Hour

Calculates the hour value from the given time argument passed to the function.

## Syntax

**Hour(*Time*)**

*Time*:

A string or expression that can represent a time value. This includes and combination of time literals, numbers that look like times, strings that look like times, and times from functions.

## Return Value

Returns an integer between 0 and 23 that is the hour of the parameter (*Time*).

## Related Functions

[Minute](#) | [Second](#)

## Example

```
Dim varMyHour, varMyTime
varMyTime = "08:04:23 PM"
varMyHour = Hour(varMyTime)
' stores hours value.
```

## Minute

Calculates the minute value from the given time argument passed to the function.

## Syntax

**Minute(*Time*)**

*Time*:

A string or expression that can represent a time value. This includes any combination of time literals, numbers that look like times, strings that look like times, and times from functions.

## Return Value

Returns an integer between 0 and 59 representing the minute of the parameter (*Time*).

## Related Functions

[Hour](#) | [Second](#)

## Example

```
Dim varMyMin, varMyTime
varMyTime = "08:04:23 PM"
varMyMin = Minute(varMyTime)
' stores minutes value.
```

## Month

Calculates the month from the given date argument passed to the function using the Gregorian Calendar.

## Syntax

**Month(*Date*)**

*Date*:

A string or expression that can represent a date value. This includes any combination of date literals, numbers that look like dates, strings that look like dates, and dates from functions.

## Return Value

Returns an integer between 1 and 12 inclusive, that represents the month of the year.

## Related Functions

[Date](#) | [Year](#) | [WeekDay](#) | [Day](#)

## Example

```
Dim varMyBDate, varMyMonth
varMyBDate = "08 July 1958"
varMyMonth = Month(varMyBDate)
' returns 7 for July
```

## Now

Determines the current date and time according to the setting of the computer's system date and time using the Gregorian Calendar. Unlike other functions, Now does not require trailing parentheses.

## Syntax

**Now()**

## Return Value

The Now function returns a Variant data type containing a date and time value that is stored internally as a double data type.

The number represents a date and time from January 1, 100 through December 31, 9999. Numbers to the left of the decimal point represent the date and numbers to the right represent the time.

## Related Functions

[Date](#) | [Time](#) | [Timer](#)

## Example

```
Dim vntToday
vntToday = Now
' stores current system date and time.
```

## Second

Calculates the second value from the given time argument passed to the function.

## Syntax

**Second**(*Time*)

*Time*:

A string or expression that can represent a time value. This includes and combination of time literals, numbers that look like times, strings that look like times, and times from functions.

## Return Value

Returns an integer that is the second portion of the parameter (*Time*).

## Related Functions

[Hour](#) | [Minute](#)

## Example

```
Dim varMySec, varMyTime
varMyTime = "08:04:23 PM"
varMySec = Second(varMyTime)
' stores seconds value.
```

## Time

Gets the current time in string format.

Time/date functions can only be used with dates from 1980 to 2035. You should check that the date you are using is valid with Cicode similar to the following:

```
IF StrToDate(Arg1) > 0 THEN
...
ELSE
...
END
```

## Syntax

**Time**([*Format*])

*Format*:

The format of the time:

0 - Short time format, hh:mm

1 - Long time format., hh:mm:ss

If omitted, the default *Format* is 0.

## Return Value

The current time (as a string).

## Related Functions

[Date](#)

## Example

```
! If the current time is 10:45:30;  
Variable=Time();  
! Sets Variable to "10:45".  
Variable=Time(0);  
! Sets Variable to "10:45".  
Variable=Time(1);  
! Sets Variable to "10:45:30".
```

## See Also

[Date and Time Functions](#)

## Time (statement)

Sets the system time.

## Syntax

**Time** = *timeVariable*

*timeVariable*:

You must enclose a Time literal within number signs (# #), for example #12:14:00 PM#.

## Related Functions

[Date Statement](#)

## Example

```
' Time statement example  
Dim varMyTime  
' Assign a time.  
varMyTime = #4:35:17 PM#  
' Set system time to variant varMyTime.  
Time = varMyTime
```

## Timer

The Timer event is used to track elapsed time or can be displayed as a stopwatch in a dialog.

## Syntax

**Timer()**

## Return Value

The number of seconds since midnight.

## Related Functions

[Date](#) | [Time](#) | [Now](#)

## Example

```
Dim TS As Single
Dim TE As Single
Dim TEL As Single

TS = Timer
MsgBox "Starting Timer"
TE = Timer
TT = TE - TS
Print TT
```

## TimeValue

Calculates a time. The TimeValue function expects the argument value (*Time*) to be a string or any expression that can represent a time value.

## Syntax

**TimeValue(*Time*)**

*Time*:

A string or expression that can represent a time value. This includes and combination of time literals, numbers that look like times, strings that look like times, and times from functions.

## Return Value

Returns a variant (of date data type) corresponding to the parameter (*Time*).

## Related Functions

[DateValue](#)

## Example

```
Dim varMyTime
varMyTime = TimeValue("2:35:17 PM")
' stores time as 14:35:17
```

## WeekDay

Calculates the weekday value of the given date argument passed to the function. Date values in VBA are evaluated using the Gregorian Calendar.

## Syntax

**WeekDay(Date)**

*Date:*

A string or expression that can represent a date value. This includes any combination of date literals, numbers that look like dates, strings that look like dates, and dates from functions.

## Return Value

Returns an integer between the range of 1-7 inclusive representing the whole number for the weekday:

Return Value	Description
1	Sunday
2	Monday
3	Tuesday
4	Wednesday
5	Thursday
6	Friday
7	Saturday

## Related Functions

[Date](#) | [Year](#) | [Month](#) | [Day](#)

## Example

```
Dim varMyBDate, varMyWeekDay
varMyBDate = #8/07/1958#
varMyWeekDay = WeekDay(varMyBDate)
' returns 3 (Tuesday)
```

## Year

Calculates the year from the given date argument passed to the function. Date values in VBA are evaluated using the Gregorian Calendar.

## Syntax

**Year(*Date*)**

*Date*:

A string or expression that can represent a date value. This includes any combination of date literals, numbers that look like dates, strings that look like dates, and dates from functions.

## Return Value

Returns an integer representing a year 1930-2029 inclusive.

## Related Functions

[Date](#) | [Month](#) | [WeekDay](#) | [Day](#)

## Example

```
Dim varMyBDate, varMyYear
varMyDate = "08/07/58"
varMyYear = Year(varMyBDate)
' returns 1958
```

## File I/O Functions

VBA file Input/Output (I/O) functions are provided to enable read and write disk file functionality.

The file I/O functions predefined in VBA are:

<a href="#">ChDir</a>	Changes the system environment current directory on the specified drive.
<a href="#">ChDrive</a>	Changes the system environment current drive to the specified drive.
<a href="#">Close</a>	Closes the file/s previously opened with the Open statement.
<a href="#">CurDir, CurDir\$</a>	Returns the current system environment path for the specified drive (Drv).
<a href="#">Dir</a>	Returns a file or directory name that matches the given File and Attrib arguments.

<a href="#">EOF</a>	Returns a boolean True or False value during file access that indicates whether the current position of an open file has reached the end of the file.
<a href="#">FileCopy</a>	Copies a file from Src to Dest.
<a href="#">FileLen</a>	Determines the byte length of a file.
<a href="#">FreeFile</a>	Retrieves the next sequential system file number available for association with a file.
<a href="#">Get #</a>	Reads data from a disk file into a variable.
<a href="#">GetAttr</a>	Returns an Integer representing the attribute settings of a file, directory, or volume.
<a href="#">Input</a>	Reads data from a Sequential file and assigns that data to variables. Input function returns characters from a file opened in Input or Binary mode.
<a href="#">Kill</a>	Deletes files from disk.
<a href="#">Line Input #</a>	Reads a single line from an open sequential file and assigns it to a String variable.
<a href="#">Loc</a>	Returns a number indicating the current position within a file opened using the Open statement.
<a href="#">LOF</a>	Returns a number indicating the byte length of a sequential file opened using the Open statement.
<a href="#">MkDir</a>	Creates the directory specified in the Path parameter.
<a href="#">Name</a>	Renames the disk file specified in the OldFileName parameter, to the name specified in the NewFileName parameter.
<a href="#">Open</a>	Enables input/output (I/O) to a disk file.
<a href="#">Print (function)</a>	Displays a message in the Plant SCADA Kernel and the Cicode Editor output window.
<a href="#">Print #</a>	Reads data from OutputList and writes that data to a sequential file.
<a href="#">Put #</a>	Writes data from a variable to a disk file.
<a href="#">RmDir</a>	Deletes the directory specified in the Path parameter.
<a href="#">Seek</a>	Sets the current position within a file opened using the Open statement, ready for the next read or write action.

Write #	Writes data to a Sequential file opened in output or append mode and reads that data from a list of variables.
---------	--

## ChDir

ChDir statement changes the system environment current directory on the specified drive.

The parameter Path must be a string or expression that can represent a valid DOS file structure path value. The parameter Dir must be a string or expression that can represent a valid DOS file structure directory name. The Path and Dir parameters together, must be limited to less than 128 characters. The Path drive letter is optional, unless the directory is on another drive. The required Dir parameter must be a valid directory name.

**Note:** The file system keeps track of the current drive, and the current directory of every drive. Use the [CurDir](#), [CurDir\\$](#) statement to determine the current directory. The current drive letter can be extracted from the Left character returned in the CurDir statement.

The ChDir statement changes the current directory but not the current drive. To change the current drive, use the [ChDrive](#) statement.

## Syntax

**ChDir** *Path* *Dir*

*Path:*

A string or expression that can represent a valid DOS file structure path value. This includes a directory name, and may include a relative or static directory or folder structure and drive letter, in the order:

[<driveletter>:] [\<rootdirectoryname>] [\<subdirectory> ... \<subdirectory>\] directoryname

Note that the path can be relative to the current directory. A single period represents the current directory (.), and two periods represent the parent directory of the current directory (..). For example:

chdir .. ' changes to the parent directory of the current directory

chdir ..\test ' changes to the test subdirectory of the parent directory

*Dir:*

A string or expression that can represent a valid DOS file structure directory name. Dir is not case sensitive. Dir is often used with the Path parameter.

## Related Functions

[ChDrive](#) | [CurDir](#), [CurDir\\$](#) | [Dir](#) | [MkDir](#) | [RmDir](#)

## Example

```
Dim strPath as String
strPath = CurDir()' store current path
ChDir "\"' change to root dir on current drive
<statements>' do stuff in root directory
ChDir strPath' change back to previous path
```

## ChDrive

Changes the system environment current drive to the specified drive.

The parameter *Drv* must be a string or expression that can represent a valid DOS file structure drive letter. The *Drv* may be local to the computer, or mapped from anywhere on the network connected to the computer. If *Drv* contains more than one letter, only the first character is used.

---

**Note:** The file system keeps track of the current drive, and the current directory of every drive. Use the [CurDir](#), [CurDir\\$](#) statement to determine the current directory. The current drive letter can be extracted from the Left character returned in the CurDir statement.

The ChDrive statement changes the current drive but not the current directory on any drive. To change the current directory, use the [ChDir](#) statement.

## Syntax

**ChDrive***Drv*

*Drv*:

A string or expression that can represent a valid DOS file structure drive letter. *Drv* is case insensitive and must end with a colon (:). The *Drv* may be local to the computer, or mapped from anywhere on the network connected to the computer. *Drv* is often included as part of the Path parameter.

## Related Functions

[ChDir](#) | [CurDir](#), [CurDir\\$](#) | [Dir](#) | [RmDir](#) | [MkDir](#)

## Example

```
Dim strCurPath as String
strCurPath = CurDir$()' store current path as string
ChDir "\'" change to root directory of current drive
<statements>' do stuff in root directory
ChDrive "C'" change to C drive (if not already there)
<statements>' do stuff in current directory on C drive
ChDrive strCurPath' change back to previous drive
ChDir strCurPath' change back to previous path
```

## Close

Closes the file(s) previously opened with the Open statement.

The optional *FileNumList* parameter can contain one or more valid file associated reference numbers using the following syntax:

[[#]FileNum] [, [#]FileNum] ...

Where *Filenum* is any valid number associated with an open file.

If the Close statement is used without any arguments it closes all open files. When the Close statement is executed, the association of a file with its file number ends.

## Syntax

### **CloseFileNumList**

*FileNumList:*

Must contain one or more valid integer or numeric expression values representing associated file numbers using the following syntax:

[[#]filenumber] [, [#]filenumber] ... where filenumber is any valid number associated with an open file.

## Related Functions

[FileCopy](#) | [FreeFile](#) | [Name](#) | [Open](#)

## Example

```
Dim strFileContents As String
Dim strTemp As String
Open "c:\test.txt" For Input As #1 ' open file.
Do While Not EOF(1) ' loop until end of file
    strTemp = Input(10, #1) ' read next ten characters
    strFileContents = strFileContents & strTemp ' join strings
Loop
Close #1
```

## CurDir, CurDir\$

Both CurDir and CurDir\$ functions return the current system environment path for the specified drive (*Drv*).

The parameter *Drv* must be a string or expression that can represent a valid DOS file structure drive letter. The *Drv* may be local to the computer, or mapped from anywhere on the network connected to the computer. If *Drv* contains more than one letter, only the first character is used.

---

**Note:** The file system keeps track of the current drive, and the current directory of every drive. Use the CurDir statement to determine the current directory. The current drive letter can be extracted from the Left character returned in the CurDir statement.

---

If no *Drv* is specified or if *Drv* is a zero-length string (" "), CurDir functions return the system environment path for the current drive.

## Syntax

### **CurDir(*Drv*)**

*Drv:*

A string or expression that can represent a valid DOS file structure drive letter. *Drv* is case insensitive and must end with a colon (:). The *Drv* may be local to the computer, or mapped from anywhere on the network connected to the computer. *Drv* is often included as part of the Path parameter.

## Return Value

CurDir returns a Variant containing a string; CurDir\$ returns a String.

## Related Functions

[ChDir](#) | [ChDrive](#) | [Dir](#) | [MkDir](#) | [RmDir](#)

## Example

```
Dim vntCurPath As Variant
Dim strCurPath As String
vntCurPath = CurDir() ' store current path as variant
strCurPath = CurDir$() ' store current path as string
```

## Dir

Dir function returns a file or directory name that matches the given *File* and *Attrib* arguments.

- The *File* argument is optional, and represents a string expression that specifies a valid file name, and may include a DOS path structure including directory or folder names, and a drive letter. You must specify *File* the first time you call the Dir function, or an error occurs.
- The *Attrib* argument is optional, and can be a constant or numeric expression whose sum specifies file attribute values. If you specify file attributes in the function call, *File* must be included. If the Volume attribute value (8) is specified, all other attribute values are ignored.

Dir supports the use of multiple-character (\*) and single-character (?) wildcards to specify multiple files.

Dir returns the first file name that matches both *File* and *Attrib*. To get any additional file names that match, call Dir again with no arguments. When no more file names match, Dir returns a zero-length string (""). Once a zero-length string is returned, you must specify argument/s in the next call (to reset the function), or an error occurs.

Calling Dir with any argument will reset the function, and it will treat the call as a new call. Previous arguments passed to the Dir function are overwritten and forgotten (reset). You can reset the function (by supplying arguments in the function call) at any time, even if it has not yet returned every possible argument match result.

Calling Dir with the Directory attribute (16) does not continually return Directory names. You will need to check the attribute value of every return result to determine if the return is a valid directory name. To do so, use the [GetAttr](#) function. Because file names are retrieved in no particular order, you may want to store returned file names in an array and then sort the array.

---

**Note:** The file system keeps track of the current drive, and the current directory of every drive. Use the [CurDir](#), [CurDir\\$](#) statement to determine the current directory. The current drive letter can be extracted from the Left character returned in the CurDir statement.

---

## Syntax

**Dir(*File*, *Attrib*)**

*File*:

A string or expression that can represent a valid file name, and may include a DOS path structure including

directory or folder names, and a drive letter.

*Attrib:*

A number or expression that can represent a sum of the attribute values of a file . This can be a constant or a numeric expression which includes any combination of attribute numeric values, whose sum specifies all relevant attributes of a file. Where:

0 = Normal

1 = Read Only

2 = Hidden

4 = System

8 = Volume

16 = Directory or Folder

32 = Archive

Possible combinations of values can sum to 0, 1, 2, 3, in fact every number from 0 to 64, each representing a unique combination of attribute values. For example, a file attribute value of 6 represents that the file has both System (4) and Hidden (2) attributes set.

## Return Value

Returns a String representing the name of a file, directory, or folder that matches a specified pattern or file attribute, or the volume label of a drive. If *File* is not found, a zero-length string (" ") is returned. If *Attrib* is omitted, all files are returned that match *File*.

## Related Functions

[ChDir](#) | [ChDrive](#) | [CurDir, CurDir\\$](#) | [MkDir](#) | [RmDir](#)

## Example

```
Dim strCurPath As String ' declare string to store current path
Dim strFileName As String ' declare string to store retrieved file name
Dim intFileCount As Integer ' declare integer to keep count of retrieved files
Dim arrFileList() As String ' declare string array to store file names
strCurPath = CurDir$() ' store current path for later restoration
ChDir "\" ' change to root directory of current drive
strFileName = Dir (*.dat) ' retrieve file name with .dat extension
Do ' initialize loop
    If strFileName = "" Then ' check to see if valid filename returned
        exit do ' exit from loop
    Else
        intFileCount = intFileCount + 1 ' increment file counter variable
        arrFileList(intFileCount) = strFileName ' store file name in array Redim
        arrFileList(intFileCount) ' increase array size to count value
        strFileName = Dir() ' retrieve next file name to match original Dir call
    EndIf
Loop Until strFileName = "" ' loop again
ChDir strCurPath ' restore previous current directory
```

## EOF

EOF function returns a Boolean True or False value during file access that indicates whether the current position of an open file has reached the end of the file. The required FileNum argument must contain an Integer representing any valid system file number associated with an open file.

---

**Note:** The file system keeps track of all open files and the current position of access within every file. Every statement or function that accesses the data within a file, alters the current position within that file. The Loc function can be used to determine the current position within an open file.

---

Use the LOF and Loc functions instead of EOF when reading binary files with the Input function, or use Get when using the EOF function.

---

**Note:** An error occurs with files opened for Binary access, when the file is read using the Input function until EOF returns True.

---

## Syntax

**EOF(FileNum)**

*FileNum:*

An Integer or numeric expression representing any valid number in the range 1 to 511 inclusive, which is referenced by the file system to be associated with an open file.

## Return Value

Returns an Integer containing the Boolean value False until the end of the file has been reached. Returns True when the end of a file opened for Random or sequential Input has been reached.

## Related Functions

[FileLen](#) | [Loc](#) | [LOF](#) | [Seek](#)

## Example

```
Dim strFileContents as String, strTemp as String
Open "c:\test.txt" For Input As #1 ' open file
Do While Not EOF(1) ' loop until end of file
    strTemp = Input(10, #1) ' read next ten characters
    strFileContents = strFileContents & strTemp ' join strings
Loop
Close #1
```

## FileCopy

Copies a file from *Src* to *Dest*.

The required source file (*Src*) and destination file (*Dest*) arguments must be valid string expressions representing valid file names. *Src* is the file name of the file to copy from. *Dest* is the file name to be copied to. Both *Src* and *Dest* arguments may contain a DOS path structure including directory or folder names, and a drive letter.

If the *Dest* file does not exist, it will be created by the FileCopy statement. If the *Dest* file already exists, it will be overwritten.

The FileCopy statement does not work on a currently open file. Both the *Src* and *Dest* files must be closed before using the FileCopy statement. To close an open file, use the Close statement.

**Note:** The file system keeps track of the current drive, and the current directory of every drive. Use the [CurDir](#), [CurDir\\$](#) statement to determine the current directory. The current drive letter can be extracted from the Left character returned in the CurDir statement.

## Syntax

**FileCopy***Src*, *Dest*

*Src*:

A string or expression that can represent a valid DOS file structure FileName. Src is case insensitive. This may include a relative or static Path including directory or folder structure and drive letter. To specify multiple files, the FileName may consist of multiple-character ( \* ) and single-character ( ? ) wildcards in the file name.

*Dest*:

A string or expression that can represent a valid DOS file structure FileName. Dest is case insensitive. This may include a relative or static Path including directory or folder structure and drive letter. To specify multiple files, the FileName may consist of multiple-character ( \* ) and single-character ( ? ) wildcards in the file name.

## Related Functions

[Close](#) | [FreeFile](#) | [Kill](#) | [Name](#) | [Open](#)

## Example

```
Dim SourceFile as String, DestinationFile as String
SourceFile = "SRCFILE.Dat" ' Define source file name.
DestinationFile = "DESTFILE.Dat" ' Define target file name.
FileCopy SourceFile, DestinationFile ' Copy source to target.
```

## FileLen

FileLen function determines the byte length of a file. The required *File* argument must be valid string expression representing a valid file name. *File* may contain a DOS path structure including directory or folder names, and a drive letter.

The FileLen function returns the size of a file immediately before it was most recently opened. To obtain the length of a file that is already open, use the LOF function.

## Syntax

**FileLen**(*File*)

*File*:

A string or expression that can represent a valid file name, and may include a DOS path structure including directory or folder names, and a drive letter.

## Return Value

Returns a Long value representing the length of the file measured in bytes.

## Related Functions

[EOF](#) | [Loc](#) | [LOF](#) | [Seek](#)

## Example

```
Dim lonFileSize As Long
lonFileSize = FileLen("C:\TESTFILE.txt") ' returns length of file
in bytes
```

## FreeFile

Retrieves the next sequential system file number available for association with a file. Use the FreeFile function to retrieve an unassociated file number from the file system. This number can be used by the Open statement to be associated with a file.

## Syntax

**FreeFile**

## Return Value

Returns an Integer reference number ready for being associated with a file.

## Related Functions

[Close](#) | [FileCopy](#) | [Kill](#) | [Name](#) | [Open](#)

## Example

```
Dim intFileNum as Integer
intFileNum = FreeFile 'retrieve next free file number
Open "c:\TEST.txt" For Output As #intFileNum
Write #intFileNum, "This is a sample line of text."
Close #intFileNum
```

## Get #

Get statement reads data from a disk file into a variable.

The required *FileNum* argument is a system reference number associated with an open file. The optional *RecNum* argument is the byte position where the read starts for files opened in Binary mode. If you omit *RecNum*, the next record or byte following the last Get or Put statement (or pointed to by the last Seek function) is read. You

must include delimiting commas.

The required *VarName* is the name of the variable where the file data is read (copied) to.

### Random mode

For files opened in Random mode, the following rules apply:

- If the length of the data being read is less than the length specified in the *Len* clause of the Open statement, Get reads subsequent records on record-length boundaries. The space between the end of one record and the beginning of the next record is padded with the existing contents of the file buffer. Because the amount of padding data can't be determined with any certainty, it is generally a good idea to have the record length match the length of the data being read.
- If the variable being read into is a variable-length string, Get reads a 2-byte descriptor containing the string length and then reads the data that goes into the variable. Therefore, the record length specified by the *Len* clause in the Open statement must be at least 2 bytes greater than the actual length of the string.
- If the variable being read into is a Variant of numeric type, Get reads 2 bytes identifying the VarType of the Variant and then the data that goes into the variable. For example, when reading a Variant of VarType 3, Get reads 6 bytes: 2 bytes identifying the Variant as VarType 3 (Long) and 4 bytes containing the Long data. The record length specified by the *Len* clause in the Open statement must be at least 2 bytes greater than the actual number of bytes required to store the variable.

---

**Note:** You can use the Get statement to read a Variant array from disk, but you can't use Get to read a scalar Variant containing an array. You also can't use Get to read objects from disk.

---

- If the variable being read into is a Variant of VarType 8 (String), Get reads 2 bytes identifying the VarType, 2 bytes indicating the length of the string, and then reads the string data. The record length specified by the *Len* clause in the Open statement must be at least 4 bytes greater than the actual length of the string.
- If the variable being read into is a dynamic array, Get reads a descriptor whose length equals 2 plus 8 times the number of dimensions, that is,  $2 + 8 * \text{NumberOfDimensions}$ . The record length specified by the *Len* clause in the Open statement must be greater than or equal to the sum of all the bytes required to read the array data and the array descriptor. For example, the following array declaration requires 118 bytes when the array is written to disk.
- If the variable being read into is a fixed-size array, Get reads only the data. No descriptor is read.
- If the variable being read into is any other type of variable (not a variable-length string or a Variant), Get reads only the variable data. The record length specified by the *Len* clause in the Open statement must be greater than or equal to the length of the data being read.

Get reads elements of user-defined types as if each were being read individually, except that there is no padding between elements. On disk, a dynamic array in a user-defined type (written with Put) is prefixed by a descriptor whose length equals 2 plus 8 times the number of dimensions, that is,  $2 + 8 * \text{NumberOfDimensions}$ . The record length specified by the *Len* clause in the Open statement must be greater than or equal to the sum of all the bytes required to read the individual elements, including any arrays and their descriptors.

### Binary mode

For files opened in Binary mode, all of the Random rules apply, except:

- The *Len* clause in the Open statement has no effect. Get reads all variables from disk contiguously; that is, with no padding between records.
- For any array other than an array in a user-defined type, Get reads only the data. No descriptor is read.

Get reads variable-length strings that aren't elements of user-defined types without expecting the 2-byte length

descriptor. The number of bytes read equals the number of characters already in the string.

## Syntax

**Get #(*FileNum*, *RecNum*, *VarName*)**

*FileNum*:

An Integer or numeric expression representing any valid number in the range 1 to 511 inclusive, which is referenced by the file system to be associated with an open file.

*RecNum*:

The byte position where the read starts for files opened in Binary mode. If you omit RecNum, the next record or byte following the last Get or Put statement (or pointed to by the last Seek function) is read.

*VarName*:

A string representing a valid variable name.

## Related Functions

[GetAttr](#) | [Input](#) | [Line Input #](#) | [Print #](#) | [Put #](#) | [Write #](#)

## Example

```
Type Record ' Define user-defined type.  
ID As Integer  
Name As String * 20  
End Type  
  
Dim recRecord As Record  
Dim intPosition As Integer  
Dim intFileNum as Integer  
intFileNum = FreeFile 'retrieve next free file number  
' Open sample file for random access.  
Open "TESTFILE.txt" For Random As #intFileNum  
' Read the sample file using the Get statement.  
intPosition = 3 ' Define third record number.  
Get #intFileNum, intPosition, recRecord ' Read third record.  
Close #intFileNum ' Close file.
```

## GetAttr

GetAttr function returns an Integer representing the attribute settings of a file, directory, or volume.

The required *File* argument must be valid string expression representing a valid file name. *File* may contain a DOS path structure including directory or folder names, and a drive letter.

To determine which attributes are set, use the **AND** operator to perform a bitwise comparison of the value returned by the GetAttr function and the value of the individual file attribute you want. If the result is not zero, that attribute is set for the named file. For example, the return value of the following **AND** expression is zero if the Archive attribute is not set:

```
Const AttrArchive = 32  
Result = GetAttr(FileName) And AttrArchive ' A nonzero value is returned if the Archive
```

attribute is set.

## Syntax

### **GetAttr(*File*)**

*File*:

A string or expression that can represent a valid file name, and may include a DOS path structure including directory or folder names, and a drive letter.

## Return Value

Returns an Integer number indicating the sum Attribute value of a file, directory, or folder for the *File* argument, where:

- 0 = Normal
- 1 = Read Only
- 2 = Hidden
- 4 = System
- 8 = Volume
- 16 = Directory or Folder
- 32 = Archive

## Related Functions

[Get #](#) | [Line Input #](#) | [Put #](#)

## Example

```
Dim intAttrVal
' Assume file TESTFILE has hidden attribute set.
intAttrVal = GetAttr("TESTFILE.txt") ' Returns 2.
' Assume file TESTFILE has hidden and read-only attributes set.
intAttrVal = GetAttr("TESTFILE.txt") Returns 3.
' Assume MYDIR is a directory or folder.
intAttrVal = GetAttr("MYDIR") ' Returns 16.
```

## Input

*Input #* statement reads data from a Sequential file and assigns that data to variables. *Input* function returns characters from a file opened in Input or Binary mode.

The *Input #* statement has two parameters *FileNum* and *VarList*. The required *FileNum* argument is the associated file number used in the *Open* statement when the file was opened. The required *VarList* argument is a comma delimited list of variables that are assigned values read from the file.

The *Input* function has two parameters: *Num* and *FileNum*. The required *Num* argument is a number or valid numeric expression specifying the number of characters (bytes) to be read from the file. *FileNum* is the

associated file number used in the Open statement when the file was opened.

The file system tracks all open files and the current position of access within every file. Every statement or function that accesses the data within a file, alters the current position within that file. The Loc function can be used to determine the current position within an open file.

Use the LOF and Loc functions instead of EOF when reading binary files with the Input function, or use Get when using the EOF function.

An error occurs with files opened for Binary access, when the file is read using the Input function until EOF returns True.

Data read with the Input # statement has usually been written to a file with the Write # statement. Data read with the Input function has usually been written to a file with the Print # or Put statements.

When saving data to a file for future reading with the Input # statement, use the Write # statement instead of the Print # statement to write the data to the file. Using Write # properly delimits each separate data field, so it can be read back in using Input #. Using Write # also formats the data in a manner that will allow correct read operations in most locales.

## Syntax

**Input #(*FileNum*, *VarList*)**

*FileNum*:

An Integer or numeric expression representing any valid number in the range 1 to 511 inclusive, which is referenced by the file system to be associated with an open file.

*VarList*:

A predefined valid VBA variable name or comma delimited list of valid variable names.

## Return Value

Input # statement returns data record by record from a file opened in Input or Binary mode. Data items in a file must appear in the same order as the variables in *VarList* and match variables of the same data type. If a variable is numeric and the data is not numeric, a value of zero is assigned to the variable.

Input function returns a String containing characters from a file opened in Input or Binary mode. The Input function returns all of the characters it reads, including commas, carriage returns, linefeeds, quotation marks, and leading spaces.

## Related Functions

[Get #](#) | [GetAttr](#) | [Line Input #](#) | [Print #](#) | [Put #](#) | [Write #](#)

## Example

```
Dim strFileContents As String
Dim strTemp As String
Dim strString As String
Dim intFileNum as Integer
Dim intNumber as Integer
intFileNum = FreeFile 'retrieve next free file number
Open "c:\test.txt" For Input As #intFileNum ' open file.
```

```
Do While Not EOF(intFileNum) ' loop until end of file
    strTemp = Input(10, #intFileNum) ' read next ten characters
    strFileContents = strFileContents & strTemp ' join strings
Loop
Input #intFileNum, strString, intNumber ' Read data into two variables.
Close #intFileNum
```

## Kill

Kill statement deletes files from disk.

The required *File* argument must be valid string expression representing a valid file name. *File* may contain a DOS path structure including directory or folder names, and a drive letter.

Kill supports the use of multiple-character (\*) and single-character (?) wildcards to specify multiple files. The Kill statement does not work on a currently open file. To remove a directory use the [RmDir](#) statement.

The file system tracks the current drive and the current directory of every drive. Use the [CurDir](#), [CurDir\\$](#) statement to determine the current directory. The current drive letter can be extracted from the Left character returned in the CurDir statement.

## Syntax

**Kill** *File*

*File*:

A string or expression that can represent a valid file name, and may include a DOS path structure including directory or folder names, and a drive letter.

## Related Functions

[Close](#) | [FileCopy](#) | [FreeFile](#) | [Name](#) | [Open](#)

## Example

```
' Assume TESTFILE is a file containing some data.
Kill "TestFile"

' Delete all Dat files in current directory.
Kill "*.*.Dat"
```

## Line Input #

Line Input # statement reads a single line from an open sequential file and assigns it to a String variable.

The required *FileNum* argument is a system reference number associated with an open file. The required *VarName* is the name of the variable where the file data is read (copied) to.

---

**Note:** The number sign (#) preceding *FileNum* is not optional.

The Line Input # statement reads from a file one character at a time until it encounters a carriage return (Chr(13)) or carriage return-linefeed (Chr(13) + Chr(10)) sequence. Carriage return - linefeed sequences are skipped rather than appended to the character string.

---

**Note:** The file system keeps track of all open files and the current position of access within every file. Every statement or function that accesses the data within a file, alters the current position within that file. The Loc function can be used to determine the current position within an open file.

---

Data read with the Line Input # statement has usually been written to a file with the Print # statement.

## Syntax

**Line Input # FileNum, VarName**

*FileNum:*

An Integer or numeric expression representing any valid number in the range 1 to 511 inclusive, which is referenced by the file system to be associated with an open file.

*VarName:*

A string representing a valid variable name.

## Related Functions

[Get #](#) | [GetAttr](#) | [Input](#) | [Print #](#) | [Put #](#) | [Write #](#)

## Example

```
Dim strTextLine As String
Dim intFileNum As Integer
Open "c:\TEST.txt" For Input As #intFileNum intFileNum = FreeFile
'retrieve next free file number
Do While Not EOF(intFileNum) ' Loop until end of file.
    Line Input #intFileNum, strTextLine ' Read line into variable.
    Print TextLine ' Print line.
Loop
Close #intFileNum
```

## Loc

Loc function returns a number indicating the current position within a file opened using the Open statement.

The required *FileNum* argument must contain an Integer representing any valid number associated with an open file.

## Syntax

**Loc(*FileNum*)**

*FileNum:*

An Integer or numeric expression representing any valid number in the range 1 to 511 inclusive, which is referenced by the file system to be associated with an open file.

## Return Value

Returns a Long representing the current position within a file, the value dependant upon which file access mode the file was opened with:

- If the file was opened in Random mode, the Loc function will return a number representing the last record read from or written to the file.
- If the file was opened in Sequential mode, the Loc function will return a number representing the current byte position in the file divided by 128. (However, information returned by Loc for Sequential files is neither used nor required.)
- If the file was opened in Binary mode, the Loc function will return a number representing the position of the last byte read from or written to the file.

## Related Functions

[EOF](#) | [FileLen](#) | [LOF](#) | [Seek](#)

## Example

```
Dim lonLoc As Long
Dim strLine As String
Open "TESTFILE.txt" For Binary As #1 ' Open file
Do While lonLoc < LOF(1) ' Loop until end of file
    strLine = strLine & Input(1, #1) ' Read character into variable
    lonLoc = Loc(1) ' Get current position within file
Loop
<statements> ' Do stuff with retrieved data
Close #1 ' Close file
```

## LOF

LOF function returns a number indicating the byte length of a sequential file opened using the Open statement.

The required *FileNum* argument must contain an Integer representing any valid number associated with an open file.

---

**Note:** The file system keeps track of all open files and the current position of access within every file. Every statement or function that accesses the data within a file, alters the current position within that file. The Loc function can be used to determine the current position within an open file.

---

The LOF function returns the size of a file that is already open. To obtain the length of a file that is not open, use the FileLen function.

Use the LOF and Loc functions instead of EOF when reading binary files with the Input function.

## Syntax

**LOF(*FileNum*)**

*FileNum*:

An Integer or numeric expression representing any valid number in the range 1 to 511 inclusive, which is

referenced by the file system to be associated with an open file.

## Return Value

Returns a Long representing the size of a file in bytes.

## Related Functions

[EOF](#) | [FileLen](#) | [Loc](#) | [Seek](#)

## Example

```
Dim lonFileSize As Long  
lonFileSize = LOF "C:\TESTFILE.txt" ' returns length of file in bytes
```

## MkDir

The MkDir statement creates the directory specified in the Path parameter.

The required parameter Path must be a string or expression that can represent a valid DOS file structure path value, must contain a directory name, may contain a relative path structure, and may contain a drive letter. The Path parameter must be limited to less than 128 characters.

The MkDir statement is relative to the current directory. If no path structure is provided, the directory is created in the current directory. If no drive is specified, the MkDir statement creates the directory on the current drive.

---

**Note:** The file system keeps track of the current drive, and the current directory of every drive. Use the CurDir statement to determine the current directory. The current drive letter can be extracted from the Left character returned in the CurDir statement.

---

## Syntax

**MkDir Path**

*Path:*

A string or expression that can represent a valid DOS file structure path value. This includes a directory name, and may include a relative or static directory or folder structure and drive letter, in the order:

```
[<driveletter>:] [\<rootdirectoryname>] [\<subdirectory> ...  
\<subdirectory>\] directoryname
```

The path can be relative to the current directory. A single period represents the current directory (.). Two periods represent the parent directory of the current directory(..). For example:

```
chdir .. ' changes to the parent directory of the current directory  
chdir ..\test ' changes to the test subdirectory of the parent directory
```

## Related Functions

[ChDir](#) | [ChDrive](#) | [CurDir, CurDir\\$](#) | [Dir](#) | [RmDir](#)

## Example

```
Dim strPath As String
Dim strDir As String
strPath = CurDir() ' store current path
strDir = "Temp"
ChDir "\" ' change to root dir on current drive
MkDir strDir ' create new directory
ChDir strPath ' change back to previous path
```

## Name

The Name statement renames the disk file specified in the *OldFileName* parameter, to the name specified in the *NewFileName* parameter.

The required parameter *OldFileName* must be valid existing file name, may contain a path structure, and may contain a drive letter.

The *NewFileName* parameter must be a string or expression that can represent a valid DOS file name value, may contain a relative path structure, and may contain a drive letter. The *NewFileName* parameter must be limited to less than 128 characters.

The Name statement uses the file system relative to the current directory. If no path structure is provided, the *NewFileName* file is expected to be in the current directory. If no drive is specified, the Name statement expects the file to be on the current drive.

Using Name, you can move a file from one directory or folder to another. If the path in *NewFileName* exists and is different from the path in *OldFileName*, the Name statement moves the file to the new directory or folder and renames the file, if necessary. If *NewFileName* and *OldFileName* have different paths and the same file name, Name moves the file to the new location and leaves the file name unchanged.

Name does not support the use of multiple-character ( \* ) and single-character (?) wildcards to specify multiple files.

The Name statement does not work on a currently open file. You must close an open file before renaming it.

---

**Note:** The file system keeps track of the current drive, and the current directory of every drive. Use the [CurDir](#), [CurDir\\$](#) statement to determine the current directory. The current drive letter can be extracted from the Left character returned in the CurDir statement.

---

## Syntax

**Name** *OldFileName NewFileName*

*OldFileName*:

A string or expression that can represent a valid file name, and may include a DOS path structure including directory or folder names, and a drive letter.

*NewFileName*:

A string or expression that can represent a valid file name, and may include a DOS path structure including directory or folder names, and a drive letter.

## Related Functions

[Close](#) | [FileCopy](#) | [FreeFile](#) | [Kill](#) | [Open](#)

## Example

```
Dim strNewFileName As String
Dim strOldFileName As String
strOldFileName = "c:\temp\oldfile.txt"
strNewFileName = "newfile.txt"
ChDir "\" ' change to root dir on current drive
Name strOldFileName strNewFileName ' moves file to root dir and renames it
ChDir strPath ' change back to previous path
```

## Open

Open statement enables input/output (I/O) to a disk file.

The required *File* argument must be a valid string expression representing a valid file name. *File* may contain a DOS path structure including directory or folder names, and a drive letter.

The required *Mode* argument must be a valid keyword specifying the file I/O mode: Append, Binary, Input, Output, or Random. If unspecified, the file is opened for Random access.

The optional *Access* argument must be a valid keyword specifying the operations permitted on the open file: Read, Write, or Read Write.

The optional *Lock* argument must be a valid keyword specifying the operations permitted on the open file by other processes: Shared, Lock Read, Lock Write, and Lock Read Write.

The required *FileNum* argument must contain an Integer representing the number that will be associated with the file. This is the file system reference number supplied by the FreeFile statement that can be used in functions such as Get #, Input #, Line Input #, Print #, and Write #. In Binary, Input, and Random modes, you can open a file using a different file number without first closing the file. In Append and Output modes, you must close a file before opening it with a different file number.

---

**Note:** The file system tracks all open files and the current position of access within every file. Every statement or function that accesses the data within a file, alters the current position within that file. The Loc function can be used to determine the current position within an open file.

---

The optional *RecLen* argument must be a number less than or equal to 32,767 (bytes). For files opened for Random access, this value is the record length. For sequential files, this value is the number of characters buffered. The Len clause is ignored if mode is Binary.

You must open a file before any I/O operation can be performed on it. Open allocates a buffer for I/O to the file and determines the mode of access to use with the buffer. If the file is already opened by another process and the specified type of access is not allowed, the Open operation will not succeed and an error message will be generated.

If the file specified by pathname doesn't exist, it is created when a file is opened for Append, Binary, Output, or Random modes.

## Syntax

**Open(*File For Mode Access Lock As #FileNum Len=RecLen*)**

***File:***

A string or expression that can represent a valid file name, and may include a DOS path structure including directory or folder names, and a drive letter.

***Mode:***

A VBA keyword specifying the file I/O mode: Append, Binary, Input, Output, or Random.

***Lock:***

A VBA keyword specifying the operations permitted on the open file by other processes: Shared, Lock Read, Lock Write, and Lock Read Write.

***Access:***

A VBA keyword specifying the operations permitted on the open file: Read, Write, or Read Write.

***FileNum:***

An Integer or numeric expression representing any valid number in the range 1 to 511 inclusive, which is referenced by the file system to be associated with an open file.

***RecLen:***

An Integer or numeric expression representing the byte length of a file record as a number less than or equal to 32,767.

## Related Functions

## Example

```
' The following code opens the file TESTFILE in sequential-input
mode.
Open "TESTFILE" For Input As #1
' Close before reopening in another mode.
Close #1

' This example opens the file in Binary mode for writing
operations only.
Open "TESTFILE" For Binary Access Write As #1
' Close before reopening in another mode.
Close #1

' The following example opens the file in Random mode. The file
contains records of the user-defined type Record.
Type Record ' Define user-defined type.
ID As Integer
Name As String * 20
End Type
Dim recRecord As Record ' Declare variable.
Open "TESTFILE" For Random As #1
' Close before reopening in another mode.
Close #1

' This code example opens the file for sequential output; any
process can read or write to file.
Open "TESTFILE" For Output Shared As #1
```

```
' Close before reopening in another mode.  
Close #1  
  
' This code example opens the file in Binary mode for reading;  
other processes can't read file.  
Open "TESTFILE" For Binary Access Read Lock Read As #1  
' Close before reopening in another mode.  
Close #1
```

## Print (function)

Displays a message in the Runtime Kernel, and the Cicode Editor output window if you are in debug mode.

**Note:** Do not confuse this function with the [Print #](#) statement, which prints data to disk.

## Related Functions

[TraceMsg](#) (Cicode function)

## Print #

Print # statement reads data from *OutputList* and writes that data to a sequential file.

The Print # statement has two parameters *FileNum* and *OutputList*. The required *FileNum* argument is the associated file number used in the Open statement when the file was opened. The required *OutputList* argument is a delimited list of expressions whose values are written to the file.

**Note:** The number sign hash character (#) preceding *FileNum* is not optional. This character indicates disk file access with the file referenced by the system file number that follows it. Do not confuse Print # which prints to disk, with Print which displays data on the screen.

Data written with Print # is usually read from a file with Line Input # or Input.

**Note:** If you want to read the data from a file using the Input # statement, use the Write # statement instead of the Print # statement to write the data to the file. Using Write # properly delimits each separate data field, so it can be read back in using Input #. Using Write # also formats the data in a manner that will allow correct read operations in most locales.

If you omit expressionlist, the Print # statement prints a blank line in the file, but you must include the comma. Because Print # writes an image of the data to the file, you must delimit the data so it is printed correctly. If you use commas as delimiters, Print # also writes the blanks between print fields to the file.

The Print # statement usually writes Variant data to a file the same way it writes any other data type. However, there are some exceptions:

If the data being written is a Variant of VarType 0 (Empty), Print # writes nothing to the file for that data item.

If the data being written is a Variant of VarType 1 (Null), Print # writes the literal #NULL# to the file.

If the data being written is a Variant of VarType 7 (Date), Print # writes the date to the file using the Short Date format defined in the WIN.INI file. When either the date or the time component is missing or zero, Print # writes only the part provided to the file.

## Syntax

**Print #**FileNum, *OutputList*

*FileNum*:

An Integer or numeric expression representing any valid number in the range 1 to 511 inclusive, which is referenced by the file system to be associated with an open file.

*OutputList*:

One or more formatted numeric and/or string expressions to be written to the file using the following syntax:

[ {Spc( s ) | Tab [( n ) ] } ] [expression] [charpos]

Where:

[ ] square brackets are used for illustrative purposes to indicate in the code that the arguments they enclose are optionally used in the *OutputList*. Do not use the square brackets themselves in your code.

{ } curly braces are required to encompass and delineate the arguments they enclose, and to separate their contents from the other arguments in the *OutputList*.

( | ) vertical line are used for illustrative purposes to indicate in the code that either side of the line is an alternative argument. You can use the argument provided on one of the line or the other, but not both arguments at the same time within the same set of curly braces. Do not include the vertical line in your code.

{Spc(s)} argument is optionally used to insert 's' number of space characters in the output file at the position of the argument in the *OutputList*. The *Spc* argument must be enclosed by curly braces to delineate it from an *expression*. The *Spc* argument can be repeated any number of times to insert spaces in the file between *expressions*. The *Spc* argument is mutually exclusive with the *Tab* argument when used within the same set of curly braces.

{Tab(n)} argument is optionally used to position the insertion point to an absolute column number in the output file at the position of the argument in the *OutputList*, where 'n' is the column number. Use *Tab*with no argument to position the insertion point at the beginning of the next print zone. The *Tab* argument must be enclosed by curly braces to delineate it from an *expression*. The *Tab* argument can be repeated any number of times to insert tabs in the file between *expressions*. The *Tab* argument is mutually exclusive with the *Spc* argument when used within the same set of curly braces.

*expression* argument represents a valid numeric or string expression to output to the file. The *expression* argument can be repeated any number of times.

*charpos* is the character that determines the position of the next character in the output. A semicolon means the next character is printed immediately after the last character; a comma means the next character is printed at the start of the next print zone. Print zones begin every 14 columns. If neither character is specified, the next character is printed on the next line.

## Return Value

Input # statement returns data record by record from a file opened in Input or Binary mode. Data items in a file must appear in the same order as the variables in *VarList* and match variables of the same data type. If a variable is numeric and the data is not numeric, a value of zero is assigned to the variable.

## Related Functions

[Get #](#) | [GetAttr](#) | [Input](#) | [Line Input #](#) | [Put #](#) | [Write #](#)

## Example

The following example writes data to a test file.

```
Dim I, FNum, FName ' Declare variables.  
For I = 1 To 3  
FNum = FreeFile ' Determine next file number.  
FName = "TEST" & FNum  
Open FName For Output As FNum ' Open file.  
Print #1, "This is test #" & I ' Write string to file.  
Print #1, "Here is another "; "line"; I  
Next I  
Close ' Close all files.  
The following example writes data to a test file and reads it back.  
Dim FileData, Msg, NL ' Declare variables.  
NL = Chr(10) ' Define newline.  
Open "TESTFILE" For Output As #1 ' Open to write file.  
Print #1, "This is a test of the Print # statement."  
Print #1, ' Print blank line to file.  
Print #1, "Zone 1", "Zone 2" ' Print in two print zones.  
Print #1, "With no space between" ; "." ' Print two strings together.  
Close #1  
Open "TESTFILE" for Input As #2 ' Open to read file.  
Do While Not EOF(2)  
Line Input #2, FileData ' Read a line of data.  
Msg = Msg & FileData & NL ' Construct message.  
MsgBox Msg  
Loop  
Close #2 ' Close all open files.  
Kill "TESTFILE" ' Remove file from disk.
```

## Put #

Put # statement writes data from a variable to a disk file.

The required *FileNum* argument is a system reference number associated with an open file.

---

**Note:** The number sign (#) preceding *FileNum* is not optional.

The optional *RecNum* argument is the byte position where the read starts for files opened in Binary mode. The first record or byte in a file is at position 1, the second record or byte is at position 2, and so on. If you omit *RecNum*, the next record or byte following the last Get or Put statement (or pointed to by the last Seek function) is read. You must include delimiting commas.

---

**Note:** The file system keeps track of all open files and the current position of access within every file. Every statement or function that accesses the data within a file, alters the current position within that file. The Loc function can be used to determine the current position within an open file.

The required *VarName* is the name of the variable where the file data is read (copied) from.

Data written with the Put # statement is usually read from a file with the Get # statement.

### Random mode

For files opened in Random mode, the following rules apply:

- If the length of the data being written is less than the length specified in the Len clause of the Open statement, Put writes subsequent records on record-length boundaries. The space between the end of one record and the beginning of the next record is padded with the existing contents of the file buffer. Because the amount of padding data can't be determined with any certainty, it is generally a good idea to have the record length match the length of the data being written. If the length of the data being written is greater than the length specified in the Len clause of the Open statement, an error occurs.
- If the variable being written is a variable-length string, Put writes a 2-byte descriptor containing the string length and then the variable. The record length specified by the Len clause in the Open statement must be at least 2 bytes greater than the actual length of the string.
- If the variable being written is a Variant of a numeric type, Put writes 2 bytes identifying the VarType of the Variant and then writes the variable. For example, when writing a Variant of VarType 3, Put writes 6 bytes: 2 bytes identifying the Variant as VarType 3 (Long) and 4 bytes containing the Long data. The record length specified by the Len clause in the Open statement must be at least 2 bytes greater than the actual number of bytes required to store the variable.

---

**Note:** You can use the Put statement to write a Variant array to disk, but you can't use Put to write a scalar Variant containing an array to disk. You also can't use Put to write objects to disk.

---

- If the variable being written is a Variant of VarType 8 (String), Put writes 2 bytes identifying the VarType, 2 bytes indicating the length of the string, and then writes the string data. The record length specified by the Len clause in the Open statement must be at least 4 bytes greater than the actual length of the string.
- If the variable being written is a dynamic array, Put writes a descriptor whose length equals 2 plus 8 times the number of dimensions, that is,  $2 + 8 * \text{NumberOfDimensions}$ . The record length specified by the Len clause in the Open statement must be greater than or equal to the sum of all the bytes required to write the array data and the array descriptor. For example, the following array declaration requires 118 bytes when the array is written to disk.

```
Dim MyArray(1 To 5,1 To 10) As Integer
```

The 118 bytes are distributed as follows: 18 bytes for the descriptor ( $2 + 8 * 2$ ), and 100 bytes for the data ( $5 * 10 * 2$ ).

- If the variable being written is a fixed-size array, Put writes only the data. No descriptor is written to disk.
- If the variable being written is any other type of variable (not a variable-length string or a Variant), Put writes only the variable data. The record length specified by the Len clause in the Open statement must be greater than or equal to the length of the data being written.

Put writes elements of user-defined types as if each were written individually, except there is no padding between elements. On disk, a dynamic array in a user-defined type written with Put is prefixed by a descriptor whose length equals 2 plus 8 times the number of dimensions, that is,  $2 + 8 * \text{NumberOfDimensions}$ . The record length specified by the Len clause in the Open statement must be greater than or equal to the sum of all the bytes required to write the individual elements, including any arrays and their descriptors.

### Binary mode

For files opened in Binary mode, all of the Random rules apply, except:

- The Len clause in the Open statement has no effect. Put writes all variables to disk contiguously; that is, with no padding between records.
- For any array other than an array in a user-defined type, Put writes only the data. No descriptor is written.
- Put writes variable-length strings that aren't elements of user-defined types without the 2-byte length descriptor. The number of bytes written equals the number of characters in the string. For example, the following statements write 10 bytes to file number 1:

```
VarString$ = String$(10, " ")
```

Put writes variable-length strings that are not elements of user-defined types without the 2-byte length descriptor.

```
Put #1,,VarString$
```

## Syntax

**Put #** *FileNum*, *RecNum*, *VarName*

*FileNum*:

An Integer or numeric expression representing any valid number in the range 1 to 511 inclusive, which is referenced by the file system to be associated with an open file.

*RecNum*:

The byte position where the read starts for files opened in Binary mode. The first record or byte in a file is at position 1, the second record or byte is at position 2, and so on. If you omit RecNum, the next record or byte following the last Get or Put statement (or pointed to by the last Seek function) is read.

*VarName*:

A string representing a valid variable name.

## Related Functions

[Get #](#) | [GetAttr](#) | [Input](#) | [Line Input #](#) | [Put #](#) | [Write #](#)

## Example

```
' This example uses the Put statement to write data to a file.  
' Five records of the user-defined type Record are written to the file.  
Type Record ' Define user-defined type.  
ID As Integer  
Name As String * 20  
End Type  
  
Dim MyRecord As Record, RecordNumber ' Declare variables.  
' Open file for random access.  
Open "TESTFILE" For Random As #1 Len = Len(MyRecord)  
For RecordNumber = 1 To 5 ' Loop 5 times.  
    MyRecord.ID = RecordNumber ' Define ID.  
    MyRecord.Name = "My Name" & RecordNumber ' Create a string.  
    Put #1, RecordNumber, MyRecord ' Write record to file.  
Next RecordNumber  
Close #1 ' Close file.
```

## RmDir

The RmDir statement deletes the directory specified in the *Path* parameter.

The required parameter *Path* must be a string or expression that can represent a valid DOS file structure path value, must contain a directory name, may contain a relative path structure, and may contain a drive letter. The

*Path* parameter must be limited to less than 128 characters.

The RmDir statement is relative to the current directory. If no path structure is provided, the directory is expected to be a subdirectory of the current directory. If no drive is specified, the RmDir statement deletes the directory on the current drive.

The current directory cannot be deleted. To change the current directory to another directory, use the ChDir statement. The directory to be deleted must be empty and contain no files or sub-directories. To delete files in a directory, use the Kill statement.

---

**Note:** The file system keeps track of the current drive, and the current directory of every drive. Use the [CurDir](#), [CurDir\\$](#) statement to determine the current directory. The current drive letter can be extracted from the Left character returned in the CurDir statement.

---

## Syntax

**RmDir** *Path*

*Path*:

A string or expression that can represent a valid DOS file structure path value. This includes a directory name, and may include a relative or static directory or folder structure and drive letter, in the order:

[<driveletter>:] [\<rootdirectoryname>] [\<subdirectory> ...  
\<subdirectory>\] directoryname

---

**Note:** The path can be relative to the current directory. A single period represents the current directory (.). Two periods represent the parent directory of the current directory (..). For example, chdir .. changes to the parent directory of the current directory. chdir ..\test changes to the test subdirectory of the parent directory

---

## Related Functions

[ChDir](#) | [ChDrive](#) | [CurDir](#), [CurDir\\$](#) | [Dir](#) | [MkDir](#)

## Example

```
Dim strDir As String
strDir = CurDir ' retrieve current directory name
Kill "*.*" ' delete all files from current directory
ChDir "\" ' change to root dir on current drive
RmDir strDir ' delete directory
```

## Seek

Sets the current position within a file opened using the Open statement, ready for the next read or write action.

The required *FileNum* argument must contain an Integer representing any valid system file number associated with an open file.

The required *Position* argument must contain an Integer or expression representing a valid number.

---

**Note:** The file system keeps track of all open files and the current position of access within every file. Every statement or function that accesses the data within a file, alters the current position within that file. The [Loc](#) function can be used to determine the current position within an open file.

---

## Syntax

**Seek** *FileNum*, *Position*

*FileNum*:

An Integer or numeric expression representing any valid number in the range 1 to 511 inclusive, which is referenced by the file system to be associated with an open file.

*Position*:

An Integer or expression representing a valid numeric value.

## Related Functions

[EOF](#) | [FileLen](#) | [Loc](#) | [LOF](#)

## Example

```
Open "TESTFILE" For Input As #1 ' Open file for reading.  
For i = 1 To 24 Step 3 ' Loop until end of file.  
    Seek #1, i ' Seek to byte position  
    MyChar = Input(1, #1) ' Read next character of data.  
    Print MyChar 'Print character of data  
Next i  
Close #1 ' Close file.
```

## Write #

Write # statement writes data to a Sequential file opened in output or append mode and reads that data from a list of variables.

The Write # statement has two parameters *FileNum* and *VarList*. The required *FileNum* argument is the associated file number used in the Open statement when the file was opened. The required *VarList* argument is a comma delimited list of variables that are assigned values read from the file.

---

**Note:** The file system keeps track of all open files and the current position of access within every file. Every statement or function that accesses the data within a file, alters the current position within that file. The [Loc](#) function can be used to determine the current position within an open file.

---

Data written to a file with the Write # statement is usually read with the Input # statement.

---

**Note:** When saving data to a file for future reading with the Input # statement, use the Write # statement instead of the Print # statement to write the data to the file. Using Write # properly delimits each separate data field , so it can be read back in using Input #. Using Write # also formats the data in a manner that will allow correct read operations in most locales.

---

## Syntax

**Write #***FileNum*, *VarList*

*FileNum*:

An Integer or numeric expression representing any valid number in the range 1 to 511 inclusive, which is referenced by the file system to be associated with an open file.

**VarList:**

A predefined valid VBA variable name or comma delimited list of valid variable names.

## Related Functions

[Get #](#) | [GetAttr](#) | [Input](#) | [Line Input #](#) | [Print #](#) | [Put #](#)

## Example

```
Dim strFileContents As String
Dim strTemp As String
Dim strString As String
Dim intFileNum as Integer
Dim intNumber as Integer
intFileNum = FreeFile 'retrieve next free file number
Open "c:\test.txt" For Output As #intFileNum ' open file.
Write #intFileNum, "This is a test of the Write # statement."
Close #intFileNum
```

## Math/Trigonometry Functions

VBA math functions are provided to assist with number manipulation and calculation in your formulas.

Mathematical functions can be used in VBA statements, and will (like all other functions), return a value to the caller.

## Numeric Functions

Plant SCADA uses the following predefined numeric functions:

<a href="#">Abs</a>	returns the absolute value of a number (Num ).
<a href="#">Exp</a>	returns base log (e) to the power of (Num ).
<a href="#">Fix</a>	returns the Integer value of a number (Num ).
<a href="#">Int</a>	returns the Integer value of a number (Num ).
<a href="#">Log</a>	returns the natural log of a number (Num ).
<a href="#">Rnd</a>	returns a random value influenced by (Num ).
<a href="#">Sgn</a>	returns a value indicating the Sign of (Num ).
<a href="#">Sqrt</a>	returns the square root value of a number (Num ).

### Abs

Calculates the absolute (positive) value of a number. The absolute value of a number is the number without its sign. Abs does not round the number, and ignores the fractional value of the number.

## Syntax

**Abs(Num)**

*Num:*

An integer or expression representing a valid numeric value.

## Return Value

Returns the absolute value of the number (*Num*) provided in the argument.

The data type of the return value is the same as that of the number argument. However, if the number argument is a Variant of VarType (String) and can be converted to a number, the return value will be a Variant of VarType (Double). If the numeric expression results in a null, Abs returns a null.

## Related Functions

[Sgn](#)

## Example

```
Variable=Abs(-67); ! Sets Variable to 67.  
Variable=Abs(67); ! Sets Variable to 67.
```

## Exp

Calculates the exponential of a number. The exponential is the base of the natural logarithm  $e$  raised to a power ( $e^{\text{Num}}$ ). The Exp function complements the Log function and is sometimes referred to as the antilogarithm.

---

**Note:** The value of the constant  $e$  is approximately 2.71828.

---

## Syntax

**Exp(Num)**

*Num:*

An Integer or expression representing a valid numeric value.

## Return Value

Returns the value equivalent to the base of the natural logarithm ( $e$ ) raised to the power of the number (*Num*) provided in the argument.

## Related Functions

[Log](#)

## Example

```
Variable=Exp(1); ! Sets Variable to 2.7182...
```

## Fix

Calculates the integer portion of a number. Fix does not round the number, and ignores the fractional value of the number.

Fix expects the argument (*Num*) to be a valid numeric value. If the argument value is positive, rounds the *Num* down by dropping any fractional value. If the argument value is negative, rounds the *Num* up to the next integer number greater than or equal to *Num*.

Do not confuse Fix with Int , which rounds a negative argument value (*Num*) down to the next integer number less than or equal to *Num*.

## Syntax

**Fix(*Num*)**

*Num*:

An Integer or expression representing a valid numeric value.

## Return Value

Returns the Integer value of the number (*Num*) provided in the argument.

## Related Functions

[Abs](#) | [Int](#) | [Sgn](#) | [Sqrt](#)

## Example

```
Dim vntVar
vntVar = Fix(99.2) ' returns 99
vntVar = Fix(99.8) ' returns 99
vntVar = Fix(-99.8) ' returns -99
vntVar = Fix(-99.2) ' returns -99
```

## Int

Calculates the integer portion of a number. Int does not round the number, and ignores the fractional value of the number.

Int expects the argument (*Num*) to be a valid numeric value. If the argument value is positive, rounds the *Num* down by dropping any fractional value. If the argument value is negative, rounds the *Num* down to the next integer number less than or equal to *Num*.

Do not confuse Int with Fix, which rounds a negative argument value (*Num*) up to the next integer number greater than or equal to *Num*.

## Syntax

**Int(Num)**

*Num:*

An Integer or expression representing a valid numeric value.

## Return Value

Returns the integer value of the number (*Num*) provided in the argument. If *Num* contains a Null, Int returns a Null.

## Related Functions

[Abs](#) | [Fix](#) | [Rnd](#) | [Sgn](#) | [Sqrt](#)

## Example

```
Dim vntVar
vntVar = Int(99.2) ' returns 99
vntVar = Int(99.8) ' returns 99
vntVar = Int(-99.8) ' returns -100
vntVar = Int(-99.2) ' returns -100
```

## Log

Calculates the natural logarithm of a number.

Log expects the argument (*Num*) to be a valid numeric value. The argument value must be greater than zero.

The natural logarithm is the logarithm to the base *e*. You can calculate the base-*n* logarithms for any number *X* by dividing the natural logarithm of *X* by the natural logarithm of *n* as follows:

$$\text{Log}_n(X) = \text{Log}(X) / \text{Log}(n)$$

---

**Note:** The value of the constant *e* is approximately 2.71828.

---

## Syntax

**Log(Num)**

*Num:*

An Integer or expression representing a valid numeric value.

## Return Value

Returns the natural log of the number (*Num*) provided in the argument.

## Related Functions

[Exp](#)

## Example

```
Variable=Log(100); ! Sets Variable to 2 (i.e. 100=10 to the power of 2).
```

## Rnd

Generates a decimal fraction number using the optional argument value (*Num*) to determine the sequence of the (random) number generation.

Rnd expects the argument (*Num*) if supplied, to be a valid numeric value.

If *Num* is less than zero, Rnd generates the same number every time, using *Num* as the seed. If *Num* is equal than zero, Rnd repeats the most recently generated number. If *Num* is greater than zero, Rnd generates the next random number in the sequence. If *Num* is not supplied, Rnd generates the next random number in the sequence.

Before calling Rnd, use the Randomize statement without an argument to initialise the random-number generator with a seed based on the system timer.

---

**Note:** The square brackets [ ] in the syntax indicate that the argument is optional.

Do NOT include the square brackets in your code.

---

## Syntax

**Rnd[(*Num*)]**

*Num*:

An Integer or expression representing a valid numeric value.

## Return Value

Returns a (random) decimal fraction number influenced by the (*Num*) provided in the argument. The return value lies in the range of less than 1 but greater than or equal to 0.

## Related Functions

[Randomize](#)

## Example

```
Dim vntRndValue
Randomize ' Initialize random-number generator.
vntRndValue = Int((6 * Rnd) + 1) ' returns a value between 1 and 6
```

## Sgn

Indicates the sign of a number. Sgn does not round the number, and ignores the fractional value of the number. Sgn expects the argument (*Num*) to be a valid numeric value. If *Num* is greater than zero, Sgn returns the value of 1. If *Num* is equal to zero, Sgn returns the value of 0. If *Num* is less than zero, Sgn returns the value of -1.

## Syntax

**Sgn(*Num*)**

*Num*:

An Integer or expression representing a valid numeric value.

## Return Value

Returns a value indicating the Sign (+ or -) value of the (*Num*) provided in the argument.

## Related Functions

[Abs](#) | [Fix](#) | [Int](#) | [Sqrt](#)

## Example

```
Dim vntVal
vntVal = Sgn(99.8) ' returns 1
vntVal = Sgn(-99.8) ' returns -1
vntVal = Sgn(0) ' returns 0
```

## Sqrt

Calculates the square root of a number. Sqrt expects the argument (*Num*) to be a valid numeric value greater than or equal to 0.

## Syntax

**Sqrt(*Num*)**

*Num*:

An Integer or expression representing a valid numeric value.

## Return Value

Returns the square root value of the (*Num*) provided in the argument.

## Related Functions

[Abs](#) | [Fix](#) | [Int](#) | [Sgn](#)

## Example

```
Variable=.Sqrt(4);  
! Sets Variable to 2.
```

## Trigonometric Functions

Plant SCADA uses the following trigonometric functions:

Atn	returns the Arctangent value of a number (Num ).
Cos	returns the Cosine value of angle (Rad ).
Sin	returns the Sine value of angle (Rad ).
Tan	returns the Tangent value of angle (Rad ).

Trigonometry uses angles and ratios, axes, degrees, Pi, radians and angular conversions. VBA supports the use of Decimal numbers by default, as well as Hexadecimal and Octal numbers. See [Numbers](#).

When using numbers in VBA, you must consider the data type of the variables that hold and store the numbers, as well as the behaviour of VBA when dealing with numbers. See .

### Atn

Calculates the trigonometric Arctangent value of a Tangent number.

The Atn function expects the argument (*Num*) to be a valid tangent value between the range of - Pi/2 to + Pi/2 (representing the ratio of the two sides of a right-angle triangle), and calculates the corresponding angle in radians.

Atn is the inverse trigonometric function of Tan (which takes an angle as its argument, and returns the ratio of two sides of a right-angle triangle). Do not confuse Atn with the Cotangent, which is the inverse of a Tangent (1/tangent).

## Syntax

**Atn(*Num*)**

*Num*:

An integer or expression representing a valid numeric value.

## Return Value

Returns the Arctangent value of the angle (*Num*) provided in the argument.

## Related Functions

[Cos](#) | [Sin](#) | [Tan](#)

## Example

```
Dim Msg, Pi' Declare variables.  
Pi = 4 * Atn(1)' Calculate Pi
```

### Cos

Calculates the trigonometric Cosine value of an angle.

The Cos function expects the argument (*Rad*) to be a valid angle value in radians, and calculates the ratio of the two sides of a right-angle triangle on either side of the angle. The ratio is the length of the side adjacent to the angle divided by the length of the hypotenuse.

**Note:** To convert degrees to radians, multiply degrees by Pi/180. To convert radians to degrees, multiply radians by 180/Pi.

## Syntax

**Cos(*Rad*)**

*Rad*:

An angle expressed in radians. It must be a valid numeric value.

## Return Value

Returns the Cosine value of the angle (*Rad*) provided in the argument.

The result lies in the range - 1 to +1.

Cos will return a double.

## Related Functions

[Atn](#) | [Sin](#) | [Tan](#)

## Example

```
Variable=Cos(0.7854); ! Sets Variable to 0.7071...
```

### Sin

Calculates the trigonometric Sine value of an angle. The Sin function expects the argument (*Rad*) to be a valid angle value in radians, and calculates the ratio of two sides of a right-angle triangle. The ratio is the length of the side opposite to the angle divided by the length of the hypotenuse.

To convert degrees to radians, multiply degrees by Pi/180 . To convert radians to degrees, multiply radians by 180/Pi. For more information, see Circle Maths.

## Syntax

**Sin(*Rad*)**

*Rad:*

An angle expressed in radians. Must be a valid numeric value.

## Return Value

Returns the Sine value of the angle (*Rad*) provided in the argument. The result lies in the range - 1 to + 1.

## Related Functions

[Atn](#) | [Cos](#) | [Tan](#)

## Example

```
Variable=Sin(0.7854); ! Sets Variable to 0.7071
```

## Tan

Calculates the trigonometric Tangent value of an angle. The Tan function expects the argument (*Rad*) to be a valid angle value in radians, and calculates the ratio of two sides of a right-angle triangle. The ratio is the length of the side opposite to the angle divided by the length of the side adjacent to the angle.

**Note:** To convert degrees to radians, multiply degrees by Pi/180. To convert radians to degrees, multiply radians by 180/Pi.

## Syntax

**Tan(*Rad*)**

*Rad:*

An angle expressed in radians. Must be a valid numeric value.

## Return Value

Returns the Tangent value of the angle (*Rad*) provided in the argument. Tan will return as a double.

## Example

```
Variable=Tan(1); ! Sets Variable to 1.5574...
```

## Miscellaneous Functions

The miscellaneous functions predefined in VBA are:

<a href="#">Beep statement</a>	Sounds a tone through the computer's speaker.
<a href="#">Randomize statement</a>	Initializes the random number generator.

Rem statement	Used to include explanatory remarks in a program.
SendKeys statement	Sends keystrokes to the active window as if entered at the keyboard.

## Beep

The Beep statement sounds a tone through the computer's speaker. The frequency and duration of the beep depends on the computer's hardware.

## Syntax

Beep

## Related Functions

[SendKeys](#)

## Example

```
If (TestTag_1 <1) OR (TestTag_1 > 100) Then
    Beep
Else
    Startup_AN38.Value = TestTag_1
End If
```

## Randomize

The Randomize statement initializes the random number generator.

It has one optional parameter number. This parameter can be any valid number and is used to initialize the random number generator. If you omit the parameter then the value returned by the Timer event is used as the default parameter to seed the random number generator.

## Syntax

`Randomize[number]`

## Related Functions

[Timer](#)

## Example

```
Dim MValue
' Initialise random-number generator
Randomize
```

```
MValue = Int((6 * Rnd) + 1)  
Print MValue
```

## Rem

Used to include explanatory comments in a program.

## Syntax

**Rem Comment**

*Comment:*

The text of any comment you want to include in the code.

## Example

```
' This is another way to comment  
Rem This is a remark
```

## SendKeys

Sends one or more keystrokes to the active window of the active application as if they had been entered at the keyboard.

The value of the *Wait* argument determines when the SendKeys function completes and returns control to VBA. If omitted, *Wait* is treated as FALSE by default.

---

**Note:** You can't use SendKeys to send keystrokes to an application that is not designed to run in Microsoft Windows. Sendkeys also can't send the PRINT SCREEN key {PRTSC} to any application..

---

## Syntax

**SendKeys(keys, wait)**

*keys:*

The string that is sent to the active window.

*wait:*

Enter TRUE or FALSE.

If *wait* is true the keystrokes must be processed before control is returned to the calling procedure. This argument is optional. If you omit it, it is assumed to be false.

## Return Value

None

## Example

```
Dim intCounter As Integer ' Declare variables.
```

```

Dim dblProgID As Double, ' Launch Windows Calculator program.
dblProgID = Shell("Calc.exe", 1) ' Set up counting loop.
For intCounter = 1 To 5 ' Send keystrokes to Calculator
    SendKeys intCounter & "{+}", True ' to add the value of intCounter each time
Next intCounter ' Return focus to Calculator.
AppActivate "Calculator" ' Send keystrokes to Close Calculator.
SendKeys "%{F4}", True

```

## Procedural Statements

VBA procedural function statements are provided to assist with conditional code execution and program flow:

<a href="#">Call statement</a>	Transfers control to a Sub procedure, function procedure, or dynamic-link library (DLL) procedure.
<a href="#">Function statement</a>	Declares and defines a procedure that can receive arguments and return a value of a specified data type.
<a href="#">End Function statement</a>	Ends a program or a block of statements within a function.
<a href="#">Sub statement</a>	Declares and defines a Sub procedures name, parameters and code.
<a href="#">End Sub statement</a>	Ends a program or a block of statements within a subroutine.
<a href="#">CicodeCallOpen function</a>	Calls a Cicode function from VBA.
<a href="#">CicodeCallReturn function</a>	Obtains the return value of the most recently completed Cicode function opened with the VBA CicodeCallOpen function.

Cicode functions used to handle VBA functions and statements:

<a href="#">VbCallOpen Function function</a>	Opens a VBA function or subroutine from Cicode.
<a href="#">VbCallRun Function function</a>	Runs the opened VBA function or subroutine from Cicode.
<a href="#">VbCallReturn Function function</a>	Obtains the return value of the completed VBA function previously opened with the Cicode VbCallOpen function.

### Call

The Call Statement transfers control to a Sub procedure, Function procedure, or dynamic-link library (DLL) procedure.

The required *ProcedureName* is the name of the function or subroutine to call. The optional *Parameters* is the list of arguments to pass to the called function or subroutine.

You are not required to use the Call statement when calling an VBA subroutine or a DLL function. Parentheses must be used in the argument list if the Call statement is being used.

## Syntax

**Call ProcedureName[Parameter(s)]**

## Related Functions

[End Function](#) | [Sub](#) | [End Sub](#) | [Exit](#)

## Example

```
Call Beep
```

### CicodeCallOpen

The CicodeCallOpen function is used to call a Cicode function from VBA. It is used to initiate and execute a call to the Cicode function and returns an integer value representing either an error code or the success of this VBA function making the call.

**Note:** This VBA function does not return the actual return-value of the Cicode function being called. You can obtain that return value by using the associated [CicodeCallReturn](#) function.

#### **WARNING**

##### **UNINTENDED EQUIPMENT OPERATION**

Do not nest the CicodeCallOpen and CicodeCallReturn functions. Nesting these functions can lead to unintended equipment operation when your program is run.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

For details, see *Calling Cicode from VBA* in the topic Using VBA in Command or Expression Fields.

## Syntax

*ReturnValue* = **CicodeCallOpen(FunctName, ArgList)**

*ReturnValue*:

The return value for the function in the range of 0 to 3.

*FunctName*:

The name of the Cicode function being called.

*Arglist*:

A variable length comma separated argument list of all the arguments to be passed to the Cicode function being opened (dependant upon which Cicode function is being called and the arguments that Cicode function requires). The argument list should not be enclosed within brackets, although when using variable names as arguments, those variable arguments within the list need to be individually enclosed within brackets to force the

passing of the variable to Cicode by value.

## Return Value

CicodeCallOpen returns a integer data type containing a value in the range of 0 to 3:

- 0 if CicodeCallOpenfunction was successful
- 1 for CicodeCallOpenfunction general error
- 2 for specified Cicode function not found
- 3 for incorrect number of arguments for specified Cicode function passed in <ArgList>.

## Related Functions

[CicodeCallReturn](#)

## Example

In the following example, a VBA variable is enclosed in brackets to force the passing of the variable by value. See [Passing Variables Byref and Byval](#).

```
Dim vntRet as Variant
' declare modular variant variable to store function results
Function TestCicode() As Integer
' declare local variables
Dim intRet As Integer
Dim strReply as String
Dim intMaxScale as Integer
' copy current tag value to variable
' uses the project variable tag named MAX_SCALE
intMaxScale = MAX_SCALE
' call Cicode function
' for example: TrnSetScale( AN, Pen, Percent, Scale)
intRet = CicodeCallOpen( "TrnSetScale", 53, -1, 100, (IntMaxScale)
)
' Note the syntax used:
' - brackets around the VBA function argument list.
' (This is only necessary when the VBA function is preceded
by an equals (=) sign .)
' - double quotes around the Cicode function name
' - no brackets around the Cicode function argument list
' - brackets around individual variable arguments
' test results
If intRet = 0 Then
'
    ' insert code for successful completion here
'

    vntRet = CicodeCallReturn()
    strReply = "CicodeCallOpen Function successfully called"
Else
'
    ' insert code for unsuccessful completion here
'
```

```
Select Case intRet
Case = 1
    ' assign return comment for this case
    strReply = "CicodeCallOpen Function call error (unsuccessful)"
Case = 2
    ' assign return comment for this case
    strReply = "Cicode Function not found"
Case = 3
    ' assign return comment for this case
    strReply = "Wrong number of arguments "_
    & "in Cicode CallOpen function call"
Case Else
    ' assign return comment for this case
    strReply = "Unknown error"
End Select
End If
' display return comment for your information
MsgBox strReply
' assign return value for this function
TestCicode = intRet
End Function
```

## CicodeCallReturn

The CicodeCallReturn function is used to obtain the return value of the most recently completed Cicode function opened and run with the VBA CicodeCallOpen function.

No arguments are passed to the CicodeCallReturn function, as it will return the result of the most recent return-value for the Cicode function called by the VBA CicodeCallOpen function.

The CicodeCallReturn function should be used in its own separate line of VBA code and must not be nested with the CicodeCallOpen function. For details, see *Calling Cicode from VBA* in the topic Using VBA in Command or Expression Fields.

## Syntax

*ReturnValue* = **CicodeCallReturn()**

*ReturnValue*:

The return value of the Cicode function specified in the most recent call of the CicodeCallOpen function. Note that the return data type of CicodeCallReturn will depend upon the return data type of the completed Cicode function most recently called by the CicodeCallOpen function.

## Return Value

CicodeCallReturn returns the return-value of the completed Cicode function most recently called by the CicodeCallOpen function.

## Related Functions

[CicodeCallOpen](#)

## Example

```
' declare modular variant variable to store function results
Dim vntRet as Variant
Function TestCicode() As Integer
    ' declare local variables
    Dim intRet As Integer
    Dim strReply as String
    Dim intMaxScale as Integer
    ' copy current tag value to variable
    ' uses the project variable tag named MAX_SCALE
    intMaxScale = MAX_SCALE
    ' call Cicode function
    ' for example: TrnSetScale( AN, Pen, Percent, Scale)
    intRet = CicodeCallOpen( "TrnSetScale", 53, -1, 100, (IntMaxScale)
)
    ' Note the syntax used:
    ' - brackets around the VBA function argument list
    ' - double quotes around the Cicode function name
    ' - no brackets around the Cicode function argument list
    ' - brackets around individual variable arguments
    ' test results
    If intRet = 0 Then
        '
        ' insert code for successful completion here
        '
        vntRet = CicodeCallReturn()
        strReply = "CicodeCallOpen Function successfully called"
    Else
        '
        ' insert code for unsuccessful completion here
        '

        Select Case intRet
        Case = 1
            ' assign return comment for this case
            strReply = "CicodeCallOpen Function call error (unsuccessful)"
        Case = 2
            ' assign return comment for this case
            strReply = "Cicode Function not found"
        Case = 3
            ' assign return comment for this case
            strReply = "Wrong number of arguments " _
                & "in Cicode CallOpen function call"
        Case Else
            ' assign return comment for this case
            strReply = "Unknown error"
        End Select
    End If
    ' display return comment for your information
    MsgBox strReply
    ' assign return value for this function
    TestCicode = intRet
End Function
```

## End Function

The End Function statement ends a program or a block of statements within a function. A VBA function starts with the FUNCTION statement and finishes with the END FUNCTION statement. All other statements that lie between the FUNCTION and END FUNCTION statements will be executed by the function when called to do so.

## Syntax

**End {Function | Sub | If}**

## Related Functions

[Call](#) | [Sub](#) | [End Sub](#) | [Exit](#)

## Example

```
Function GetColor2( c% ) As Long
    GetColor2 = c% * 25
    If c% > 2 Then
        GetColor2 = 255 ' 0x0000FF - Red
    End If
    If c% > 5 Then
        GetColor2 = 65280 ' 0x00FF00 - Green
    End If
    If c% > 8 Then
        GetColor2 = 16711680 ' 0xFF0000 - Blue
    End If
End Function
Sub TestColor2
    Dim I as integer
    For I = 1 to 10
        Print GetColor2(I)
    Next I
End Sub
```

## End Sub

The End Sub statement ends a program or a block of statements within a subroutine. A VBA subroutine starts with the SUB statement and finishes with the END SUB statement. All other statements that lie between the SUB and END SUB statements, will be executed by the subroutine, when called to do so.

## Syntax

**End Sub**

## Related Functions

[Call](#) | [End Function](#) | [Sub](#)

## Example

```
Function GetColor2( c% ) As Long
GetColor2 = c% * 25
If c% > 2 Then
    GetColor2 = 255 ' 0x0000FF - Red
End If
If c% > 5 Then
    GetColor2 = 65280 ' 0x00FF00 - Green
End If
If c% > 8 Then
    GetColor2 = 16711680 ' 0xFF0000 - Blue
End If
End Function
Sub TestColor2
    Dim I as integer
    For I = 1 to 10
        Print GetColor2(I)
    Next I
End Sub
```

## Function

The **Function** statement declares and defines a function procedure, its name, parameters, and code to be enacted upon when the subroutine is called. Functions differ from subroutines in that functions return a value, whereas subroutines do not.

The required *FunctionName* is the name of the function being declared. The optional *ArgList* is the list of arguments used within the function.

A VBA function starts with the **FUNCTION** statement and finishes with the **END FUNCTION** statement. All other statements that lie between the **FUNCTION** and **END FUNCTION** statements will be executed by the function when called to do so.

## Syntax

**Function** *FunctionName* *[(ArgList)]* *[As type]*

## Related Functions

[Call](#) | [End Function](#) | [Sub](#) | [End Sub](#) |

## Example

```
Function GetColor2( c% ) As Long
GetColor2 = c% * 25
If c% > 2 Then
    GetColor2 = 255 ' 0x0000FF - Red
End If
If c% > 5 Then
    GetColor2 = 65280 ' 0x00FF00 - Green
End If
```

```
If c% > 8 Then
    GetColor2 = 16711680 ' 0xFF0000 - Blue
End If
End Function
Sub TestColor2
    Dim I as integer
    For I = 1 to 10
        Print GetColor2(I)
    Next I
End Sub
```

## Sub

Declares and defines a subroutine procedure, its name, parameters, and code to be enacted upon when the subroutine is called. Subroutines differ from functions in that functions return a value, whereas subroutines do not.

The required *SubroutineName* is the name of the subroutine being declared.

The optional *ArgList* is the list of arguments used within the subroutine.

A VBA subroutine starts with the SUB statement and finishes with the END SUB statement. All other statements that lie between the SUB and END SUB statements, will be executed by the subroutine, when called to do so.

## Syntax

**Sub**

## Related Functions

[Call](#) | [End Function](#) | [End Sub](#) | [Exit](#)

## Example

```
Function GetColor2( c% ) As Long
GetColor2 = c% * 25
If c% > 2 Then
    GetColor2 = 255 ' 0x0000FF - Red
End If
If c% > 5 Then
    GetColor2 = 65280 ' 0x00FF00 - Green
End If

End Function
Sub TestColor2
    Dim I as integer
    For I = 1 to 10
        Print GetColor2(I)
    Next I
End Sub
```

## VbCallOpen Function

The VbCallOpen function is a Cicode function used to call a VBA function or subroutine from Cicode. It is used to initiate a call to the VBA function or subroutine and returns a handle (of OBJECT data type) to that opened function call.

VbCallOpen is used in conjunction with VbCallRun and VbCallReturn functions, which can all be nested to implement the entire function set with a single line of Cicode. For further information, see the section "Calling VBA from Cicode".

## Syntax

*ReturnValue* = **VbCallOpen**(*FunctName*, *ArgList*)

*ReturnValue*:

The handle to the opened VBA function.

*FunctName*:

The name of the VBA function or subroutine being called.

*ArgList*:

A comma separated list of arguments to pass to the function or subroutine being called.

## Return Value

VbCallOpen returns an Object data type containing a handle to the VBA function being called. If the function cannot open the VBA function or subroutine the return value is zero.

## Related Functions

[VbCallRun Function](#) | [VbCallReturn Function](#)

## Example

```
FUNCTION
TestCitectVBA()
INT iRet;
STRING sMsg = "Hello";
INT iVal = 123;

iRet = VbCallReturn(VbCallRun(VbCallOpen("CiVBATest",
iVal)));
Message("TestCitectVBA Function", "CiVBATest = " +
IntToStr(iRet), 0);
END
```

## Example

```
Function CiVBATest(Value As Integer) As Integer
CiVBATest = Value * 2
End Function
```

## VbCallReturn Function

Used to obtain the return value of the completed VBA function (previously opened with the Cicode VbCallOpen function), and requires the handle returned from the VbCallRun function call.

VbCallReturn is used in conjunction with VbCallOpen and VbCallRun functions, which can all be nested to implement the entire function set with a single line of Cicode. For details, see *Calling VBA from Cicode* in the topic Using VBA in Command or Expression Fields.

## Syntax

*ReturnValue* = **VbCallReturn**(*CallHandle*)

*ReturnValue*:

The value returned by the completed VBA function (which was previously opened by the Cicode VbCallOpen function). The data type of the return value is dependent upon the data type of the return value for the VBA function opened.

*CallHandle*:

The handle to the previously opened VBA function as returned by the Cicode VbCallRun function

## Return Value

VbCallReturn returns the completed return value for the VBA function.

## Related Functions

[VbCallOpen Function](#) | [VbCallRun Function](#)

## Example 1

```
FUNCTION
TestCitectVBA()
INT iRet;
STRING sMsg = "Hello";
INT iVal = 123;

iRet = VbCallReturn(VbCallRun(VbCallOpen("CiVBATest",
iVal)));
Message("TestCitectVBA Function", "CiVBATest = " +
IntToStr(iRet), 0);
END
```

## Example 2

```
Function CiVBATest(Value As Integer) As Integer
CiVBATest = Value * 2
End Function
```

## Example 3

```
FUNCTION VBA_from_Cicode()
    INT iRet;
    WHILE TRUE DO
        iRet = TestFunc("TestVBA")
        Sleep(5);
    END
END
INT FUNCTION TestFunc(STRING sFun)
    RETURN VbCallReturn(VbCallRun(VbCallOpen(sFun)));
END
```

## VbCallRun Function

Used to execute the VBA function or subroutine (previously opened with the Cicode VbCallOpen function), and requires the handle returned from the VbCallOpen function call.

The VbCallRun function provides an opportunity for the opened VBA function to complete and return a value in the multi-threaded Plant SCADA environment. It passes its argument value (of OBJECT data type) through as its return value upon completion.

VbCallRun is used in conjunction with VbCallOpen and VbCallReturn functions, which can all be nested to implement the entire function set with a single line of Cicode. For details, see *Calling VBA from Cicode* in the topic Using VBA in Command or Expression Fields.

## Syntax

*ReturnValue* = **VbCallRun**(*CallHandle*)

*ReturnValue*:

The handle to the opened VBA function passed in as *CallHandle*.

*CallHandle*:

The handle to the previously opened VBA function as returned by the VbCallOpen function.

## Return Value

VbCallRun (passes through and) returns a Object data type containing a handle to the VBA function being called.

## Related Functions

[VbCallOpen Function](#) | [VbCallReturn Function](#)

## Example

```
FUNCTION
TestCitectVBA()
INT iRet;
STRING sMsg = "Hello";
INT iVal = 123;
```

```
iRet = VbCallReturn(VbCallRun(VbCallOpen("CiVBATest",
iVal)));
Message("TestCitectVBA Function", "CiVBATest = " +
IntToStr(iRet), 0);
END
```

## Example

```
Function CiVBATest(Value As Integer) As Integer
CiVBATest = Value * 2
End Function
```

## String Functions

VBA strings functions are provided to create, edit and implement strings within VBA code. The strings functions predefined in VBA are:

<a href="#">Asc</a>	Returns a numeric value that is the ASCII code for the first character in a string.
<a href="#">Chr</a>	Converts an ASCII number to a one character string.
<a href="#">InStr</a>	Returns the character position of the first occurrence of string2 within string1.
<a href="#">LCase</a>	Returns a copy of string in which all characters have been converted to lowercase.
<a href="#">Left, Left\$</a>	Returns the left most characters of a string parameter.
<a href="#">Len</a>	Determines the number of characters in the string argument.
<a href="#">Line Input #</a>	Reads a single line from an open sequential file and assigns it to a string variable.
<a href="#">LTrim</a>	Strips any leading spaces from a string variable.
<a href="#">Mid</a>	Returns a substring within a string.
<a href="#">Option Compare</a>	Determines the default string comparison method.
<a href="#">Option Explicit</a>	Forces explicit declaration of all variables.
<a href="#">Right</a>	Returns the right most characters of a string parameter.
<a href="#">RTrim</a>	Strips any trailing spaces from a string variable.
<a href="#">Space</a>	Adds a specified number of spaces in a print statement.

<a href="#">StrComp</a>	Returns a variant that is the result of the comparison of two strings.
<a href="#">String</a>	Create a string that consists of one character repeated a specific number of times.
<a href="#">Trim</a>	Strips any leading and trailing spaces from Str variable.
<a href="#">UCase</a>	Returns a copy of string in which all characters have been converted to uppercase.

## Asc

Converts a text string character to its numeric ASCII code value. The Asc function expects the argument *Str* to be a valid string expression. If *Str* contains no characters, a runtime error occurs. The Asc function performs the opposite of the [Chr](#) function, which converts a number into its string character ASCII code value.

## Syntax

**Asc(*Str*)**

*Str*:

A string or expression that can represent a valid text value.

## Return Value

Returns the numeric ASCII code value of the first character in *Str* provided in the argument.

## Related Functions

[Chr](#)

## Example

```
Dim vntVar ' declare result holder variable
vntVar = Asc("A")' returns 65
vntVar = Asc("Z")' returns 90
vntVar = Asc("a")' returns 97
vntVar = Asc("z")' returns 122
vntVar = Asc("Apple")' returns 65
vntVar = Asc("Zoe")' returns 90
```

## Chr

Converts a number into its string character ASCII code value.

The Chr function expects the argument *Num* to be a valid numeric integer (whole positive number within the range 0 to 255 inclusive). If *Chr* contains no number, a runtime error occurs.

---

**Note:** Values 8, 9, 10, and 13 convert to backspace, tab, linefeed, and carriage return characters respectively.

The Chr function performs the opposite of the [Asc](#) function, which converts a text string character to its numeric ASCII code value.

## Syntax

**Chr(Num)**

*Num:*

An integer or expression representing a valid numeric value.

## Return Value

Returns a single character string representing the ASCII character code value of the number *Num* provided in the argument.

## Related Functions

[Asc](#)

## Example

```
Dim vntVar ' declare result holder variable
vntVar = Chr(65) ' returns "A"
vntVar = Chr(97) ' returns "a"
vntVar = Chr(90) ' returns "Z"
vntVar = Chr(122) ' returns "z"
```

## InStr

Returns the character position of the first occurrence of *String2* within *String1*.

## Syntax

**InStr(StartPos, StringToSearch, StringToMatch )**

*StartPos:*

A numeric expression that sets the starting position for the search. If omitted, search begins at the first character position. If Num contains Null, an error occurs. An Integer or expression representing a valid numeric value.

*StringToSearch:*

The string expression being searched. A string or expression that can represent a valid text value.

*StringToMatch:*

The string expression being searched for. A string or expression that can represent a valid text value.

## Return Value

Returns a variant containing a Long data type indicating the result of the string search. Returns 0 if:

- *StringToSearch* is of zero length.
- *StringToMatch* is not found.
- *StartPos* is longer than *StringToMatch*.

Returns a value representing the count position where character match was first found.

Returns Null if *StringToSearch* or *StringToMatch* contains null.

## Related Functions

[IsNull](#) | [Left, Left\\$](#) | [Mid](#) | [Right](#) | [StrComp](#)

## Example

```
Dim strToSearch as String
Dim strToFind as String
Dim lngPosition as Long
strToSearch = "Good Bye"
' note this has an uppercase "B"
strToFind = "bye"
' note this has a lowercase "b"
lngPosition = InStr(1, strToSearch, strToFind, 0)
' returns 0 (Did not find match)
lngPosition = InStr(1, strToSearch, strToFind, 1)
' returns 6 (Position of first character in match)
```

## LCase

Converts all uppercase letters in *Str* to lowercase letters. All lowercase letters and non-letter characters remain unchanged.

## Syntax

**LCase(*Str*)**

*Str*:

A string or expression that can represent a valid text value.

## Return Value

Returns a string.

## Related Functions

[UCase](#)

## Example

```
Dim strMixedCase as String
Dim strLowerCase as String
Dim strUpperCase as String
strMixedCase = "AbCdE"
strLowerCase = LCase(strMixedCase) ' returns "abcde"
strUpperCase = UCase(strMixedCase) ' returns "ABCDE"
```

## Left, Left\$

Returns the left most *Num* characters of *Str*.

The required *Str* argument is a String expression from which the leftmost characters are returned. If *Str* contains **Null**, **Null** is returned.

The required *Num* argument is a Variant (Long) numeric expression indicating how many characters to return. If 0, a zero-length string (" ") is returned. If greater than or equal to the number of characters in string, the entire string is returned.

## Syntax

**Left**(*Str*, *Num*)

*Str*:

A string or expression that can represent a valid text value.

*Num*:

An Integer or expression representing a valid numeric value.

## Return Value

The Left function returns a variant containing a String data type. The Left\$ function returns a String.

## Related Functions

[InStr](#) | [Mid](#) | [Right](#)

## Example

```
Dim strGreeting as String
Dim strTest
strGreeting = "Hello World"
strTest = Left(strGreeting, 1) ' Returns "H".
strTest = Left(strGreeting, 7) ' Returns "Hello W".
strTest = Left(strGreeting, 20) ' Returns "Hello World".
```

## Len

The Len function determines the number of characters in the *Str* argument. The LenB function determines the number of bytes in the *VarName* argument.

- The *Str* argument can be any valid string expression. If *Str* contains **Null**, **Null** is returned.
- The *VarName* argument can be any valid variable name. If *VarName* contains **Null**, **Null** is returned. If *VarName* is a Variant, LenB treats it the same as a String and returns the number of characters it contains.

## Syntax

**Len(*Str*)**

*Str*:

A string or expression that can represent a valid text value.

## Return Value

Returns a Long.

## Related Functions

[InStr](#) | [Left](#), [Left\\$](#) | [Mid](#) | [Right](#)

## Example

```
Dim strTest as String
Dim lngStringLength as Long
strTest = "VBA"
lngStringLength = Len(strTest) ' returns 3
```

## Line Input #

Line Input # statement reads a single line from an open sequential file and assigns it to a String variable.

The required *FileNum* argument is a system reference number associated with an open file. The required *VarName* is the name of the variable where the file data is read (copied) to.

---

**Note:** The number sign (#) preceding *FileNum* is not optional.

---

The Line Input # statement reads from a file one character at a time until it encounters a carriage return (Chr(13)) or carriage return-linefeed (Chr(13) + Chr(10)) sequence. Carriage return - linefeed sequences are skipped rather than appended to the character string.

---

**Note:** The file system keeps track of all open files and the current position of access within every file. Every statement or function that accesses the data within a file, alters the current position within that file. The Loc function can be used to determine the current position within an open file.

---

Data read with the Line Input # statement has usually been written to a file with the Print # statement.

## Syntax

**Line Input # FileNum, VarName**

*FileNum:*

An Integer or numeric expression representing any valid number in the range 1 to 511 inclusive, which is referenced by the file system to be associated with an open file.

*VarName:*

A string representing a valid variable name.

## Related Functions

[Get #](#) | [GetAttr](#) | [Input](#) | [Print #](#) | [Put #](#) | [Write #](#)

## Example

```
Dim strTextLine As String
Dim intFileNum As Integer
Open "c:\TEST.txt" For Input As #intFileNum intFileNum = FreeFile
'retrieve next free file number
Do While Not EOF(intFileNum) ' Loop until end of file.
    Line Input #intFileNum, strTextLine ' Read line into variable.
    Print TextLine ' Print line.
Loop
Close #intFileNum
```

## LTrim

Strips any leading spaces from *Str* variable.

## Syntax

**LTrim(*Str*)**

*Str:*

A string or expression that can represent a valid text value.

## Return Value

Returns a string.

## Related Functions

[Trim](#)

## Example

```
Dim strTest as String
Dim strResult as String
Dim lngStartLength as Long
Dim lngFinishLength as Long
strTest = " VBA"
lngStartLength = Len(strTest) ' returns 9
strResult = LTrim(strTest) ' returns "VBA"
lngStringLength = Len(strResult) ' returns 3
```

## Mid

The Mid Function extracts a portion of a string from Str.

---

**Note:** To determine the number of characters in a string, use the Len function.

The *Str* argument can be any valid string expression. If *Str* contains Null, Null is returned.

The required *Num* argument is a Long numeric expression that sets the starting position for the extraction. If *Num* is greater than the number of characters in string, Mid returns a zero-length string ("").

The optional *Len* argument is a Variant containing a Long data type representing the number of characters to return. If omitted or if there are fewer than *Len* characters in *Str* (including the character at position *Num*), all characters from the *Num* position to the end of the string are returned.

## Syntax

**Mid(*Str*, *Num*, *Len*)**

*Str*:

A string or expression that can represent a valid text value. If *Str* contains Null, Null is returned.

*Num*:

A Long numeric expression that sets the starting position for the extraction. If *Num* is greater than the number of characters in string, Mid returns a zero-length string ("").

*Len*:

A Variant containing a Long data type representing the number of characters to return. If omitted or if there are fewer than *Len* characters in *Str* (including the character at position *Num*), all characters from the *Num* position to the end of the string are returned.

## Return Value

The Mid function returns a Variant (containing a String data type).

## Related Functions

[InStr](#) | [Left](#), [Left\\$](#) | [Right](#)

## Example

```
Dim strSource as String
Dim strFirstWord as String
Dim strSecondWord as String
Dim strThirdWord as String
Dim lngPosition as Long
Dim lngNextPosition as Long
Dim lngWordLength as Long
strSource = "Mid Function Demo" ' Create test string.
lngPosition = 1 ' Start at character position 1
lngNextPosition = Instr(lngPosition, strSource, " ") ' Locate first space character
lngWordLength = lngNextPosition - lngPosition ' calculate word length
strFirstWord = Mid(strSource, lngPosition, lngWordLength) ' Returns first word "Mid"
lngPosition = lngNextPosition + 1 ' Move to next word position
lngNextPosition = Instr(lngPosition, strSource, " ") ' Locate next space character
lngWordLength = lngNextPosition - lngPosition ' calculate word length
strSecondWord = Mid(strSource, lngPosition, lngWordLength) ' Returns second word
"Function"
lngPosition = lngNextPosition + 1 ' Move to next word position
lngNextPosition = Instr(lngPosition, strSource, " ") ' Locate next space character
lngWordLength = lngNextPosition - lngPosition ' calculate word length
strThirdWord = Mid(strSource, lngPosition, lngWordLength) ' Returns third word
"Demo"
```

## Option Compare

Determines how strings are compared within a VBA module. The optional Option Compare statement if used, must be placed at the top of the VBA file along with any other Option declarations.

If an Option Compare statement is not included, the default text comparison method is Binary.

## Syntax

**Option Compare {Binary | Text}**

## Related Functions

[InStr](#) | [StrComp](#)

## Example

```
Option Compare Binary
Dim vntResult as Variant
vntResult = StrComp("VBA rules!", "vba Rules!")
' returns 1 (strings unequal)
```

## Example

```
Option Compare Text
Dim vntResult as Variant
```

```
vntResult = StrComp("VBA rules!", "vba Rules!")
' returns 0 (strings equal)
```

## Option Explicit

Forces explicit declaration of all variables.

The optional Option Explicit statement if used, must be placed at the top of the VBA file. This causes a check of variable declarations at compile time. Setting this option is a good way to catch misspelling of variables in your code.

## Syntax

**Option Explicit**

## Related Functions

[Const](#) | [Dim](#)

## Example

```
Option Explicit
' various statements go here
' a compile error will occur with the following line
strMyVar = "This string assignment won't work"
'because strMyVar is not explicitly declared
```

## Right

Returns the right most *Num* characters of *Str*. The required *Str* argument is a String expression from which the rightmost characters are returned. If *Str* contains **Null**, **Null** is returned.

The required *Num* argument is a Variant (Long) numeric expression indicating how many characters to return. If 0, a zero-length string (" ") is returned. If greater than or equal to the number of characters in string, the entire string is returned.

**Note:** To determine the number of characters in a string, use the *Len* function.

## Syntax

**Right(*Str*, *Num*)**

*Str*:

A string or expression that can represent a valid text value.

*Num*:

An Integer or expression representing a valid numeric value.

## Return Value

The Right function returns a variant containing a string data type.  
The Right\$ function returns a string.

## Related Functions

[InStr](#) | [Left](#), [Left\\$](#) | [Mid](#)

## Example

```
Dim strGreeting as String
Dim strTest
strGreeting = "Hello World"
strTest = Right(strGreeting, 1) ' Returns "d"
strTest = Right(strGreeting, 5) ' Returns "World"
strTest = Right(strGreeting, 20) ' Returns "Hello World"
```

## RTrim

Strips any trailing spaces from Str variable.

## Syntax

**RTrim**(*Str*)  
*Str*:  
A string or expression that can represent a valid text value.

## Return Value

Returns a String.

## Related Functions

[LTrim](#) | [Trim](#)

## Example

```
Dim strTest as String
Dim strResult as String
Dim lngStartLength as Long
Dim lngFinishLength as Long
strTest = "VBA "
lngStartLength = Len(strTest) ' returns 9
strResult = RTrim(strTest) ' returns "VBA"
lngStringLength = Len(strResult) ' returns 3
```

## Space

Creates a String consisting of the specified number *Num* of spaces. The Space function is useful for formatting output and clearing data in fixed-length strings.

## Syntax

**Space(Num)**

*Num*:

An Integer or expression representing a valid numeric value.

## Return Value

Returns a Variant containing a String data type.

## Related Functions

[String](#)

## Example

```
Dim strTest as String
' Returns a string with 10 spaces.
strTest = Space(10)

' Insert 10 spaces between two strings.
strTest = "Hello" & Space(10) & "World"
```

## StrComp

Returns an integer that is the result of the comparison of two strings.

The required *String1* argument is any valid string expression. The required *String2* argument is any valid string expression.

The optional *Compare* argument is a numeric expression that specifies the type of string comparison. It can be omitted, 0, or 1. Specify 0 (default) to perform a binary comparison. Specify 1 to perform a textual comparison. If compare is Null, an error occurs.

## Syntax

**StrComp(String1, String2)**

*String1*:

A string or expression that can represent a valid text value.

*String2*:

A string or expression that can represent a valid text value.

## Return Value

Returns a variant containing an integer data type indicating the result of the string compare:

- Returns -1 where *String1* is less than *String2*.
- Returns 0 where *String1* is equal to *String2*.
- Returns 1 where *String1* is greater than *String2*.
- Returns **Null** where *String1* or *String2*s **Null**.

## Example

```
Dim strTest1 as String
Dim strTest2 as String
Dim strTest3 as String
Dim vntComp
strTest1 = "ABCD"
strTest2 = "abcd"
strTest3 = NULL
vntComp = StrComp(strTest1, strTest2) ' Returns -1 (less than)
vntComp = StrComp(strTest1, strTest1) ' Returns 0 (equal to)
vntComp = StrComp(strTest2, strTest1) ' Returns 1 (greater than)
vntComp = StrComp(strTest1, strTest3) ' Returns NULL (strTest3 is NULL)
```

## String

Creates a string that consists of one character repeated a specific number of times.

The required *Num* argument is Long numeric expression indicating how many characters to return. If *Num* contains **Null**, **Null** is returned.

The required *Character* argument is a String expression from which the first character is repeated and returned, or is a Variant (Long) representing a valid character code. If character contains **Null**, **Null** is returned.

## Syntax

**String(Num)**

*Num*:

An Integer or expression representing a valid numeric value.

## Related Functions

[Space](#)

## Example

```
Dim strTest as String
strTest = String(5, "*")
' Returns *****
strTest = String(5, 42)
```

```
' Returns "44444"  
strTest = String(10, "Today")  
' Returns "TTTTTTTTTT"
```

## Trim

Strips any leading and trailing spaces from *Str* variable.

## Syntax

**Trim(*Str*)**

*Str*:

A string or expression that can represent a valid text value.

## Return Value

Returns a String.

## Related Functions

[LTrim](#) | [RTrim](#)

## Example

```
Dim strTest as String  
Dim strResult as String  
Dim lngStartLength as Long  
Dim lngFinishLength as Long  
strTest = " VBA "  
lngStartLength = Len(strTest)  
' returns 9  
strResult = Trim(strTest)  
' returns "VBA"  
lngStringLength = Len(strResult)  
' returns 3
```

## UCase

Converts all lowercase letters in *Str* to uppercase letters. All uppercase letters and non-letter characters remain unchanged.

## Syntax

**UCase(*Str*)**

*Str*:

A string or expression that can represent a valid text value.

## Return Value

Returns a string.

## Related Functions

[LCase](#)

## Example

```
Dim strMixedCase as String
Dim strLowerCase as String
Dim strUpperCase as String
strMixedCase = "AbCdE"
strLowerCase = LCase(strMixedCase) ' returns "abcde"
strUpperCase = UCase(strMixedCase) ' returns "ABCDE"
```

## ASCII/ANSI Character Code Listings

The table below shows the Latin 1 ANSI character set.

Codes 0-31 are control codes. The standard ASCII codes are from 32-127 (decimal) and are common regardless of the ANSI set being used. The remaining codes from 160-255 (decimal) vary between languages dependent upon the ANSI set being used.

## Driver Reference Help

The Driver Reference Help is designed to assist you in setting up and configuring device communications for a Plant SCADA system.

The information presented here includes reference and configuration information for each of the drivers included with Plant SCADA.

**Note:** Before you attempt to implement a driver, have a clear understanding of how drivers operate within a Plant SCADA system. Understand the concepts in the [I/O Devices](#) section of the Plant SCADA Help before you start configuring a driver.

Accessing Driver Information		
<b>Locating a particular driver</b> If you already know the driver required to connect to a particular device, you can access the associated reference information by locating the driver's name in the <a href="#">Table Of Contents</a> .	<b>Industry-standard drivers</b> If you are aware that a particular device supports a generic communications protocol, you may find the required configuration information via the list of <a href="#">Industry-Standard Drivers</a> .	<b>Checking for updated drivers</b> To confirm if a new or updated driver is available, go to the <b>Connectivity Hub</b> at the AVEVA Knowledge and Support Center. It is located at <a href="https://softwaresupport.aveva.com">https://softwaresupport.aveva.com</a> .

## Safety Information

### Hazard categories and special symbols

The following symbols and special messages may appear in this manual or on the product to warn of potential hazards or to call attention to information that clarifies or simplifies a procedure.

Symbol	Description
 or 	The addition of either symbol to a "Danger" or "Warning" safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.
	This is the safety alert symbol. It is used to alert you to personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.

#### DANGER

**DANGER** indicates an imminently hazardous situation, which, if not avoided, will result in death or serious injury.

#### WARNING

**WARNING** indicates a potentially hazardous situation, which, if not avoided, can result in death or serious injury.

#### CAUTION

**CAUTION** indicates a potentially hazardous situation which, if not avoided, can result in minor or moderate injury.

#### NOTICE

NOTICE used without a safety alert symbol, indicates a potentially hazardous situation which, if not avoided, can result in property or equipment damage.

### Please Note

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by AVEVA for any consequences arising out of the use of this material.

## Before You Begin

Plant SCADA is a Supervisory Control and Data Acquisition (SCADA) solution. It facilitates the creation of software to manage and monitor industrial systems and processes. Due to Plant SCADA's central role in controlling systems and processes, you must appropriately design, commission, and test your Plant SCADA project before implementing it in an operational setting. Observe the following:

### **WARNING**

#### **UNINTENDED EQUIPMENT OPERATION**

Do not use Plant SCADA or other SCADA software as a replacement for PLC-based control programs. SCADA software is not designed for direct, high-speed system control.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

### **WARNING**

#### **LOSS OF CONTROL**

- The designer of any control scheme must consider the potential failure modes of control paths and, for certain critical control functions, provide a means to achieve a safe state during and after a path failure. Examples of critical control functions are emergency stop and overtravel stop, power outage and restart.
- Separate or redundant control paths must be provided for critical control functions.
- System control paths may include communication links. Consideration must be given to the implications of unanticipated transmission delays or failures of the link.
- Observe all accident prevention regulations and local safety guidelines.<sup>1</sup>
- Each implementation of a control system created using Plant SCADA must be individually and thoroughly tested for proper operation before being placed into service.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

1. For additional information, refer to NEMA ICS 1.1 (latest edition) "Safety Guidelines for the Application, Installation, and Maintenance of Solid State Control", and to NEMA ICS 7.1 (latest edition) "Safety Standards for Construction and Guide for Selection, Installation and Operation of Adjustable-Speed Drive Systems" or their equivalent governing your particular location.

## Industry-Standard Drivers

Consider the communication capabilities of a device to determine if it supports any industry-standard protocols, such as Modbus or OPC. If this is the case, you may be able to use one of the following generic Plant SCADA drivers that support these standards.

**Note:** To confirm if a new or updated driver pack is available for a driver, go to the **Communication Drivers** page at the AVEVA Knowledge and Support Center. It is located at <https://softwaresupport.aveva.com/>.

Generic Device Type	Communications Method	Plant SCADA Driver
Modbus (ASCII-based data framing)	Serial	MODBUSA
Modbus (RTU-based data framing)	Serial	MODBUS
Modbus/TCP (Ethernet)	Ethernet	MODNET
Modbus Plus	SA85 Interface Board	MBPLUS
OPC DA Client	OPC via OPC Server (see below)	OPC

**Note:** If you use OPC to connect a device to Plant SCADA, you will need to purchase a third party application to establish an OPC Server. If you take this approach, use an OPC Server application recommended by the manufacturer of the device to which you are trying to connect.

## ABCLX Driver

The ABCLX Driver enables Plant SCADA to connect to [ControlLogix PLCs via Ethernet](#). It can be installed in parallel with a functional ControlLogix system, allowing engineering and testing to be conducted without any impact on operation.

No additional hardware (other than an Ethernet module) is required to connect to the ControlLogix system. This allows you to replace ControlView operator stations on a step-by-step basis.

**Note:** Prior to version 3, the ABCLX driver (then known as the ABLogix driver) was installed as a TCP/IP board driver. Since then, the driver has been installed as an ABCLX-type board driver. If you are upgrading an existing project which used a version 2.x ABLogix driver, you will need to alter the board type in your existing project to ABCLX type. Additionally, the format used for the port definition in the **Special Options** field for the Ports settings has changed.

[Logging](#)

## ControlLogix PLCs via Ethernet

Typically, the ControlLogix CPU module you want to connect to will be mounted on the same PLC backplane as Ethernet module your I/O Server communicates with. If not, you must set up a route path to indicate the location of the CPU you want to use.

See [Using a Route Path To Locate a Remote CPU](#).

**Note:** The ABCLX driver will not perform on a slow network, or a network that has an inconsistent connection to an I/O device in the field (for example, a wireless or dial-up connection). This is because the driver downloads all

---

the tags from the PLC and subscribes them before it comes online. Attempting to do this over a slow network can take too long and may cause the driver to time out on startup.

---

- [ControlLogix PLCs - Communication Settings](#)

### ControlLogix PLCs - Device Address

For ControlLogix PLCs connected via Ethernet, this field must be left blank.

## See Also

- [ControlLogix PLCs via Ethernet](#)

### ControlLogix PLCs - Software Requirements

You will need to have access to Rockwell's RSLogix 5000 Enterprise Series controller configuration software (obtainable from your ControlLogix system supplier) and its associated tools.

This software provides access to controller configuration, project code, tag definitions and data values. Use it to:

- Configure each Ethernet Module IP address
- Create tags for each controller
- Download the projects to the controllers.

---

#### Note:

- To configure Plant SCADA to communicate with ControlLogix system PLCs, you can use RSLogix 5000 to export PLC tag definitions to comma separated value (CSV) files, and use Windows Clipboard to copy them directly into Plant SCADA Studio.
  - Plant SCADA tags can only support arrays of 256 bytes. If your ControlLogix system has arrays larger than this, you might have to subdivide them into segments using the offset and array size in the tag address. See [Mapping to More Than an Individual Element of an Array](#) for more information.
- 

## See Also

- [ControlLogix PLCs via Ethernet](#)

### ControlLogix PLCs - Communication Settings

The following tables show the settings for communication with a ControlLogix device. To establish communication with the device, configure the associated **Board**, **Port** and **I/O Device** in Plant SCADA Studio's **Topology** activity. If you use the Express Communications Wizard to connect to a device, these will be automatically configured for you using the settings outlined below.

## Boards

Field	Value
Board Name	A unique name (up to 16 alphanumeric character) per server for the computer board being used to connect with the device. This is used by Plant SCADA in the Ports settings.
Board Type	The type of board. Select ABCLX from the drop-down list (see Note below).
Address	This field must be "0" (zero).
I/O Port	Leave this field blank.
Interrupt	Leave this field blank.
Special Options	Leave this field blank.
Comment	Any useful comment.

**Note:** Prior to version 3, the ABCLX driver (then known as the ABLogix driver) was installed as a TCP/IP board driver. Since version 3, the driver has been installed as an ABCLX-type board driver. If you are upgrading an existing project which used a version 2.x ABLogix driver, you will need to alter the board type in your existing project to ABCLX type.

## Ports

Field	Value
Port Name	A unique name (up to 16 alphanumeric character) for the computer port being used to connect with the device. This is used by Plant SCADA in the I/O Device settings.
Port Number	An integer value, unique to the board as defined in the Board name field. The Ethernet port needs no identification; however the Plant SCADA communication database requires a value in this field.
Board Name	The name of the board this port is attached to as defined on the Board settings.
Baud Rate	Leave this field blank.

Field	Value
Data Bits	Leave this field blank.
Stop Bits	Leave this field blank.
Parity	Leave this field blank.
Special Options	The IP address of the Ethernet module on the ControlLogix system PLC, appended with a forward slash and the slot number (zero based) of the backplane containing the controller CPU module, in the format: x.x.x.x[/n]. For example: "192.168.0.1/0" (See Note below.)
Comment	Any useful comment.

**Note:** With the release of Version 3 of the ABCLX driver (formerly known as the ABLogix driver), the format used for the port definition in the Special Options field of the Ports settings has changed. If you are upgrading from Version 2.x (ABLogix), you will have to adjust the content of this field.

## I/O Devices

Field	Value
Name	A unique name (up to 16 alphanumeric character) for the I/O Device being identified. Each I/O Device must have a unique name in the Plant SCADA system.
Number	A unique number for the I/O Device (0–16383). Each I/O Device must have a unique number in the Plant SCADA system, (unless redundancy of the I/O Device is being used—See <a href="#">Configuring Redundancy</a> for more information).
Address	Leave this field blank. <b>Note:</b> See <a href="#">Session Control</a> for additional configuration information if you are using the Session Disable feature.
Protocol	This field must be "ABCLX". Default is "ABCLX" when the Plant SCADA Express I/O Device Wizard is used to complete these forms.
Port Name	This field must contain one of the names

Field	Value
	previously defined in the Port Names field of the Port settings. There must be only one I/O device per port.
Comment	Any useful comment. This is viewed in the Devices records database.

[ControlLogix PLCs via Ethernet](#)

## Data Types

When configuring your variable tags to communicate with the ControlLogix system, you must select a Plant SCADA data type that is compatible with the data type used by the ControlLogix system controller.

Ideally, you should match the data type of the Plant SCADA variable tag with the data type of the mapped ControlLogix system PLC tag as per the following table:

ControlLogix Data Description	Plant SCADA Address Format	Access rights	Plant SCADA Data Type
BOOL	<TagName>	R/W	DIGITAL
SINT	<TagName>	R/W	BYTE
INT	<TagName>	R/W	INTEGER
DINT	<TagName>	R/W	LONG
REAL	<TagName>	R/W	REAL
STRING	<TagName>	R/W	STRING

For example, if the ControlLogix tag you are addressing uses a "float" data type, you should select "real" in the Data Type field of the Variable Tags settings.

---

**Note:** Plant SCADA reads a string data type from the ControlLogix PLC as a null terminated string. Therefore, if you need to read a 12 character string, you will have to configure the string length on the PLC to at least 13 characters to allow for the null character.

## See Also

[Data Types - Data Coercion](#)

## Data Types - Data Coercion

The ABCLX driver also supports a number of data conversions from a Plant SCADA data type to a native PLC data type. However, as it is possible to coerce from a large data type to a smaller one in both directions, care must be taken so that the range of the smaller type is respected, otherwise the driver will return BAD\_DATA\_TYPE back to Plant SCADA. It is recommended you only rely on these conversions where circumstances demand it.

The following matrix table details the conversions supported by the driver. The plus sign (+) represents those conversions that are impacted by range differences.

PLC DATA TYPES	Plant SCADA DATA TYPES										
	DIGITAL	BYTE	INTEGER	LONG	REAL	DIGITAL ARRAY	BYTE ARRAY	INTEGER ARRAY	LONG ARRAY	REAL ARRAY	STRING
BOOLEAN	YES										
SINT		YES	+ YES	+ YES	+ YES						
INT		+ YES	YES	+ YES	+ YES						
DINT		+ YES	+ YES	YES	+ YES						
REAL		+ YES	+ YES	+ YES	YES						
BOOLEAN ARRAY						YES					
SINT ARRAY							YES	+ YES	+ YES	+ YES	
INT ARRAY							+ YES	YES	+ YES	+ YES	
DINT ARRAY							+ YES	+ YES	YES	+ YES	
FLOAT ARRAY							+ YES	+ YES	+ YES	YES	
STRING											YES

[Data Types](#)

## Adding Tags to Your Project

A separate variable tag must be added to your Plant SCADA project for each data-point (memory register) on the I/O devices you want to communicate with.

ControlLogix system PLC controllers use a tag-based addressing system. The tags associated with a controller are each assigned a unique name using the RSLogix 5000 Enterprise Series controller configuration software. (See [ControlLogix PLCs - Software Requirements](#).)

You use the ControlLogix system PLC tag name when you specify the address for a tag in your Plant SCADA project. However, any square braces "[ ]" should be replaced with "{ }", and forward slashes "/" should be used to access bits within words, rather than a period ".".

**Note:** The ABCLX driver supports [Individual Tag Addressing](#) and [Array Tag Addressing](#). [Addressing Program Tags](#) support is also available for both these types of addressing. Local tag addressing is also supported.

Your Plant SCADA variable tags are defined using the **Variable Tags** view. For Plant SCADA to compile correctly, you must include appropriate values for the following fields:

Field	Value
Variable Tag Name	A unique name per project for the variable tag (up to 79 alphanumeric characters in Version 6, 32 characters for earlier versions). This can be used by Plant SCADA graphic pages and in Cicode where defined.
Data Type	The type of variable. Select from the drop-down menu. It must be one of the predefined types used in Plant SCADA.
I/O Device Name	The name of an I/O Device defined in the I/O Devices form which is used to identify the ControlLogix PLC controller (CPU module).
Address	The name of a predefined ControlLogix system PLC tag, either <a href="#">Individual Tag Addressing</a> , <a href="#">Array Tag Addressing</a> or addressed as part of a <a href="#">Addressing Program Tags</a> .

**Note:** Plant SCADA does not indicate any compile errors if an invalid address is entered in the Variable Tag settings. Any variable tag values with an invalid address will display as "#COM" at run time on the graphic pages where they have been positioned.

## Individual Tag Addressing

When declaring a Plant SCADA variable tag using individual tag addressing, type in the ControlLogix tag name, as defined on the ControlLogix PLC, into the **Address** field of the Variable Tag.

## Examples

### Single Byte within a structure

PLC Tag Address	SingleStructure.SingleByte
PLC Tag Type	SINT
Plant SCADA Tag Name	SingleStructure_SingleByte
Plant SCADA Tag Address	SingleStructure.SingleByte

Plant SCADA Tag Type	BYTE
----------------------	------

**Single Digital**

PLC Tag Address	SingleBoolean
PLC Tag Type	BOOLEAN
Plant SCADA Tag Name	SingleBoolean
Plant SCADA Tag Address	SingleBoolean
Plant SCADA Tag Type	DIGITAL

**Single 82nd bit from a digital array**

PLC Tag Address	DigitalArray
PLC Tag Type	BOOL[128]
Plant SCADA Tag Name	SingleDigital_81
Plant SCADA Tag Address	SingleDigital{81}
Plant SCADA Tag Type	DIGITAL

**Single 7th bit from fourth item in a long array**

PLC Tag Address	LongArray
PLC Tag Type	DINT[256]
Plant SCADA Tag Name	SingleBit_3_7
Plant SCADA Tag Address	LongArray{3}/7
Plant SCADA Tag Type	DIGITAL

**See Also**

[Adding Tags to Your Project](#)

**Array Tag Addressing**

Arrays can exist in the ControlLogix system PLC and/or the Plant SCADA tag database.

Within the ControlLogix system PLC, they are defined using the RSLogix 5000 Enterprise Series configuration software. See [ControlLogix PLCs - Software Requirements](#).

Plant SCADA accesses the tag arrays within the ControlLogix system PLCs via the **Address** field of the Variable Tags for each tag or tag array. Equally, the way to define Plant SCADA tag arrays is also to use the Address field of the Plant SCADA Variable Tags for each tag array required in Plant SCADA.

---

**Note:** Plant SCADA tag arrays are simple, not complex, arrays. This means they can only contain elements of the same data type; for example, a digital tag array in Plant SCADA will only include digital type variables.

---

Tag arrays can be extremely flexible and quite complicated. It is possible to declare a tag array in Plant SCADA which maps to a tag array in a ControlLogix system PLC, or which maps to a contiguous sequence of tags (of the same data type) which may or may not be defined as a tag array in the ControlLogix system PLC.

## See Also

- [Mapping to Individual Elements of an Array](#)
- [Individual Tag Address Type Mapping](#)
- [Mapping to More Than an Individual Element of an Array](#)
- [Mapping Data Types for Array Tag Addressing](#)

### Mapping to Individual Elements of an Array

To map to an individual tag in a ControlLogix PLC tag array, use { } brackets to define the array element as a zero-based index. Use the following syntax:

<TagName>{<IndexNumber>}

Where:

<TagName> =	the ControlLogix tag name as defined on the ControlLogix system PLC.
{ } =	the required braces to define the array element index.
<IndexNumber> =	the zero-based index number of the array element.

**Note:** With versions of Citect SCADA prior to version 6, curly brackets { } were required when addressing arrays. This is no longer the case, as Version 6 supports the use of both curly brackets and square brackets [ ].

---

### Individual Tag Address Type Mapping

You should match the data type of the Plant SCADA variable tag with the data type of the mapped ControlLogix system PLC tag as per the following table:

ControlLogix Data Description	Plant SCADA Address Format	Access rights	Plant SCADA Data Type
BOOL	<TagName>{<IndexNumber>}	R/W	DIGITAL
SINT	<TagName>{<IndexNumber>}	R/W	BYTE
INT	<TagName>{<IndexNumber>}	R/W	INTEGER
DINT	<TagName>{<IndexNumber>}	R/W	LONG

	er>}		
REAL	<TagName>{<IndexNumber>}	R/W	REAL
String structure (see below) or STRING (supplied by RSLinx)	<TagName>{<IndexNumber>}	R/W	STRING

The string structure must follow the format:

```
{
DINT LEN
SINT[ ] DATA
}
```

## Examples

### Single integer within an array of integers

PLC Tag Address	IntegerArray
PLC Tag Type	INT[5]
Plant SCADA Tag Name	IntegerArray_5
Plant SCADA Tag Address	IntegerArray{5}
Plant SCADA Tag Type	INTEGER

### Single float within an array of structures

PLC Tag Address	StructureArray[5].SingleFloat
PLC Tag Type	REAL
Plant SCADA Tag Name	StructureArray_5_SingleFloat
Plant SCADA Tag Address	StructureArray{5}.SingleFloat
Plant SCADA Tag Type	REAL

## See Also

[Mapping to Individual Elements of an Array](#)

[Mapping to More Than an Individual Element of an Array](#)

### Mapping to More Than an Individual Element of an Array

Plant SCADA can only handle simple (same-type) arrays of up to 256 bytes in length, so when declaring variable arrays to access ControlLogix system PLC arrays (or data structures larger than 256 bytes), you will need to split

them into smaller structures of less than 256 bytes. For example, you'll need to declare multiple variable arrays each accessing a separate 256 byte portion of the larger structure.

To map to a portion of an array greater than a single tag, you identify the starting position for the array, and the size of the array to map using the syntax:

`<TagName>/<ArrayOffset>!A[<ArraySize>]`

Where:

<code>&lt;TagName&gt; =</code>	The ControlLogix tag name as defined on the PLC.
<code>/&lt;ArrayOffset&gt; =</code>	The zero based offset of the item index used within the PLC (not on bit widths or other sizes) representing the starting point for the tag array value (optional).
<code>!A&lt;ArraySize&gt; =</code>	The zero based array size to return using the item count within the PLC, (not on bit widths or any other sizes).

#### Note:

- The array offset value is a zero-based item count used within the PLC to define the start of the array structure which is being mapped to the Plant SCADA variable tag array being declared. The array size value is a continuation of the same count and is used to define the size of the array structure being mapped to the Plant SCADA variable tag array being declared. They are used together to determine the start and end points of the variable tag array data in the ControlLogix system PLC which will be mapped to for the Plant SCADA variable tag array being declared in the Plant SCADA Variable Tags.
- Plant SCADA ignores all characters following an exclamation mark "!" in the tag address field, so that tag-based drivers like the ABCLX driver can use square brackets in the tag address for device array addressing. Therefore, you must precede an array address schema with an exclamation mark when defining an array in a Plant SCADA variable tag address.

## See Also

[Mapping to Individual Elements of an Array](#)

## Mapping Data Types for Array Tag Addressing

You should match the data type of the Plant SCADA variable tag array with the mapped ControlLogix PLC tag array as per the following table:

ControlLogix Data Description	Plant SCADA Address Format	Access rights	Plant SCADA Data Type
Array of BOOL	<code>&lt;TagName&gt;/&lt;ArrayOffset&gt;!A[&lt;ArraySize&gt;]</code>	R/W	DIGITAL array
Array of SINT	<code>&lt;TagName&gt;/&lt;ArrayOffset&gt;!A[&lt;ArraySize&gt;]</code>	R/W	BYTE array
Array of INT	<code>&lt;TagName&gt;/&lt;ArrayOffset&gt;!A[&lt;ArraySize&gt;]</code>	R/W	INTEGER array

Array of DINT	<TagName>/<ArrayOffset>!A[<ArraySize>]	R/W	LONG array
Array of REAL	<TagName>/<ArrayOffset>!A[<ArraySize>]	R/W	REAL array

## Examples

### Configuration of an array of 128 integers

PLC Tag Address	IntegerArray
PLC Tag Type	INT[128]
Plant SCADA Tag Name	IntegerArray_128
Plant SCADA Tag Address	IntegerArray!A[128]
Plant SCADATag Type	INT

### Configuration of an array of 64 floats offset by 32 items

PLC Tag Address	LargeFloatArray
PLC Tag Type	FLOAT[256]
Plant SCADA Tag Name	LargeFloatArray_32_64
Plant SCADA Tag Address	LargeFloatArray/32!A[64]
Plant SCADA Tag Type	FLOAT

### Configuration of an array of digitals within a structure

PLC Tag Address	SingleStructure.BooleanArray
PLC Tag Type	BOOLEAN[2048]
Plant SCADA Tag Name	SingleStructureBooleanArray
Plant SCADA Tag Address	SingleStructure.BooleanArray!A[2048]
Plant SCADA Tag Type	DIGITAL

### Configuration of an array of 256 bytes, offset by 256 items within an array of structures at element 32

PLC Tag Address	StructureArray.LargeByteArray
PLC Tag Type	SINT[1024]
Plant SCADA Tag Name	StructureArray_32_LargeByteArray_256_256

Plant SCADA Tag Address	StructureArray{32}.LargeByteArray/256!A[256]
Plant SCADA Tag Type	BYTE

## Addressing Program Tags

ControlLogix program tags contain data that is used exclusively by the routines within an individual program. These tags can be viewed as local variables.

Individual tag addressing and array tag addressing are available for program tags by using PROGRAM:<TaskName> as a prefix.

## Examples

### Single Byte within a structure in program MyProgram.

PLC Tag Address	MyProgram.SingleStructure.SingleByte
PLC Tag Type	SINT
Plant SCADA Tag Name	MyProgram_SingleStructure_SingleByte
Plant SCADA Tag Address	PROGRAM:MyProgram.SingleStructure.SingleByte
Plant SCADA Tag Type	BYTE

### Single Digital in program MyProgram

PLC Tag Address	MyProgram.SingleBoolean
PLC Tag Type	BOOLEAN
Plant SCADA Tag Name	MyProgram_SingleBoolean
Plant SCADA Tag Address	PROGRAM:MyProgram.SingleBoolean
Plant SCADA Tag Type	DIGITAL

### Single integer within an array of integers in program MyProgram

PLC Tag Address	MyProgram.IntegerArray[5]
PLC Tag Type	INT
Plant SCADA Tag Name	MyProgram_IntegerArray_5
Plant SCADA Tag Address	PROGRAM:MyProgram.IntegerArray{5}
Plant SCADA Tag Type	INTEGER

## Configuring Quality and Timestamp Tags

The Plant SCADA ABCLX driver can use additional variable tags for quality and time stamp values. Quality or time stamp tags are duplicates of a variable tag, with an appended "!Q" or "!T" or "!M" in the address field to define their purpose. Their data type needs to be Long to enable them to store a quality or time stamp value.

**Note:** The quickest way to create a quality or timestamp tag in Plant SCADA is to locate the relevant variable tag using the Variable Tags dialog box, edit it as required to create a quality or timestamp tag, and save it. This creates a copy of the original variable tag with the required changes saved.

### To create a quality tag:

1. From the Plant SCADA **Studio** select **System Model** activity, then select **Variables**.
2. On the menu below command bar, select **Variables**.
3. Add a row to the grid editor.
4. Type the following information in columns, or in the fields of the **Property Grid**.
  - In the **Tag Name** field, enter an appropriate and unique name for the quality tag. Common practice suggests using a name such as "<Tagname>\_Quality".
  - In the **Data Type** field, select **Long** from the drop-down menu (if not already selected).
  - In the **I/O Device** field, select the appropriate I/O device for the tag (if not already displayed).
  - In the **Address** field, enter the name of the tag you want to associate with the quality value (if not already displayed), and append "!Q" directly to the end of the address (without the quotes and without any spaces).
5. Click **Save**.

**Note:** If there is already an exclamation mark with other declarations included in the tag address, there is no need to include another one. For example, a quality tag monitoring TagName!A[64] can be addressed as TagName!Q.

The quality value generated by the ABCLX driver is a mask of the quality level and quality status field values as per the following table:

Quality level	Quality status	Value (Hex)
QLEVEL_UNCERTAIN	QSTATUS_NONE	0x00
QLEVEL_GOOD	QSTATUS_NOTDEFINED	0x01
QLEVEL_BAD	QSTATUS_INITIAL	0x02
N/A	QSTATUS_STALE	0x03
N/A	QSTATUS_ERRORDATA	0x04
N/A	QSTATUS_WRITE	0x05

**Note:** The quality is calculated by shifting up the quality level by 8 bits and OR masking in the quality status.

## Examples

Quality tag settings for a single long in root of PLC:

Plant SCADA Tag Name	SingleLong_Quality
Plant SCADA Tag Address	SingleLong!Q
Plant SCADA Tag Type	LONG

Quality tag settings for an array of 256 bytes, offset by 256 items within an array of structures at element 32:

Plant SCADA Tag Name	StructureArray_32_.LargeByteArray_256_256_Quality
Plant SCADA Tag Address	StructureArray{32}.LargeByteArray/256!Q
Plant SCADA Tag Type	LONG

### To create a timestamp tag:

- From the Plant SCADA Studio select **System Model** activity, then select **Variables**.
- On the menu below command bar, select **Variables**.
- Add a row to the grid editor.
- Type the following information in columns, or in the fields of the **Property Grid**.
  - In the **Tag Name** field, enter an appropriate and unique name for the timestamp tag. Common practice suggests using a name such as "<Tagname>\_sTimestamp" (for seconds) or "<Tagname>\_msTimestamp" (for milliseconds).
  - In the **Data Type** field, select **Long** from the drop-down menu (if not already selected).
  - In the **I/O Device** field, select the appropriate I/O device for the tag (if not already displayed).
  - In the **Address** field, enter the name of the tag you want to associate with a timestamp value (if not already displayed), and append "!T" or "!M" (as appropriate).
- Click **Save**.

#### Note:

- If there is already an exclamation mark with other declarations included in the tag address, there is no need to include them for timestamping. For example, a timestamp tag monitoring TagName!A[64] can be addressed as TagName!A[64]T.
- Timestamps store the number of seconds since 01/01/1970 when using the "!T" element, or the number of milliseconds since midnight using the "!M" element. If you want to store a complete time in millisecond accuracy, create two separate timestamp tags, one for seconds and one for milliseconds, each addressed appropriately.

## Examples

Timestamp tag settings for a single long in root of PLC:

Plant SCADA Tag Name	SingleLong_msTimestamp
Plant SCADA Tag Address	SingleLong!M
Plant SCADA Tag Type	LONG

Timestamp setting for an array of 256 Bytes offset by 256 items within an array of structures at element 32:

Plant SCADA Tag Name	StructureArray_32_.LargeByteArray_256_256_sTimestamp
Plant SCADA Tag Address	StructureArray{32}.LargeByteArray/256!A[256]T
Plant SCADA Tag Type	LONG

**Note:** A timestamp value is based on the time a value change is detected by the ABCLX driver in UTC time, so the timestamp is only as accurate as the polling cycle of the I/O device. If, for example, the data value changed while the unit was not polling, the timestamp value will not be accurate.

## Addressing Statistics Tags

Statistics tags contain driver statistics data.

Statistics name	Statistics tag address	Data type
AvgGroupPollTime	Statistics_AvgGroupPollTime	LONG
OptimisedBlocks	Statistics_OptimisedBlocks	LONG
SessionThreadState	Statistics_SessionThreadState	LONG
SessionState	Statistics_SessionState	LONG
BackendPendingResp	Statistics_BackendPendingResp	LONG
SocketThreadState	Statistics_SocketThreadState	LONG
CacheDelayedReply	Statistics_CacheDelayedReply	LONG
GroupPollCounter	Statistics_GroupPollCounter	LONG
MissedGroupPolls	Statistics_MissedGroupPolls	LONG
ForwardOpens	Statistics_ForwardOpens	LONG
TagsSubscribed	Statistics_TagsSubscribed	LONG
GoodTags	Statistics_GoodTags	LONG
BadTags	Statistics_BadTags	LONG
QTMTags	Statistics_QTMTags	LONG

SessionDisabled	Statistics_SessionDisabled	LONG
DelayedWrites	Statistics_DelayedWrites	LONG
TagConfigWarnings	Statistics_TagConfigWarnings	LONG
LostMessageCount	Statistics_LostMessageCount	LONG
TimeoutDirWrites	Statistics_TimeoutDirWrites	LONG
InitTimeout	Statistics_InitTimeout	LONG

## Advanced Configuration and Maintenance

This section provides advanced configuration instructions.

- [Scan Rates](#)

### Using a Route Path To Locate a Remote CPU

A route path allows you to indicate the location of a particular CPU on a ControlLogix network in relation to the Ethernet module you're using as your initial point of communication. It maps out a communication channel across a network of PLCs by defining a series of ports and addresses that eventually lead to the destination CPU.

This information is configured in the [ABCLX] section of the Citect.ini file, using the following syntax:

*IOServer name.Port name.RoutePath=/P:m/A:n,...,/P:m/A:n*

where:

<i>IOServer name =</i>	I/O server name
<i>Port name =</i>	Port name on I/O server
<i>m =</i>	Port type/number on the module 0 - Reserved 1 - Backplane 2 - Port A 3 - Port B 4 - Port C

*n* =

The slot number if the module is on the backplane, or the address of the module, which will either be a CNET address, IP address or DH address. It can also be an IP address if it is an EIP module

## Example

Starting from the initial Ethernet module, each point in the communication path is defined with a Port value and Address in the following format:

/P:*m*/A:*n*,

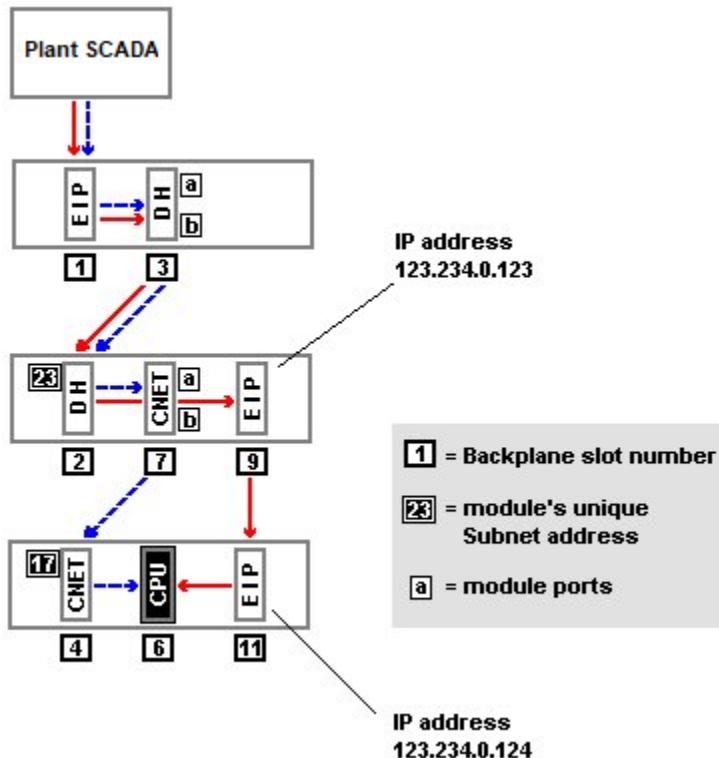

Include an appropriate numeric value for "m" to indicate if the next communication point is on the same backplane, or connected via a particular port. The value for "n" will then become a backplane slot number, or a module's unique address.

If you are attempting to route from one Ethernet module to another, you'll have to use "2" (Port A) for "m", and the destination IP address for "n". For example:

/P:2/A:123.234.0.124,

Simply recreate this syntax for each point in the communication path, separated by commas, to complete the Route Path parameter.

Consider the following diagram, showing a Plant SCADA I/O server, and a network of three ControlLogix PLC backplanes. There are two example route paths represented, one distinguished by a dotted line.

The syntax for the first example (solid line) would be:

IOServerName.PortName.RoutePath=/P:1/A:3,/P:2/A:23,/P:1/A:9,/P:2/A:123.234.0.124,/P:1/A:6

The syntax for the second example would be:

IOServerName.PortName.RoutePath=/P:1/A:3,/P:2/A:23,/P:1/A:7,/P:2/A:17,/P:1/A:6

## Configuring Redundancy

Redundancy is handled in Plant SCADA by the Plant SCADA clients. They determine which I/O server to request I/O device data from. This is done by allowing the scan rate to be specified per I/O device, and then configuring multiple I/O devices to the same PLC.

The inactive unit under redundancy will receive a STATUS\_UNIT command from Plant SCADA every configured WatchTime. The reply sent back to Plant SCADA will be based on the current state of the status tag condition. If the condition isn't met the standby unit will be set to UNIT\_OFFLINE until the status tag condition passes. The status group polling rate remains unchanged on the inactive unit. See [Stop\\_Unit Handling](#).

A status tag can be defined in the Citect.ini file to determine whether or not to set a unit offline or online depending on the condition of the status tag. If the condition is true the unit is allowed to come online, otherwise the unit is set to offline.

The status tag is polled at the same rate configured for the groups of the corresponding unit. The driver supports STATUS\_UNIT commands on the inactive server, so even though a particular unit is not currently servicing Plant SCADA requests, the state of the status condition will be checked periodically allowing the unit to be taken either offline or online.

Both the primary and standby devices will be offline if both have the same status condition and the condition is not passing. All points in the system for that unit would therefore be #COM.

The status tag can be defined either in the main [ABCLX] section to apply to all devices or a status can be defined specifically for a particular device within the [<IOServerName>.<IOPortName>] section.

The inactive unit under redundancy will receive a STATUS\_UNIT command from Plant SCADA every configured WatchTime. The reply sent back to Plant SCADA will be based on the current state of the status tag condition. If the condition isn't met, the standby unit will be set to UNIT\_OFFLINE until the status tag condition passes. The status group polling rate remains unchanged on the inactive unit.

## Stop\_Unit Handling

If the driver receives a **STOP\_UNIT** command from the I/O Server for a particular device, then the driver places the unit offline and adjusts the polling rate based on the inactive scan adjust. When the **INIT\_UNIT** command is received again, the driver will start polling again and place the unit back online.

If the unit is currently offline, the **STOP\_UNIT** command will not be sent down to the driver so the driver will not know to stop polling the PLC.

## Performance Tuning

There are two ways you can fine tune the performance of the ABCLX driver on your Plant SCADA system:

- [Optimizing Driver to PLC Communications](#)
- [Optimizing Client To Server Communications](#)

### Optimizing Driver to PLC Communications

The ABCLX driver connects to the ControlLogix system devices using the Ethernet/IP network. To know the

connection state of all configured PLCs, the driver supports the use of Status Tags for the system and for each device.

To minimize network traffic, the ABCLX driver also supports the use of different scan rates for different devices, and active and inactive devices. See [Status Tags](#) and [Scan Rates](#).

---

**Note:** The ABCLX driver maintains an internal tag cache and services Plant SCADA DCB requests from the internal cache.

You can also adjust the System Overhead Time Slice in the PLC to the highest value possible. The higher you make the number, the better the MSG performance will be. However, this may have an adverse performance impact on the control program being executed by the ControlLogix controller.

The System Overhead Time Slice in the PLC is adjusted from the ControlLogix programming software by right clicking on the controller and navigating to the "Controller Properties" then click on the "Advanced" tab.

It is also good engineering practice to arrange your variable.dbf by IO Device then DataType. This allows Plant SCADA to create requests by blocking the same data types within an IO Device together.

### Optimizing Client To Server Communications

Due to this driver being a front-end/back-end driver, there are no transport delays between Plant SCADA and the driver involved in processing a read request from the driver cache. This means that under heavy loads, the driver could use up most the CPU processing requests. The driver can tune the CPU usage and throughput to help manage the resources of the I/O server. The standard driver parameters MaxPending and Delay can be used as follows:

```
[ABCLX]
MaxPending=x
Delay=y
```

Where:

- $x$  = the maximum number of simultaneous requests the driver will receive from Plant SCADA.
- $y$  = the average delay applied to the requests to control CPU usage.

### Examples

```
[ABCLX]
MaxPending=256
Delay=50
```

The above example would mean that the driver is capable of servicing 256 requests every 50 milliseconds.

```
[ABCLX]
MaxPending=1
Delay=0
```

This example would mean the driver would reply to every request as quickly as possible, which could cause CPU issues.

### Customizing a Project using Citect.ini Parameters

The ABCLX driver supports the following parameter categories:

- ABCLX Specific Parameters
- Logging Parameters.

There are also device-specific parameters you can use to override global parameters. See [Global and Device-Specific Parameters](#).

## **WARNING**

### **UNINTENDED EQUIPMENT OPERATION**

- Do not under any circumstances change or remove any citect.ini parameters without an informed understanding of the possible implications of your actions.
- Do not delete sections of the citect.ini file without an informed understanding of the possible implications of your actions.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** At times during the life cycle of a driver, circumstances may call for the creation of specific citect.ini parameters that remain undocumented. Always seek the advice of Technical Support regarding the possible implementation of undocumented parameters before you make any changes to a citect.ini file.

## **ABCLX Specific Parameters**

## **WARNING**

### **UNINTENDED EQUIPMENT OPERATION**

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

The following table describes the driver-specific citect.ini parameters.

[ABCLX] Parameter	Allowable Values	Default Value	Description
ConnTimeout	5000 to 30000 (milliseconds)	15000	Timeout for establishing TCP/IP connection.
FailOnBadData	0 or 1	1	Used by the ABCLX driver to determine whether or not to force the display of good data within a block read which contains bad tags during commissioning.  When this parameter is set to 1, a block read

			<p>which contains a bad tag would result in the whole block returning #COM.</p> <p>This can be system wide if placed in the driver's general section, or device specific if placed under a specific device's section.</p> <p>See also <a href="#">Global and Device-Specific Parameters</a>.</p>
ForwardOpenPoolSize	1 - 32	4	<p>Used by the ABCLX driver to determine the number of Forward Open services can be used on the device.</p> <p>This can be system wide if placed in the driver's general section, or device specific if placed under a specific device's section.</p> <p>See also <a href="#">Global and Device-Specific Parameters</a>.</p>
InitTimeOut	0 to 360000 (milliseconds)	180000	Timeout for the retrieval of the tag database and initialization functions.
LostMsgRetry	There is no set limit but the recommended value is between 1-5	3	<p>If the driver does not get a reply to a message sent to the device, this parameter specifies the number of times the driver will retry sending that message before setting the I/O device offline.</p> <p>See Knowledge base article KB5452 for details.</p> <p>This can be system wide if placed in the driver's general section, or device specific if placed under a specific device's section.</p> <p>See also <a href="#">Global and</a></p>

			Device-Specific Parameters.
LostMsgTimeout	There is no set limit but the recommended value is in between 1000 – 2000 if ExclusiveConnection parameter is set to 1, otherwise 300 - 2000 is recommended.	1000 if the ExclusiveConnection parameter is set to 1, otherwise, 300.	This parameter specifies the message timeout (in milliseconds) See Knowledge Base article KB5452 for details. This can be system wide if placed in the driver's general section, or device specific if placed under a specific device's section. See also <a href="#">Global and Device-Specific Parameters</a> .
MaxBackendQueue	1-20	10	Used by the ABCLX driver to restrict the number of writes queued for a device. This can be used in conjunction with the ForwardOpenPoolSize to limit loading on PLCs. This can be system wide if placed in the driver's general section, or device specific if placed under a specific device's section. See also <a href="#">Global and Device-Specific Parameters</a> .

MissedPollTolerance	1 - 5	3	<p>Number of polls that can be missed before the unit is taken offline.</p> <p>This can be system wide if placed in the driver's general section, or device specific if placed under a specific device's section.</p> <p>If this parameter is enabled, the driver will log the following information to the I/O server syslog file:</p> <ul style="list-style-type: none"><li>• All tags downloaded from the PLC (STATISTICS log category).</li><li>• All subscribed Plant SCADA tags (REPORT log category). Note that any tags that do not exist in the PLC are logged under the WARNING debug level.</li><li>• All optimized blocks the driver generates (VALIDATE log category).</li></ul> <p>This can be system wide if placed in the driver's general section, or device specific if placed under a specific device's section.</p> <p>See also <a href="#">Global and Device-Specific Parameters</a>.</p>
---------------------	-------	---	--

OptimizeUserDefinedData Type	0 - 1	1	<p>By default, the optimization for reading structures is enabled (default is 1). In this case ,the driver will retrieve the whole structure in one packet provided the size of the structure is 460 bytes or less.</p> <p>If we disable this INI parameter (set the value to 0), the driver will send the add item request as multiple service requests.</p>
RegisteringTagsToPLCDelayTime	0 to 1000 milliseconds	0	<p>The delay time period (in milliseconds) between requests to register a block of tags.</p> <p>This can be system wide if placed in the driver's general section, or device specific if placed under a specific device's section.</p> <p>See also <a href="#">Global and Device-Specific Parameters</a>.</p>
ScanRate	100 to 30000 milliseconds	500	<p>The time period (in milliseconds) between each poll of the root group.</p> <p>This can be system wide if placed in the driver's general section, or device specific if placed under a specific device's section.</p> <p>See also <a href="#">Global and Device-Specific Parameters</a>.</p>

## Logging Parameters

### WARNING

#### UNINTENDED EQUIPMENT OPERATION

Do not under any circumstances change or remove any of the undocumented citect.ini parameters.

Before deleting sections of the citect.ini file, confirm that no undocumented parameters will be deleted.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

[ABCLX] Parameter	Description	Allowable Values	Default Value
DebugLevel	The trace level used for the log file.	Any combination of the following, separated by a pipe character ( ):  ERROR WARN TRACE DEBUG ALL  See <a href="#">Logging</a> for examples.	-
DebugCategory	The categories used for the log file.	Any combination of the following, separated by a pipe character ( ):  TAG= Tag configuration trace SOCK= Socket trace EIP= EIP session trace DCB= Front-end driver trace BUFF= Dump a counted buffer to hex THRD= Thread trace STATISTICS = All tags downloaded from PLC REPORT = All Plant SCADA tags subscribed VALIDATE = All optimized blocks the driver generated ALL = all of the above.  See <a href="#">Logging</a> for examples.	-

LogFileArchive	This parameter has been deprecated.	-	-
LogFileSize	This parameter has been deprecated.	-	-
LogTagInfo	<p>If this parameter is enabled, the driver will log the following information to the I/O server syslog file:</p> <ul style="list-style-type: none"> <li>• All tags downloaded from the PLC (STATISTICS log category).</li> <li>• All subscribed Plant SCADA tags (REPORT log category). Note that any tags that do not exist in the PLC are logged under the WARNING debug level.</li> <li>• All optimized blocks the driver generates (VALIDATE log category).</li> </ul> <p>See also <a href="#">Global and Device-Specific Parameters</a>.</p>	0 or 1	0

## See Also

[Logging](#)

[Global and Device-Specific Parameters](#)

### **WARNING**

#### **UNINTENDED EQUIPMENT OPERATION**

Do not change protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

With the current release of the ABCLX driver, there are device-specific parameters you can use to override global

parameters; they are:

- FailOnBadData
- ForwardOpenPoolSize
- InactiveScanAdjust
- LogTagInfo
- LostMsgRetry
- LostMsgTimeout
- MaxBackendQueue
- MissedPollTolerance
- RegisteringTagsToPLCDelayTime
- StatusTag
- ScanRate

For more details, see [ABCLX Specific Parameters](#).

## Examples

Implementation of global parameters:

```
[ABCLX]  
Watchtime=5  
ScanRate=1000
```

Implementation of a device-specific parameter:

```
[CLServer.CLServerPort]  
ScanRate=500
```

## Session Control

You can use session control to release any current references to tags on the ControlLogix PLCs. This is required if you want to modify or delete any of your PLC tags, as the Logix5000 software cannot access a tag if Plant SCADA is currently subscribed to it. You can also use session control to load a refreshed tag list from a PLC.

Session control is achieved by using the **SessionDisable:x** tag. This tag needs to be configured on a virtual device on a virtual channel. The virtual channel is specified by entering 0.0.0.0 as the IP address in the **Special Options** field of the Ports form. There should be a single virtual port and virtual device configured for each I/O server, and the virtual devices should not be configured for redundancy; i.e., the network numbers for the virtual units should not be the same. Otherwise it is not possible to communicate with a specific virtual unit from a Plant SCADA client.

Device Data Description	Plant SCADA Address Format	Access rights	Plant SCADA Data Type
Session Disable and Enable	SessionDisable: x	R/W	INTEGER

Where:

x = the address entered for the specified device in the I/O Devices form. It needs to be unique across all systems. If this tag is written to with a 1, the session is disabled. Writing a 0 to this tag will re-enable the session.

## Status Tags

A status tag can be defined in the Citect.INI file to determine whether or not to set all or any ControlLogix system PLC devices offline or online depending on the condition of the status tag. If the condition is true, the device is allowed to come online; otherwise the device is set to offline by the ABCLX driver.

There can be one general status tag (defined in the general [ABCLX] section of the project Citect.INI file) which determines the online status of all I/O devices using the ABCLX driver. There can also be an individual status tag set for each I/O device (using the syntax [IOServerName.IOPortName]) that will override the general section status tag.

By default, no status tag is created for the driver or a device until defined in the project Citect.INI file.

The status tag is polled at the same rate configured for the groups of the corresponding device. The ABCLX driver supports STATUS\_UNIT commands on the inactive server, so even though a particular device is not currently servicing Plant SCADA requests, the state of the status condition will be checked periodically allowing the device to be taken offline or online. See [Stop\\_Unit Handling](#).

### Note:

- If both the primary and standby devices have the same status condition and the condition does not meet requirements, both will be taken offline. All points in the system for that unit will display "#COM".
- Supported PLC data types for status tags are BOOL, SINT, INT, DINT and REAL. The STRING type is not supported.
- PLC data type REAL cannot be used with bit operator's '&', '!&' to form a status tag expression. The driver will ignore decimal point values in REAL condition checks, the maximum REAL number that can be correctly read is 2^32 for the purposes of the condition check

The syntax for a status tag is:

**StatusTag=<TagName><Operator><Operand>**

where:

<TagName> = the name of the PLC tag address whose value is to be used in the comparison operation;

<Operator> = the comparison operator (see operator list below);

<Operand> = the value to be used in the comparison operation against the value of <TagName>.

The comparison operator can be one of the following:

Operator	Description
>	<TagName> is greater than <Operand>
>=	<TagName> is greater than or equal to <Operand>
<	<TagName> is less than <Operand>
<=	<TagName> is less than or equal to <Operand>
&	<TagName> has common asserted bit(s) with

	<Operand>
=	<TagName> is equal to <Operand>
!&	<TagName> has no common asserted bit(s) with <Operand>
!=	<TagName> is not equal to <Operand>

## Examples

Bring all ABCLX driver devices online only when the integer tag named "TankLevel" is greater than 100:

[ABCLX]

StatusTag=TankLevel>100

Bring any device on the port named "Port1" on the I/O server named "CLServer" online only when the digital tag named "isReady" is true (where 0=false and 1=true):

[CLServer.Port1]

StatusTag=isReady=1

Bring the device named "Port123" on the I/O server named "CLServer" online only when the current value shares common asserted bits with "5".

[CLServer.Port123]

StatusTag=TagName&5

If the current value for the tag called "TagName" was 3, the example above would set the status to true and bring the device online, as 3 and 5 share a common bit (3 = 0011 in binary, and 5 = 0101). If the value for TagName were 2, the device would remain off line as 2 and 5 do not share common bits (2 = 0010, 5 = 0101).

With the example below, the port named "Port123" on "CLServer" will come online only when the current value for TagName does not share common asserted bits with "5".

[CLServer.Port123]

StatusTag=TagName!&5

## Mode Detection

The PLC mode is determined by two things. Firstly, the physical key position in the PLC; and secondly, when in REMOTE mode, whether or not the PLC has been set to RUN mode or PROGRAM mode. This state is represented in the PLC by a numeric value that can be queried.

The following table sets out the different values and the corresponding PLC mode:

Mode Value	Key Position	Mode
0x1060	RUN	RUN
0x3060	REMOTE	RUN
0x3070	REMOTE	PROGRAM
0x2070	PROGRAM	PROGRAM

These values can be used to set up a status tag to determine what mode the PLC is currently in, as shown below.

Status Tag	Configuration Description
@Mode<0x2000	Key position in RUN
@Mode>0x3000	Key position in REMOTE
@Mode!&0x1000	Key position in PROGRAM
@Mode!&0x10	PLC in RUN mode
@Mode&0x10	PLC in PROGRAM mode

Hence the unit can be taken offline or back online depending on the key position and the current mode of the PLC to display #COM for the points on this unit.

### Identifying Bad Tags Using 'FailOnBadData'

A bad tag is defined as any tag that does not exist within the ControlLogix system, which is something that can occur when developing large systems.

During the commissioning phase a project, you need to clearly identify any blocks of data that include bad tags. The FailOnBadData parameter helps achieve this by allowing you to run your project in two different modes:

- When **FailOnBadData** is **off**, the ABCLX driver will not return "#COM" for a block of data if at least one valid value is in the read block.
- If **FailOnBadData** is **on**, if any tag values in a blocked read are missing or inaccessible, the whole block is rejected and will return "#COM". This highlights the presence of bad tags and identifies where corrective action is required. This default behavior is the preferred mode of operation when you are running a project.

By default FailOnBadData is on (1). See [ABCLX Specific Parameters](#).

### Example

Display reads that include a bad tag in the block with #COM:

```
[ABCLX]
FailOnBadData=1
```

Ignore any bad tags in the block reads and just show 0 for those tags:

```
[ABCLX]
FailOnBadData=0
```

### Scan Rates

The Plant SCADA ABCLX driver can define I/O devices with different scan rates. This provides you with the ability to better tune your system, by ordering the tag database into logical groups and defining different scan rates for each group. For example, tags that are being read frequently can be placed in a group that is scanned frequently, and tags that are read infrequently can be placed in a group that is scanned infrequently.

By default, all tags are scanned at the default scan rate defined by the ScanRate parameter in the project

Citect.INI file.

**Note:** If you have configured I/O server redundancy in your project, it may be considered an inefficient use of network bandwidth to be continually polling devices non-critical to the currently inactive server. To help reduce unnecessary network traffic, the ABCLX driver supports the use of the InactiveScanAdjust parameter, which applies a delay factor to the scan rate of currently inactive I/O Servers.

See [ABCLX Specific Parameters](#) for details.

## Examples

Set the project scan rate to 1 second (1000 milliseconds):

```
[ABCLX]  
ScanRate=1000
```

Set the project scan rate to 1 second (1000 milliseconds), and the inactive server scan adjust rate to a factor of 5:

```
[ABCLX]  
ScanRate=1000  
InactiveScanAdjust=5
```

Set a faster (half second) scan rate for a specific port named "Port1" on the I/O server named "CLServer":

```
[CLServer.Port1]  
ScanRate=500
```

Set a slower (5 second) scan rate for a specific port named "Port123" on the I/O port named "CLServer":

```
[CLServer.Port123]  
ScanRate=5000
```

## ABCLX Specific Errors

The following errors, listed in (hexadecimal) order, are specific to the Plant SCADA ABCLX driver:

Error Value (in Hex)	Error Description
0x20000006	Failed to read tag
0x20000007	Failed to write to tag
0x20000009	Failed to initialize channel and download PLC tag database
0x2000000B	Failed to initialize unit and start polling tags
0x2000000C	The configured status condition is currently false
0x20000010	Failed to access the Citect Variable.DBF file
0x20000011	Failed to access the Citect Units.DBF file
0x20000015	Unit initialization is still in progress
0x20000016	The PLC session or TCP/IP connection has failed

0x20000002	Connect Error
0x20000019	Database initialization in progress
0x2000001a	CTAPI server unavailable
0x2000001b	Failed to open Variable.DBF, this error can be logged before Citect V6.
0x2000001c	Failed to open Units.DBF, this error can be logged before Citect V6.
0x2000001d	Direct Read Failure, Time Out
0x2000001e	Write failure, Time Out

## Logging

The ABCLX driver can log combinations of trace levels across different categories. This is achieved by setting the following INI parameters.

### [ABCLX]DebugLevel

This parameter allows you to define the trace level. The options include:

Option	Description
WARN	Output warning messages.
ERROR	Output error messages.
TRACE	Output trace messages.
DEBUG	Output debug messages.
ALL	All of the above.

### [ABCLX]DebugCategory

This parameter allows you to enable logging for a particular category of trace. The options include:

Option	Description
TAG	Tag configuration trace.
SOCK	Socket trace.

EIP	EIP session trace.
DCB	Front end driver trace.
BUFF	Dump a counted buffer to hex.
THRD	Thread trace.
STATISTICS	All tags downloaded from PLC.
REPORT	All subscribed Plant SCADA tag.
VALIDATE	All optimized blocks generated by the driver.
ALL	All of the above.

In both cases, you can use any combination of the available options separated by a pipe character ( | ).

#### Example

```
[ABCLX]
DebugLevel=WARNING | ERROR | TRACE
DebugCategory=ALL
```

In most cases, you can set the DebugLevel and DebugCategory parameters to ALL. If this results in a large, cumbersome log file that causes older data to be overwritten, you can consider refining the debug options.

---

**Note:** These parameters do not have a value specified by default. To enable logging for this driver, you need to manually configure these parameters in your INI file.

The events generated by the ABCLX driver are logged in the following Plant SCADA syslog file:

```
syslog.IOServer.<Cluster name>.<IO Server name>.dat
```

This file is located in the directory specified by the Citect.ini parameter **[CtEdit]Logs**. By default, this location will be:

```
%PROGRAMDATA%\AVEVA Plant SCADA <VersionNumber>\Logs
```

The size of the syslog file and its rollover process is configured via the **[Debug]SysLogSize** and **[Debug]SysLogArchive** INI parameters. For more information, see the topic *Debug Parameters* in the Plant SCADA documentation.

---

**Note:** If the number of messages being processed for a driver exceeds the value specified by the Plant SCADA parameter **[Kernel]ErrorBuffers**, the pending messages will not be logged. If this occurs, you can increase the value of this parameter so that all the messages generated by the driver are reported. The number of messages that are not logged can be monitored via the Kernel's General window under the item "Lost Errors". If you adjust **[Kernel]ErrorBuffers** and Lost Errors are still occurring, you may need to adjust the level of system logging.

[Logging Parameters](#)

## Driver Kernel Additional Fields

The Kernel Driver window, launched via the Page Driver Kernel command, displays information about each driver in the Plant SCADA system. The statistics it presents include read requests, physical reads, digital reads per second, register reads, cache reads, error count, timeouts, and so on. See the Plant SCADA User Guide for details on the general statistics it presents.

In the case of the ABCLX driver, the Kernel Driver window includes additional fields that are not normally supported. Press "V" to see these additional fields. They are:

Field	Description
Session Thread State	Current state of the driver EIP session thread: 0 – Thread is stopped 1 – Thread is starting 2 – Thread is running 3 – Thread is stopping
Session State	Current state of the driver EIP session to the PLC: 0 – The session has not been initialized yet 1 – The session is connecting to the PLC and downloading the PLC tag database 2 – The session has connected to the PLC and downloaded the PLC tag database 3 – The session is subscribing the tags to the PLC 4 – The session is currently polling the subscribed tags 5 – The session has terminated unexpectedly and will be restarted
Socket Thread State	Current state of the socket to the PLC (same thread states as Session Thread State above)
Backend Pending Resp	Number of requests currently awaiting response from the PLC
Cache Delayed Reply	Number of cache read requests currently being delayed by driver
Group Poll Counter	Number of polls sent out by the driver
Missed Group Polls	Number of polls that were skipped by the driver
Avg Group Poll Time	Average time in milliseconds for a complete scan of the tags
Forward Opens	Number of Forward Open sessions to the PLC

Optimized Blocks	Number of optimized blocks created by the driver. Should match number of Forward Opens.
Tags Subscribed	Number of non Quality and non Timestamp Plant SCADA tags for this unit
Good Tags	Number of tags that were successfully resolved in the PLC
Bad Tags	Number of tags that were not successfully resolved in the PLC
QTM Tags	Number of Quality and Timestamp tags subscribed to
Session Disabled	Indicates whether session is currently disabled. Value of 1 indicates session is disabled.
Tag Config Warnings	Number of tags that still are considered good but have some issue that needs to be looked at
Init Timeout	Number of connection attempts that have been timed out

## Frequently Asked Questions

### Why do I get a "Channel Offline Cannot Talk" error message when the ABCLX driver is coming online?

There can be several reasons why ABCLX driver cannot bring its devices online at startup. You should initially confirm that the Boards, Ports and I/O Devices dialog boxes are filled out correctly. You should also confirm that you have enough idle time in your PLC program to allow communication requests to take place.

For details on how to diagnose this problem, search the **Tech Notes, FAQ** page of the AVEVA Knowledge and Support Center for article **#4009, ABCLX Does Not Come Online**. This tech note also includes information about parameter settings and adjustments that might impact this process.

### Why does it take so long for the ABCLX driver to come online?

When the ABCLX driver attempts to bring devices online, it initiates a process of downloading and subscribing the required tags from the associated devices. If a project has many tags, this process can overlap with driver polling, causing unnecessary delays. Insufficient idle time in the PLC processor can also cause Plant SCADA driver requests to be prolonged unnecessarily.

For details on how Plant SCADA brings the ABCLX driver online, search the **Tech Notes, FAQ** page of the AVEVA Knowledge and Support Center for article **#4001, How Does Plant SCADA Bring ABCLX Online?**.

## Every time I start Plant SCADA, I see a nuisance hardware alarm for my ABCLX device that becomes inactive after about 30 seconds. How do I stop this happening?

Hardware alarms are generated by Plant SCADA whenever InitUnit times out or reports an error. In the case of ABCLX driver, this can occur because the required tags have not downloaded and completed subscription.

As a result, there is no workaround or solution for suppressing this hardware alarm. However, the speed at which a driver comes online can be impacted by network bandwidth, PLC CPU utilization, and the number of tags and the number of bad tags.

Search the **Tech Notes, FAQ** page of the AVEVA Knowledge and Support Center for articles #4009 and #4001 for details on how to diagnose and fine-tune the startup process.

## Using CTAPI to read tags from an ABCLX device causes blank tags to appear.

Using CTAPI to read tags from a device using the ABCLX driver causes the first tag to display its value correctly, but the rest to appear blank. This is caused by request block changes in CTAPI.

To resolve this, change the Protdir.dbf entry for ABCLX from a Max\_Length of 2048 to 2032, and Bit\_Block from 2048 to 2032 on all Plant SCADA computers on the system. This allows the requested tags to be read correctly; however this reduces the maximum request length from 256 bytes to 254 bytes, which reduces the maximum size of arrays and strings.

Make this change to the protdir.dbf file in the \AVEVA Plant SCADA 2020 R2\bin and the \AVEVA Plant SCADA 2020 R2\user\include directories.

For more details, search the **Tech Notes, FAQ** page of the AVEVA Knowledge and Support Center for article #4069.

## Is it possible to address ControlLogix multidimensional arrays in Plant SCADA if the total length does not exceed 256 bytes?

The ABCLX driver supports multidimensional arrays of up to three dimensions.

## The I/O device does not come online and the "Channel Offline" error is reported

The v18 and v19 firmware revision onwards by Rockwell for its Logix5000 series processors contain changes in the communications protocol between the SCADA and the PLCs. In some circumstances these changes result in the inability for Plant SCADA to communicate with the controller (PLC) and bring tags online using the ABCLX driver version v3.04.16.000 or later. In certain situations, where ABCLX driver configuration is all correct and during runtime Kernel -> Driver page (ABCLX) confirms that there is no bad tags at all and all configured tags are successfully subscribed, still ABCLX fails to bring the device (unit) online and keeps flickering between Starting and Offline states with Init Timeout count increments.

### Solution:

In this situation, make sure External Access is granted (Read or Read/Write) for all tags including Add-On Instructions (AOI) and User-Defined data type (UDT) structure elements in the PLC project. If this is not the case or this cannot be cross-checked, please follow these steps to resolve the issue.

1. In RSLogix5000 project, select Tools > Export > Tags. Ensure that the file name follows the naming convention of PLC\_PROJECT\_NAME-Tags.csv and that the Tags and Logic Comments fields are both set to All.

2. Copy the tag export CSV file into the main SCADA project directory. The ABCLX driver will search for this file in that location only.
3. Once the CSV file is put inside the SCADA project folder, compile the project and run.

Please note that despite the fact External Access is granted (not set to None) for all the tags including Add-On Instructions (AOI) and User-Defined data type (UDT) structure elements in the PLC project, the ABCLX driver log still records following traces (error):

```
2020-12-06 14:14:03.081 +10:00 [TRACE] [EIP ] [0x00005b78] [ProcessPLCProjectName()] Attempting to
open tag export CSV file C:\ProgramData\AVEVA Plant SCADA 2020 R2\User\UDT_Test1\NewTest-Tags.csv
2020-12-06 14:14:03.081 +10:00 [ERROR] [EIP ] [0x00005b78][ProcessPLCProjectName()] Tag export CSV file
C:\ProgramData\AVEVA Plant SCADA <VersionNumber> \User\UDT_Test1\NewTest-Tags.csv could not be
open, the I/O device may not be able to connect due to tags with no external access.
```

Please ignore these messages as long as it is confirmed that External Access is granted (not set to None) to all tags including Add-On Instructions (AOI) and User-Defined data type (UDT) structure elements in the PLC project. If this is not the case, please follow the above-mentioned steps.

For more details, search the **Tech Notes**, **FAQ** page of the AVEVA Knowledge and Support Center for article #6037.

## ABMLXEIP Driver

The ABMLXEIP driver was developed to enable communications between Plant SCADA and Allen-Bradley MicroLogix devices. It is an ABMLXEIP-type board driver, which supports communication using the Encapsulation protocol over EtherNet/IP.

This driver supports reading and writing values for data files of various types, addressed in accordance with the DF1 protocol conventions.

---

**Note:** To communicate with MicroLogix devices via serial, use the **ABDF1FD** driver.

## Safety Information

### Hazard categories and special symbols

The following symbols and special messages may appear in this manual or on the product to warn of potential hazards or to call attention to information that clarifies or simplifies a procedure.

Symbol	Description
 or 	The addition of either symbol to a "Danger" or "Warning" safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.
	This is the safety alert symbol. It is used to alert you to personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.
<b>⚠ DANGER</b>	<b>DANGER</b> indicates an imminently hazardous situation, which, if not avoided, will result in death or serious injury.
<b>⚠ WARNING</b>	<b>WARNING</b> indicates a potentially hazardous situation, which, if not avoided, can result in death or serious injury.
<b>⚠ CAUTION</b>	<b>CAUTION</b> indicates a potentially hazardous situation which, if not avoided, can result in minor or moderate injury.
<b>NOTICE</b>	NOTICE used without a safety alert symbol, indicates a potentially hazardous situation which, if not avoided, can result in property or equipment damage.

## Please Note

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by AVEVA for any consequences arising out of the use of this material.

## Before You Begin

Plant SCADA is a Supervisory Control and Data Acquisition (SCADA) solution. It facilitates the creation of software to manage and monitor industrial systems and processes. Due to Plant SCADA's central role in controlling systems and processes, you must appropriately design, commission, and test your Plant SCADA project before implementing it in an operational setting. Observe the following:

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not use Plant SCADA or other SCADA software as a replacement for PLC-based control programs. SCADA software is not designed for direct, high-speed system control.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**⚠ WARNING****LOSS OF CONTROL**

- The designer of any control scheme must consider the potential failure modes of control paths and, for certain critical control functions, provide a means to achieve a safe state during and after a path failure. Examples of critical control functions are emergency stop and overtravel stop, power outage and restart.
- Separate or redundant control paths must be provided for critical control functions.
- System control paths may include communication links. Consideration must be given to the implications of unanticipated transmission delays or failures of the link.
- Observe all accident prevention regulations and local safety guidelines.<sup>1</sup>
- Each implementation of a control system created using Plant SCADA must be individually and thoroughly tested for proper operation before being placed into service.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

1. For additional information, refer to NEMA ICS 1.1 (latest edition) "Safety Guidelines for the Application, Installation, and Maintenance of Solid State Control", and to NEMA ICS 7.1 (latest edition) "Safety Standards for Construction and Guide for Selection, Installation and Operation of Adjustable-Speed Drive Systems" or their equivalent governing your particular location.

## Allen-Bradley MicroLogix via Ethernet

The ABMLXEIP Driver connects to the Allen-Bradley MicroLogix 1000, 1100, 1200, and 1500 devices.

An Ethernet card and a properly configured EtherNet/IP Interface module is required to enable the driver to communicate with a device.

**Note:** The MicroLogix 1100 device does not require an Ethernet/IP module since it comes with a built-in Ethernet port.

## See Also

[Device Address](#)

[Software Requirements](#)

[Communication Settings](#)

## Device Address

For this device, an address is not required.

The address information is placed in the **Special Options** field in the **Ports** settings by the Express Communications Wizard. In this case, the field is left blank.

## See Also

[Allen-Bradley MicroLogix via Ethernet](#)

## Software Requirements

The following software is required when using the ABMLXEIP driver:

- RSLogix 500 software to create and configure various data files within a MicroLogix device
- ENI utility to configure the EtherNet/IP Interface Module.

---

**Note:** The MicroLogix 1100 requires Rockwell's BOOTP-DHCP server to configure the IP address for the built-in Ethernet port.

---

## See Also

[Allen-Bradley MicroLogix via Ethernet](#)

## Communication Settings

To establish communication with a device, the associated **Board**, **Port** and **I/O Device** need to be correctly configured in Plant SCADA Studio's **Topology** activity.

If you use the Express Communications Wizard to connect to a device, these settings will be automatically configured for you. However, if you need to manually configure them, use the information outlined below.

## Boards

Field	Value
Board Name	A unique name (up to 16 alphanumeric characters) per server for the computer board being used to connect with the device. This is used by Plant SCADA in the Ports settings.
Board Type	The type of board. Input ABMLXEIP.
Address	This field must be "0" (zero).
I/O Port	Leave this field blank.

Interrupt	Leave this field blank.
Special Options	Leave this field blank.
Comment	Any useful comment.

## Ports

Field	Value
Port Name	A unique name (up to 16 alphanumeric character) for the computer port being used to connect with the device. This is used by Plant SCADA in the I/O Devices settings.
Port Number	An integer value, unique to the board as defined in the Board Name field. The Ethernet port needs no identification; however, the Plant SCADA communication database requires a value in this field.
Board Name	The name of the board this port is attached to as defined in the Boards settings.
Baud Rate	Leave this field blank.
Data Bits	Leave this field blank.
Stop Bits	Leave this field blank.
Parity	Leave this field blank.
Special Options	IP Address of EtherNet/IP interface module
Comment	Any useful comment.

## Devices

Field	Value
Name	A unique name (up to 16 alphanumeric character) for the I/O Device being identified. Each I/O Device must have a unique name in the Plant SCADA system.
Number	A unique number for the I/O Device (0–16383).

	Each I/O Device must have a unique number in the Plant SCADA system, (unless redundancy of the I/O Device is being used).
Address	Leave this field blank.
Protocol	Enter ABMLXEIP.
Port Name	This field must contain one of the names previously defined in the Port Names field of the Ports settings. There must be only one I/O device per port.
Comment	Any useful comment.

## Tag Addressing

The address format for reading and writing values to and from MicroLogix PLC controllers depends on which MicroLogix data file you would like to address.

For each data file type, the following conventions apply:

f	file number
e	element number (or slot number for input and output data files)
s	sub-element number (or word number for input and output data files)
b	bit number (or terminal number for input and output data files)

For the allowable range of values, the following conventions apply:

[y - z]	the number range from y to z inclusive
x, [y - z]	the number x and the number range from y to z inclusive.

Each data file type also has correct address formats and a range of allowable values. The file types are:

- [Output Data File](#)
- [Input Data File](#)
- [Status Data File](#)

- Bit Data File
- Timer Data File
- Counter Data File
- Control Data File
- Integer Data File
- Float Data File
- Long Word Data File
- String Data File

## Output Data File

Plant SCADA Type	Tag Address Rule	Allowable Value Ranges
INT	Of:e.s	f - file number: 0, optional e - slot number: [0-30] s - word number: [0-255]
DIGITAL	Of:e.s/b	f - file number: 0, optional e - slot number: [0-30] s - word number: [0-255] b - terminal number: [0-15]

## Examples

Examples	Meaning
O:1.3	Output data file, slot 1, word 3
00:1.3	Output data file 0, slot 1, word 3
O:1.3/2	Output data file, slot 1, word 3, terminal 2
00:1.3/2	Output data file 0, slot 1, word 3, terminal 2

## See Also

Plant SCADA Type	Tag Address Rule	Allowable Ranges
LONG	Lf:e	f - file number: [9-255] e - element number:[0-255]

## Examples

Examples	Meaning
L16:10	Long Word data file 16, element 10

## See Also

[Tag Addressing](#)

## String Data File

Plant SCADA Type	Tag Address Rule	Allowable Value Ranges
INT	STf:e.s STf:e.LEN STf:e.DATA[n]	f - file number: [9-255] e - element number: [0-255] s - sub-element number: [0-41] n - a pair of characters (high & low bytes): [0-40]
STRING	STf:e.DATA	f - file number: [9-255] e - element number: [0-255] <b>Note:</b> This tag would cover the entire string contents (excluding length byte)

## Examples

Examples	Meaning
ST9:1.0	String data file 9, element 1, sub-element 0
ST9:1.LEN	String data file 9, element 1, sub-element 1 (which is LEN)
ST9:3.DATA	String data file 9, element 3, entire string contents
ST9:1.DATA[2]	String data file 9, element 1, characters 5 and 6 [*see table below]

The DATA[x] string can specify certain characters only as shown in the following table:

DATA[0]	Indicates characters 1 and 2
DATA[1]	Indicates characters 3 and 4
DATA[2]	Indicates characters 5 and 6
etc...	etc...

[Tag Addressing](#)

## Advanced Configuration and Maintenance

This section provides instructions for advanced configuration and maintenance tasks. It includes the following topics:

[Configuring Redundancy](#)

[Optimizing Communications](#)

[Customizing a Project using Citect.ini Parameters](#)

## Configuring Redundancy

In order to support Plant SCADA redundancy, at least two I/O devices need to be configured for the same PLC, i.e. one as Primary and all others as Standby. While the primary I/O device services Plant SCADA requests, all standby I/O devices are polled for their status every configured **WatchTime** to determine whether they are online.

Both the Primary and Standby devices will be offline if both have the same inoperable status condition. All tags in the system for that unit would be #COM.

## Optimizing Communications

As the ABMLXEIP driver is a front-end/back-end driver, there are no transport delays when processing read requests between Plant SCADA and the driver cache. If many requests are being serviced simultaneously, the CPU of the I/O Server may be pushed to its performance limitations.

This may lead to communication problems, evidenced by #COM appearing occasionally on graphics pages, or "Command canceled" errors appearing in the Kernel Window.

If this happens, you can tune the driver throughput to help manage the resources of the I/O server. The standard driver parameters you can use to achieve this are **MaxPending** and **Delay**.

MaxPending limits the number of requests handled simultaneously, and can be used as follows:

[ABF1FD]MaxPending=x

where:

x = the maximum number of requests the driver can service simultaneously.

You can also implement a time delay to steady the flow of requests to the driver, rather than having them sent in bursts. The standard driver parameter Delay can be used as follows:

[ABMLXEIP]Delay=x

where:

x = the time delay (in milliseconds) between the delivery of each message.

The two can be used in tandem to maximize the number of requests managed simultaneously, while improving system stability.

## Examples

[ABF1FD]MaxPending=1

The above example would mean the driver would service just one request at a time, and would wait for a reply to each request before the next one is sent.

[ABF1FD]MaxPending=256

The above example would mean that the driver is capable of servicing up to 256 requests at the same time. This means up to 256 requests can be sent before waiting for a response.

[ABMLXEIP]Delay=20

This example would result in a 20 millisecond delay between each request sent, slowing the rate of delivery to a manageable pace.

---

**Note:** MaxPending=1 would make the Delay parameter redundant, as only one request would be handled at a time.

## Customizing a Project using Citect.ini Parameters

The ABMLXEIP driver supports the following parameter categories:

- Common Parameters
- Specific Parameters
- Logging Parameters.

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

- Do not under any circumstances change or remove any citect.ini parameters without an informed understanding of the possible implications of your actions.
- Do not delete sections of the citect.ini file without an informed understanding of the possible implications of your actions.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** At times during the life cycle of a driver, circumstances may call for the creation of specific citect.ini parameters that remain undocumented. Always seek the advice of Technical Support regarding the possible implementation of undocumented parameters before you make any changes to a citect.ini file.

**Common Parameters****⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

Parameters grouped beneath the [ABLMXEIP] category in the citect.ini file are global and impact MicroLogix system PLCs.

The following table describes the common citect.ini driver parameters.

[ABLMXEIP] Parameter	Allowable Values	Default Value	Description
Block	1 to 248	248	A value (bytes) used by the Plant SCADA I/O server to determine if two or more packets can be blocked into one data request before being sent to the ABMLXEIP driver. Do not make this value greater than 248, as this is the maximum number of bytes that can be requested from the device. For this setting to have a bearing, the PROTDIR.DBF file will

			need to be altered.
Delay	0 to 300	20	The time delay (in milliseconds) between the delivery of each message. Use this parameter to avoid messages being sent in bursts.
MaxPending	1 to 256	5	The maximum number of pending commands that the Plant SCADA ABMLXEIP driver holds ready for immediate execution.
Retry	0 to 5	3	The number of times to retry a command after a timeout. This is also the maximum number of total retries before the device is considered offline.
Timeout	100 to 30000	3000	Specifies how many milliseconds to wait for a response before considering a write or polling request to be invalid and displaying an error message in Plant SCADA. Connection timeout will be TimeOut * 3.
Watchtime	5 to 30	30	The period (in seconds) that the Plant SCADA ABMLXEIP driver uses to check the communications link to the MicroLogix system and attempts to bring offline units back online. Also determines the rate of STATUS_UNIT commands to the driver. See <a href="#">Configuring Redundancy</a> .

### Specific Parameters

#### **WARNING**

##### **UNINTENDED EQUIPMENT OPERATION**

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

The following table describes the driver-specific Citect.ini parameters.

[ABLMXEIP] Parameter	Allowable Values	Default Value	Description
ENIOnlyMode	1 - enabled 0 - disabled	0	This parameter enables a communication method that works exclusively with an ENI Ethernet/IP module. It does not support communication with the built-in port on a MicroLogix 1100.  You should only enable this parameter if you are experiencing difficulties communicating with a device (other than an MicroLogix 1100) via an Ethernet/IP module.

### Logging Parameters

#### **WARNING**

##### **UNINTENDED EQUIPMENT OPERATION**

Do not under any circumstances change or remove any of the undocumented citect.ini parameters.

Before deleting sections of the citect.ini file, confirm that no undocumented parameters will be deleted.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

[ABMLXEIP] Parameter	Description	Allowable Values	Default Value
DebugLevel	The trace level used for the log file.	Any combination of the following, separated by a pipe character ( ): ERROR WARN TRACE ALL See <a href="#">Logging</a> for examples.	-
DebugCategory	The categories used for the log file.	Any combination of the following, separated by a pipe character ( ): TAG= Tag configuration trace SOCK= Socket trace EIP= EIP session trace DCB= Front-end driver trace BUFF= Dump a counted buffer to hex THRD= Thread trace ALL = all of the above. See <a href="#">Logging</a> for examples.	-

## Troubleshooting

The following topics provide information about the tools available to diagnose and resolve any unexpected behavior from the ABMLXEIP driver at runtime:

- [Logging](#)
- [Specific Errors](#)
- [Kernel Diagnostics.](#)

## Logging

The ABMLXEIP driver can log combinations of trace levels across different categories. This is achieved by setting the following INI parameters.

### [ABMLXEIP]DebugLevel

This parameter allows you to define the trace level. The options include:

Option	Description
WARN	Output warning messages.
ERROR	Output error messages.
TRACE	Output trace messages.
ALL	All of the above.

### [ABMLXEIP]DebugCategory

This parameter allows you to enable logging for a particular trace category. The options include:

Option	Description	Notes
TAG	Tag configuration trace.	N/A for ABMLXEIP driver
SOCK	Socket trace.	
EIP	EIP session trace.	
DCB	Front end driver trace.	
BUFF	Dump a counted buffer to hex.	
THRD	Thread trace.	
ALL	All of the above.	

In both cases, you can use any combination of the available options separated by a pipe character ( | ).

#### Example

```
[ABMLXEIP]
DebugLevel=WARNING|ERROR|TRACE
DebugCategory=ALL
```

In most cases, you can set the DebugLevel and DebugCategory parameters to ALL. If this results in a large, cumbersome log file that causes older data to be overwritten, you can consider refining the debug options.

---

**Note:** These parameters do not have a value specified by default. To enable logging for this driver, you need to manually configure these parameters in your INI file.

The events generated by the ABMLXEIP driver are logged in the following Plant SCADA syslog file:

syslog.IOServer.<Cluster name>.<IO Server name>.dat

This file is located in the directory specified by the Citect.ini parameter [**CtEditLogs**]. By default, this location will be:

%PROGRAMDATA%\AVEVA Plant SCADA <VersionNumber>\Logs

The size of the syslog file and its rollover process is configured via the [**DebugSysLogSize**] and [**DebugSysLogArchive**] INI parameters. For more information, see the topic *Debug Parameters* in the Plant SCADA documentation.

**Note:** If the number of messages being processed for a driver exceeds the value specified by the Plant SCADA parameter [Kernel]ErrorBuffers, the pending messages will not be logged. If this occurs, you can increase the value of this parameter so that all the messages generated by the driver are reported. The number of messages that are not logged can be monitored via the Kernel's General window under the item "Lost Errors". If you adjust [Kernel]ErrorBuffers and Lost Errors are still occurring, you may need to adjust the level of system logging.

[Troubleshooting](#)

## Specific Errors

The following errors, listed in (hexadecimal) sequence, are specific to the Plant SCADA ABMLXEIP protocol:

Error Value	Error Definition
0x01000	Bad request from SCADA – device cannot service the request (device error)
0x10001	Bad response to ECHO command from the device (driver error)
0x10002	Bad response to READ command from the device (driver error)
0x10003	Bad response to WRITE command from the device (driver error)
0x10004	Unrecognized message from the device (driver error)
0x10006	Device cannot process requests at the current rate of delivery. Increase the Delay parameter value, or decrease the MaxPending parameter value. See <a href="#">Optimizing Communications</a> .

You may require additional information to enable you to rectify an error. This information should be detailed in the documentation that accompanied the MicroLogix system.

[Troubleshooting](#)

## Kernel Diagnostics

The Plant SCADA Kernel Driver window, launched via the Page Driver Kernel command, displays information about each driver in the Plant SCADA system. The statistics it presents include: read requests; physical reads; digital reads per second; register reads; cache reads; error count; timeouts; etc. See the Plant SCADA User Guide for details on the general statistics it presents.

The following ABMLXEIP driver statistics are maintained and displayed per channel:

Driver Statistics Entry	Description
Total Requests	Total requests made to the device
Total Req Bytes	Length of all requests made (in bytes)
Min Bytes per Req	Minimum request length (in bytes)
Max Bytes per Req	Maximum request length (in bytes)
Ave Bytes per Req	Average request length (in bytes)
Total Replies	Total replies received from the device
Total Rep Bytes	Length of all replies received (in bytes)
Min Bytes per Rep	Minimum reply length (in bytes)
Max Bytes per Rep	Maximum reply length (in bytes)
Ave Bytes per Rep	Average reply length (in bytes)
Total Connects	Total number of successful connects and reconnects to the device
Last Req in Queue	Number of requests sent to the device during the last attempt
Max Req in Queue	Maximum number of requests sent to the device at one time
Min Wait (ms)	Minimum wait for a response from the device (in milliseconds)
Max Wait (ms)	Maximum wait for a response from the device (in milliseconds)
Ave Wait (ms)	Average wait for a response from the device (in milliseconds)

## ABTCP Driver

The ABTCP protocol supports TCP/IP and Data Highway Plus communication with Allen-Bradley PLC-5/250, PLC-2, PLC-3, SLC-500, and PLC-5 series PLCs.

No additional software is required by when Data Highway Plus is used with the KT, KTX, KTXD, PKTX cards, or the 5136-SD-ISA or 5136-SD-PCI boards. Unlike the ABEI protocol, the Allen-Bradley Interchange software is not required.

When using TCP/IP, the physical communication layer is usually Ethernet. This requires an Ethernet board installed in your computer, and an Ethernet Interface with a transceiver installed at the PLC end. It is recommended you setup your specific Ethernet card as required and confirm basic network communications before proceeding with the communications configuration for the ABTCP driver.

The same Ethernet card that is being used for communication can be used for PLC communication

The Resource Manager of the PI can provide access to Data Highway (DH/DH+) links, permitting to communicate through the PI to PLC-5s, PLC-2s, PLC-3s, and SLC-500s (via offlink addressing). An AB-KA module provides similar indirect communication through PLCs.

The maximum request length for the ABTCP protocols is 1888 bits.

Other I/O Devices may also be supported. Contact Technical Support for further information.

## Hot Standby Support

The ABTCP protocol supports hot standby in the case that the PLC is put into **program** mode. See the [\[ABTCP\]Status](#) parameter.

## Safety Information

### Hazard categories and special symbols

The following symbols and special messages may appear in this manual or on the product to warn of potential hazards or to call attention to information that clarifies or simplifies a procedure.

Symbol	Description
 or 	The addition of either symbol to a "Danger" or "Warning" safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.
	This is the safety alert symbol. It is used to alert you to personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.

**⚠ DANGER**

**DANGER** indicates an imminently hazardous situation, which, if not avoided, will result in death or serious injury.

**⚠ WARNING**

**WARNING** indicates a potentially hazardous situation, which, if not avoided, can result in death or serious injury.

**⚠ CAUTION**

**CAUTION** indicates a potentially hazardous situation which, if not avoided, can result in minor or moderate injury.

**NOTICE**

NOTICE used without a safety alert symbol, indicates a potentially hazardous situation which, if not avoided, can result in property or equipment damage.

**Please Note**

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by AVEVA for any consequences arising out of the use of this material.

**Before You Begin**

Plant SCADA is a Supervisory Control and Data Acquisition (SCADA) solution. It facilitates the creation of software to manage and monitor industrial systems and processes. Due to Plant SCADA's central role in controlling systems and processes, you must appropriately design, commission, and test your Plant SCADA project before implementing it in an operational setting. Observe the following:

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not use Plant SCADA or other SCADA software as a replacement for PLC-based control programs. SCADA software is not designed for direct, high-speed system control.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**⚠ WARNING****LOSS OF CONTROL**

- The designer of any control scheme must consider the potential failure modes of control paths and, for certain critical control functions, provide a means to achieve a safe state during and after a path failure. Examples of critical control functions are emergency stop and overtravel stop, power outage and restart.
- Separate or redundant control paths must be provided for critical control functions.
- System control paths may include communication links. Consideration must be given to the implications of unanticipated transmission delays or failures of the link.
- Observe all accident prevention regulations and local safety guidelines.<sup>1</sup>
- Each implementation of a control system created using Plant SCADA must be individually and thoroughly tested for proper operation before being placed into service.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

1. For additional information, refer to NEMA ICS 1.1 (latest edition) "Safety Guidelines for the Application, Installation, and Maintenance of Solid State Control", and to NEMA ICS 7.1 (latest edition) "Safety Standards for Construction and Guide for Selection, Installation and Operation of Adjustable-Speed Drive Systems" or their equivalent governing your particular location.

## Supported Devices via TCP/IP

The following devices are supported by the ABTCP driver via TCP/IP:

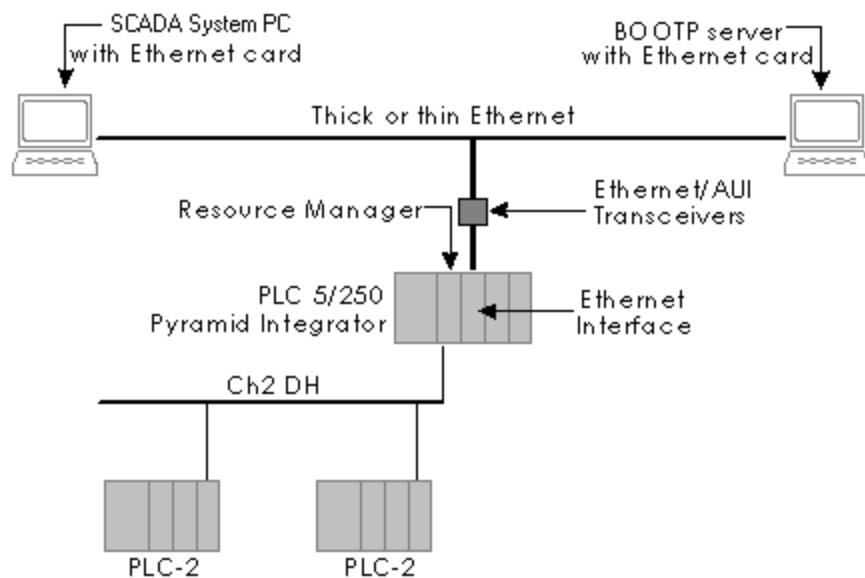

- Allen-Bradley PLC-2
- Allen-Bradley PLC-3
- Allen-Bradley PLC-5
- Allen-Bradley PLC-5/250
- Allen-Bradley SLC-500

**Note:** You can communicate with these devices directly using TCP/IP, or via a [Data Highway Board](#).

### Allen-Bradley PLC-2 via TCP/IP

The information included in the following pages describes how to connect Allen-Bradley PLC-2 devices using the ABTCP protocol to a Plant SCADA system.

Using this method, you can connect to multiple PLCs as in the following diagram:

You cannot make a direct physical Ethernet connection to a PLC-2. An Ethernet Interface (EI) must be provided - typically by using a 5/250 Pyramid Integrator.

The Allen-Bradley Ethernet arrangement requires a BOOTP server. The BOOTP server is required by the EI modules to download configuration information. Refer to your Allen-Bradley documentation for BOOTP information.

The diagram above does not show all of the possible connection options - consult your Allen-Bradley manuals for more information.

#### Allen-Bradley PLC-2 via TCP/IP - Device Address

The address for this device uses the following format:

`-la-Pn -T`

where:

*a* = the destination IP address in standard Internet dot format. (For example, 192.9.2.60)

*n* = the destination Port number. Often one physical port has several virtual ports, used for different purposes. Use this option only if you want to override the default of 2222.

*-T* = forces the driver to use TCP (the default), rather than UDP (-U).

This information is placed in the **Special Options** field of Plant SCADA's **Ports** settings by the Express Communications Wizard.

#### Allen-Bradley PLC-2 via TCP/IP - Hardware Setup

Because this driver does not receive information regarding the state of the physical transport layer, no specific details can be given for setting up communications. Follow these general steps:

1. Set up the PLC 5/250 resource manager or AB-KA module. Assign the IP address, and test that it is valid by using the Ping program.
2. Set up the PLC-2 and 1771-KA/KA2 for communications on the DH network to which it is connected. Be sure to set the Node Address, Baud Rate, and Write Options on each PLC communication module.

3. Check that you can communicate to the PLC using offlink addressing. You can use the utility accompanying the Allen-Bradley Interchange software to verify that you can communicate from a PC over Ethernet.

## Plant SCADA Computer Setup

Setup your specific Ethernet card as required and confirm basic network communications before proceeding with the communications configuration for the ABTCP driver. Refer to the documentation accompanying your hardware for instruction. You must also setup TCP/IP protocol on your Plant SCADA computer.

### Allen-Bradley PLC-2 via TCP/IP - Communication Settings

To establish communication with a device, the associated Board, Port and I/O Device need to be correctly configured in Plant SCADA Studio's **Topology** activity.

If you use the Express Communications Wizard to connect to a device, these settings will be automatically configured for you. However, if you need to manually configure them, use the settings outlined below.

## Boards

Field	Value
Board Type	Enter TCPIP.
Address	Enter 0.
I/O Port	Leave this field blank.

Data Bits	Leave this field blank.
Stop Bits	Leave this field blank.
Parity	Leave this field blank.
Special Options	Enter the destination IP address of Ethernet module. Use the following format: <b>-Ia -Pn -T</b>

Field	Value
	<p>where:</p> <p><b>a</b> = the destination IP address in standard Internet dot format. (For example, 192.9.2.60)</p> <p><b>n</b> = the destination Port number. Often one physical port has several virtual ports, used for different purposes. Use this option only if you want to override the default of 2222.</p> <p><b>-T</b> = forces the driver to use TCP (the default), rather than UDP (-U).</p>

## I/O Devices

Field	Value
I/O Device Address	Specify the <a href="#">Offlink Address</a> in the form: <b>PMM:C[options],u</b>
I/O Device Protocol	Enter ABTCP2.

### Allen-Bradley PLC-2 via TCP/IP - Data Types

Data Types	Address Format	Plant SCADA Data Type
Digital Data	x/y	DIGITAL
Integer	x	BCD / INT / LONG /LONGBCD

Where:

**x** = a word in octal (0 - 3777)

**y** = a bit number in octal (0 - 17)

## Examples

Data Type	DIGITAL
Address	200/12
Comment	Digital Data - Word Number 200 / Bit Number 12
Data Type	INT
Address	1700

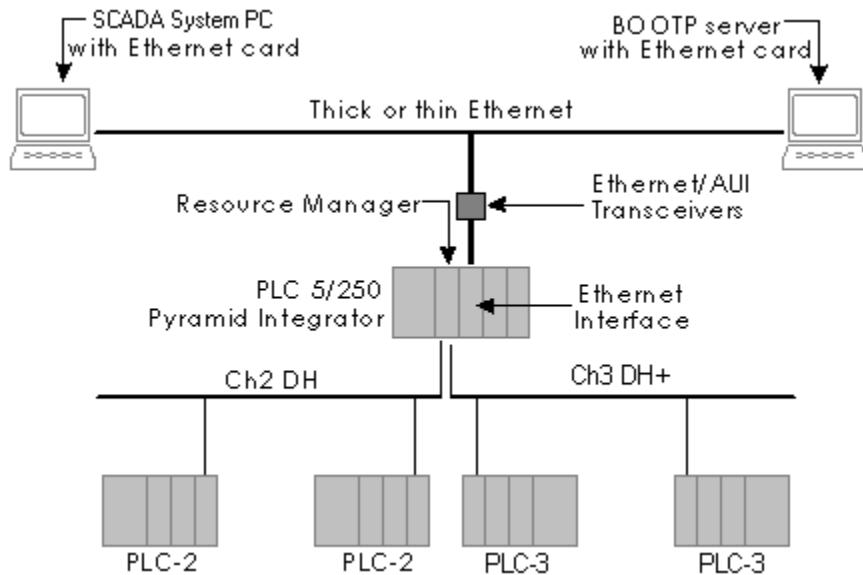

Comment	Integer - Word Number 1700
---------	----------------------------

Allen-Bradley PLC-2s support remapping reads and writes.

## Allen-Bradley PLC-3 via TCP/IP

The information included in the following pages describes how to connect the Allen-Bradley PLC-3 devices using the ABTCP protocol to a Plant SCADA system.

Using this method, you can connect to multiple PLCs as in the following diagram:

You cannot make a direct physical Ethernet connection to a PLC-3. An Ethernet Interface (EI) must be provided - typically by using a 5/250 Pyramid Integrator.

The Allen-Bradley Ethernet arrangement requires a BOOTP server. The BOOTP server is required by the AB EI modules to download configuration information. Refer to your Allen-Bradley documentation for BOOTP information.

The diagram above does not show all the possible connection options. Consult your Allen-Bradley manuals for more information.

## Allen-Bradley PLC-3 via TCP/IP - Device Address

The address for this device uses the following format:

-la -Pn -T

where:

a = the destination IP address in standard Internet dot format. (For example, 192.9.2.60)

n = the destination Port number. Often one physical port has several virtual ports, used for different purposes. The default is 2222.

-T = forces the driver to use TCP (the default), rather than UDP (-U).

This information is placed in the **Special Options** field of Plant SCADA's **Ports** settings by the Express Communications Wizard.

## Allen-Bradley PLC-3 via TCP/IP - Hardware Setup

Because this driver does not receive information regarding the state of the physical transport layer, no specific details can be given for setting up communications. Be sure to follow these general steps:

1. Set up the PLC 5/250 resource manager or AB-KA module. Assign the IP address, and test that it is valid by using the Ping program (explained in the TCP/IP Guide).
2. Set up the PLC-3 and 1775-KA for communications on the DH network to which it is connected. Set the Node Address and Options on each PLC communication module.
3. Check that you can communicate to the PLC using offlink addressing. You can use the utility accompanying the Allen-Bradley Interchange software to verify that you can communicate from a PC over Ethernet.

## Plant SCADA Computer Setup

Setup your specific Ethernet card as required and confirm basic network communications before proceeding with the communications configuration for the ABTCP driver. Refer to the documentation accompanying your hardware for instruction. Setup TCP/IP protocol on your Plant SCADA computer.

## Allen-Bradley PLC-3 via TCP/IP - Communication Settings

To establish communication with a device, the associated Board, Port and I/O Device need to be correctly configured in Plant SCADA Studio's **Topology** activity.

If you use the Express Communications Wizard to connect to a device, these settings will be automatically configured for you. However, if you need to manually configure them, use the settings outlined below.

### Boards

Field	Value
Board Type	Enter TCPIP.
Address	Enter 0.
I/O Port	Leave this field blank.
Interrupt	Leave this field blank.
Special Options	Leave this field blank.

### Ports

Field	Value
Port Number	Leave this field blank.
Baud Rate	Leave this field blank.

Field	Value
Data Bits	Leave this field blank.
Stop Bits	Leave this field blank.
Parity	Leave this field blank.
Special Options	<p>Enter the destination IP address of Ethernet module. Use the following format:</p> <p><b>-la -Pn -T</b></p> <p>where:</p> <p><b>a</b> = the destination IP address in standard Internet dot format. (For example, 192.9.2.60)</p> <p><b>n</b> = the destination Port number. Often one physical port has several virtual ports, used for different purposes. Use this option only if you want to override the default of 2222.</p> <p><b>-T</b> = forces the driver to use TCP (the default), rather than UDP (-U).</p>

## I/O Devices

Field	Value
I/O Device Address	Specify the <a href="#">Offlink Address</a> in the form: <b>PMM:C[options],u</b>
I/O Device Protocol	Enter ABTCP3.

### Allen-Bradley PLC-3 via TCP/IP - Data Types

**Note:** The Allen-Bradley PLC-3 has many data types. The driver makes a separate request for each different data type, and each request has a finite overhead. It is more efficient to read fewer data types, so you should move the I/O and other data into a few main blocks to be read by Plant SCADA.

Data Types	Address Format	Plant SCADA Data Type
Output image	<b>Of:O/o</b> (f is optional)	DIGITAL
Input image	<b>If:O/o</b> (f is optional)	DIGITAL
Timer Control bits	<b>TCTL:w/t</b>	DIGITAL
Timer Control bits	<b>TCTL:w/o</b>	DIGITAL

Data Types	Address Format	Plant SCADA Data Type
Timer Preset bits	<b>TPRE:w/o</b>	DIGITAL
Timer Accumulator bits	<b>TACC:w/o</b>	DIGITAL
Counter Control bits	<b>CCTL:w/t</b>	DIGITAL
Counter Control bits	<b>CCTL:w/o</b>	DIGITAL
Counter Preset bits	<b>CPRE:w/o</b>	DIGITAL
Counter Accumulator bits	<b>CACC:w/o</b>	DIGITAL
ASCII	<b>Af:w/o</b>	DIGITAL
BCD	<b>Df:w/o</b>	DIGITAL
REAL	<b>Ef:w/o (o = 0 to 37)</b>	DIGITAL
LONG	<b>Hf:w/o (o = 0 to 37)</b>	DIGITAL
Integer	<b>Nf:w/o</b>	DIGITAL
Binary	<b>Bf:w/o</b>	DIGITAL
Status words	<b>Sf:w/o</b>	DIGITAL
Pointer Section and File	<b>PFIL:w/o</b>	DIGITAL
Pointer word	<b>PWRD:w/o</b>	DIGITAL
Output image	<b>Of:O (f is optional)</b>	BCD / INT
Input image	<b>If:O (f is optional)</b>	BCD / INT
Timer Control	<b>TCTL:w</b>	BCD / INT

Address	I:1/15
Comment	Input Image - Element Number 1 / Bit Number 15
Data Type	INT
Address	N7:3
Comment	Integer - File Number 7 : Element Number 3

Allen Bradley PLC-3s support remapping reads and writes.

### Allen-Bradley PLC-5 via TCP/IP

The information included in the following pages describes how to connect the Allen-Bradley PLC-5 devices using the ABTCP protocol to a Plant SCADA system.

Using this method, you can connect to multiple PLCs as in the following diagram:

The Allen-Bradley Ethernet arrangement requires a BOOTP server. The BOOTP server is required by the AB EI modules to down-load configuration information. Refer to your Allen-Bradley documentation for BOOTP information.

This diagram does not show all the possible connection options. Consult your Allen-Bradley manuals for more information.

#### Allen-Bradley PLC-5 via TCP/IP - Device Address

The address for this device uses the following format:

`-la -Pn -T`

Where:

*a* = the destination IP address in standard Internet dot format. (For example, 192.9.2.60)

*n* = the destination Port number. Often one physical port has several virtual ports, used for different purposes. The default is 2222.

*-T* = forces the driver to use TCP (the default), rather than UDP (-U).

This information is placed in the **Special Options** field of Plant SCADA's **Ports** settings by the Express Communications Wizard.

#### Allen-Bradley PLC-5 via TCP/IP - Hardware Setup

There are two methods of connecting to a PLC-5 series PLC:

- direct
- offlink.

## Direct Ethernet

PLC-5E model PLCs can support a direct Ethernet connection. In this case all that you need to do is assign the PLC an IP address, by using the BOOTP utility (refer to the Allen-Bradley documentation). Test that the network and IP address is valid by using the Ping program (explained in the TCP/IP Guide).

## Offlink

In the case that you have PLC-5s that are not Ethernet capable, or if they are connected via DH or DH+ through a 5/250 or AB-KA, you can still access them through [Offlink Addressing](#). Follow these general steps:

1. Set up the PLC 5/250 resource manager or AB-KA module. Assign the IP address, and test that it is valid by using the Ping program (explained in the TCP/IP Guide).
2. Set up the PLC-5 for communications on the DH or DH+ network to which it is connected. Set the Node Address, Baud rate etc.
3. Check that you can communicate to the PLC using offlink addressing. You can use the utility accompanying the Allen-Bradley Interchange software to verify that you can communicate from a PC over Ethernet.

### Hints and Tips

- The EI module may be mounted in the rack of the PLC-5/250, or PLC-5 series controllers, or built into the PLC-5 \*E controllers. The module has a DIX connector that requires an AUI cable to attach via a transceiver to the thin or thick Ethernet cable.
- The EI module requires a Signal Quality Error (SQE) test - also known as a heartbeat. Set your Ethernet transceiver with the SQE test enabled.
- If your **machine is very slow** and has a heavy processing load, you may find that this protocol is generating timeout errors (decimal 21). Setting the [Kernel]Idle parameter less than the default may fix this problem.

## Plant SCADA Computer Setup

Setup your specific Ethernet card as required and confirm basic network communications before proceeding with the communications configuration for the ABTCP driver. Refer to the documentation accompanying your hardware for instructions.

[Setup the TCP/IP protocol](#) on your Plant SCADA computer.

### Allen-Bradley PLC-5 via TCP/IP - Communication Settings

To establish communication with a device, the associated Board, Port and I/O Device need to be correctly configured in Plant SCADA Studio's **Topology** activity.

If you use the Express Communications Wizard to connect to a device, these settings will be automatically configured for you. However, if you need to manually configure them, use the settings outlined below.

## Boards

Field	Value
Board Type	Enter TCPIP.
Address	Enter 0.
I/O Port	Leave this field blank.
Interrupt	Leave this field blank.
Special Options	Leave this field blank.

## Ports

Field	Value
Port Number	Leave this field blank.
Baud Rate	Leave this field blank.
Data Bits	Leave this field blank.
Stop Bits	Leave this field blank.
Parity	Leave this field blank.
Special Options	<p>Enter the destination IP address of Ethernet module. Use the following format:</p> <p><b>-la -Pn -T</b></p> <p>where:</p> <p><b>a</b> = the destination IP address in standard Internet dot format. (For example, 192.9.2.60)</p> <p><b>n</b> = the destination Port number. Often one physical port has several virtual ports, used for different purposes. Use this option only if you want to override the default of 2222.</p> <p><b>-T</b> = forces the driver to use TCP (the default), rather than UDP (-U).</p>

## I/O Devices

Field	Value
I/O Device Address	<p>You can leave this field blank if your PLC has a direct Ethernet connection.</p> <p>If you have your PLC connected to a DH+ or DH</p>

Field	Value
	network, and accessed through another 5/250 or AB-KA, specify the <a href="#">Offlink Address</a> in the form: <b>PMM:C[options],u</b>
I/O Device Protocol	Enter ABTCP5.

**Allen-Bradley PLC-5 via TCP/IP - Data Types**

**Note:** The Allen-Bradley PLC-5 has many data types. The driver makes a separate request for each different data type, and each request has a finite overhead. It is more efficient to read fewer data types, so you should move the I/O and other data into a few main blocks to be read by Plant SCADA.

Data Types	Address Format	Plant SCADA Data Type
Output image	O:O/o	DIGITAL

Allen Bradley PLC-5 Series support remapping reads and writes.

### Allen-Bradley PLC-5/250 via TCP/IP

The information included in the following pages describes how to connect Allen-Bradley PLC-5/250 devices using the ABTCP protocol to a Plant SCADA system. Using this method, you can connect to multiple PLCs as in the following diagram:

The Allen-Bradley Ethernet arrangement requires a BOOTP server. The BOOTP server is required by the EI modules to download configuration information. Refer to your Allen-Bradley documentation for BOOTP information.

This diagram does not show all of the possible connection options. Consult your Allen-Bradley manuals for more information.

### Allen-Bradley PLC-5/250 via TCP/IP - Device Address

The address for this device uses the following format:

-la -Pn -T

where:

*a* = the destination IP address in standard Internet dot format. (For example 192.9.2.60)

*n* = the destination Port number. Often one physical port has several virtual ports, used for different purposes. The default is 2222.

-T = forces the driver to use TCP (the default), rather than UDP (-U).

This information is placed in the **Special Options** field of Plant SCADA's **Ports** settings by the Express Communications Wizard.

### Allen-Bradley PLC-5/250 via TCP/IP - Hardware Setup

There are two methods of connecting to a PLC-5 series PLC:

- direct
- offlink.

#### Direct Ethernet

PLC-5E model PLCs can support a direct Ethernet connection. In this case all that you need to do is assign the PLC an IP address, by using the BOOTP utility (refer to the Allen-Bradley documentation). Test that the network and IP address is valid by using the Ping program (explained in the TCP/IP Guide).

#### Offlink

In the case that you have PIs connected via DH or DH+ through another 5/250 or AB-KA, you can still access them through [Offlink Addressing](#). Follow these general steps:

1. Set up the PLC 5/250 resource manager or AB-KA module. Assign the IP address, and test that it is valid by using the Ping program (explained in the TCP/IP Guide).
2. Set up the PLC-5 for communications on the DH or DH+ network to which it is connected. Set the Node Address, Baud rate etc.
3. Check that you can communicate to the PLC using offlink addressing. You can use the utility accompanying the Allen-Bradley Interchange software to verify that you can communicate from a PC over Ethernet.

### Plant SCADA Computer Setup

It is recommended you setup your specific Ethernet card as required and confirm basic network communications before proceeding with the communications configuration for the ABTCP driver. Refer to the documentation accompanying your hardware for instruction.

[Setup the TCP/IP protocol](#) on your Plant SCADA computer.

### Allen-Bradley PLC-5/250 via TCP/IP - Communication Settings

To establish communication with a device, the associated Board, Port and I/O Device need to be correctly configured in Plant SCADA Studio's **Topology** activity.

If you use the Express Communications Wizard to connect to a device, these settings will be automatically configured for you. However, if you need to manually configure them, use the settings outlined below.

### Boards

I/O Device Protocol	Enter ABTCP250.

### Allen-Bradley PLC-5/250 via TCP/IP - Data Types

**Note:** The Allen-Bradley PLC-5/250 has many data types. The driver makes a separate request for each different data type, and each request has a finite overhead. It is more efficient to read fewer data types, so you should move the I/O and other data into a few main blocks to be read by Plant SCADA.

Data Types	Address Format	Plant SCADA Data Type
Output image	O:O/o	DIGITAL

Allen Bradley 5/250 PLCs support remapping reads and writes.

## Allen-Bradley SLC-500 via TCP/IP

The information included in the following pages describes how to connect Allen-Bradley SLC-500 devices using the ABTCP protocol to a Plant SCADA system.

All SLC models (500, 5/01, 5/02, 5/03, and 5/04) are supported. Using this method, you can connect to multiple SLCs as in the following diagram:

You cannot make a direct physical Ethernet connection to an SLC. An Ethernet Interface (EI) must be provided - typically by using a 5/250 Pyramid Integrator.

The Allen-Bradley Ethernet arrangement requires a BOOP server. The BOOP server is required by the AB EI modules to download configuration information. Refer to your Allen-Bradley documentation for BOOP information. Often a 1747-AIC module is used between the SLCs and the DH-485 networks, to give a convenient programming port.

This diagram does not show all the possible connection options - consult your Allen-Bradley manuals for more information.

### Allen-Bradley SLC-500 via TCP/IP - Device Address

The address for this device uses the following format:

-Ia-Pn -T

where:

*a* = the destination IP address in standard Internet dot format. (For example, 192.9.2.60)

*n* = the destination Port number. Often one physical port has several virtual ports, used for different purposes. The default is 2222.

*-T* = forces the driver to use TCP (the default), rather than UDP (-U).

This information is placed in the **Special Options** field of Plant SCADA's **Ports** settings by the Express Communications Wizard.

### Allen-Bradley SLC-500 via TCP/IP - Hardware Setup

Because this driver does not receive information regarding the state of the physical transport layer, no specific details can be given for setting up communications. Follow these general steps:

1. Set up the PLC 5/250 resource manager (or AB-KA module). Assign the IP address, and test that it is valid by using the Ping program.
2. Set up the SLC for communications on the DH, DH+, or DH-485 network to which it is connected. Be sure to set the Node Address, Baud Rate, and Maximum Number of Nodes on each SLC.
3. Check that you can communicate to the SLC using offlink addressing. You can use the utility accompanying the Allen-Bradley Interchange software to verify that you can communicate from a PC over Ethernet.

## Plant SCADA Computer Setup

Setup your specific Ethernet card as required and confirm basic network communications before proceeding with the communications configuration for the ABTCP driver. Refer to the documentation accompanying your hardware for instruction.

Setup TCP/IP protocol on your Plant SCADA computer.

### Allen-Bradley SLC-500 via TCP/IP - Communication Settings

To establish communication with a device, the associated Board, Port and I/O Device need to be correctly configured in Plant SCADA Studio's **Topology** activity.

If you use the Express Communications Wizard to connect to a device, these settings will be automatically configured for you. However, if you need to manually configure them, use the settings outlined below.

## Boards

Allen-Bradley SLC500 Series PLCs support remapping reads only.

## Supported Devices via Data Highway

The ABTCP driver can be used to communicate with Allen-Bradley I/O devices via Data Highway Plus, using the KT, KTX, KTXD, PKTX cards, or the 5136-SD-PCI board from SS Technologies.

Windows detects the hardware and assigns it an address. Plant SCADA retrieves the configuration details from Windows and, at run-time, downloads appropriate interface firmware to the board, enabling communication. No additional software is required.

You can use this method to communicate with the following devices:

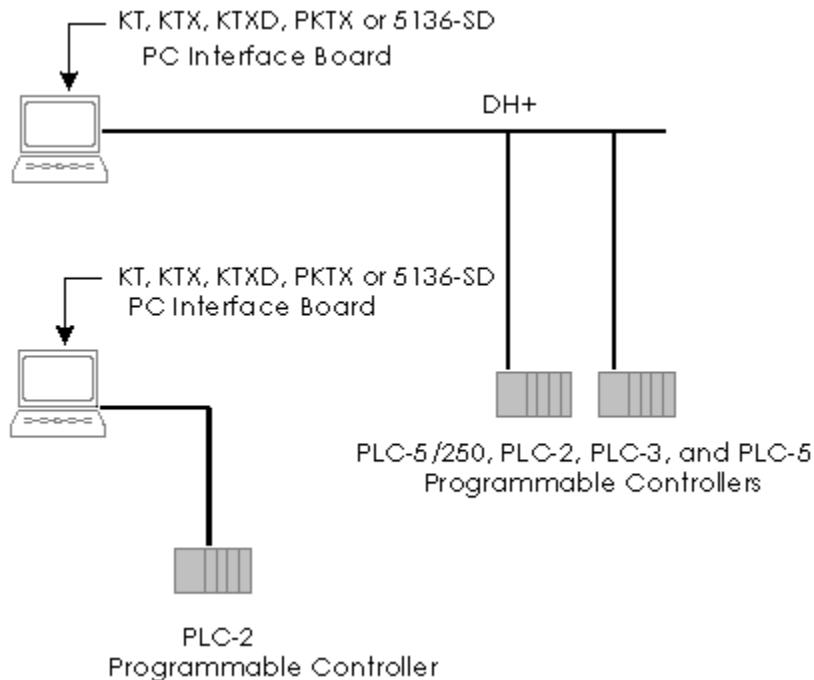

- [Allen-Bradley PLC-2](#)
- [Allen-Bradley PLC-3](#)
- [Allen-Bradley PLC-5](#)

- Allen-Bradley PLC-5/250
- Allen-Bradley SLC-500

When you first start up your computer after installing the 5136-SD-PCI board, a message may display indicating that new hardware has been detected. It is not necessary to install the board using Add New Hardware in the Windows Control Panel, since Plant SCADA detects the Windows configuration. If the card has been previously installed through Control Panel, you will need to uninstall it. Plant SCADA supports the installation and use of only one 5136-SD-PCI board in a computer at a time.

### Allen-Bradley PLC-2 via Data Highway

Plant SCADA can use the ABTCP driver to communicate with Allen-Bradley (AB) PLCs over Data Highway Plus via KT, KTX, KTXD, PKTX, 5136-SD and 5136-SD-PCI cards. Using this method, you can connect to single PLCs or to multiple PLCs as in the following diagram:

This arrangement does not use TCP/IP, even though the ABTCP driver is being used. This method does not support DH-485.

### Allen-Bradley PLC-2 via Data Highway - Device Address

The address for an Allen-Bradley PLC-2 connected to a KT (or KTX, KTXD, or 5136-SD) board is specified as:

**xKT:C[options],u**

Where:

**x** = the board number. If the number is not specified in the ports for then use 1.

**C** = the channel number, for example, KT card = 0, KTX card = 0 or 1.

**u** = the station number of the remote PLC in octal. Station numbers are between 0 and 77 (octal) for DH+ channels, and between 1 and 376 (octal) for DH channels.

**[options]** If required, you can use the [Offlink Address](#) options to allow communication with a station (PLC) that is not on the local link.

#### Example

**1KT:0,1** specifies Port ID **1KT** for access to PLC Station **1**.

### Allen-Bradley PLC-2 via Data Highway - KT Board Setup

Before you install a KT board in your computer, select a starting memory address and an interrupt number. Use an interrupt number and address that has not been used by any of the existing boards in your computer. If you have any other proprietary boards installed, check the documentation accompanying these boards to determine the interrupt numbers and addresses that have been used. (If you are using an EISA bus computer, run the EISA configuration program.)

**Note:** The following information gives specific details on how to set up the KT card - not the KTX or KTXD.

### KT Card Polling vs Interrupts

You can specify the communications to operate via polling or interrupt. This is controlled by the [\[ABTCP\] Polltime](#). If you set this parameter to a value other than 0, then polling will be used instead of interrupts.

### KT Card Switch Settings

Set the configuration options of the 1784-KT board to the following. Refer to your Allen-Bradley documentation for further information.

#### Board Address Switches

Memory Location Range	SW 1	SW 2	SW 3	SW 4	SW 5	SW 6
A000:0000-3F FF	Closed	Closed	Closed	Open	Closed	Open
A400:0000-3F FF	Open	Closed	Closed	Open	Closed	Open
A800:0000-3F FF	Closed	Open	Closed	Open	Closed	Open
AC00:0000-3F FF	Open	Open	Closed	Open	Closed	Open
B400:0000-3F FF	Open	Closed	Open	Open	Closed	Open
B800:0000-3F FF	Closed	Open	Open	Open	Closed	Open
C000:0000-3F	Closed	Closed	Closed	Closed	Open	Open

FF						
C400:0000-3F FF	Open	Closed	Closed	Closed	Open	Open
C800:0000-3F FF	Closed	Open	Closed	Closed	Open	Open
CC00:0000-3F FF *	Open	Open	Closed	Closed	Open	Open
D000:0000-3F FF	Closed	Closed	Open	Closed	Open	Open
D400:0000-3F FF	Open	Closed	Open	Closed	Open	Open
D800:0000-3F FF	Closed	Open	Open	Closed	Open	Open

\* Recommended address **0xCC00**.

This board uses a base memory size of 16k. To prevent conflict with other boards in your system, no memory overlap can exist when setting the memory address. You also require this base memory size when configuring an EISA bus computer.

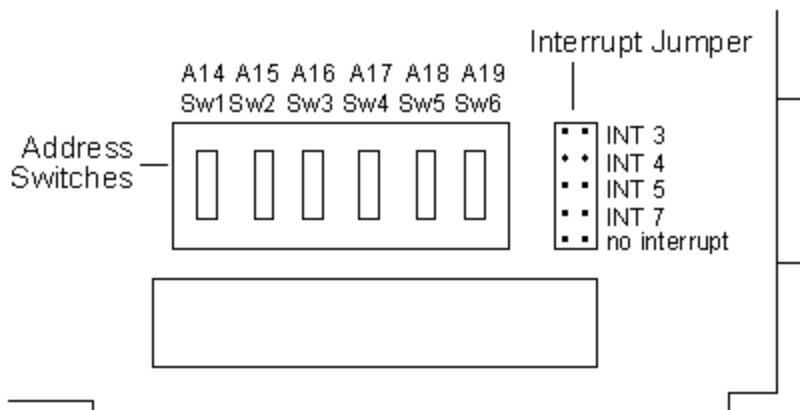

The EISA configuration utility may disable the interrupts of boards that are not set-up correctly. If you cannot get a response from the KT board, check the EISA configuration for the board. If there is still no response, try another interrupt. If you set the KT board to an interrupt that is used by a COM port, the EISA configuration will move the COM port to another interrupt. If you do not get a response from the KT board, disable the COM port that was re-configured.

## Interrupt Jumper Setting

Jumper Selection	Interrupt Selection
INT 3	IRQ3
INT 4	IRQ4
INT 5	IRQ5
INT 7	IRQ7
no interrupt	NONE

\* Recommended interrupt 5 .

The following figure shows the location of the Address Switches and Interrupt Jumper.

Use an AB diagnostics application to confirm your settings.

## Setting up a PKTX Board

This is a plug and play card. No special setup is required - just confirm that the Base Memory Jumper is set to the 32-bit position. Do not attempt to manually install a driver when Windows notifies you it has detected new hardware.

It is recommended that **no** interrupts are set on this board. Interrupt request levels (IRQ) and base memory address values are automatically assigned. Plant SCADA will retrieve these configurations and use them to communicate with a board.

---

**Note:** To properly initialize the Windows component of the Plant SCADA CIKT board driver, you may need to restart your PC after installing the PKTX board, and then again after running your Plant SCADA project for the first time. Do not abort the project start up - allow it to execute right up to the menu page.

---

## Allen-Bradley PLC-2 via Data Highway - 5136-SD-PCI Setup

Communication with Allen-Bradley I/O devices via Data Highway Plus can be established using the 5136-SD-PCI board from SS Technologies. This board was developed with Plug and Play functionality, enabling a simple setup. Plant SCADA supports the installation and use of only one 5136-SD-PCI board in a computer at a time.

Once you have installed the board into the PCI slot in your computer, Windows detects the new hardware and assigns it an address. Plant SCADA retrieves the configuration details from Windows and, at run-time, downloads appropriate interface firmware to the board, enabling communication. No additional software is required.

Once you have installed the board, you will need to set the [Communications Settings](#).

---

**Note:** When you first start up your computer after installing the 5136-SD-PCI board, a message may display indicating that new hardware has been detected. It is not necessary to install the board using Add New Hardware in the Windows Control Panel, since Plant SCADA detects the Windows configuration. If the card has been previously installed through Control Panel, you will need to uninstall it.

---

## Allen-Bradley PLC-2 via Data Highway - 5136-SD-PCI Testing

---

**Note:** For full details of the 5136-SD-PCI board, please refer to its hardware guide.

---

Once the 5136-SD-PCI board is installed, you can tell whether it is functioning correctly by monitoring its LEDs. You will not need to remove your computer's cover to do this, as the board's LEDs are visible at the back of the machine.

The board has two LEDs, the Network LED and the System LED. The first time you start up the computer with the board installed, the System LED will be red. When Plant SCADA successfully downloads the communications firmware to the board, it turns the System LED off. If the loader does not run successfully, the System LED will remain red.

The Network LED displays a flickering green whenever the card is active (transmitting) on the network. The Network LED should never turn off as long as there is a node on the network. If it does not display green, check your hardware or network cable.

### Allen-Bradley PLC-2 via Data Highway - Communication Settings

To establish communication with a device, the associated Board, Port and I/O Device need to be correctly configured in Plant SCADA Studio's **Topology** activity.

If you use the Express Communications Wizard to connect to a device, these settings will be automatically configured for you. However, if you need to manually configure them, use the settings outlined below.

## Boards

Field	Value
Board Type	For a <b>KT</b> , <b>KTX</b> , <b>KTXD</b> , or <b>PKTX</b> card, enter CIKT. For a <b>5136-SD</b> or <b>5136-SD-PCI</b> card, enter SSTAB.
Address	For a <b>KT</b> board, enter the address of the card (e.g. 0xCC00). For a <b>KTX</b> or <b>KTXD</b> board, enter the first two digits of the address of the card (e.g. 0xD0). For a <b>PKTX</b> board, enter 0xFFFF. For a <b>PKTXD</b> board channel A, enter 0xEEEE (0xEEEE) For a <b>PKTXD</b> board channel B, enter 0xEEEB. The driver uses this to determine the type of card and then auto-detects the address. Do not append zeros. For a <b>5136-SD</b> board, enter the address of the card, which needs to lie on a 1K boundary (i.e. it can be changed in 0x0400 increments - e.g. 0xCC00). For a <b>Series 2</b> card the board address needs to lie on a 2K boundary (i.e. it can be changed in 0x0800 increments - e.g. 0xD800). For a <b>5136-SD-PCI</b> interface board, enter 0xFFFF. This value indicates that the board is a PCI board.
I/O Port	For a <b>KT</b> , <b>KTX</b> , <b>KTXD</b> , or <b>PKTX</b> board, enter a unique DH+ address in Octal (e.g. 0o77) If using both channels of a <b>PKTXD</b> card, you should give each channel a unique address. For a <b>5136-SD</b> board, enter the I/O Port address of the

Field	Value
	<p>card (e.g. 0x250). For a <b>5136-SD-PCI</b> board, leave this field blank.</p>
Interrupt	<p>For a <b>KT</b>, <b>KTX</b> or <b>KTXD</b> - and polling is not being used - enter the IRQ number set on the card. For a <b>PKTX</b> card, leave this field blank For a <b>5136-SD</b> card, leave this field blank. For a <b>5136-SD-PCI</b> card, enter zero.</p>
Special Options	<p>For <b>KT</b>, <b>KTX</b>, <b>KTXD</b>, or <b>PKTX ISA</b> boards the following special options are available:          -bx specifies a board number. Use this only if more than one card is installed. The default is x=1.          Sn to select the speed on the Data Highway Plus network; n represents the speed required and is one of the following numbers:          n = 1 for 115 kbaud          n = 2 for 230 kbaud          The speed is set, by default, to 57 kbaud.</p> <p>For <b>KT</b>, <b>KTX</b>, <b>KTXD</b>, or <b>PKTX PCI</b> boards the following special option is available:          Sn to select the speed on the Data Highway Plus network. n represents the speed required and is one of the following numbers:          n = 1 for 115 kbaud          n = 2 for 230 kbaud          The speed is set, by default, to 57 kbaud.</p> <p>For the <b>5136-SD</b> board the following special options are available:          -pN to set the Data Highway/Data Highway Plus address of the card to N. By default, N is a decimal value. If you need to specify the address as an octal value then N will take the format OoXX where XX is the octal address.          -Sn to select the speed on the Data Highway Plus network. n represents the speed required and is one of the following numbers:          n = 1 for 115 kbaud          n = 2 for 230 kbaud          The speed is set, by default, to 57 kbaud.</p> <p>-T to use 5136-SD-PCI interface card instead of ISA interface card.</p> <p>For the <b>5136-SD-PCI</b> board the following special options are available:          -pN to set the Data Highway/Data Highway Plus</p>

Field	Value
	<p>address of the card to N. N is, by default, in decimal format. If you wish to specify an octal value, use the format OoXX where XX is the octal address.</p> <p>-Sn to set the speed of the Data Highway Plus network, where n represents the speed, and is one of the following numbers.</p> <ul style="list-style-type: none"> <li>n = 1 for 115 kbaud</li> <li>n = 2 for 230 kbaud</li> </ul> <p>The speed is set, by default, to 57 kbaud.</p>

## Ports

Field	Value
Port Number	A unique number for each port, starting from 1.
Baud Rate	Leave this field blank.
Data Bits	Leave this field blank.
Stop Bits	Leave this field blank.
Parity	Leave this field blank
Special Options	Leave this field blank.

## I/O Devices

Field	Value
I/O Device Address	<p>Specify the PLC address as:</p> <p><b>xKT:C[options],u</b></p> <p>where:</p> <p>x = the board number. If the number is not specified in the ports for then use 1.</p> <p>C = the channel number, for example, KT card = 0, KTX card = 0 or 1.</p> <p>u = the station number of the remote PLC in octal. Station numbers are between 0 and 77 (octal) for DH+ channels, and between 1 and 376 (octal) for DH channels.</p> <p>[options] If required, you can use the <a href="#">Offlink Address</a> options to allow communication with a station (PLC) that is not on the local link.</p>

Field	Value
	For example: 1KT:0,1 specifies Port ID 1KT for access to PLC Station 1 .
I/O Device Protocol	Enter ABTCP2.

### Allen-Bradley PLC-2 via Data Highway - Data Types

Data Types	Address Format	Plant SCADA Data Type
Digital Data	x/y	DIGITAL
Integer	x	BCD / INT / LONG /LONGBCD

Where:

- **x** = Word in octal (0 - 3777)
- **y** = Bit number in octal (0 - 17)

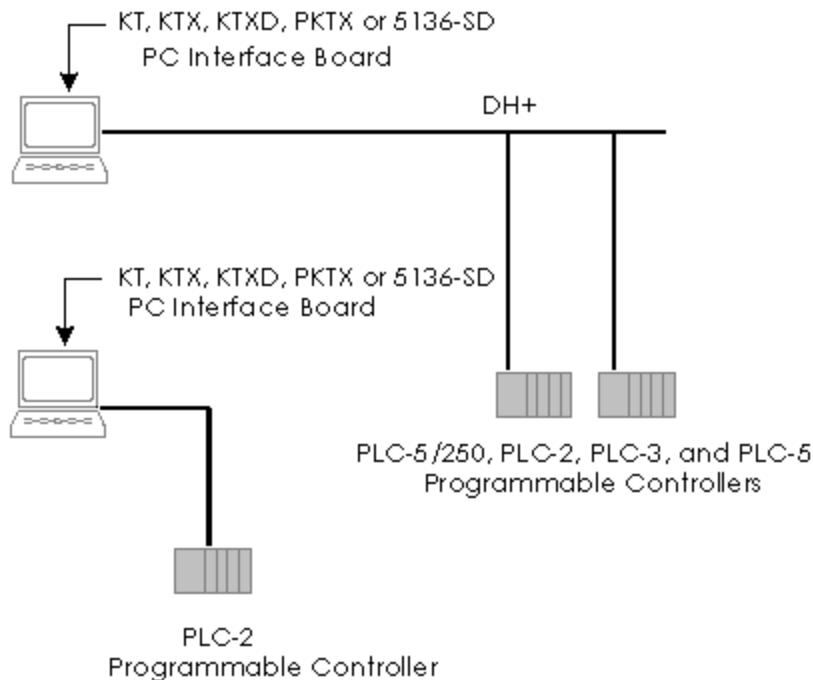

#### Examples

Data Type	DIGITAL
Address	200/12
Comment	Digital Data - Word Number 200 / Bit Number 12
Data Type	INT
Address	1700
Comment	Integer - Word Number 1700

Allen Bradley PLC-2s support remapping reads and writes.

### Allen-Bradley PLC-3 via Data Highway

Plant SCADA can use the ABTCP driver communicate to Allen-Bradley PLC-3s over Data Highway Plus via KT, KTX, KTXD, PKTX, 5136-SD and 5136-SD-PCI cards. Using this method, you can connect to single PLCs or to multiple PLCs as in the following diagram:

This arrangement does not use TCP/IP - even though the ABTCP driver is being used.

A 1775-S5 scanner module provides a DH+ port for PLC3.

This method does not support DH-485.

### Allen-Bradley PLC-3 via Data Highway - Device Address

The address for an Allen-Bradley PLC-3 connected to a KT (or KTX, KTXD, or 5136-SD) board is specified as:

**xKT:C[options],u**

Where:

- **x** = the board number. If the number is not specified in the ports for then use 1.
- **C** = the channel number, for example, KT card = 0, KTX card = 0 or 1.
- **u** = the station number of the remote PLC in octal. Station numbers are between 0 and 77 (octal) for DH+ channels, and between 1 and 376 (octal) for DH channels.
- **[options]** If required, you can use the [Offlink Address](#) options to allow communication with a station (PLC) that is not on the local link.

#### Example

**1KT:0,1** specifies Port ID **1KT** for access to PLC Station **1**.

### Allen-Bradley PLC-3 via Data Highway - KT Board Setup

Before you install a KT board in your computer, select a starting memory address and an interrupt number. Use an interrupt number and address that has not been used by any of the existing boards in your computer. If you have any other proprietary boards installed, check the documentation accompanying these boards to determine the interrupt numbers and addresses that have been used. (If you are using an EISA bus computer, run the EISA

configuration program.)

**Note:** The following information gives specific details on how to set up the KT card - not the KTX or KTXD.

## KT Card Polling vs Interrupts

You can specify the communications to operate via polling or interrupt. This is controlled by the [\[ABTCP\] Poltime](#). If you set this parameter to a value other than 0, then polling will be used instead of interrupts.

## KT Card Switch Settings

Set the configuration options of the 1784-KT board to the following. Refer to your Allen-Bradley documentation for further information.

### Board Address Switches

Memory Location Range	SW 1	SW 2	SW 3	SW 4	SW 5	SW 6
A000:0000-3F FF	Closed	Closed	Closed	Open	Closed	Open
A400:0000-3F FF	Open	Closed	Closed	Open	Closed	Open
A800:0000-3F FF	Closed	Open	Closed	Open	Closed	Open
AC00:0000-3F FF	Open	Open	Closed	Open	Closed	Open
B400:0000-3F FF	Open	Closed	Open	Open	Closed	Open
B800:0000-3F FF	Closed	Open	Open	Open	Closed	Open
C000:0000-3F FF	Closed	Closed	Closed	Closed	Open	Open
C400:0000-3F FF	Open	Closed	Closed	Closed	Open	Open
C800:0000-3F FF	Closed	Open	Closed	Closed	Open	Open
CC00:0000-3F FF *	Open	Open	Closed	Closed	Open	Open
D000:0000-3F FF	Closed	Closed	Open	Closed	Open	Open

D400:0000-3F FF	Open	Closed	Open	Closed	Open	Open
D800:0000-3F FF	Closed	Open	Open	Closed	Open	Open

\* Recommended address **0xCC00**.

This board uses a base memory size of 16k. To prevent conflict with other boards in your system, no memory overlap can exist when setting the memory address. You will also require this base memory size when configuring an EISA bus computer.

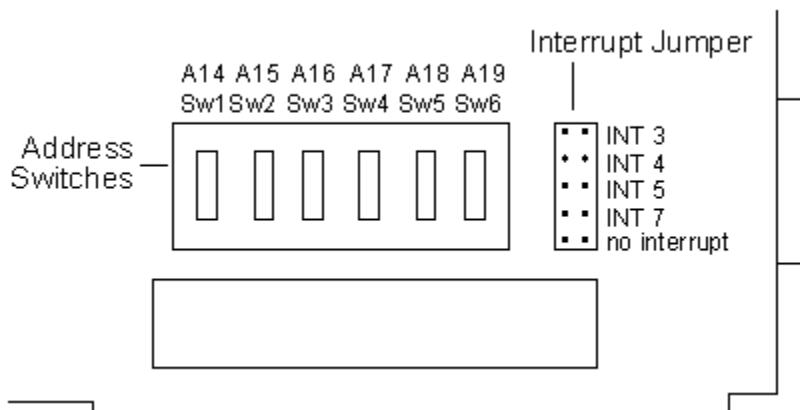

The EISA configuration utility may disable the interrupts of boards that are not set-up correctly. If you can not get a response from the KT board, check the EISA configuration for the board. If there is still no response, try another interrupt. If you set the KT board to an interrupt that is used by a COM port, the EISA configuration will move the COM port to another interrupt. If you do not get a response from the KT board, disable the COM port that was re-configured.

## Interrupt Jumper Setting

Jumper Selection	Interrupt Selection
INT 3	IRQ3
INT 4	IRQ4
INT 5	IRQ5
INT 7	IRQ7
no interrupt	NONE

\* Recommended interrupt **5**.

The following figure shows the location of the Address Switches and Interrupt Jumper.

Use an AB diagnostics application to confirm your settings.

## Setting up a PKTX Board

This is a plug and play card. No special setup is required - just confirm that the Base Memory Jumper is set to the 32-bit position. Do not attempt to manually install a driver when Windows notifies you it has detected new hardware.

Set **no** interrupts on this board. Interrupt request levels (IRQ) and base memory address values are automatically assigned. Plant SCADA will retrieve these configurations and use them to communicate with a board.

---

**Note:** To properly initialize the Windows component of the Plant SCADA CIKT board driver, you may need to restart your PC after installing the PKTX board, and then again after running your Plant SCADA project for the first time. Do not abort the project start up - allow it to execute right up to the menu page.

---

### Allen-Bradley PLC-3 via Data Highway - 5136-SD-PCI Setup

Communication with Allen-Bradley I/O devices via Data Highway Plus can be established using the 5136-SD-PCI board from SS Technologies. This board was developed with Plug and Play functionality, enabling a simple setup. Plant SCADA supports the installation and use of only one 5136-SD-PCI board in a computer at a time.

Once you have installed the board into the PCI slot in your computer, Windows detects the new hardware and assigns it an address. Plant SCADA retrieves the configuration details from Windows and, at run-time, downloads appropriate interface firmware to the board, enabling communication. No additional software is required.

Once you have installed the board, you will need to set the [Communication Settings](#).

---

**Note:** When you first start up your computer after installing the 5136-SD-PCI board, a message may display indicating that new hardware has been detected. It is not necessary to install the board using Add New Hardware in the Windows Control Panel, since Plant SCADA detects the Windows configuration. If the card has been previously installed through Control Panel, you will need to uninstall it.

---

For more information, see:

[Testing the functionality of 5136-SD-PCI boards](#)

### Allen-Bradley PLC-3 via Data Highway - 5136-SD-PCI Test

---

**Note:** For full details of the 5136-SD-PCI board, please refer to its hardware guide.

Once the 5136-SD-PCI board is installed, you can tell whether it is functioning correctly by monitoring its LEDs. You will not need to remove your computer's cover to do this, as the board's LEDs are visible at the back of the machine.

The board has two LEDs, the Network LED and the System LED. The first time you start up the computer with the board installed, the System LED will be red. When Plant SCADA successfully downloads the communications firmware to the board, it turns the System LED off. If the loader does not run successfully, the System LED will remain red.

The Network LED displays a flickering green whenever the card is active (transmitting) on the network. The Network LED should never turn off as long as there is a node on the network. If it does not display green, check your hardware or network cable.

### Allen-Bradley PLC-3 via Data Highway - Communication Settings

To establish communication with a device, the associated Board, Port and I/O Device need to be correctly configured in Plant SCADA Studio's **Topology** activity.

If you use the Express Communications Wizard to connect to a device, these settings will be automatically configured for you. However, if you need to manually configure them, use the settings outlined below.

## Boards

Field	Value
Board Type	For a <b>KT</b> , <b>KTX</b> , <b>KTXD</b> , or <b>PKTX</b> card, enter CIKT. For a <b>5136-SD</b> or <b>5136-SD-PCI</b> card, enter SSTAB.
Address	For a <b>KT</b> board, enter the address of the card (e.g. 0xCC00). For a <b>KTX</b> or <b>KTXD</b> board, enter the first two digits of the address of the card (e.g. 0xD0). For a <b>PKTX</b> board, enter 0xFFFF. For a <b>PKTXD</b> board channel A, enter 0xEEEA (0xEEEE) For a <b>PKTXD</b> board channel B, enter 0xEEEB. The driver uses this to determine the type of card and then auto-detects the address. Do not append zeros. For a <b>5136-SD</b> board, enter the address of the card, which needs to be on a 1K boundary (i.e. it can be changed in 0x0400 increments - e.g. 0xCC00). For a <b>Series 2</b> card the board address needs to lie on a 2K boundary (i.e. it can be changed in 0x0800 increments - e.g. 0xD800). For a <b>5136-SD-PCI</b> interface board, enter 0xFFFF. This value indicates that the board is a PCI board.
I/O Port	For a <b>KT</b> , <b>KTX</b> , <b>KTXD</b> , or <b>PKTX</b> board, enter a unique DH+ address in Octal (e.g. 0o77) If using both channels of a <b>PKTXD</b> card, you should give each channel a unique address. For a <b>5136-SD</b> board, enter the I/O Port address of the card (e.g. 0x250). For a <b>5136-SD-PCI</b> board, leave this field blank.
Interrupt	For a <b>KT</b> , <b>KTX</b> or <b>KTXD</b> - and polling is not being used - enter the IRQ number set on the card. For a <b>PKTX</b> card, leave this field blank For a <b>5136-SD</b> card, leave this field blank. For a <b>5136-SD-PCI</b> card, enter zero.
Special Options	For <b>KT</b> , <b>KTX</b> , <b>KTXD</b> , or <b>PKTX ISA</b> boards the following special options are available: -bx specifies a board number. Use this only if more

Field	Value
	<p>than one card is installed. The default is x=1. Sn to select the speed on the Data Highway Plus network; n represents the speed required and is one of the following numbers:</p> <ul style="list-style-type: none"> <li>n = 1 for 115 kbaud</li> <li>n = 2 for 230 kbaud</li> </ul> <p>The speed is set, by default, to 57 kbaud.</p> <p>For <b>KT</b>, <b>KTX</b>, <b>KTXD</b>, or <b>PKTX PCI</b> boards the following special option is available:</p> <p>Sn to select the speed on the Data Highway Plus network. n represents the speed required and is one of the following numbers:</p> <ul style="list-style-type: none"> <li>n = 1 for 115 kbaud</li> <li>n = 2 for 230 kbaud</li> </ul> <p>The speed is set, by default, to 57 kbaud.</p> <p>For the <b>5136-SD</b> board the following special options are available:</p> <ul style="list-style-type: none"> <li>-pN to set the Data Highway/Data Highway Plus address of the card to N. By default, N is a decimal value. If you need to specify the address as an octal value then N will take the format OoXX where XX is the octal address.</li> <li>-Sn to select the speed on the Data Highway Plus network. n represents the speed required and is one of the following numbers:</li> </ul> <ul style="list-style-type: none"> <li>n = 1 for 115 kbaud</li> <li>n = 2 for 230 kbaud</li> </ul> <p>The speed is set, by default, to 57 kbaud.</p> <ul style="list-style-type: none"> <li>-T to use 5136-SD-PCI interface card instead of ISA interface card.</li> </ul> <p>For the <b>5136-SD-PCI</b> board the following special options are available:</p> <ul style="list-style-type: none"> <li>-pN to set the Data Highway/Data Highway Plus address of the card to N. N is, by default, in decimal format. If you wish to specify an octal value, use the format OoXX where XX is the octal address.</li> <li>-Sn to set the speed of the Data Highway Plus network, where n represents the speed, and is one of the following numbers.</li> </ul> <ul style="list-style-type: none"> <li>n = 1 for 115 kbaud</li> <li>n = 2 for 230 kbaud</li> </ul> <p>The speed is set, by default, to 57 kbaud.</p>

## Ports

Field	Value
Port Number	A unique number for each port, starting from 1.
Baud Rate	Leave this field blank.
Data Bits	Leave this field blank.
Stop Bits	Leave this field blank.
Parity	Leave this field blank
Special Options	Leave this field blank.

## I/O Devices

Field	Value
I/O Device Address	<p>Specify the PLC address as:</p> <p><b>xKT:C[options],u</b></p> <p>where:</p> <p><b>x</b> = the board number. If the number is not specified in the ports for then use 1.</p> <p><b>C</b> = the channel number, for example, KT card = 0, KTX card = 0 or 1.</p> <p><b>u</b> = the station number of the remote PLC in octal.</p> <p>Station numbers are between 0 and 77 (octal) for DH+ channels, and between 1 and 376 (octal) for DH channels.</p> <p><b>[options]</b> If required, you can use the <a href="#">Offlink Address</a> options to allow communication with a station (PLC) that is not on the local link.</p> <p>For example: <b>1KT:0,1</b> specifies Port ID 1KT for access to PLC Station 1 .</p>
I/O Device Protocol	Enter ABTCP3.

### Allen-Bradley PLC-3 via Data Highway - Data Types

---

**Note:** The Allen-Bradley PLC-3 has many data types. The driver makes a separate request for each different data type, and each request has a finite overhead. It is more efficient to read fewer data types, so you should move the I/O and other data into a few main blocks to be read by Plant SCADA.

Data Types	Address Format	Plant SCADA Data Type
Output image	<b>O:f:O/o</b> (f is optional)	DIGITAL
Input image	<b>I:f:O/o</b> (f is optional)	DIGITAL
Timer Control bits	<b>TCTL:w/t</b>	DIGITAL
Timer Control bits	<b>TCTL:w/o</b>	DIGITAL
Timer Preset bits	<b>TPRE:w/o</b>	DIGITAL
Timer Accumulator bits	<b>TACC:w/o</b>	DIGITAL
Counter Control bits	<b>CCTL:w/t</b>	DIGITAL
Counter Control bits	<b>CCTL:w/o</b>	DIGITAL
Counter Preset bits	<b>CPRE:w/o</b>	DIGITAL
Counter Accumulator bits	<b>CACC:w/o</b>	DIGITAL
ASCII	<b>Af:w/o</b>	DIGITAL
BCD	<b>Df:w/o</b>	DIGITAL
REAL	<b>Ef:w/o</b> (o = 0 to 37)	DIGITAL
LONG	<b>Hf:w/o</b> (o = 0 to 37)	DIGITAL
Integer	<b>Nf:w/o</b>	DIGITAL
Binary	<b>Bf:w/o</b>	DIGITAL
Status words	<b>Sf:w/o</b>	DIGITAL
Pointer Section and File	<b>PFIL:w/o</b>	DIGITAL
Pointer word	<b>PWRD:w/o</b>	DIGITAL
Output image	<b>O:f:O</b> (f is optional)	BCD / INT
Input image	<b>I:f:O</b> (f is optional)	BCD / INT
Timer Control	<b>TCTL:w</b>	BCD / INT
Timer Preset	<b>TPRE:w</b>	BCD / INT

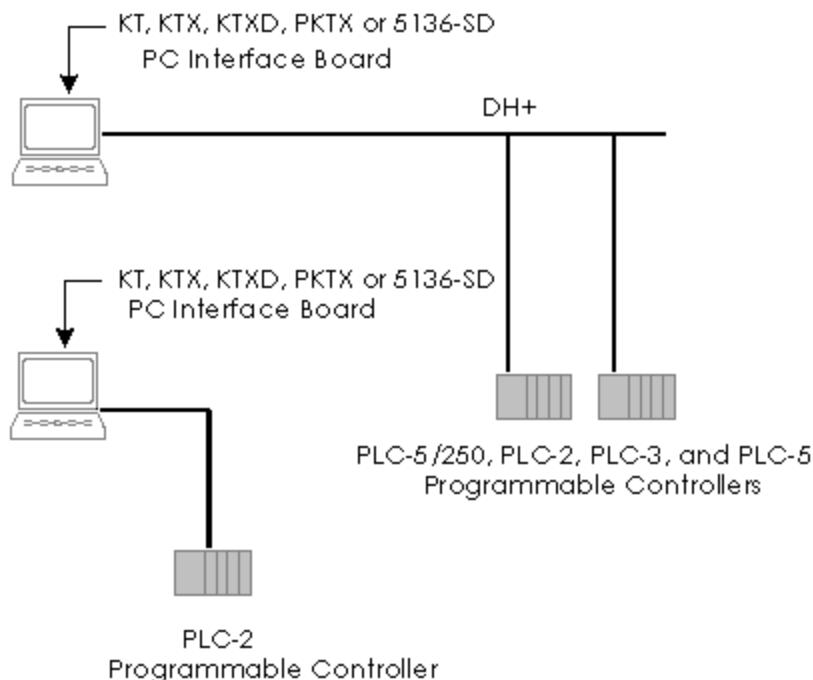

Data Types	Address Format	Plant SCADA Data Type
Timer Accumulator	<b>TACC:w</b>	BCD / INT
Counter Control	<b>CCTL:w</b>	BCD / INT
Counter Preset	<b>CPRE:w</b>	BCD / INT
Counter Accumulator	<b>CACC:w</b>	BCD / INT
Integer	<b>Nf:w</b>	BCD / INT
BCD	<b>Df:w</b>	BCD / INT

Pointer word	<b>PWRD:w</b>	BCD / INT
Long	<b>Hf:w</b>	LONG / LONGBCD
Floating Point	<b>Ff:w</b>	REAL

Where:

n =	Optional Module Number 0 to 8 decimal
f =	File Number 0 to 999 decimal
:w =	Element Number 0 to 9999 decimal
:O =	Element Number 0 to 7777 octal
/o =	Bit Number 0 to 17 octal PRE = Preset Value ACC = Accumulated Value
.C =	Control Sub Element LEN = Length POS = Position
.P =	PID Sub Element SP = Set Point KP = Proportional Gain KI = Integral Gain KD = Derivative Gain BIAS = Output Bias %

	MAXS = Maximum Scaled Value MINS = Minimum Scaled Value DB = Deadband SO = Set Output % MAXO = Maximum Output % MINO = Minimum Input % UPD = Update Time PVH = PV Alarm High PVL = PV Alarm Low PVDB = PV Alarm Deadband PV = Process Variable ERR = Error OUT = Output DVP = Deviation Alarm + DVN = Deviation Alarm - DVDB = Deviation Alarm Deadband MAXI = Maximum Input MINI = Minimum Input TIE = Tieback %
.t =	Timer bits EN = Enable TT = Timing DN = Done BS LK
.c =	Counter bits CU = Count Up CD = Count Down DN = Done OV = Overflow UN = Underflow LK
.r =	Control bits EN = Enable EU = Enable Unloading DN = Done EM = Empty ER = Error UL = Unload IN = Inhibit Comparisons FD = Found
.p =	PID bits EN = Enable CT = Cascaded Type

CL = Cascaded Loop
PVT = PV Tracking
DO = Derivative Of
SWM = Software A/M Mode
CA = Control Action
MO = Mode
PE = PID Equation
INI = PID Initialized
SPOR = SP Out of Range
OLL = Output Limit Low
OLH = Output Limit High
EWD = Error Within Deadband
DVPA = Deviation Low Alarm
DVNA = Deviation High Alarm
PVLA = PV Low Alarm
PVHA = PV High Alarm

This arrangement does not use TCP/IP - even though the ABTCP driver is being used.

This method does not support DH-485.

### Allen-Bradley PLC-5 via Data Highway - Device Address

The address for an Allen-Bradley PLC-5 connected to a KT (or KTX, KTXD, or 5136-SD) board is specified as:

**xKT:C[options],u**

where:

- **x** = the board number. If the number is not specified in the ports for then use 1.
- **C** = the channel number, for example, KT card = 0, KTX card = 0 or 1.
- **u** = the station number of the remote PLC in octal. Station numbers are between 0 and 77 (octal) for DH+ channels, and between 1 and 376 (octal) for DH channels.
- **[options]** If required, you can use the [Offlink Address](#) options to allow communication with a station (PLC) that is not on the local link.

### Example

**1KT:0,1** specifies Port ID **1KT** for access to PLC Station **1**.

### Allen-Bradley PLC-5 via Data Highway - KT Board Setup

Before you install a KT board in your computer, select a starting memory address and an interrupt number. Use an interrupt number and address that has not been used by any of the existing boards in your computer. If you have any other proprietary boards installed, check the documentation accompanying these boards to determine the interrupt numbers and addresses that have been used. (If you are using an EISA bus computer, you must run

the EISA configuration program.)

**Note:** The following information gives specific details on how to set up the KT card - not the KTX or KTXD.

## KT Card Polling vs Interrupts

You can specify the communications to operate via polling or interrupt. This is controlled by the [\[ABTCP\] Poltime](#). If you set this parameter to a value other than 0, then polling will be used instead of interrupts.

## KT Card Switch Settings

Set the configuration options of the 1784-KT board to the following. Refer to your Allen-Bradley documentation for further information.

### Board Address Switches

Memory Location Range	SW 1	SW 2	SW 3	SW 4	SW 5	SW 6
A000:0000-3F FF	Closed	Closed	Closed	Open	Closed	Open
A400:0000-3F FF	Open	Closed	Closed	Open	Closed	Open
A800:0000-3F FF	Closed	Open	Closed	Open	Closed	Open
AC00:0000-3F FF	Open	Open	Closed	Open	Closed	Open
B400:0000-3F FF	Open	Closed	Open	Open	Closed	Open
B800:0000-3F FF	Closed	Open	Open	Open	Closed	Open
C000:0000-3F FF	Closed	Closed	Closed	Closed	Open	Open
C400:0000-3F FF	Open	Closed	Closed	Closed	Open	Open
C800:0000-3F FF	Closed	Open	Closed	Closed	Open	Open
CC00:0000-3F FF *	Open	Open	Closed	Closed	Open	Open
D000:0000-3F FF	Closed	Closed	Open	Closed	Open	Open

D400:0000-3F FF	Open	Closed	Open	Closed	Open	Open
D800:0000-3F FF	Closed	Open	Open	Closed	Open	Open

\* Recommended address **0xCC00**.

This board uses a base memory size of 16k. To prevent conflict with other boards in your system, no memory overlap can exist when setting the memory address. You will also require this base memory size when configuring an EISA bus computer.

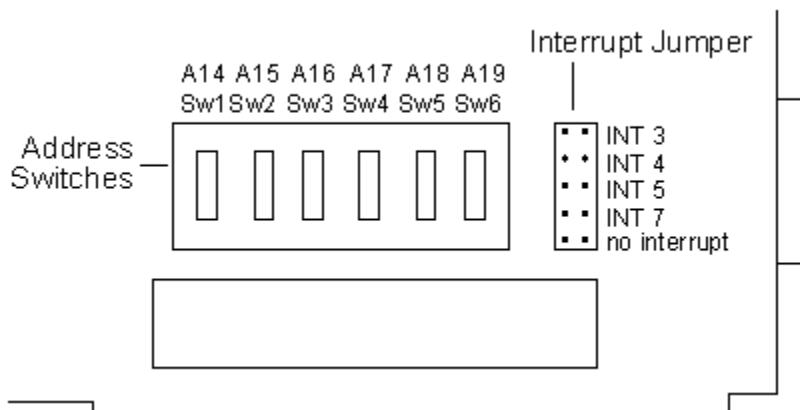

The EISA configuration utility may disable the interrupts of boards that are not set-up correctly. If you cannot get a response from the KT board, check the EISA configuration for the board. If there is still no response, try another interrupt. If you set the KT board to an interrupt that is used by a COM port, the EISA configuration will move the COM port to another interrupt. If you do not get a response from the KT board, disable the COM port that was re-configured.

## Interrupt Jumper Setting

Jumper Selection	Interrupt Selection
INT 3	IRQ3
INT 4	IRQ4
INT 5	IRQ5
INT 7	IRQ7
no interrupt	NONE

\* Recommended interrupt **5**.

The following figure shows the location of the Address Switches and Interrupt Jumper.

Use an AB diagnostics application to confirm your settings.

## Setting up a PKTX Board

This is a plug and play card. No special setup is required - just confirm that the Base Memory Jumper is set to the 32-bit position. Do not attempt to manually install a driver when Windows notifies you it has detected new hardware.

Set **no** interrupts on this board. Interrupt request levels (IRQ) and base memory address values are automatically assigned. Plant SCADA will retrieve these configurations and use them to communicate with a board.

---

**Note:** To properly initialize the Windows component of the Plant SCADA CIKT board driver, you may need to restart your PC after installing the PKTX board, and then again after running your Plant SCADA project for the first time. Do not abort the project start up - allow it to execute right up to the menu page.

---

### Allen-Bradley PLC-5 via Data Highway - 5136-SD-PCI Setup

Communication with Allen-Bradley I/O devices via Data Highway Plus can be established using the 5136-SD-PCI board from SS Technologies. This board was developed with Plug and Play functionality, enabling a simple setup. Plant SCADA supports the installation and use of only one 5136-SD-PCI board in a computer at a time.

Once you have installed the board into the PCI slot in your computer, Windows detects the new hardware and assigns it an address. Plant SCADA retrieves the configuration details from Windows and, at run-time, downloads appropriate interface firmware to the board, enabling communication. No additional software is required.

Once you have installed the board, you will need to set the [Communication Settings](#).

---

**Note:** When you first start up your computer after installing the 5136-SD-PCI board, a message may display indicating that new hardware has been detected. It is not necessary to install the board using Add New Hardware in the Windows Control Panel, since Plant SCADA detects the Windows configuration. If the card has been previously installed through Control Panel, you will need to uninstall it.

---

### Allen-Bradley PLC-5 via Data Highway - 5136-SD-PCI Test

---

**Note:** For full details of the 5136-SD-PCI board, please refer to its hardware guide.

Once the 5136-SD-PCI board is installed, you can tell whether or not it is functioning correctly by monitoring its LEDs. You will not need to remove your computer's cover to do this, as the board's LEDs are visible at the back of the machine.

The board has two LEDs, the Network LED and the System LED. The first time you start up the computer with the board installed, the System LED will be red. When Plant SCADA successfully downloads the communications firmware to the board, it turns the System LED off. If the loader does not run successfully, the System LED will remain red.

The Network LED displays a flickering green whenever the card is active (transmitting) on the network. The Network LED should never turn off as long as there is a node on the network. If it does not display green, check your hardware or network cable.

### Allen-Bradley PLC-5 via Data Highway - Communication Settings

To establish communication with a device, the associated Board, Port and I/O Device need to be correctly configured in Plant SCADA Studio's **Topology** activity.

If you use the Express Communications Wizard to connect to a device, these settings will be automatically configured for you. However, if you need to manually configure them, use the settings outlined below.

## Boards

Field	Value
Board Type	For a <b>KT</b> , <b>KTX</b> , <b>KTXD</b> , or <b>PKTX</b> card, enter CIKT. For a <b>5136-SD</b> or <b>5136-SD-PCI</b> card, enter SSTAB.
Address	For a <b>KT</b> board, enter the address of the card (e.g. 0xCC00). For a <b>KTX</b> or <b>KTXD</b> board, enter the first two digits of the address of the card (e.g. 0xD0). For a <b>PKTX</b> board, enter 0xFFFF. For a <b>PKTXD</b> board channel A, enter 0xEEEA (0xEEEE) For a <b>PKTXD</b> board channel B, enter 0xEEEB. The driver uses this to determine the type of card and then auto-detects the address. Do not append zeros. For a <b>5136-SD</b> board, enter the address of the card, which needs to lie on a 1K boundary (i.e. it can be changed in 0x0400 increments - e.g. 0xCC00). For a <b>Series 2</b> card the board address needs to lie on a 2K boundary (i.e. it can be changed in 0x0800 increments - e.g. 0xD800). For a <b>5136-SD-PCI</b> interface board, enter 0xFFFF. This value indicates that the board is a PCI board.
I/O Port	For a <b>KT</b> , <b>KTX</b> , <b>KTXD</b> , or <b>PKTX</b> board, enter a unique DH+ address in Octal (e.g. 0o77) If using both channels of a <b>PKTXD</b> card, you should give each channel a unique address. For a <b>5136-SD</b> board, enter the I/O Port address of the card (e.g. 0x250). For a <b>5136-SD-PCI</b> board, leave this field blank.
Interrupt	For a <b>KT</b> , <b>KTX</b> or <b>KTXD</b> - and polling is not being used - enter the IRQ number set on the card. For a <b>PKTX</b> card, leave this field blank For a <b>5136-SD</b> card, leave this field blank. For a <b>5136-SD-PCI</b> card, enter zero.
Special Options	For <b>KT</b> , <b>KTX</b> , <b>KTXD</b> , or <b>PKTX ISA</b> boards the following special options are available: -bx specifies a board number. Use this only if more than one card is installed. The default is x=1. Sn to select the speed on the Data Highway Plus network; n represents the speed required and is one

Field	Value
	<p>of the following numbers:  n = 1 for 115 kbaud  n = 2 for 230 kbaud  The speed is set, by default, to 57 kbaud.</p> <p>For <b>KT</b>, <b>KTX</b>, <b>KTXD</b>, or <b>PKTX PCI</b> boards the following special option is available:</p> <p>-Sn to select the speed on the Data Highway Plus network. n represents the speed required and is one of the following numbers:</p> <p>n = 1 for 115 kbaud  n = 2 for 230 kbaud  The speed is set, by default, to 57 kbaud.</p> <p>For the <b>5136-SD</b> board the following special options are available:</p> <p>-pN to set the Data Highway/Data Highway Plus address of the card to N. By default, N is a decimal value. If you need to specify the address as an octal value then N will take the format OoXX where XX is the octal address.</p> <p>-Sn to select the speed on the Data Highway Plus network. n represents the speed required and is one of the following numbers:</p> <p>n = 1 for 115 kbaud  n = 2 for 230 kbaud  The speed is set, by default, to 57 kbaud.</p> <p>-T to use 5136-SD-PCI interface card instead of ISA interface card.</p> <p>For the <b>5136-SD-PCI</b> board the following special options are available:</p> <p>-pN to set the Data Highway/Data Highway Plus address of the card to N. N is, by default, in decimal format. If you wish to specify an octal value, use the format OoXX where XX is the octal address.</p> <p>-Sn to set the speed of the Data Highway Plus network, where n represents the speed, and is one of the following numbers.</p> <p>n = 1 for 115 kbaud  n = 2 for 230 kbaud  The speed is set, by default, to 57 kbaud.</p>

## Ports

Field	Value
Port Number	A unique number for each port, starting from 1.
Baud Rate	Leave this field blank.
Data Bits	Leave this field blank.
Stop Bits	Leave this field blank.
Parity	Leave this field blank
Special Options	Leave this field blank.

## I/O Devices

Field	Value
I/O Device Address	<p>Specify the PLC address as:</p> <p>xKT:C[options],u</p> <p>where:</p> <p>x = the board number. If the number is not specified in the ports for then use 1.</p> <p>C = the channel number, for example, KT card = 0, KTX card = 0 or 1.</p> <p>u = the station number of the remote PLC in octal.</p> <p>Station numbers are between 0 and 77 (octal) for DH+ channels, and between 1 and 376 (octal) for DH channels.</p> <p>[options] If required, you can use the <a href="#">Offlink Address</a> options to allow communication with a station (PLC) that is not on the local link.</p> <p>For example: 1KT:0,1 specifies Port ID 1KT for access to PLC Station 1 .</p>
I/O Device Protocol	Enter ABTCP5.

## Allen-Bradley PLC-5 via Data Highway - Data Types

---

**Note:** The Allen-Bradley PLC-5 has many data types. The driver makes a separate request for each different data type, and each request has a finite overhead. It is more efficient to read fewer data types, so you should move the I/O and other data into a few main blocks to be read by Plant SCADA.

Data Types	Address Format	Plant SCADA Data Type
Output image	<b>O:O/o</b>	DIGITAL
Input image	<b>I:O/o</b>	DIGITAL
Status words 0 to 127 (to 128 for w parameter)	<b>S:w/b</b>	DIGITAL

Data Type	INT
Address	N7:3
Comment	Integer - File Number 7 : Element Number 3

Allen Bradley PLC-5 Series support remapping reads and writes.

**Allen-Bradley PLC-5/250 via Data Highway**

Plant SCADA can use the ABTCP driver communicate to Allen-Bradley PLC-5/250s over Data Highway Plus via KT, KTX, KTXD, PKTX, 5136-SD and 5136-SD-PCI cards. Using this method you can connect to single PLCs or to multiple PLCs as in the following diagram:

This arrangement does not use TCP/IP even though the ABTCP driver is being used.

This method does not support DH-485.

### Allen-Bradley PLC-5/250 via Data Highway - Device Address

The address for an Allen-Bradley PLC-5/250 connected to a KT (or KTX, KTXD, or 5136-SD) board is specified as:

**xKT:C[options],u**

where:

- **x** = the board number. If the number is not specified in the ports for then use 1.
- **C** = the channel number, for example, KT card = 0, KTX card = 0 or 1.
- **u** = the station number of the remote PLC in octal. Station numbers are between 0 and 77 (octal) for DH+ channels, and between 1 and 376 (octal) for DH channels.
- **[options]** If required, you can use the [Offlink Address](#) options to allow communication with a station (PLC) that is not on the local link.

#### Example

**1KT:0,1** specifies Port ID **1KT** for access to PLC Station **1**.

### Allen-Bradley PLC-5/250 via Data Highway - KT Board Setup

Before you install a KT board in your computer, select a starting memory address and an interrupt number. Use an interrupt number and address that has not been used by any of the existing boards in your computer. If you have any other proprietary boards installed, check the documentation accompanying these boards to determine the interrupt numbers and addresses that have been used. (If you are using an EISA bus computer, you must run the EISA configuration program.)

**Note:** The following information gives specific details on how to set up the KT card - not the KTX or KTXD.

## KT Card Polling vs Interrupts

You can specify the communications to operate via polling or interrupt. This is controlled by the [\[ABTCP\] Polltime](#). If you set this parameter to a value other than 0, then polling will be used instead of interrupts.

## KT Card Switch Settings

Set the configuration options of the 1784-KT board to the following. Refer to your Allen-Bradley documentation for further information.

### Board Address Switches

Memory Location Range	SW 1	SW 2	SW 3	SW 4	SW 5	SW 6
A000:0000-3F FF	Closed	Closed	Closed	Open	Closed	Open
A400:0000-3F FF	Open	Closed	Closed	Open	Closed	Open
A800:0000-3F FF	Closed	Open	Closed	Open	Closed	Open
AC00:0000-3F FF	Open	Open	Closed	Open	Closed	Open
B400:0000-3F FF	Open	Closed	Open	Open	Closed	Open
B800:0000-3F FF	Closed	Open	Open	Open	Closed	Open
C000:0000-3F FF	Closed	Closed	Closed	Closed	Open	Open
C400:0000-3F FF	Open	Closed	Closed	Closed	Open	Open
C800:0000-3F FF	Closed	Open	Closed	Closed	Open	Open
CC00:0000-3F FF *	Open	Open	Closed	Closed	Open	Open
D000:0000-3F FF	Closed	Closed	Open	Closed	Open	Open

D400:0000-3F FF	Open	Closed	Open	Closed	Open	Open
D800:0000-3F FF	Closed	Open	Open	Closed	Open	Open

\* Recommended address **0xCC00**.

This board uses a base memory size of 16k. To prevent conflict with other boards in your system, no memory overlap can exist when setting the memory address. You will also require this base memory size when configuring an EISA bus computer.

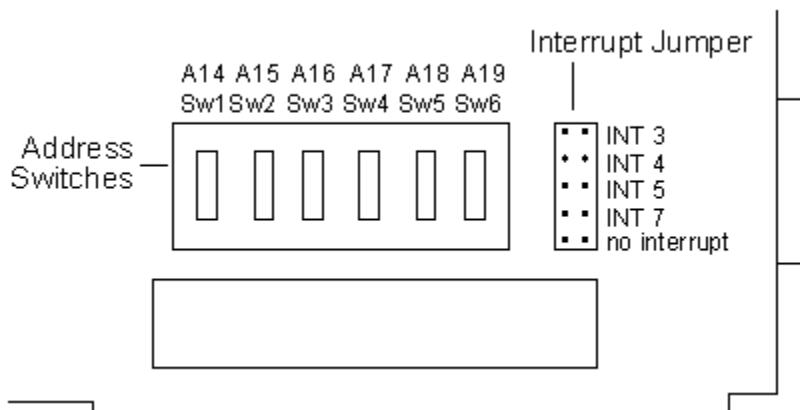

The EISA configuration utility may disable the interrupts of boards that are not set-up correctly. If you cannot get a response from the KT board, check the EISA configuration for the board. If there is still no response, try another interrupt. If you set the KT board to an interrupt that is used by a COM port, the EISA configuration will move the COM port to another interrupt. If you do not get a response from the KT board, disable the COM port that was re-configured.

## Interrupt Jumper Setting

Jumper Selection	Interrupt Selection
INT 3	IRQ3
INT 4	IRQ4
INT 5	IRQ5
INT 7	IRQ7
no interrupt	NONE

\* Recommended interrupt **5**.

The following figure shows the location of the Address Switches and Interrupt Jumper.

Use an AB diagnostics application to confirm your settings.

## Setting up a PKTX Board

This is a plug and play card. No special setup is required - just confirm that the Base Memory Jumper is set to the 32-bit position. Do not attempt to manually install a driver when Windows notifies you it has detected new hardware.

It is recommended that **no** interrupts are set on this board. Interrupt request levels (IRQ) and base memory address values are automatically assigned. Plant SCADA will retrieve these configurations and use them to communicate with a board.

---

**Note:** To properly initialize the Windows component of the Plant SCADA CIKT board driver, you may need to restart your PC after installing the PKTX board, and then again after running your Plant SCADA project for the first time. Do not abort the project start up - allow it to execute right up to the menu page.

---

### Bradley PLC-5/250 via Data Highway - 5136-SD-PCI Setup

Communication with Allen-Bradley I/O devices via Data Highway Plus can be established using the 5136-SD-PCI board from SS Technologies. This board was developed with Plug and Play functionality, enabling a simple setup. Plant SCADA supports the installation and use of only one 5136-SD-PCI board in a computer at a time.

Once you have installed the board into the PCI slot in your computer, Windows detects the new hardware and assigns it an address. Plant SCADA retrieves the configuration details from Windows and, at run-time, downloads appropriate interface firmware to the board, enabling communication. No additional software is required.

Once you have installed the board, you will need to set the [Communication Settings](#).

---

**Note:** When you first start up your computer after installing the 5136-SD-PCI board, a message may display indicating that new hardware has been detected. It is not necessary to install the board using Add New Hardware in the Windows Control Panel, since Plant SCADA detects the Windows configuration. If the card has been previously installed through Control Panel, you will need to uninstall it.

---

### Allen-Bradley PLC-5/250 via Data Highway - 5136-SD-PCI Test

---

**Note:** For full details of the 5136-SD-PCI board, please refer to its hardware guide.

Once the 5136-SD-PCI board is installed, you can tell whether it is functioning correctly by monitoring its LEDs. You will not need to remove your computer's cover to do this, as the board's LEDs are visible at the back of the machine.

The board has two LEDs, the Network LED and the System LED. The first time you start up the computer with the board installed, the System LED will be red. When Plant SCADA successfully downloads the communications firmware to the board, it turns the System LED off. If the loader does not run successfully, the System LED will remain red.

The Network LED displays a flickering green whenever the card is active (transmitting) on the network. The Network LED should never turn off as long as there is a node on the network. If it does not display green, check your hardware or network cable.

### Allen-Bradley PLC-5/250 via Data Highway - Communication Settings

To establish communication with a device, the associated Board, Port and I/O Device need to be correctly configured in Plant SCADA Studio's **Topology** activity.

If you use the Express Communications Wizard to connect to a device, these settings will be automatically

configured for you. However, if you need to manually configure them, use the settings outlined below.

## Boards

Field	Value
Board Type	For a <b>KT</b> , <b>KTX</b> , <b>KTXD</b> , or <b>PKTX</b> card, enter CIKT. For a <b>5136-SD</b> or <b>5136-SD-PCI</b> card, enter SSTAB.
Address	For a <b>KT</b> board, enter the address of the card (e.g. 0xCC00). For a <b>KTX</b> or <b>KTXD</b> board, enter the first two digits of the address of the card (e.g. 0xD0). For a <b>PKTX</b> board, enter 0xFFFF. For a <b>PKTXD</b> board channel A, enter 0xEEEA (0xEEEE) For a <b>PKTXD</b> board channel B, enter 0xEEEB. The driver uses this to determine the type of card and then auto-detects the address. Do not append zeros. For a <b>5136-SD</b> board, enter the address of the card, which needs to lie on a 1K boundary (i.e. it can be changed in 0x0400 increments - e.g. 0xCC00). For a <b>Series 2</b> card the board address needs to lie on a 2K boundary (i.e. it can be changed in 0x0800 increments - e.g. 0xD800). For a <b>5136-SD-PCI</b> interface board, enter 0xFFFF. This value indicates that the board is a PCI board.
I/O Port	For a <b>KT</b> , <b>KTX</b> , <b>KTXD</b> , or <b>PKTX</b> board, enter a unique DH+ address in Octal (e.g. 0o77) If using both channels of a <b>PKTXD</b> card, you should give each channel a unique address. For a <b>5136-SD</b> board, enter the I/O Port address of the card (e.g. 0x250). For a <b>5136-SD-PCI</b> board, leave this field blank.
Interrupt	For a <b>KT</b> , <b>KTX</b> or <b>KTXD</b> - and polling is not being used - enter the IRQ number set on the card. For a <b>PKTX</b> card, leave this field blank For a <b>5136-SD</b> card, leave this field blank. For a <b>5136-SD-PCI</b> card, enter zero.
Special Options	For <b>KT</b> , <b>KTX</b> , <b>KTXD</b> , or <b>PKTX</b> ISA boards the following special options are available: -bx specifies a board number. Use this only if more than one card is installed. The default is x=1.

Field	Value
	<p>Sn to select the speed on the Data Highway Plus network; n represents the speed required and is one of the following numbers:</p> <p>n = 1 for 115 kbaud  n = 2 for 230 kbaud  The speed is set, by default, to 57 kbaud.</p> <p>For <b>KT, KTX, KTXD, or PKTX PCI</b> boards the following special option is available:</p> <p>Sn to select the speed on the Data Highway Plus network. n represents the speed required and is one of the following numbers:</p> <p>n = 1 for 115 kbaud  n = 2 for 230 kbaud  The speed is set, by default, to 57 kbaud.</p> <p>For the <b>5136-SD</b> board the following special options are available:</p> <ul style="list-style-type: none"> <li>-pN to set the Data Highway/Data Highway Plus address of the card to N. By default, N is a decimal value. If you need to specify the address as an octal value then N will take the format OoXX where XX is the octal address.</li> <li>-Sn to select the speed on the Data Highway Plus network. n represents the speed required and is one of the following numbers:</li> </ul> <p>n = 1 for 115 kbaud  n = 2 for 230 kbaud  The speed is set, by default, to 57 kbaud.</p> <ul style="list-style-type: none"> <li>-T to use 5136-SD-PCI interface card instead of ISA interface card.</li> </ul> <p>For the <b>5136-SD-PCI</b> board the following special options are available:</p> <ul style="list-style-type: none"> <li>-pN to set the Data Highway/Data Highway Plus address of the card to N. N is, by default, in decimal format. If you wish to specify an octal value, use the format OoXX where XX is the octal address.</li> <li>-Sn to set the speed of the Data Highway Plus network, where n represents the speed, and is one of the following numbers.</li> </ul> <p>n = 1 for 115 kbaud  n = 2 for 230 kbaud  The speed is set, by default, to 57 kbaud.</p>

## Ports

Field	Value
Port Number	A unique number for each port, starting from 1.
Baud Rate	Leave this field blank.
Data Bits	Leave this field blank.
Stop Bits	Leave this field blank.
Parity	Leave this field blank
Special Options	Leave this field blank.

## I/O Devices

Field	Value
I/O Device Address	<p>Specify the PLC address as:</p> <p>xKT:C[options],u</p> <p>where:</p> <p>x = the board number. If the number is not specified in the ports for then use 1.</p> <p>C = the channel number, for example, KT card = 0, KTX card = 0 or 1.</p> <p>u = the station number of the remote PLC in octal.</p> <p>Station numbers are between 0 and 77 (octal) for DH+ channels, and between 1 and 376 (octal) for DH channels.</p> <p>[options] If required, you can use the <a href="#">Offlink Address</a> options to allow communication with a station (PLC) that is not on the local link.</p> <p>For example: 1KT:0,1 specifies Port ID 1KT for access to PLC Station 1 .</p>
I/O Device Protocol	Enter ABTCP250.

### Allen-Bradley PLC-5/250 via Data Highway - Data Types

---

**Note:** The Allen-Bradley PLC-5/250 has many data types. The driver makes a separate request for each different data type, and each request has a finite overhead. It is more efficient to read fewer data types, so you should move the I/O and other data into a few main blocks to be read by Plant SCADA.

Allen Bradley 5/250 PLCs support remapping reads and writes.

### Allen-Bradley SLC-500 via Data Highway

Plant SCADA can use the ABTCP driver communicate to Allen-Bradley PLC-5/250s over Data Highway Plus via KT, KTX, KTXD, PKTX, 5136-SD and 5136-SD-PCI cards. Using this method, you can connect to single PLCs or to multiple PLCs as in the following diagram:

Only the SLC-5/04 can support a direct DH+ connection.

This method does not support DH-485.

### Allen-Bradley SLC-500 via Data Highway - Device Address

The address for an Allen-Bradley SLC-500 connected to a KT (or KTX, KTXD, or 5136-SD) board is specified as:

**xKT:C[options],u**

Where:

- **x** = the board number. If the number is not specified in the ports for then use 1.
- **C** = the channel number, for example, KT card = 0, KTX card = 0 or 1.
- **u** = the station number of the remote PLC in octal. Station numbers are between 0 and 77 (octal) for DH+ channels, and between 1 and 376 (octal) for DH channels.
- **[options]** If required, you can use the [Offlink Address](#) options to allow communication with a station (PLC) that is not on the local link.

#### Example

**1KT:0,1** specifies Port ID **1KT** for access to PLC Station **1**.

### Allen-Bradley SLC-500 via Data Highway - KT Board Setup

Before you install a KT board in your computer, select a starting memory address and an interrupt number. Use an interrupt number and address that has not been used by any of the existing boards in your computer. If you have any other proprietary boards installed, check the documentation accompanying these boards to determine the interrupt numbers and addresses that have been used. (If you are using an EISA bus computer, you must run the EISA configuration program.)

**Note:** The following information gives specific details on how to set up the KT card - not the KTX or KTXD.

### KT Card Polling Vs Interrupts

You can specify the communications to operate via polling or interrupt. This is controlled by the [\[ABTCP\] Polltime](#). If you set this parameter to a value other than 0, then polling will be used instead of interrupts.

### KT Card Switch Settings

Set the configuration options of the 1784-KT board to the following. Refer to your Allen-Bradley documentation for further information.

#### Board Address Switches

Memory Location Range	SW 1	SW 2	SW 3	SW 4	SW 5	SW 6
A000:0000-3F FF	Closed	Closed	Closed	Open	Closed	Open
A400:0000-3F	Open	Closed	Closed	Open	Closed	Open

FF						
A800:0000-3F FF	Closed	Open	Closed	Open	Closed	Open
AC00:0000-3F FF	Open	Open	Closed	Open	Closed	Open
B400:0000-3F FF	Open	Closed	Open	Open	Closed	Open
B800:0000-3F FF	Closed	Open	Open	Open	Closed	Open
C000:0000-3F FF	Closed	Closed	Closed	Closed	Open	Open
C400:0000-3F FF	Open	Closed	Closed	Closed	Open	Open
C800:0000-3F FF	Closed	Open	Closed	Closed	Open	Open
CC00:0000-3F FF *	Open	Open	Closed	Closed	Open	Open
D000:0000-3F FF	Closed	Closed	Open	Closed	Open	Open
D400:0000-3F FF	Open	Closed	Open	Closed	Open	Open
D800:0000-3F FF	Closed	Open	Open	Closed	Open	Open

\* Recommended address **0xCC00**.

This board uses a base memory size of 16k. To prevent conflict with other boards in your system, no memory overlap can exist when setting the memory address. You will also require this base memory size when configuring an EISA bus computer.

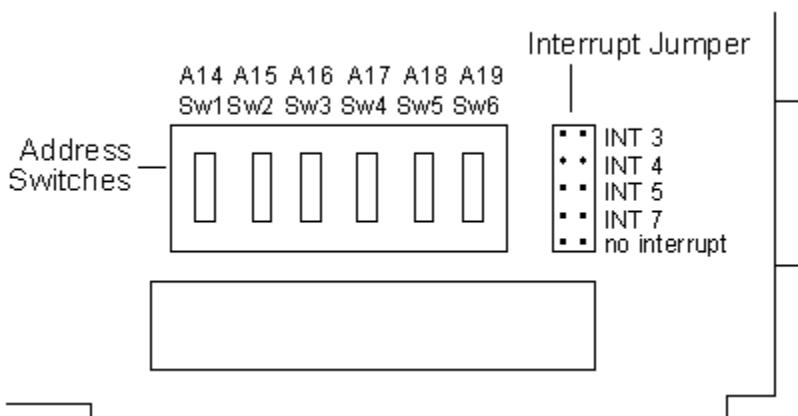

The EISA configuration utility may disable the interrupts of boards that are not set-up correctly. If you cannot get a response from the KT board, check the EISA configuration for the board. If there is still no response, try another interrupt. If you set the KT board to an interrupt that is used by a COM port, the EISA configuration will move the COM port to another interrupt. If you do not get a response from the KT board, disable the COM port that was re-configured.

## Interrupt Jumper Setting

Jumper Selection	Interrupt Selection
INT 3	IRQ3
INT 4	IRQ4
INT 5	IRQ5
INT 7	IRQ7
no interrupt	NONE

\* Recommended interrupt 5.

The following figure shows the location of the Address Switches and Interrupt Jumper.

Use an AB diagnostics application to confirm your settings.

## Setting up a PKTX Board

This is a plug and play card. No special setup is required - just confirm that the Base Memory Jumper is set to the 32-bit position. Do not attempt to manually install a driver when Windows notifies you it has detected new hardware.

Set **no** interrupts on this board. Interrupt request levels (IRQ) and base memory address values are automatically assigned. Plant SCADA will retrieve these configurations and use them to communicate with a board.

---

**Note:** To properly initialize the Windows component of the Plant SCADA CIKT board driver, you may need to restart your PC after installing the PKTX board, and then again after running your Plant SCADA project for the first time. Do not abort the project start up - allow it to execute right up to the menu page.

---

## Allen-Bradley SLC-500 via Data Highway - 5136-SD-PCI Setup

Communication with Allen-Bradley I/O devices via Data Highway Plus can be established using the 5136-SD-PCI board from SS Technologies. This board was developed with Plug and Play functionality, enabling a simple setup. Plant SCADA supports the installation and use of only one 5136-SD-PCI board in a computer at a time.

Once you have installed the board into the PCI slot in your computer, Windows detects the new hardware and assigns it an address. Plant SCADA retrieves the configuration details from Windows and, at run-time, downloads appropriate interface firmware to the board, enabling communication. No additional software is required.

Once you have installed the board, you will need to set the [Communication Settings](#).

**Note:** When you first start up your computer after installing the 5136-SD-PCI board, a message may display indicating that new hardware has been detected. It is not necessary to install the board using Add New Hardware in the Windows Control Panel, since Plant SCADA detects the Windows configuration. If the card has been previously installed through Control Panel, you will need to uninstall it.

### Allen-Bradley SLC-500 via Data Highway - 5136-SD-PCI Test

**Note:** For full details of the 5136-SD-PCI board, please refer to its hardware guide.

Once the 5136-SD-PCI board is installed, you can tell whether or not it is functioning correctly by monitoring its LEDs. You will not need to remove your computer's cover to do this, as the board's LEDs are visible at the back of the machine.

The board has two LEDs, the Network LED and the System LED. The first time you start up the computer with the board installed, the System LED will be red. When Plant SCADA successfully downloads the communications firmware to the board, it turns the System LED off. If the loader does not run successfully, the System LED will remain red.

The Network LED displays a flickering green whenever the card is active (transmitting) on the network. The Network LED should never turn off as long as there is a node on the network. If it does not display green, check your hardware or network cable.

### Allen-Bradley SLC-500 via Data Highway - Communication Settings

To establish communication with a device, the associated Board, Port and I/O Device need to be correctly configured in Plant SCADA Studio's **Topology** activity.

If you use the Express Communications Wizard to connect to a device, these settings will be automatically configured for you. However, if you need to manually configure them, use the settings outlined below.

## Boards

Field	Value
Board Type	For a <b>KT</b> , <b>KTX</b> , <b>KTXD</b> , or <b>PKTX</b> card, enter CIKT. For a <b>5136-SD</b> or <b>5136-SD-PCI</b> card, enter SSTAB.
Address	For a <b>KT</b> board, enter the address of the card (e.g. 0xCC00). For a <b>KTX</b> or <b>KTXD</b> board, enter the first two digits of the address of the card (e.g. 0xD0). For a <b>PKTX</b> board, enter 0xFFFF. For a <b>PKTXD</b> board channel A, enter 0xEEEE (0xEEEE) For a <b>PKTXD</b> board channel B, enter 0xEEEB. The driver uses this to determine the type of card and then auto-detects the address. Do not append zeros. For a <b>5136-SD</b> board, enter the address of the card,

Field	Value
	<p>which needs to lie on a 1K boundary (i.e. it can be changed in 0x0400 increments - e.g. 0xCC00).</p> <p>For a <b>Series 2</b> card the board address needs to lie on a 2K boundary (i.e. it can be changed in 0x0800 increments - e.g. 0xD800).</p> <p>For a <b>5136-SD-PCI</b> interface board, enter 0xFFFF. This value indicates that the board is a PCI board.</p>
I/O Port	<p>For a <b>KT, KTX, KTXD, or PKTX</b> board, enter a unique DH+ address in Octal (e.g. 0o77)</p> <p>If using both channels of a <b>PKTXD</b> card, you should give each channel a unique address.</p> <p>For a <b>5136-SD</b> board, enter the I/O Port address of the card (e.g. 0x250).</p> <p>For a <b>5136-SD-PCI</b> board, leave this field blank.</p>
Interrupt	<p>For a <b>KT, KTX or KTXD</b> - and polling is not being used - enter the IRQ number set on the card.</p> <p>For a <b>PKTX</b> card, leave this field blank</p> <p>For a <b>5136-SD</b> card, leave this field blank.</p> <p>For a <b>5136-SD-PCI</b> card, enter zero.</p>
Special Options	<p>For <b>KT, KTX, KTXD, or PKTX ISA</b> boards the following special options are available:</p> <ul style="list-style-type: none"> <li>-bx specifies a board number. Use this only if more than one card is installed. The default is x=1.</li> <li>Sn to select the speed on the Data Highway Plus network; n represents the speed required and is one of the following numbers:</li> <li>n = 1 for 115 kbaud</li> <li>n = 2 for 230 kbaud</li> </ul> <p>The speed is set, by default, to 57 kbaud.</p> <p>For <b>KT, KTX, KTXD, or PKTX PCI</b> boards the following special option is available:</p> <ul style="list-style-type: none"> <li>Sn to select the speed on the Data Highway Plus network. n represents the speed required and is one of the following numbers:</li> <li>n = 1 for 115 kbaud</li> <li>n = 2 for 230 kbaud</li> </ul> <p>The speed is set, by default, to 57 kbaud.</p> <p>For the <b>5136-SD</b> board the following special options are available:</p> <ul style="list-style-type: none"> <li>-PN to set the Data Highway/Data Highway Plus address of the card to N. By default, N is a decimal</li> </ul>

Field	Value
	<p>value. If you need to specify the address as an octal value then N will take the format OoXX where XX is the octal address.</p> <p>-Sn to select the speed on the Data Highway Plus network. n represents the speed required and is one of the following numbers:</p> <ul style="list-style-type: none"> <li>n = 1 for 115 kbaud</li> <li>n = 2 for 230 kbaud</li> </ul> <p>The speed is set, by default, to 57 kbaud.</p> <p>-T to use 5136-SD-PCI interface card instead of ISA interface card.</p> <p>For the <b>5136-SD-PCI</b> board the following special options are available:</p> <ul style="list-style-type: none"> <li>-pN to set the Data Highway/Data Highway Plus address of the card to N. N is, by default, in decimal format. If you wish to specify an octal value, use the format OoXX where XX is the octal address.</li> <li>-Sn to set the speed of the Data Highway Plus network, where n represents the speed, and is one of the following numbers.</li> </ul> <ul style="list-style-type: none"> <li>n = 1 for 115 kbaud</li> <li>n = 2 for 230 kbaud</li> </ul> <p>The speed is set, by default, to 57 kbaud.</p>

## Ports

Field	Value
Port Number	A unique number for each port, starting from 1.
Baud Rate	Leave this field blank.
Data Bits	Leave this field blank.
Stop Bits	Leave this field blank.
Parity	Leave this field blank.
Special Options	Leave this field blank.

## I/O Devices

Field	Value
I/O Device Address	Specify the PLC address as:

Field	Value
	<p><b>xKT:C[options],u</b></p> <p>where:</p> <p>x = the board number. If the number is not specified in the ports for then use 1.</p> <p>C = the channel number, for example, KT card = 0, KTX card = 0 or 1.</p> <p>u = the station number of the remote PLC in octal. Station numbers are between 0 and 77 (octal) for DH+ channels, and between 1 and 376 (octal) for DH channels.</p> <p>[options] If required, you can use the <a href="#">Offlink Address</a> options to allow communication with a station (PLC) that is not on the local link.</p> <p>For example: 1KT:0,1 specifies Port ID 1KT for access to PLC Station 1 .</p>
I/O Device Protocol	Enter ABTCP500.

### Allen-Bradley SLC-500 via Data Highway - Data Types

**Note:** The Allen Bradley SLC500 has many data types. The protocol makes a separate request for each different data type, and each request has a finite overhead. It is more efficient to read fewer data types, so you should move the I/O and other data into a few main blocks to be read by Plant SCADA.

Data Types	Address Format	Plant SCADA Data Type
Status words	S:w/b	DIGITAL
Timer	Tf:w.t	DIGITAL
Timer	Tf:w/b	DIGITAL
Counter	Cf:w.c	DIGITAL
Counter	Cf:w/b	DIGITAL
Control	Rf:w.r	DIGITAL
Control	Rf:w/b	DIGITAL
Binary	Bf:w/b	DIGITAL
Integer	Nf:w/b	DIGITAL
Output image	O:O.o	INT
Input image	I:O.o	INT

Data Types	Address Format	Plant SCADA Data Type
Status words	<b>S:w</b>	BCD / INT / LONG / LONGBCD/ REAL
Timer	<b>Tf:w.T</b>	BCD / INT / LONG / LONGBCD/ REAL
Counter	<b>Cf:w.T</b>	BCD / INT / LONG / LONGBCD/ REAL
Control	<b>Rf:w.C</b>	BCD / INT / LONG / LONGBCD/ REAL
Binary	<b>Bf:w</b>	BCD / INT / LONG / LONGBCD/ REAL
Integer	<b>Nf:w</b>	BCD / INT / LONG / LONGBCD/ REAL

Where:

<b>f</b>	File Number 0 to 999 decimal
<b>:w</b>	Element number 0 to 999 decimal
<b>:O</b>	Element number 0 to 277 octal
<b>/b</b>	Bit Number 0 to 15 decimal
<b>/o</b>	Bit Number 0 to 17 octal
<b>.T</b>	Timer/Counter Sub Element: PRE - Preset Value ACC - Accumulated Value
<b>.t</b>	Timer bits: EN - Enable TT - Timing DN - Done
<b>.C</b>	Control Sub Element: LEN - Length POS – Position
<b>.c</b>	Counter bits: CU - Count Up CD - Count Down DN - Done OV - Overflow

	UN - Underflow
.r	Control bits: EN - Enable DN - Done ER - Error UL - Unload IN - Inhibit comparisons FD - Found

Allen-Bradley SLC500 Series PLCs support remapping reads only.

## Offlink Addressing

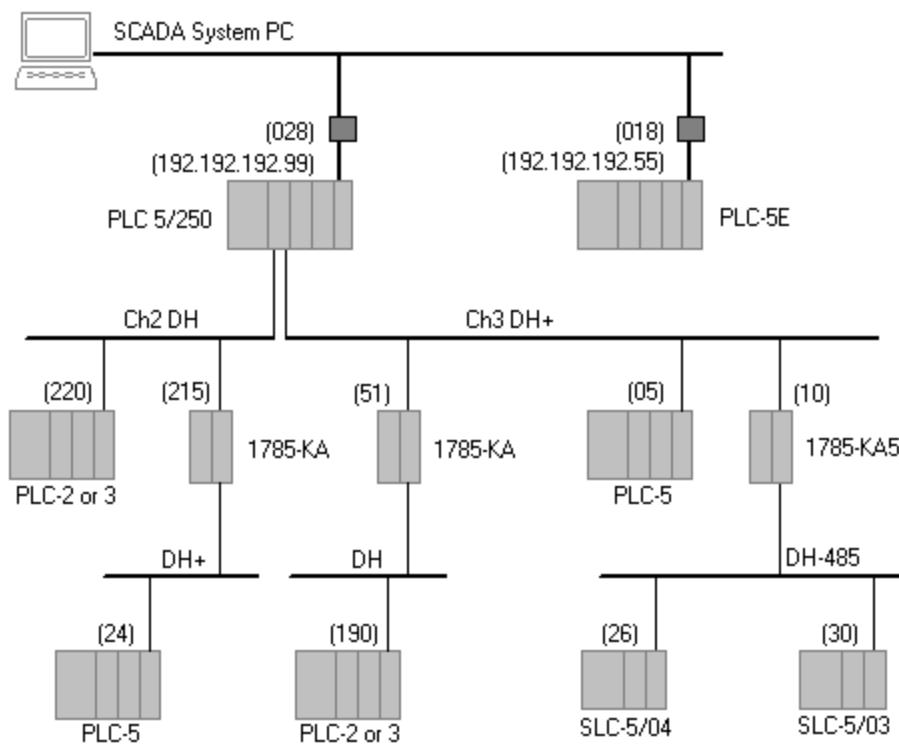

Offlink addressing allows communication with a station (PLC) that is not on the local link and is required for PLCs that cannot have support and Ethernet interface (like SLCs). This is done via 1785-KA, 1785-KA5 or PI routing. The 1785-KA is a communications adaptor card for providing exchange between DH and DH+. The format for offlink addressing is:

**PMM:C[options],u**

Where:

- **P** = the router module pushwheel number (0 to 4) or board number.
- **MM** = the module type (RM, KA or KT)
- **C** = the channel number (0, 2 or 3)
- **[options]** is one or more of the following:
  - **/B:b** where b is the bridge address (1 to 376 octal).
  - **/L:l** where l is the link id (0 to 65535 decimal)
  - **/G:g** where g is the gateway to the final DH-485 link (1 to 376 octal)
  - **/KA** When communicating through a 1785-KA from DH+ to DH
- **u** = the station number of the remote PLC in octal. Station numbers are between 0 and 77 (octal) for DH+ channels, and between 1 and 376 (octal) for DH channels.

Consider the following diagram and examples:

In the picture above station addresses are noted (in parentheses) next to each unit. Each unit is addressed as follows:

Station Number	Address
028	IP address: 192.192.192.99
018	IP address: 192.192.192.55
220	ORM:2,220
05	ORM:3,05
24	ORM:2,0215
190	ORM:3/B:51/KA,190
26	ORM:3/B:10/L:0,26
30	ORM:3/G:10/L1,30

Be aware that the SLCs may be addressed in either Single Hop (link is set to 0) or Gateway (where the incoming DH+ link ID is used) modes.

For detailed information on off-link addressing refer to the Allen Bradley Interchange Software Reference Manual.

## ABTCP Driver Parameters

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

[ABTCP] Parameter	Allowable Values	Default Value	Description
Block	10 - 256	236	A value (bytes) used by the I/O Server to determine if two or more packets can be blocked into one data request before being sent to the I/O Device. For example, if you set the value to 10, and the I/O Server receives two simultaneous data requests - one for byte 3, and another for byte 8 - the two requests will be blocked into a single physical data request packet. This single request packet is then sent to the I/O Device, saving on bandwidth and processing.
Delay	0 to 300	0	The period (in milliseconds) to wait between receiving a response and sending the next command.
MaxBits	0 to 2048	1888	The maximum read size in one request. Decrease the value for non-standard I/O Devices that do not support large reads. MaxBits should be a multiple of 8. If this value is modified from the default, then the protdir.dbf file in the Plant

			SCADA bin directory needs to be manually edited so that the MAX_LENGTH entry for your I/O Device is changed to match. For example, if MaxBits is set to 1920 bits for the ABTCP5 protocol then protdir.dbf should be modified as follows: ABTCP5 AB5 944 1920 0x37f
MaxPending	1 - 32	8	The maximum number of pending commands that the driver holds ready for immediate execution.
PollTime	0 to 300	0	The interrupt or polling service time (in milliseconds). Setting the polling time to 0 puts the driver in interrupt mode. <b>Note:</b> If you are using the PKTX or the 5136-SDI-PCI board, this parameter should be set to 10.
Retry	0 - 8	1	The number of times to retry a command after a timeout.
Status	<p>The value for this parameter is formatted as follows:</p> <p>&lt;RawType&gt;, &lt;BitWidth&gt;, &lt;UnitType&gt;, &lt;UnitAddress&gt;, &lt;UnitCount&gt;</p> <p>where...</p> <p><b>RawType =</b> 0 for Digital 1 for Int 4 for Long 8 for Byte</p> <p><b>BitWidth =</b></p>	<p>No default.</p> <p>For example, to specify the time/date seconds counter <b>S:23</b> as the status variable in a PLC-5/40E, use the following:</p> <p>[ABTCP] Status=1,16,0xd0002,23,1</p> <p>Or, to use the processor status run mode bit <b>S:1/1</b> for a PLC-5/10, use the following:</p> <p>[ABTCP] Status=0,1,0xd0002,17,16</p>	<p>Defines the register that indicates the status of the PLC (for Hot Standby). This register is checked every [ABTCP]WatchTime period.</p> <p>Usually, if the PLC is put into program mode, communications continue as normal, so the operator is unable to tell that control is suspended. However, when this parameter is used, can be made to display #COM to</p>

	<p>1 for Digital 8 for Byte 16 for Int 32 for Long</p> <p><b>UnitType =</b> Protocol specific. See the variable specification .DBF files for the particular PLC.</p> <p><b>UnitAddress =</b> The item number or bit number.</p> <p><b>UnitCount =</b> 1 for Analog 16 for Digital</p>		<p>signify that the PLC is offline (and the driver will return 0x20). If there is a standby unit configured, then it will automatically swap to it.</p> <p>For this to work correctly, you may need to manually configure the status register in your PLC. The register needs to be configured as follows, depending on whether it is a digital or analog variable:</p> <p>Digital - The variable needs to be always on, otherwise the unit is put offline.</p> <p>Analog - The variable needs to be changed for each read. If the variable has not changed since the last read, the unit is put offline.</p>
StringReverse	0 to 1	0	Set to 1 if the bytes in each word of a string needs to be swapped.
Timeout	0 to 32000	1000	Specifies how many milliseconds to wait for a response before displaying an error message.
WatchTime	0 to 128	30	The frequency (in seconds) that the driver uses to check the communications link to the I/O device.

## ABTCP Driver Specific Errors

When a hardware error is detected, Plant SCADA generates an alarm, and displays the alarm on the hardware alarm page (in the alarm description of the hardware alarm). To see the error number, make sure you have Alarm Category 255 defined with a display format that includes {ErrDesc,15} {ErrPage,10}.

There are a number of generic errors that are common to all protocols. In some cases, only the generic error is available, though often both the generic error and a specific error are given.

The following errors, listed in (hexadecimal) sequence, are specific to this protocol. Plant SCADA displays the error number and description for common protocol-specific errors. Uncommon errors are not contained in the error database, in which case will only display the error number.

You may require additional information to enable you to rectify an error. This information should be detailed in the documentation that accompanied the I/O Device (or network). If, after reviewing all documentation, you cannot rectify an error, contact Technical Support.

**0x10100PLC out of buffers**

Check the PLC configuration.

**0x10200 PLC is not online**

Check that the PLC is online.

**0x10300 Duplicated token holder detected**

If this error occurs by itself and is persistent, contact Technical Support for this product.

**0x10400 Local port is disconnected**

If this error occurs by itself and is persistent, contact Technical Support for this product.

**0x11000 Illegal command or format**

If this error occurs by itself and is persistent, contact Technical Support for this product.

**0x12000 Host will not communicate**

Check the project configuration and PLC configuration.

**0x13000 PLC hardware fault**

Address this problem at the PLC.

**0x14000 Host hardware fault**

Your hardware may not be functional. If this is persistent try using duplicate hardware.

**0x15000 Illegal data table address**

If this error occurs by itself and is persistent, contact Technical Support for this product.

**0x16000 PLC is write protected**

Change the configuration of your PLC (if desired).

**0x17000 Processor is in program mode**

Switch your processor to RUN mode (if desired).

**0x18000 Compatibility file is missing**

If this error occurs by itself and is persistent, contact Technical Support for this product.

**0x19000 PLC cannot buffer command**

If this error is persistent, check the PLC configuration and refer to your PLC documentation.

**0x1B000 PLC problem due to download**

If this error is persistent, check the PLC configuration and refer to your PLC documentation.

**0x1F001Error converting block address**

If this error is persistent, check the PLC configuration and refer to your PLC documentation.

**0x1F002 Insufficient levels of address**

If this error occurs by itself and is persistent, contact Technical Support for this product.

**0x1F003 Too many levels in address**

If this error occurs by itself and is persistent, contact Technical Support for this product.

**0x1F004 Symbol not found**

If this error occurs by itself and is persistent, contact Technical Support for this product.

**0x1F005 Symbol is of improper format**

Check the project configuration and PLC configuration.

**0x1F006 Invalid address**

The data requested by is not configured in the PLC. Check the project configuration and PLC configuration.

**0x1F007 File is of wrong size**

The data requested by is out of range or is not defined in the I/O Device. Check the project configuration and PLC configuration.

**0x1F008 Changed situation since start**

If this error is persistent, check the PLC configuration and refer to your PLC documentation.

**0x1F009 File is too large**

The data requested by is out of range or is not defined in the I/O Device. Check the project configuration and PLC configuration.

**0x1F00A Word and count too large**

The data requested by is out of range. Check the project configuration and PLC configuration.

**0x1F00B Access denied**

The PLC is denying access. If this error is persistent, check the PLC configuration and refer to your PLC documentation.

**0x1F00C Resource unavailable**

Check the project configuration and PLC configuration. If this error occurs by itself and is persistent, contact Technical Support for this product.

**0x1F00D File of wrong size**

The data requested by is out of range or is not defined in the I/O Device. Check the project configuration and PLC configuration.

**0x1F00E Shutdown cannot be executed**

If this error is persistent, check the PLC configuration and refer to your PLC documentation.

**0x1F00F File is too large**

The data requested by is not configured in the PLC. Check the project configuration and PLC configuration.

**0x1F010 Histogram overflow**

If this error is persistent, check the PLC configuration and refer to your PLC documentation.

**0x1F011Illegal data type**

The data requested by is not configured in the PLC. Check the project configuration and PLC configuration.

**0x1F012 Bad parameter**

Check the project configuration and PLC configuration.

**0x1F013 Data table deleted**

If this error occurs by itself and is persistent, contact Technical Support for this product.

**0x1FOFF \***

EXT STS error code.

**0x1FF00\***

Local STS error code.

**0x1F000 \***

Remote STS error code.

## BACNET Driver

The Plant SCADA BACNET Driver supports communication with the BACnet Data Communication Protocol, a widely accepted standard for building automation and control systems. This allows Plant SCADA to integrate with building management systems for heating and air conditioning, ventilation, lighting, security and fire detection.

The Plant SCADA BACNET Driver is designed to communicate with BACnet networks and devices using the BACnet/IP option.

## Safety Information

### Hazard categories and special symbols

The following symbols and special messages may appear in this manual or on the product to warn of potential hazards or to call attention to information that clarifies or simplifies a procedure.

Symbol	Description
 or 	The addition of either symbol to a "Danger" or "Warning" safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.
	This is the safety alert symbol. It is used to alert you to personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.

**⚠ DANGER**

**DANGER** indicates an imminently hazardous situation, which, if not avoided, will result in death or serious injury.

**⚠ WARNING**

**WARNING** indicates a potentially hazardous situation, which, if not avoided, can result in death or serious injury.

**⚠ CAUTION**

**CAUTION** indicates a potentially hazardous situation which, if not avoided, can result in minor or moderate injury.

**NOTICE**

NOTICE used without a safety alert symbol, indicates a potentially hazardous situation which, if not avoided, can result in property or equipment damage.

**Please Note**

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by AVEVA for any consequences arising out of the use of this material.

**Before You Begin**

Plant SCADA is a Supervisory Control and Data Acquisition (SCADA) solution. It facilitates the creation of software to manage and monitor industrial systems and processes. Due to Plant SCADA's central role in controlling systems and processes, you must appropriately design, commission, and test your Plant SCADA project before implementing it in an operational setting. Observe the following:

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not use Plant SCADA or other SCADA software as a replacement for PLC-based control programs. SCADA software is not designed for direct, high-speed system control.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**⚠ WARNING****LOSS OF CONTROL**

- The designer of any control scheme must consider the potential failure modes of control paths and, for certain critical control functions, provide a means to achieve a safe state during and after a path failure. Examples of critical control functions are emergency stop and overtravel stop, power outage and restart.
- Separate or redundant control paths must be provided for critical control functions.
- System control paths may include communication links. Consideration must be given to the implications of unanticipated transmission delays or failures of the link.
- Observe all accident prevention regulations and local safety guidelines.<sup>1</sup>
- Each implementation of a control system created using Plant SCADA must be individually and thoroughly tested for proper operation before being placed into service.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

1. For additional information, refer to NEMA ICS 1.1 (latest edition) "Safety Guidelines for the Application, Installation, and Maintenance of Solid State Control", and to NEMA ICS 7.1 (latest edition) "Safety Standards for Construction and Guide for Selection, Installation and Operation of Adjustable-Speed Drive Systems" or their equivalent governing your particular location.

## About the BACnet Protocol

The BACnet protocol is accepted as an ISO standard for building automation and control systems. The protocol defines a number of data link /physical layers, including ARCNET, Ethernet, BACnet/IP, Point-To-Point over RS-232, Master-Slave/Token-Passing over RS-485, and LonTalk. These networks may then be further interconnected by BACnet routers.

---

**Note:** The BACNET driver is designed to communicate to BACnet networks and devices using only BACnet/IP transport option.

---

## BACnet objects

Every BACnet device is represented as a collection of objects with a number of properties. The objects include:

- Analog Input
- Analog Output
- Analog Value
- Binary Input
- Binary Output
- Binary Value
- Multi-State Input
- Multi-State Output
- Calendar
- Event-Enrollment
- File
- Notification-Class
- Group
- Loop
- Program
- Schedule
- Command
- Device

[BACNET Supported Object Types](#)

## Communicating with BACnet

The BACNET driver is designed to communicate with BACnet networks and devices using the BACnet/IP transport option. The following diagram illustrates how Plant SCADA communicates to different types of BACnet networks.

The diagram illustrates the following:

- Each network is uniquely identified by a number.
- Each device has an address uniquely identifying it on a network.
- Each device has a unique device ID in the whole BACnet network.
- The device ID is used to uniquely identify each device in Plant SCADA.
- Each BACnet device corresponds to an I/O Device in Plant SCADA.
- Plant SCADA communicates to non-BACnet/IP networks via BACnet routers.
- Plant SCADA I/O device redundancy is provided.

**Note:** The BACNET driver only needs one port configured in Plant SCADA. This is because the driver will only initialize one instance of Cimetrics BACstac which it will use to communicate with all devices. Therefore, you only need to configure one board and one port in your Plant SCADA project.

- [Writing to BACnet Properties](#)
- [Writing to Specific Calendar and Schedule Properties](#)

## Mapping Tags to BACnet Objects

The BACNET driver represents the properties of BACnet objects as tags. A corresponding Plant SCADA data type is chosen for each of the supported properties (see [BACnet Data Type Representation](#)).

BACnet object properties are addressed using the following format:

*<object type>.<object instance>.<property type>*

Where:

- *<object type>* is one of the mnemonics (provided in the [BACNET Supported Object Types](#) table).
- *<object instance>* is the numerical object instance. Object instances may range from 0 to 4194302.
- *<property type>* is the property mnemonics indicated for the particular property type in the object type tables.

## BACnet Data Type Representation

The Plant SCADA data types that correspond to BACnet property data types are fairly straightforward for most BACnet data types. Data types which require further explanation are described below.

## BACnet Date/Time Data Types

BACnet date/time properties are represented as a string in the following formats:

- **BACnetDate:** dd/mm/yyyy  
Examples: "01/09/2008", "01/09/\*\*\*\*" if year is not specified, "\*/\*\*/\*/\*/\*" if none of the date elements are specified.
- **BACnetTime:** hh:mm:ss.mmm.  
Examples: "05:20:30:400", "05:\*\*:30:400" if hour is not specified, "\*\*:\*\*:\*\*:\*\*" if none of the time elements are specified.
- **BACnetDateTime:** dd/mm/yyyy hh:mm:ss.mmm.  
Examples: "01/09/2008 05:20:30:400", "01/09/\*\*\*\* 05:\*\*:30:400" if year and minutes are not specified.
- **BACnetWeekNDay:** dd/ww/mm.  
Examples: "04/02/03", "04/02/\*\*" if month is not specified.

## BACnet Any Data Type

For BACnet properties that can be any primitive data type, the driver supports the following BACnet data types:

- Boolean
- Real
- Unsigned
- Enumerated
- CharacterString
- BACnetDate
- BACnetTime
- BACnetDateTime.

Corresponding Plant SCADA data types can be DIGITAL, LONG, REAL or STRING.

## BACnetPriorityArray

BACnetPriorityArray is represented as a string.

Example: "NULL, NULL, NULL, NULL, NULL, NULL, NULL, NULL, NULL, 78, 89, NULL, NULL, NULL, NULL, NULL".

## Reading BACnet Properties

The BACNET driver can use change-of-value (COV) subscriptions or polling to read values from BACnet properties. In both cases, this behavior can be modified by adjusting parameters in the `citect.ini` file.

## Polling Properties

The driver will only poll BACnet properties data for the tags which have been subscribed by the I/O Server.

The polling rate will be defined by the I/O Server subscription update rate and the value of Cache Time parameter in the I/O Device configuration properties.

The I/O Server subscription update rate will depend on whether the tag is displayed on a page, has an alarm or trend tag associated with it or subscribed in Cicode. For example, the default update rate for the tag displayed on a page is 250 msec, for an alarm tag is 500 msec and for a trend tag it will depend on the trend tag configuration settings.

Also it is possible to set the minimal allowable polling rate using the Cache Time parameter in the I/O Device configuration properties. If that parameter is not set, the default value is 300 msec.

So if the I/O Server subscription update rate is less than the Cache Time value, the driver will use the Cache Time value to define how often the BACnet property will be polled.

If Cache Time value is set to 0, it will be ignored and the polling rate will be defined based on the I/O Server subscription rate.

You need to set the Cache Time parameter according to your system requirements.

## COV Subscriptions

If a BACnet device supports change-of-value reporting, the driver will use the `SubscribeCOV` service to subscribe to value changes of `PresentValue` and `SystemFlags` BACnet properties.

The driver will only send COV subscriptions for the tags which have been subscribed by the I/O Server.

The driver subscribes to COV notifications for the period defined by the `COVLifeTime` parameter.

In the following situations the driver will use polling instead of COV subscriptions:

- A device does not support COV reporting.
- `COVLifeTime` is set to 0.
- The COV subscription failed.

## See Also

[Writing to BACnet Properties](#)

## Writing to BACnet Properties

The driver uses `WriteProperty` and `WritePropertyMultiple` services for writing to BACnet properties.

The priority level when writing to commandable properties (Present Value for Analog Output, Analog Value,

Binary Output, Binary Value, Multi-state Output, Multi-state Value objects) is controlled by the WritePriority setting in the Citect.ini file and the Device object WritePriority custom property.

At start up the write priority level will be set to the value specified in the WritePriority ini setting or set to 16 (lowest priority) if not specified.

If you require a write to be performed with a specified priority, you will need to change the write priority via the value of the tag with the WritePriority address (before performing a write to a commandable property). After the write has completed, the write priority will be set back to the priority specified in the ini setting, or to the default if an ini setting is not specified.

The Device object WriteNULL custom property is used to write NULL property values. When the value of the tag with that address is set to 1, writing property value 0 will be substituted by a NULL value.

It is also possible to change the value which specifies writing a NULL from 0 to any REAL value by using the WriteNULLValue custom device property. In that case when the WriteNULL is set to 1, you can use WriteNULLValue to change the write NULL value. The value of the WriteNULLValue property will be reset back to 0 after the write is completed.

---

**Note:** The Raw and Eng Scale values in the tag configuration should be the same for the WriteNULLValue property to work correctly.

Writing to BACnet properties which have CharacterString data type currently supports only ANSI X3.4 character set.

## See Also

[Reading BACnet Properties](#)

## Writing to Specific Calendar and Schedule Properties

Tag addresses are available that allow you to write to the BACnet properties identified in the following table.

Tag address	Associated BACnet property
DateListEx	Calendar.DateList
WeeklyScheduleExInt[.Monday...Sunday] WeeklyScheduleExDig[.Monday...Sunday] WeeklyScehduleExDbl[.Monday...Sunday] WeeklyScehduleExEnum[.Monday...Sunday] WeeklyScehduleExUInt[.Monday...Sunday] WeeklyScehduleExReal[.Monday...Sunday] See <a href="#">Schedule Objects</a> .	Schedule.WeeklySchedule
ExceptionScheduleExInt[.1...31] ExceptionScheduleExDig[.1...31] ExceptionScheduleExDbl[.1...31] ExceptionScheduleExEnum[.1...31] ExceptionScheduleExUInt[.1...31]	Schedule.ExceptionSchedule

Tag address	Associated BACnet property
ExceptionScheduleExReal[.1...31] See <a href="#">Schedule Objects</a> .	

When configuring these tags, you should consider the following:

- These tags are STRING Plant SCADA data type.
- Using wildcards (\*) when writing to the schedule or calendar is not supported, for example, {{05/\*\*/2011}}. However, any unspecified entries existing in the device will be read as wildcards (\*). For example, the driver will read the Calendar entry {{05/\*\*/2011}} from the device as it is. This is interpreted as the 5th day of any month of the year 2011.
- Currently the only supported date and time format is Australian. Date: dd/mm/yyyy. Time: hh:mm:ss.mmm.
- A write will be unsuccessful if an incorrect string format is used.

The driver is only capable of writing a string no longer than 252 characters because of Plant SCADA limitations. Any attempt to write a string longer than 252 characters will be unsuccessful. The following provides examples of the limitations you need to be aware of:

- **Schedule.WeeklySchedule[0..1].BACnetDailySchedule**, **Schedule.ExceptionSchedule[0..N].BACnetSpecialEvents** and **Calendar.DateList** are BACnet lists with an arbitrary number of elements. A list with a large number of elements may not fit into the string length limitation. If the string requires more than 252 characters, the corresponding tag value will be set to empty string with BAD quality.
- For a **Calendar.DateList** property that contains a list of BACnetDate elements ("{{DT(04/11/2015)} {DT(05/11/2015)}{DT(06/11/2015)}}", the maximum number of elements in the list is 15.
- For a **Calendar.DateList** property that contains a list of BACnetDateRange elements ("{{DR(31/12/2000)(25/10/2020)}{DR(31/12/2000)(25/10/2020)}}"), the maximum number of elements in the list is 8.
- For **Schedule.WeeklySchedule** and **Schedule.ExceptionSchedule** properties, the maximum number of elements depends on the number of time-value pairs in BACnetDailySchedule or BACnetSpecialEvents lists.

For example, a **Schedule.WeeklySchedule.Monday** property that has only digital values can contain 16 time-value pairs. This number will decrease if a weekly or exception schedule contains integer or real values. Also, it will be less for an exception schedules as it will contain date/calendar references.

---

**Note:** Not every BACnet device uses the same object indexing rules. For example, with the Alerton BCM-ETH, both the schedule object index and the calendar object index start independently at 1, whereas Andover™ TAC devices use common indexing for every object type, starting at 7001.

When writing to one of these tags, you need to compose a string in a format described below. The driver will parse the string and update the corresponding property in the device.

## Calendar.DateListEx property

This tag represents a sequence of BACnetCalendarEntry.

### String format for BACnetCalendarEntry:

{DT(dd/mm/yyyy)}

or

{DR(dd/mm/yyyy)(dd/mm/yyyy)}

or

{WD(DayOfWeek/WeekOfMonth/Month)}

where:

- DT represents a 'Date' type BACnetCalendarEntry
- DR represents a 'DateRange' type BACnetCalendarEntry
- WD represents a 'WeekNDay' type BACnetCalendarEntry
- *DayOfWeek* is a numerical representation of a day: 1 for Monday, 2 for Tuesday and so on
- *WeekOfMonth* is 1 for days 1-7; 2 for days 8-14; 3 for days 15-21; 4 for days 22-28; 5 for days 29-31
- *Month* is a numerical representation of a month: 1 for January, 2 for February and so on

For example, when defining a string you could use the following:

1. CAL\_2 = "{DT(04/11/2009)}"
2. CAL\_2 = "{DT(04/11/2009)}{ DT(24/12/2020)}"
3. CAL\_2 = "{DR(31/12/2000)(25/10/2020)}"
4. CAL\_2 = "{WD(1/2/11)}{WD(7/3/10)}"
5. CAL\_2 = "{DT(04/11/2009)}{DR(03/05/2011)(15/08/2017)}{WD(4/5/3)}"

Be aware when specifying a year value (yyyy), that the driver will support 1900 to 2154. However, you will need to consider that the range supported by a device may be more restrictive.

## Schedule.WeeklySchedule Tags

These tags represent a single array of BACnet Schedule.WeeklySchedule property. Each array has seven elements to represent days of the week. You will need to create a separate tag for each day in a week. The driver reads and writes individual array elements of BACnet Schedule.WeeklySchedule property.

There are separate tag addresses for different value data types. The driver support BACnet Boolean, Signed Integer and Double data types.

**The tag address format is:**

SCH.<objectInstance>.WeeklyScheduleExDig[.Monday...Sunday]  
SCH.<objectInstance>.WeeklyScheduleExInt[.Monday...Sunday]  
SCH.<objectInstance>.WeeklyScheduleExDbl[.Monday...Sunday]  
SCH.<objectInstance>.WeeklyScheduleExEnumI[.Monday...Sunday]  
SCH.<objectInstance>.WeeklyScheduleExUInt[.Monday...Sunday]  
SCH.<objectInstance>.WeeklyScheduleExReal[.Monday...Sunday]

For example:

- The following tag represents a daily schedule for Monday, supporting an Integer data type:  
Schedule.3.WeeklyScheduleExInt.Monday
- The following tag represents a daily schedule for Saturday, supporting a Double data type:  
Schedule.1.WeeklyScheduleExDbl.Saturday

- The following tag represents a number of elements in a WeeklySchedule array:  
`Schedule.3.WeeklyScheduleExInt`
- The following tag represents a number of elements in a WeeklySchedule array:  
`Schedule.3.WeeklyScheduleExReal`
- The following tag represents a daily schedule for Monday, supporting an unsigned Integer data type:  
`Schedule.3.WeeklyScheduleExUInt.Monday`
- The following tag represents a daily schedule for Monday, supporting an enumerated data type:  
`Schedule.3.WeeklyScheduleExEnum.Saturday`

The value of these tags is represented by a string in a format.

**The string format is:**

`(time;value)(time;value)(time;value)`

where:

- *time* is in BACnetTime in a format "hh:mm:ss.mmm" or "HH:mm:ss.mmm"
- *value* is a Boolean, Signed Integer or Double, depending on a tag address.

**Example**

`(07:00:00.00;18.5)(09:15:00.00;20.5)`

**Schedule.ExceptionSchedule Tags**

These tags represent a single array element of BACnet Schedule.ExceptionSchedule property. The user will need to create a separate tag for each special event. The driver reads and writes individual array elements of BACnet Schedule.ExceptionSchedule property.

There are separate tag addresses for different value data types. The driver support BACnet Boolean, Signed Integer and Double data types.

**The tag address format is:**

`SCH.<objectInstance>.ExceptionScheduleExDig[.1...31]`  
`SCH.<objectInstance>.ExceptionScheduleExInt[.1...31]`  
`SCH.<objectInstance>.ExceptionScheduleExDbl[.1...31]`  
`SCH.<objectInstance>.ExceptionScheduleExEnum[.1...31]`  
`SCH.<objectInstance>.ExceptionScheduleExUInt[.1...31]`  
`SCH.<objectInstance>.ExceptionScheduleExReal[.1...31]`

For example:

- The following tag represents a special event number 1, supporting an Integer data type:  
`Schedule.3. ExceptionScheduleExInt.1`
- The following tag represents a special event number 4, supporting a Double data type:  
`Schedule.1. ExceptionScheduleExDbl.4`
- The following tag represents a number of elements in an ExceptionSchedule array:  
`Schedule.1. ExceptionScheduleExDbl`
- The following tag represents a special event number 3, supporting a enumerated data type:  
`Schedule.3. ExceptionScheduleExEnum.3`

Schedule.1. ExceptionScheduleExEnum.3

- The following tag represents a special event number 4, supporting unsigned Integer data type:  
Schedule.2.ExceptionScheduleExUInt.4
- The following tag represents a special event number 4, supporting real data type:  
Schedule.2.ExceptionScheduleExReal.4

The value of these tags is represented by a string in a format.

**Note:**

The driver can only read/write the first 31 special events for a configured schedule object, regardless of how many of them exist in the device. For example, for a device supporting a signed integer data type, the tag address for the first special event should be "SCH.<objectInstance>.ExceptionScheduleExInt.1". The tag address of 31st special event should be "SCH.<objectInstance>.ExceptionScheduleExInt.31".

Unlike weekly schedule events, deleting special events or exception schedule events is not supported. However, special events can be overwritten.

The driver cannot create exception schedule or special events in the device. It can only read and write to such events if they have already been created. The driver will return bad quality for non-existent exception schedule or special events, however, the tag address "SCH.<objectInstance>.ExceptionScheduleExInt" will correctly read the total number of special events configured for the schedule object in the device.

## Schedule. EffectivePeriodEx

This tag specifies the range of dates within which the Schedule object is active. This is represented as BACnetDateRange (string).

The tag addressing format is:

SCH.<objectInstance>.EffectivePeriodEx

For example the date range format is:

DR (11/01/2010)(23/06/27)

**String format for a calendar reference:**

CL(*CalendarObjectId*),(*time;value*)(*time;value*),Event Priority

where:

- *CalendarObjectId* represents a configured calendar object ID
- *time* is in BACnetTime in a format "hh:mm:ss.mmm" or "HH:mm:ss.mmm"
- *value* is a Boolean, Signed Integer or Double, depending on a tag address.

For example:

CL(3),(07:07:07.25;1),16

## String format for BACnetCalendarEntry:

DT(dd/mm/yyyy),(*time;value*)(*time;value*),Event Priority

or

DR(dd/mm/yyyy)(dd/mm/yyyy),(time;value)(time;value),Event Priority

or

WD(DayOfWeek/WeekOfMonth/Month),(time;value)(time;value),Event Priority

where:

- DT represents a 'Date' type BACnetCalendarEntry
- DR represents a 'DateRange' type BACnetCalendarEntry
- WD represents a 'WeekNDay' type BACnetCalendarEntry
- *time* is in BACnetTime format (hh:mm:ss.mmm)
- *DayOfWeek* is a numerical representation of a day: 1 for Monday, 2 for Tuesday and so on
- *WeekOfMonth* is 1 for days 1-7; 2 for days 8-14; 3 for days 15-21; 4 for days 22-28; 5 for days 29-31;
- *Month* is a numerical representation of a month: 1 for January, 2 for February and so on.

For example:

DT(05/11/2000),(07:00:00.00;18.5)(09:15:00.00;20.5),12

DR(11/01/2010)(23/06/27),(07:00:00.00;18.5)(09:15:00.00;20.5),7

## Configuring Your Project

This chapter contains the following topics:

- [BACnet Device Address](#)
- [Communication Settings](#)
- [BACstac Configuration](#).

### BACnet Device Address

The address to use for a BACnet device is the Device ID that uniquely identifies each BACnet device within a network. It can be in the range of 0 to 4194302.

See [Communicating with BACnet](#) for examples of device IDs within a BACnet system.

### See Also

[Communication Settings](#)

### Communication Settings

To establish communication with a device, configure the Boards, Ports and I/O Devices settings in Plant SCADA Studio's **Topology** activity.

If you use the Express Communications Wizard to connect to a device, these will be automatically configured for you. However, if you need to manually configure these settings, use the information outlined below.

---

**Note:** The BACNET driver only needs one port configured in Plant SCADA. This is because the driver will only initialize one instance of Cimetrics BACstac which it will use to communicate with all devices (see [BACstac](#))

[Configuration](#)). Therefore, you only need to configure one board and one port in your Plant SCADA project.

## Boards

Field	Description
Board name	This field is user defined.
Board Type	BACNET
Address	0
I/O Port	N/A
Interrupt	N/A
Special Options	N/A
Comments	This field is user defined and not used by the driver.

## Ports

Field	Description
Port Name	This field is user defined.
Port Number	Any valid number.
Board Name	Refers to the board previously defined in the Boards settings.
Baud Rate	N/A
Data Bits	N/A
Stop Bits	N/A
Parity	N/A
Special Options	N/A
Comment	This field is user defined and not used by the driver.

## I/O Devices

Field	Description
Name	This field is user defined.
Number	I/O device number. It needs to be unique for each logical device, but identical for redundant devices.
Address	<p>You can use the unique device ID that identifies each BACnet device. It can be in the range of 0 to 4194302. If only the BACnet device ID is specified, the driver will use the BACnet "Who-Is/I-Am" discovery services to obtain the MAC address and the network number of the BACnet device.</p> <p>When a BACnet device is on a different IP subnet (and cannot be discovered using Who-Is/I-Am services), you can configure additional parameters in the I/O device address field. The following options are available:</p> <p><b>BACnet/IP device:</b></p> <ul style="list-style-type: none"> <li>-i — IP address, for example “-i 127.0.0.1”</li> <li>-u — UDP port number (the default BACnet UDP port 47808 is used by default)</li> <li>-n — BACnet network number.</li> </ul> <p><b>BACnet MSTP device:</b></p> <ul style="list-style-type: none"> <li>-s — station ID, for example “-s 5”</li> <li>-n — BACnet network number.</li> </ul> <p><b>BACnet Ethernet device:</b></p> <ul style="list-style-type: none"> <li>-e — MAC address of the BACnet Ethernet device, for example “-e 00-50-56-9F-20-66”</li> <li>-n — BACnet network number.</li> </ul> <p><b>Examples</b></p> <p>BACnet/IP device address:  &lt;Device ID&gt; -i &lt; device IP Address&gt;</p> <p>&lt;Device ID&gt; -i &lt;device IP Address&gt; -u &lt;device UDP port number&gt;</p> <p>BACnet MSTP device address:  &lt;Device ID&gt; -s &lt;MSTP device station id&gt; -n &lt; network number for MSTP device&gt;</p> <p>BACnet Ethernet device address:  &lt;Device ID&gt; -e &lt;MAC address&gt; -n &lt;network number for the Ethernet device &gt;</p> <p>Note that in order to connect to MSTP device on a different IP subnet, the BBMD IP address for the MSTP</p>

Field	Description
	network needs to be configured in the BACstac ports configuration dialog.
Protocol	BACNET
Port Name	Refers to the port previously defined in the Ports settings.
Comment	This field is user defined and not used by the driver.
Cache Time	Defines the minimum rate in milliseconds at which the driver will poll BACnet properties. The default value is 300 msec.

## BACstac Configuration

The BACNET driver uses Cimetrics™ BACstac protocol stack v7.4e to communicate with BACnet devices.

When you install BACstac with the driver for the first time, the BACnet/IP ports configuration dialog is displayed. If no configuration changes are required, you can just close the dialog by clicking OK.

After BACstac is installed, you can view these configuration settings by running the file "baccfg.bat" in the BACstac application folder, for example:

C:\Program Files (x86)\Cimetrics\BACstac v7.4e\baccfg.bat

## BACNET Supported Object Types

BACnet Object Type	Address Field Mnemonic
Analog Input Objects	AI
Analog Output Objects	AO
Analog Value Objects	AV
Binary Input Objects	BI
Binary Output Objects	BO
Binary Value Objects	BV
Calendar Objects	CAL
Device Objects	DEV
Life Safety Point Objects	LSP
Life Safety Zone Objects	LSZ

BACnet Object Type	Address Field Mnemonic
Loop Objects	LOOP
Multi-state Input Objects	MI
Multi-state Output Objects	MO
Multi-state Value Objects	MV
Notification Class Objects	NC
Positive Integer Value Objects	PIV
Schedule	SCH
Structured View Objects	SV
Timer Objects	TIM

## BACNET Parameters

### UNINTENDED EQUIPMENT OPERATION

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel regarding undocumented features.

The parameters supported by the BACNET Driver are divided into the following categories:

- [Blocking Parameters](#)
- [Discovery Parameters](#)
- [Read Parameters](#)
- [Write Parameters](#)
- [APDU Parameters](#)
- [Logging Parameters.](#)

Custom settings for the BACNET driver need to be included in the citect.ini file.

Any setting under the **[BACNET]** section of the .ini file will globally impact all devices.

Settings can also be made for specific devices using the following format for the .ini file section name:

**[BACNET.<ClusterName>.<DeviceName>]**

where:

- <ClusterName> is the name of the cluster configured within the associated project, and
- <DeviceName> is the name of an I/O device specified under the **I/O Devices** tab of Plant SCADA Studio's **Topology** activity.

## Blocking Parameters

Parameter name	Description	Allowable value	Default value
FailOnBadData	Specifies whether or not to force the display of good data within a block read which contains bad tags.	1: Block read which contains a bad tag would result in the whole block returning #BAD. 0: Ignore any bad tags in the block reads and just show 0 for those tags.	1

## See Also

[BACNET Parameters](#)

## Discovery Parameters

Parameter name	Description	Allowable value	Default value
DiscoveryRate	The discovery rate in milliseconds. Specifies the rate at which the driver sends a 'WhoIs' message for dynamic device	Equal or greater than 0	20000

Parameter name	Description	Allowable value	Default value
	<p>binding.</p> <p><b>Note:</b> This parameter can only be used globally, it can not be set for a specific device.</p> <p>If this parameter is set to 0, the driver will not perform the dynamic device discovery, so the I/O Device address should include the information in order to set up the connection to the device, e.g. device IP address, port number, etc.</p>		
WholsMaxGap	Enables filtered device detection via Whols message. It Blocks adjacent or nearby Device Id numbers within 'WholsMaxGap' range into a single call to Whols message. A non zero value enables filtered device detection according to configured BacNet devices	0 to 65535	0: Use unfiltered device detection

## See Also

[BACNET Parameters](#)

## Read Parameters

Parameter name	Description	Allowable value	Default value
UseReadMultiple	Specifies whether to use the ReadPropertyMultiple Service	1: Allow 0: Not allowed	1
FastPoll	The parameter has been deprecated.		
SlowPoll	The parameter has been deprecated.		

Parameter name	Description	Allowable value	Default value
RetriesOnError	Maximum number of times read transaction will be re-transmitted in case when the message packet received from device is invalid	0 - 10	3
COVLifeTime	Sets the change-of-value (COV) subscription time (in seconds).  The driver attempts to use COV reporting for devices that support it. It subscribes to COV notifications for a period defined by COVLifeTime setting, and periodically updates the existing subscriptions. If COVLifeTime equals 0, then COV reporting is not used.	0 to 86400	3600 (1 hour)
COVExpireLag	Sets the period of time (in milliseconds) to update an existing subscription before it expires. The driver periodically updates existing COV subscriptions.	Equal to or greater than zero (0)	60000 (1 min)
COVCancelAtShutdown	Specifies whether to cancel COV subscriptions at driver shutdown	1: Cancel COV subscriptions 0: Do not cancel COV subscriptions	1

## See Also

[BACNET Parameters](#)

## Write Parameters

UNINTENDED EQUIPMENT OPERATION

Do not change these protocol parameters, except on the advice of Technical Support for this product. All these parameters default to a value tested to work in most cases.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel regarding undocumented features.

Parameter name	Description	Allowable value	Default value
WritePriority	BACnet allows you to specify a priority when writing to commandable properties. This parameter specifies the priority given to writes.	1 - 16	16
WriteQueueSize	Sets the size of the device write queue.	Equal or greater than 1	1000
UseWriteMultiple	Specifies whether to use the WritePropertyMultiple service.	1: Allowed 0: Not allowed	1

## See Also

[BACNET Parameters](#)

## APDU Parameters

APDU stands for Application Protocol Data Unit. The APDU settings allow you specify parameters for the actual data packet that is transmitted to the BACnet device.

Parameter name	Description	Allowable value	Default value
AckTimeOut	Time (in milliseconds) spent waiting for a reply to a message.	500 - 60000	6000
SegmentTimeout	Time (in milliseconds) spent waiting for a segment acknowledgment message.	500 - 60000	5000
Retries	Maximum number of times request message will be resent due to timeout on a request.	0 - 10	3

Parameter name	Description	Allowable value	Default value
FrameSize	Maximum frame size.	50 -1476	1476
MaxSegments	Maximum number of segments which may be transmitted and/or received in one segmented message.	1 - 256	10
WindowSize	Maximum number of segments which can be transmitted before an acknowledgment is sent to the initiator.	1 - 127	5

## See Also

[BACNET Parameters](#)

## Logging Parameters

[BACNET] Parameter	Description	Allowable value	Default value
DebugCategory	This parameter sets which log message categories are written to the log file.	ALL, or any combination of the following (separated by a ' ' pipe character): TAG   PROT   DCB  CACHE   THREAD   MISC	-
DebugLevel	This parameter sets the trace level for the log messages that are written to the log file.	ALL, or any combination of the following (separated by a ' ' pipe character): WARN   ERROR   TRACE   DEBUG	-
DebugUnits	This parameter sets the I/O Device name to limit logging to a specific I/O Device.	I/O device name in the format <ClusterName>.<DeviceName>	-

## See Also

[Logging](#)

## Logging

The BACNET driver can log combinations of trace levels across different categories. This is achieved by setting the following INI parameters.

### [BACNET]DebugLevel

This parameter allows you to define the trace level. The options include:

Option	Description
WARN	Output warning messages.
ERROR	Output error messages.
TRACE	Output trace messages.
DEBUG	Output debug messages.
ALL	All of the above.

### [BACNET]DebugCategory

This parameter allows you to enable logging for a particular category of trace. The options include:

Option	Description
TAG	Tag configuration trace.
PROT	Protocol level debug.
DCB	Front end driver trace.
CACHE	Cache debug.
THREAD	Thread trace.
MISC	Any other debugging.
ALL	All of the above.

In both cases, you can use any combination of the available options separated by a pipe character ( | ).

#### Example

```
[BACNET]
DebugLevel=WARNING|ERROR|TRACE
DebugCategory=ALL
```

In most cases, you can set the DebugLevel and DebugCategory parameters to ALL. If this results in a large, cumbersome log file that causes older data to be overwritten, you can consider refining the debug options.

---

**Note:** These parameters do not have a value specified by default. To enable logging for this driver, you need to

---

manually configure these parameters in your INI file.

The events generated by the BACNET driver are logged in the following Plant SCADA syslog file:

syslog.IOServer.<Cluster name>.<IO Server name>.dat

This file is located in the directory specified by the Citect.ini parameter **[CtEdit]Logs**. By default, this location will be:

%PROGRAMDATA%\AVEVA Plant SCADA <VersionNumber>\Logs

The size of the syslog file and its rollover process is configured via the **[Debug]SysLogSize** and **[Debug]SysLogArchive** INI parameters. For more information, see the topic *Debug Parameters* in the Plant SCADA documentation.

---

**Note:** If the number of messages being processed for a driver exceeds the value specified by the Plant SCADA parameter **[Kernel]ErrorBuffers**, the pending messages will not be logged. If this occurs, you can increase the value of this parameter so that all the messages generated by the driver are reported. The number of messages that are not logged can be monitored via the Kernel's General window under the item "Lost Errors". If you adjust **[Kernel]ErrorBuffers** and Lost Errors are still occurring, you may need to adjust the level of system logging.

## See Also

[Logging Parameters](#)

## BACnet Tag Import

You can use Plant SCADA's **Import Tags** tool to automatically create variable tags that represent the object properties on a BACnet device.

**To create variable tags based on BACnet object properties:**

1. In Plant SCADA Studio go to **Topology** activity and select **I/O Devices**.
2. On the Command Bar, select **Import Tags**.

The Import Variable Tags dialog box will display.

3. In the **Destination** panel, select the required **I/O Device**. The drop-down menu includes a list of all the I/O devices currently configured in your Plant SCADA project.

The device you select needs to be configured to use the BACnet protocol, otherwise an error message will display when you attempt to configure the device connection.

4. In the **Source** panel, set the **Database Type** to "BACnet".

At this point, the **External Database** field will display the address configured for the selected device on the I/O Devices Communication Settings. It will use the following format:

<device ID> -i <device IP address>

The "-i <device IP address>" component of the address is optional. However, if the device is on a different IP subnet, you will need to include the IP address.

If an address has not been configured on the I/O Devices form, use the **Browse** button to discover the device ID.

This button will display the BACnet Device Configuration dialog.

- a. To discover the **Device ID** for an I/O device, click the **Browse** button on the BACnet Device Configuration dialog.

The BACnet Device Discovery dialog will appear and display:

- a. A list of all the BACnet devices detected on the local network.

Or:

- b. A list of all devices detected in the EDE file selected in the **Tag Import Options** section of the dialog.

To view additional information about a device, double-click on it.

**Note:** If the BACnet device you are looking for is not included in the list of devices detected on the local network, you will need to return to the Import Variables Tags dialog and manually enter its device ID and IP address into the **External Database** field using the following syntax:

<device ID> -i <device IP address>

Select the required device from this list and click **OK**. The **Device ID** for the selected device will display on the BACnet Device Configuration dialog.

- b. In the **Tag Import Options** panel, select one of the following options:

- a. **Use device for tag import.**
- b. **Use EDE file for tag import.**

If you select the first option, you can view information about the device by clicking the **Device Info...** button.

If you select the EDE file option, you need to identify the required file in the **EDE Path** field. You can use the **Browse** button to locate the file.

- c. In the **Filter Options** panel, select the **Use Filters** check box to apply a filter to the tag import. The **Set Filters** button opens a dialog that lets you select the BACnet object properties you would like to include in the tag import process.
- d. In the **Advanced Options** panel, select any of the following options:

- a. **Use object name as Tag Name** — creates variable tags that are named using the following format:

<IODEVICE>\<OBJECT NAME>\OBJECT TYPE

For example, "AIO\ventilation\PresentValue".

- b. **Import BACnet Units and Descriptions to the present value tag** — imports the units and descriptions for the present value.
  - c. **Import BACnet Schedule Instances as Equipment** — generates equipment definitions based on the device's schedule instances. If you select this option, you need to specify the **Parent Equipment**.

This option is useful if you want to integrate the BACnet schedules on a device into Plant SCADA's Scheduler for runtime interaction. See the topic *Integrate BACnet Schedules into Scheduler* in the main help for more information.

- e. Click **OK** to close the BACnet Device Configuration dialog.

5. On the Import Variable Tags dialog, click **Import**.

Plant SCADA will connect to the device, read the Object\_List property (which contains a list of the BACnet objects on the device), and create the variable tags for the BACnet object properties. Variable tags are only created for the BACnet properties supported by Plant SCADA's BACNET driver.

If the **Import BACnet Schedule Instances as Equipment** option is selected, equipment definitions will be generated for each of the device's schedule instances.

## CTICMP Driver

The CTICMP driver supports TCP/IP communication with any TCP/IP Host on a network that can be pinged.

The maximum request length for the CTICMP protocol is 2048 bits.

This driver supports IP version 4 only. IPV6 is not supported.

## Safety Information

### Hazard categories and special symbols

The following symbols and special messages may appear in this manual or on the product to warn of potential hazards or to call attention to information that clarifies or simplifies a procedure.

Symbol	Description
 or 	The addition of either symbol to a "Danger" or "Warning" safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.
	This is the safety alert symbol. It is used to alert you to personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.

#### DANGER

**DANGER** indicates an imminently hazardous situation, which, if not avoided, will result in death or serious injury.

#### WARNING

**WARNING** indicates a potentially hazardous situation, which, if not avoided, can result in death or serious injury.

**⚠ CAUTION**

**CAUTION** indicates a potentially hazardous situation which, if not avoided, can result in minor or moderate injury.

**NOTICE**

NOTICE used without a safety alert symbol, indicates a potentially hazardous situation which, if not avoided, can result in property or equipment damage.

**Please Note**

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by AVEVA for any consequences arising out of the use of this material.

**Before You Begin**

Plant SCADA is a Supervisory Control and Data Acquisition (SCADA) solution. It facilitates the creation of software to manage and monitor industrial systems and processes. Due to Plant SCADA's central role in controlling systems and processes, you must appropriately design, commission, and test your Plant SCADA project before implementing it in an operational setting. Observe the following:

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not use Plant SCADA or other SCADA software as a replacement for PLC-based control programs. SCADA software is not designed for direct, high-speed system control.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**⚠ WARNING****LOSS OF CONTROL**

- The designer of any control scheme must consider the potential failure modes of control paths and, for certain critical control functions, provide a means to achieve a safe state during and after a path failure. Examples of critical control functions are emergency stop and overtravel stop, power outage and restart.
- Separate or redundant control paths must be provided for critical control functions.
- System control paths may include communication links. Consideration must be given to the implications of unanticipated transmission delays or failures of the link.
- Observe all accident prevention regulations and local safety guidelines.<sup>1</sup>
- Each implementation of a control system created using Plant SCADA must be individually and thoroughly tested for proper operation before being placed into service.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

1. For additional information, refer to NEMA ICS 1.1 (latest edition) "Safety Guidelines for the Application, Installation, and Maintenance of Solid State Control", and to NEMA ICS 7.1 (latest edition) "Safety Standards for Construction and Guide for Selection, Installation and Operation of Adjustable-Speed Drive Systems" or their equivalent governing your particular location.

## TCP/IP Hosts

The CTICMP driver uses the TCP/IP method of communication to talk to any TCP/IP device that can be pinged on a network. The physical network layer below TCP/IP does not matter. The driver can communicate over Ethernet, ATM or FDDI as long as TCP/IP is available.

The CTICMP driver provides the facilities for Plant SCADA to be configured to periodically check the status of hosts on a TCP/IP network. It achieves this by sending Echo messages (pinging) to a host and waiting for an Echo Reply message.

Echo/Echo reply message are part of the Internet Control Message Protocol (CTICMP) which is part of the Internet Protocol (IP) and is available in any TCP/IP installations.

In this documentation, TCP/IP devices on a network are referred to as 'hosts'.

---

**Note:** The same Ethernet card that is being used for Plant SCADA communication can be used for PLC communication, though this may lower performance.

---

[TCP/IP Host Data Types](#)

## TCP/IP Hosts - Device Address

This setting is used to fill out the **I/O Device Address** field in the **I/O Devices** view in Plant SCADA Studio's **Topology** activity.

For this particular device, you may leave this field blank.

## See Also

[Hardware Setup](#)

## TCP/IP Hosts - Hardware Setup

## Hints and Tips

- The first time a page is entered that has tags animating it for hosts that have not been used elsewhere, the page will take a while to draw. This is because the hosts need to be physically pinged before the driver can return the data that Plant SCADA requires to draw the page.
- The response times on the driver page in the kernel are not valid for this driver. The driver keeps information about each host in an internal cache. The response times in the kernel show how long it takes the driver to read the information out of the cache and send it back to Plant SCADA. It does not show the response time of the hosts being pinged. It will usually be 0.

---

**Note:** The I/O Device will always be online for CTICMP protocol.

---

## Required Components

TCP/IP needs to be installed on the machine on which the driver is operating. It also requires Windows Sockets Version 2.0.

## Plant SCADA Computer Setup

It is recommended that you setup your specific Ethernet card as required and confirm basic network communications before proceeding with the communications configuration for the CTICMP driver. Refer to the documentation accompanying your hardware for instructions.

## See Also

[Communication Settings](#)

## TCP/IP Hosts - Communication Settings

To establish communication with a device, configure the associated Boards, Ports and I/O Device in Plant SCADA Studio's **Topology** activity. If you use the Express Communications Wizard to connect to a device, these settings will be automatically configured for you. However, if you need to manually configure these settings, use the information outlined below.

## Board Settings

Field	Value
Board Type	Enter CTICMP.
Address	Enter 0.
I/O Port	Leave this field blank.
Interrupt	Leave this field blank.
Special Options	Leave this field blank.

## Port Settings

A port definition is required, however some fields can be left blank. Only the port name, port number and board name are required. Only one port maybe specified for the CTICMP driver.

Field	Value
Port Number	Leave this field blank.
Baud Rate	Leave this field blank.
Data Bits	Leave this field blank.
Stop Bits	Leave this field blank.
Parity	Leave this field blank.
Special Options	Leave this field blank.

## I/O Device Settings

Field	Value
I/O Device Name	Enter a unique name (different to other IO device names with the same port name). This value could be blank if only one IO device exists.
I/O Device Protocol	Enter CTICMP.
I/O Device Address	Leave this field blank.

## TCP/IP Host Data Types

Data Types	Address Format	Plant SCADA Data Type	Description/Special Usage/Limitations/ Valid Ranges
State	<i>i1.i2.i3.i4:STATE</i>	DIGITAL	Device status. 1 if it is responding, 0 if it is not responding. Read only.
Status	<i>i1.i2.i3.i4:STATUS</i>	INTEGER	Device status. 1 if it is responding, 0 if it is not responding. Read only.
Error Number	<i>i1.i2.i3.i4:ERRNUM</i>	INTEGER	A number representing the error condition of the last ping. Read only. 0: No faults 1: Not responding 2: Socket write timed out 3: Socket read timed out
Error Description	<i>i1.i2.i3.i4:ERRDESC</i>	STRING	A description of the status of the last ping. Read only. Blank when no error, or, not responding socket write timed out socket write not successful
Poll Time	<i>i1.i2.i3.i4:POLLTIME</i>	LONG	The duration, in seconds, between each ping to the host. See Driver Parameter HostPollTime for default.
Time Out	<i>i1.i2.i3.i4:TIMEOUT</i>	LONG	The time, in seconds, to wait for a response from the host after it is pinged.
Response Time	<i>i1.i2.i3.i4:RESPTIME</i>	LONG	The time, in milliseconds, it took the host to respond to the last ping. Read only.

Where:

<i>i1</i>	The first octet (most significant) of the IP address of the device to ping
<i>i2</i>	The second octet of the IP address of the device to ping

I3	The third octet of the IP address of the device to ping
I4	The fourth octet of the IP address of the device to ping

## Examples

Data Type	DIGITAL
Address	192.168.1.1:STATE
Comment	FileServer01 state
Data Type	LONG
Address	192.168.1.1:RESPTIME
Comment	FileServer01 response time

## Customizing a Project using Citect.ini Parameters

The CTICMP driver supports the following parameter categories:

- [CTICMP Driver Parameters](#)
- [Logging Parameters.](#)

### **WARNING**

#### **UNINTENDED EQUIPMENT OPERATION**

- Do not under any circumstances change or remove any citect.ini parameters without an informed understanding of the possible implications of your actions.
- Do not delete sections of the citect.ini file without an informed understanding of the possible implications of your actions.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** At times during the life cycle of a driver, circumstances may call for the creation of specific citect.ini parameters that remain undocumented. Always seek the advice of Technical Support regarding the possible implementation of undocumented parameters before you make any changes to a citect.ini file.

## CTICMP Driver Parameters

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support for this product regarding undocumented features.

[CTICMP] Parameter	Description	Allowable Values	Default Value
MaxPending	The maximum number of pending commands that the driver holds ready for immediate execution.	1 to 1024	256

## Driver Specific Parameters

[CTICMP] Parameter	Description	Allowable Values	Default Value
HostPollTime	The duration (in seconds) between each ping to hosts. This can be overwritten for individual hosts by writing to the POLLTIME variable.	0001 to 300000 (milliseconds)	500 milliseconds
HostTimeout	Specifies how many milliseconds to wait for a response before displaying an error message.	500 to 32000 (milliseconds)	3000 milliseconds
PacketSize	The size in bytes of the data buffer in the ICMP echo request.	0 to 16 (bytes)	1

## See Also

[Logging Parameters](#)

## Logging Parameters

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

- Do not change or remove any of the undocumented citect.ini parameters under any circumstances.
- Before deleting sections of the citect.ini file, confirm that no undocumented parameters will be deleted.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

[CTICMP] Parameter	Description	Allowable Values	Default Value
DebugLevel	The trace level used for the log file.	Any combination of the following, separated by a pipe character ( ): ERROR WARN TRACE DEBUG ALL For example, ERROR   TRACE. See <a href="#">Logging</a> .	-
DebugCategory	The categories used for the log file.	Any combination of the following, separated by a pipe character ( ): PROT = protocol level debug DCB = front end debug (i.e. I/O server) MISC = any other debugging BEND = Backend CACHE = Cache replication ALL = all of the above For example, PROT   DCB. See <a href="#">Logging</a> .	-

## Logging

The CTICMP driver can log combinations of trace levels across different categories. This is achieved by setting the following INI parameters.

### **[CTICMP]DebugLevel**

This parameter allows you to define the trace level. The options include:

Option	Description
WARN	Output warning messages.
ERROR	Output error messages.
TRACE	Output trace messages.
DEBUG	Output debug messages.
ALL	All of the above.

## [CTICMP]DebugCategory

This parameter allows you to enable logging for a particular category of trace. The options include:

Option	Description
PROT	Protocol level debug.
DCB	Front end driver trace.
CACHE	Cache debug.
BEND	Backend trace.
MISC	Any other debugging.
ALL	All of the above.

In both cases, you can use any combination of the available options separated by a pipe character ( | ).

### Example

```
[CTICMP]
DebugLevel=WARN | ERROR | TRACE
DebugCategory=ALL
```

In most cases, you can set the DebugLevel and DebugCategory parameters to ALL. If this results in a large, cumbersome log file that causes older data to be overwritten, you can consider refining the debug options.

---

**Note:** These parameters do not have a value specified by default. To enable logging for this driver, you need to manually configure these parameters in your INI file.

The events generated by the CTICMP driver are logged in the following Plant SCADA syslog file:

```
syslog.IOServer.<Cluster name>.<IO Server name>.dat
```

This file is located in the directory specified by the Citect.ini parameter **[CtEdit]Logs**. By default, this location will be:

```
%PROGRAMDATA%\AVEVA Plant SCADA <VersionNumber>\Logs
```

The size of the syslog file and its rollover process is configured via the **[Debug]SysLogSize** and **[Debug]SysLogArchive** INI parameters. For more information, see the topic *Debug Parameters* in the Plant SCADA documentation.

---

**Note:** If the number of messages being processed for a driver exceeds the value specified by the Plant SCADA parameter [Kernel]ErrorBuffers, the pending messages will not be logged. If this occurs, you can increase the value of this parameter so that all the messages generated by the driver are reported. The number of messages that are not logged can be monitored via the Kernel's General window under the item "Lost Errors". If you adjust [Kernel]ErrorBuffers and Lost Errors are still occurring, you may need to adjust the level of system logging.

---

## See Also

[Logging Parameters](#)

## CTICMP Driver Specific Errors

When a hardware error occurs, Plant SCADA generates an alarm, and displays the alarm on the hardware alarm page (in the alarm description of the hardware alarm). To see the error number, make sure you have Alarm Category 255 defined with a display format that includes {ErrDesc,15} {ErrPage,10}.

There are a number of generic errors that are common to all protocols. In some cases only the generic error is available, though often both the generic error and a specific error are given.

The following errors, listed in (hexadecimal) sequence, are specific to this protocol. Plant SCADA displays the error number and description for common protocol-specific errors. Uncommon errors are not contained in the Plant SCADA error database, in which case Plant SCADA will only display the error number.

You may require additional information to enable you to rectify an error. This information should be detailed in the documentation that accompanied the I/O Device (or network). If, after reviewing all documentation, you cannot rectify an error, contact AVEVA Global Customer Support.

### **0x100 GENERIC\_CHANNEL\_OFFLINE**

Unable to open a socket for the driver to use.

### **0x101 GENERIC\_CHANNEL\_OFFLINE**

Setting the socket option not successful.

### **0x102 GENERIC\_CHANNEL\_OFFLINE**

Unable to create the thread that pings the hosts.

### **0x104 GENERIC\_UNIT\_OFFLINE**

Write to the socket timed out.

### **0x105 GENERIC\_UNIT\_OFFLINE**

Write to the socket not successful.

## DNPR Driver

The DNPR driver allows Plant SCADA to communicate with devices that support DNP3 protocol subsets Level 1 and Level 2. Some level 3 features are also supported.

For an explanation of the protocol subsets, see [The DNP 3.0 Protocol](#).

---

**Note:** To successfully implement the DNPR driver, it is recommended that you are familiar with the terminology and methods involved with configuring devices for DNP 3.0 communication.

---

Communication can take place over serial (RS232) or TCP/IP transport. The type of devices the driver will

communicate with include:

- RTUs
- IEDs
- PLCs.

---

**Note:** With the release of version 7.20, Plant SCADA supports the retrieval of time-stamped data directly from field devices. This capability is enabled by the Driver Runtime Interface (DRI), a component of Plant SCADA that is used by the DNPR driver to directly update time-stamped digital alarms, time-stamped analog alarms and event-based trends. For more information, see the topic *Retrieving Time-stamped Data from Field Devices* in the main Plant SCADA help.

## Safety Information

### Hazard categories and special symbols

The following symbols and special messages may appear in this manual or on the product to warn of potential hazards or to call attention to information that clarifies or simplifies a procedure.

Symbol	Description
 or 	The addition of either symbol to a "Danger" or "Warning" safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.
	This is the safety alert symbol. It is used to alert you to personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.

### DANGER

**DANGER** indicates an imminently hazardous situation, which, if not avoided, will result in death or serious injury.

**⚠ WARNING**

**WARNING** indicates a potentially hazardous situation, which, if not avoided, can result in death or serious injury.

**⚠ CAUTION**

**CAUTION** indicates a potentially hazardous situation which, if not avoided, can result in minor or moderate injury.

**NOTICE**

**NOTICE** used without a safety alert symbol, indicates a potentially hazardous situation which, if not avoided, can result in property or equipment damage.

**Please Note**

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by AVEVA for any consequences arising out of the use of this material.

**Before You Begin**

Plant SCADA is a Supervisory Control and Data Acquisition (SCADA) solution. It facilitates the creation of software to manage and monitor industrial systems and processes. Due to Plant SCADA's central role in controlling systems and processes, you must appropriately design, commission, and test your Plant SCADA project before implementing it in an operational setting. Observe the following:

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not use Plant SCADA or other SCADA software as a replacement for PLC-based control programs. SCADA software is not designed for direct, high-speed system control.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**⚠ WARNING****LOSS OF CONTROL**

- The designer of any control scheme must consider the potential failure modes of control paths and, for certain critical control functions, provide a means to achieve a safe state during and after a path failure. Examples of critical control functions are emergency stop and overtravel stop, power outage and restart.
- Separate or redundant control paths must be provided for critical control functions.
- System control paths may include communication links. Consideration must be given to the implications of unanticipated transmission delays or failures of the link.
- Observe all accident prevention regulations and local safety guidelines.<sup>1</sup>
- Each implementation of a control system created using Plant SCADA must be individually and thoroughly tested for proper operation before being placed into service.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

1. For additional information, refer to NEMA ICS 1.1 (latest edition) "Safety Guidelines for the Application, Installation, and Maintenance of Solid State Control", and to NEMA ICS 7.1 (latest edition) "Safety Standards for Construction and Guide for Selection, Installation and Operation of Adjustable-Speed Drive Systems" or their equivalent governing your particular location.

## The DNP 3.0 Protocol

DNP 3.0 is an open protocol that has been adopted as a standard by the utilities industries. As a result, there are numerous DNP 3.0 compatible devices available that support this protocol.

### Protocol Subsets

The DNP 3.0 protocol encompasses a broad spectrum of functionality. For a lot of supported devices, it is not necessary to implement the entire protocol, as only a subset is required.

In order to maintain compatibility between subset implementations, the DNP 3.0 User Group has defined three official subsets of the DNP 3.0 protocol. These are:

- Level 1
- Level 2
- Level 3

The higher the level, the more functionality that is implemented by the subset. A lot of devices have a Level 2 implementation as their base, with selected additional functionality as required.

To support this, Plant SCADA is based on a Level 2 implementation and will fully support level 2 functionality. It will also support some of the level 3 functionality.

As the DNP3 protocol expands, further functionality will be introduced as a result of feedback regarding user requirements and needs.

## Device Setup

If a device supports multiple protocols, it should be set for the DNP 3.0 protocol.

### Communications setup

The DNPR driver can use the RS-232, TCP, or UDP communication methods, using a standard COM port, digiboard, or Ethernet card. RS-232 communications can also be expanded through an adaptor. The type of adaptor used is determined by the DNP3 network Plant SCADA is interfacing with.

Plant SCADA operates on the presumption that a DNP 3 device will use RS-232 for communication. If you use the Communications Express Wizard to connect to a device, the following settings are used by default in your project.

Setting	Value
Baud Rate	9600
Data Bits	8
Stop Bits	1
Parity	0 (None)

These settings are recommendations only; your hardware may support other values. If you do set the baud rate, data bits, stop bits, or parity to another value, manually set the new value(s) in your project.

**Note:** DNP3 is a binary protocol, which means hardware flow control (not software flow control) should be used for serial connections.

A device should also be configured so that static data required by Plant SCADA is allocated to class 0. (For more information on classing data, see [Data Acquisition within DNP3](#).)

Configuring Class 0 with points not required by Plant SCADA places an extra communication burden on the system during the regular integrity polling. Event data corresponding to the above-mentioned static data should be assigned to classes 1, 2, or 3.

The maximum request length for the DNPR protocol is 256 bytes.

### See Also

[The DNP 3.0 Protocol](#)

## Configure Your Project

This section contains reference information related to the DNPR Driver that you'll require to configure your Plant SCADA project.

**Note:** You need to set a DNP address for your Plant SCADA system using the parameter [Basic Parameters](#), otherwise a popup message will appear at startup.

## See Also

- [DNPR - Device Address](#)
- [Communication Settings](#)
- [Configure Variables](#)
- [Projects Using Super Genies](#)

## DNPR - Device Address

The Device Address for a DNP3 compatible device is:

*DNP3\_address Citect.INI\_section\_name*

For example: *128 SITERTU*

where:

- *128* - is the DNP3 address of this device (valid addresses are in the range 0...65533)
- *SITERTU* - is the name of the section heading in Citect.ini under which parameters related to SITERTU will be held.

---

**Note:** If no *Citect.INI\_section\_name* is specified, it defaults to *Unit\_x*, where *x* is the value in the Number field on the I/O Device settings (for example, *Unit\_10*).

---

## See Also

- [Communications Settings](#)

## Communication Settings

To establish communication with a device, the associated Board, Port and I/O Device require configuration in Plant SCADA Studio's **Topology** activity.

If you use the Express Communications Wizard to connect to a device, these settings will be automatically configured for you. If you need to manually configure them, you should use the values outlined below.

## Boards

### Serial Communication

The DNPR driver uses standard serial communications via a standard COM port or a dedicated serial board.

Field	Value
Board name	This field is user defined. (e.g. "Board1")
Board type	COMX
Address	0

Field	Value
I/O port	
Interrupt	
Special opt.	
Comments	This field is user defined and is not used by the driver.

**TCP/IP Communication**

Field	Value
Board name	This field is user defined. (e.g. "Board1")
Board type	TCP/IP
Address	0
I/O port	
Interrupt	
Special opt.	
Comments	This field is user defined and is not used by the driver.

**Ports****Serial communication**

Field	Value
Port Name	This field is user defined.
Port number	ComPort
Board name	Refers to the board previously defined in the 'boards' settings.
Baud rate	9600 (allowable values: 2400 – 38400)
Data bits	8
Stop bits	1
Parity	None
Special Opt	Leave this field blank
Comment	This field is user defined and is not used by the driver.

**TCP/IP communication**

Field	Value
Port Name	This field is user defined.
Port number	
Board name	Refers to the board previously defined in the 'boards' settings.
Baud rate	Leave this field blank
Data bits	Leave this field blank
Stop bits	Leave this field blank
Parity	Leave this field blank
Special Opt	<p>-laaa.bbb.ccc.ddd -Pe (Allowable values: &lt;-LP&gt; &lt;-U -T&gt;)</p> <p>where:</p> <ul style="list-style-type: none"> <li>• <i>aaa.bbb.ccc.ddd</i> is the IP address of the device</li> <li>• <i>e</i> is the port number of the device</li> <li>• <i>-U</i> for use when UDP being used (TCP is the default)</li> </ul>
Comment	This field is user defined and is not used by the driver.

**Note:** The maximum number of ports you can use is 512.

**I/O Devices**

Field	Value
Name	This field is user defined.
Number	The I/O device number. A unique number is required for each logical device, however primary and standby redundant devices require the same number.
Address	<p>DNP3_address Citect.INI_section_name</p> <p>Example: 128 SITERTU</p> <p>See <a href="#">DNPR - Device Address</a>.</p>
Protocol	DNPR
Port name	Refers to the port previously defined in the 'ports'

Field	Value
	settings.
Comment	This field is user defined and is not used by the driver.
Minimum Update Time	<p>This field is used to determine the frequency of the integrity polls.</p> <p>If this field is none zero and is smaller than the integrity poll frequency from the Citect.ini parameters, then this field will be used and the poll period will be recalculated.</p> <p>INI integrity poll frequency:</p> $\text{Integrity poll} = \text{INI poll period} * (\text{INI event poll ratio} + 1),$ <p>For more details, see the following INI parameters:</p> <ul style="list-style-type: none"> <li>[DNPR]EventPollPeriodDefault</li> <li>[&lt;unit&gt;]EventPollPeriod</li> <li>[DNPR]EventPollRatioDefault</li> <li>[&lt;unit&gt;]EventPollRatio</li> </ul> <p>New poll period recalculation:</p> $\text{Poll period} = \text{Minimum Update Time} / (\text{INI event poll ratio} + 1).$ <p><b>Note:</b> If the poll period is 0 then it will be defaulted to 10 seconds</p>

## Configure Variables

The data types used by the DNP3 protocol are represented across three main groups:

- Monitoring data types
- Control data types
- Other data types.

The tables in this section of the help describe the variable address required for each data type.

---

**Note:** Some of the data types listed in the following tables are identified as "advanced". They are recommended for experienced users who are familiar with the terminology and methods associated with the DNP 3.0 protocol.

## Monitoring Data Types

- [Binary Inputs](#)
- [Binary Outputs](#)
- [Counters](#)
- [Analog Inputs](#)

- Analog Outputs
- Time and Date
- IIN Flags

## Control Data Types

The driver can support multiple writes per Plant SCADA request for Binary Output and Analog output control.

- Binary Outputs
- Counters
- Analog Outputs
- Time and Date
- Utilities

## Other Types

- Polling Regime Data Types
- Global Data Types
- Miscellaneous Data Types

### Monitoring Data Types - Binary Inputs

This table defines the Plant SCADA variable address required for the specified DNP3 data types.

Address	Plant SCADA Type	DNP3 Type	Description
BI<n>.Val	DIGITAL	Binary Input Value Object 01 Variations 1,2 Object 02 Variations 1,2,3	R/O. Current state of Binary Input (This is Bit 7 of Status byte)
BI<n>.Val.TS	LONG	Binary Input Time Stamp (seconds since 1970)	UTC time when value last changed or when the value was acquired from the initial integrity poll
BI<n>.Val.TMS	LONG	Binary Input Time Stamp (milliseconds since midnight)	Milliseconds since midnight when value last changed or when the value was acquired from the initial integrity poll
BI<n>.Val.QUAL	LONG	Binary Input Quality	OPC quality of point converted from value of flags.

where:

- n = Point index number (range from 0 to 2048)
- R/O = read only
- W/O = write only
- R/W = read or write

## Advanced monitoring data types - binary inputs

**Note:** The following data types are only recommended for experienced users who are familiar with the terminology and methods associated with the DNP 3.0 protocol.

Address	Plant SCADA Type	DNP3 Type	Description
BI< n >.Stat	BYTE	Binary Input Status Status byte (excluding state) Object 01 Variation 2 Object 02 Variations 1,2,3	R/O. Status data related to Value. Bit 7 (State bit) not included – always zero.
BI< n >.Stat.Online	DIGITAL	Binary Input Status Online bit Object 01 Variation 2 Object 02 Variations 1,2,3	R/O. Bit 0 of Status byte. If Offline, command will not be successful. 0=Offline,1=Online.
BI< n >.Stat.Restart	DIGITAL	Binary Input Status Restart bit Object 01 Variation 2 Object 02 Variations 1,2,3	R/O. Bit 1 of Status byte Originating field device has been restarted. 0=normal, 1=Restart.
BI< n >.Stat.CommLost	DIGITAL	Binary Input Status Communication Lost bit Object 01 Variation 2 Object 02 Variations 1,2,3	R/O. Bit 2 of Status byte. If comms lost, command will not be successful. 0=normal, 1=Lost.
BI< n >.Stat.RemForced	DIGITAL	Binary Input Status Remote Forced Data bit Object 01 Variation 2 Object 02 Variations 1,2,3	R/O. Bit 3 of Status byte. Originating field device is in control 0=normal, 1=Forced.
BI< n >.Stat.LocalForced	DIGITAL	Binary Input Status Local Forced Data bit	R/O. Bit 4 of Status byte.

Address	Plant SCADA Type	DNP3 Type	Description
		Object 01 Variation 2 Object 02 Variations 1,2,3	This device is in control. 0=normal, 1=Forced.
BI< n >.Stat.ChatFilter	DIGITAL	Binary Input Status ChatterFilter bit Object 01 Variation 2 Object 02 Variations 1,2,3	R/O. Bit 5 of Status byte Low Pass Filter for filtering unwanted transitions. 0=normal, 1=Filter on.

where:

- n = Point index number (range from 0 to 2048)
- R/O = read only
- W/O = write only
- R/W = read or write

### Monitoring Data Types - Binary Outputs

This table defines the Plant SCADA variable address required for the specified DNP3 data types.

Address	Plant SCADA Type	DNP3 Type	Description
BO< n >.Val	DIGITAL	Binary Output Value Object 10 Variation 2	R/O. Current state of Binary Output.
BO< n >.Val.QUAL	LONG	Binary Output Quality	R/O. OPC quality of point converted from value of flags.

where:

- n = Point index number (range from 0 to 2048)
- R/O = read only
- W/O = write only
- R/W = read or write

### Advanced monitoring data types - binary outputs

---

**Note:** The following data types are only recommended for experienced users who are familiar with the terminology and methods associated with the DNP 3.0 protocol.

---

Address	Plant SCADA Type	DNP3 Type	Description
BO<n>.Stat	BYTE	Binary Output Status Status byte (excluding state) Object 10 Variation 2	R/O. Status data related to Value. Bit 7 (State bit) not included – always zero.
BO<n>.Stat.Online	DIGITAL	Binary Output Status Online bit Object 10 Variation 2	R/O. Bit 0 of Status byte If Offline, command will not be successful. 0=Offline,1=Online
BO<n>.Stat.Restart	DIGITAL	Binary Output Status Restart bit Object 10 Variation 2	R/O. Bit 1 of Status byte Originating field device has been restarted. 0=normal,1=Restart
BO<n>.Stat.CommLost	DIGITAL	Binary Output Status Communication Lost bit Object 10 Variation 2	R/O. Bit 2 of Status byte If comms lost, command will not be successful 0=normal,1=Lost
BO<n>.Stat.RemForced	DIGITAL	Binary Output Status Remote Forced Data bit Object 10 Variation 2	R/O. Bit 3 of Status byte Originating field device is in control 0=normal,1=Forced
BO<n>.Stat.LocalForced	DIGITAL	Binary Output Status Local Forced Data bit Object 10 Variation 2	R/O. Bit 4 of Status byte This device is in control 0=normal,1=Forced
BO<n>.Stat.SelPend	DIGITAL	Binary Output Status Plant SCADA – Object Selected in RTU	R/O. Bit 5 of Status byte This device is in control 0=not selected, 1=Selected, waiting on OPERATE

Address	Plant SCADA Type	DNP3 Type	Description
BO<n>.Stat.WrtPend	DIGITAL	Binary Output Status Plant SCADA – Select Initiated in RTU	R/O. Bit 6 of Status byte This device is in control 0=not initiated, 1=SELECT started
BO<n>.Stat. WrtFail	DIGITAL	Binary Output Status Plant SCADA – Problem in SELECT/OPERATE sequence	R/O. Bit 7 of Status byte This device is in control 0=normal, 1=Write unsuccessful
BO<n>.CtrlStat	BYTE	Binary Output Control Status Status byte Object 12 Variation(s) 1 <b>Note:</b> DNP (Subset level 2) supports an 'Immediate Freeze without acknowledgment', but as this does not verify the success of the command, only 'Immediate Freeze' is currently implemented.	R/O. Status of Control Operation. 0=Request accepted, initiated or queued 1= Request rejected – OPERATE received after SELECT had already timed-out 2= Request rejected – OPERATE received without receiving matching SELECT 3= Request rejected – Formatting errors in control request (Select, Operate or Doperate) 4= Request rejected – Control Operation not supported for this bit 5= Request rejected – Queue full or point already active 6= Request rejected – Control hardware problems 7-127=Undefined.

where:

- n = Point index number (range from 0 to 2048)
- R/O = read only

- W/O = write only
- R/W = read or write

### Monitoring Data Types - Counters

This table defines the Plant SCADA variable address required for the specified DNP3 data types.

Address	Plant SCADA Type	DNP3 Type	Description
C<n>.Val	LONG	Counter Value (16/32 bit) Object 20 Variations 1,2,5,6 Object 22 Variations 1,2	R/O. Accumulated transitions of a SW or HW point (16bit or 32bit value)
C<n>.Val.Qual	LONG	Counter Value Quality	R/O. OPC quality of point converted from value of flags.
FC<n>.Val	LONG	Frozen Counter Value (16/32 bit) Object 21 Variations 1,2,9,10	R/O. Counter value when last freeze performed. (16bit or 32bit value)
FC<n>.Val.Qual>	LONG	Frozen Counter Value Quality	R/O. OPC quality of point converted from value of flags.

where:

- n = Point index number (range from 0 to 2048)
- R/O = read only
- W/O = write only
- R/W = read or write

### Advanced monitoring data types - counters

**Note:** The following data types are only recommended for experienced users who are familiar with the terminology and methods associated with the DNP 3.0 protocol.

Address	Plant SCADA Type	DNP3 Type	Description
C<n>.Stat	BYTE	Counter Status Status byte Object 20 Variations 1,2	R/O. Status data related to Value.

Address	Plant SCADA Type	DNP3 Type	Description
		Object 22 Variations 1,2	
C<n>.Stat.Online	DIGITAL	Counter Status Online bit Object 20 Variations 1,2 Object 22 Variations 1,2	R/O. Bit 0 of Status byte If Offline, command will not be successful 0=Offline, 1=Online
C<n>.Stat.Restart	DIGITAL	Counter Status Restart bit Object 20 Variations 1,2 Object 22 Variations 1,2	R/O. Bit 1 of Status byte Originating field device has been restarted 0=normal, 1=Restart
C<n>.Stat.CommLost	DIGITAL	Counter Status Communication Lost bit Object 20 Variations 1,2 Object 22 Variations 1,2	R/O. Bit 2 of Status byte If comms lost, command will not be successful 0=normal, 1=Lost
C<n>.Stat.RemForced	DIGITAL	Counter Status Remote Forced Data bit Object 20 Variations 1,2 Object 22 Variations 1,2	R/O. Bit 3 of Status byte Originating field device is in control 0=normal, 1=Forced
C<n>.Stat.LocalForced	DIGITAL	Counter Status Local Forced Data bit Object 20 Variations 1,2 Object 22 Variations 1,2	R/O. Bit 4 of Status byte This device is in control 0=normal, 1=Forced
C<n>.Stat.RollOver	DIGITAL	Counter Status Roll Over bit Object 20 Variations 1,2 Object 22 Variations 1,2	R/O. Bit 5 of Status byte Counter has reached limit and reset to 0 0=normal, 1=Rollover
C<n>.DeltaVal	LONG	Delta Counter Value (16/32 bit) Object 20 Variations 3,4,7,8	R/O. Accumulated transitions of a SW or HW point This value is reset to 0 after each read.

Address	Plant SCADA Type	DNP3 Type	Description	
		(16bit or 32bit value)		
C<n.>.DeltaStat	BYTE	Delta Counter Status Status byte Object 20 Variations 3,4	R/O. Status data related to Value	
C<n.>.DeltaStat.Online	DIGITAL	Delta Counter Status Online bit Object 20 Variations 3,4	R/O. Bit 0 of Status byte If Offline, command will not be successful 0=Offline, 1=Online	
C<n.>.DeltaStat.Restart	DIGITAL	Delta Counter Status Restart bit Object 20 Variations 3,4	R/O. Bit 1 of Status byte Originating field device has been restarted 0=normal, 1=Restart	
C<n.>.DeltaStat.CommLos t	DIGITAL	Delta Counter Status Communication Lost bit Object 20 Variations 3,4	R/O. Bit 2 of Status byte If comms lost, command will not be successful 0=normal, 1=Lost	
C<n.>.DeltaStat.RemForce d	DIGITAL	Delta Counter Status Remote Forced Data bit Object 20 Variations 3,4	R/O. Bit 3 of Status byte Originating field device is in control 0=normal, 1=Forced	
C<n>.DeltaStat.LocalForce d	DIGITAL	Delta Counter Status Local Forced Data bit Object 20 Variations 3,4	R/O. Bit 4 of Status byte This device is in control 0=normal, 1=Forced	
C<n>.DeltaStat.RollOver	DIGITAL	Delta Counter Status Roll Over bit Object 20 Variations 3,4	R/O. Bit 5 of Status byte Counter has reached limit and reset to 0 0=normal, 1=Rollover	
FC<n>.Stat	BYTE	Frozen Counter Status	R/O.	

Address	Plant SCADA Type	DNP3 Type	Description
		Status byte Object 21 Variations 1,2	Status data related to Value
FC< n >.Stat.Online	DIGITAL	Frozen Counter Status Online bit Object 21 Variations 1,2	R/O. Bit 0 of Status byte If Offline, command will not be successful 0=Offline, 1=Online
FC< n >.Stat.Restart	DIGITAL	Frozen Counter Status Restart bit Object 21 Variations 1,2	R/O. Bit 1 of Status byte Originating field device has been restarted 0=normal, 1=Restart
FC< n >.Stat.CommLost	DIGITAL	Frozen Counter Status Communication Lost bit Object 21 Variations 1,2	R/O. Bit 2 of Status byte If comms lost, command will not be successful 0=normal, 1=Lost
FC< n >.Stat.RemForced	DIGITAL	Frozen Counter Status Remote Forced Data bit Object 21 Variations 1,2	R/O. Bit 3 of Status byte Originating field device is in control 0=normal, 1=Forced
FC< n >.Stat.LocalForced	DIGITAL	Frozen Counter Status Local Forced Data bit Object 21 Variations 1,2	R/O. Bit 4 of Status byte This device is in control 0=normal, 1=Forced
FC< n >.Stat.RollOver	DIGITAL	Frozen Counter Status Roll Over bit Object 21 Variations 1,2	R/O. Bit 5 of Status byte Counter has reached limit and reset to 0 0=normal, 1=Rollover

where:

- n = Point index number (range from 0 to 2048)
- R/O = read only

- W/O = write only
- R/W = read or write

### Monitoring Data Types - Analog Inputs

This table defines the Plant SCADA variable address required for the specified DNP3 data types.

Address	Plant SCADA Type	DNP3 Type	Description
AI<n>.Val	LONG	Analog Input Value (16/32 bit) Object 30 Var(s) 1,2,3,4 Object 32 Var(s) 1,2,3,4	R/O. Current value of Analog Input(16bit or 32bit value)
AI<n>.Val.Float	REAL	Analog Input Value (float) Object 30 Var(s) 5 Object 32 Var(s) 5,7	R/O. Current value of Analog Input (float value)
AI<n>.Val.TS	LONG	Analog Input Time Stamp (seconds since 1970)	UTC time when value last changed or when the value was acquired from the initial integrity poll.
AI<n>.Val.TMS	LONG	Analog Input Time Stamp (milliseconds since midnight)	Milliseconds since midnight when value last changed or when the value was acquired from the initial integrity poll.
AI<n>.Val.Qual	LONG	Analog Input Quality	OPC quality of point converted from value of flags.

where:

- n = Point index number (range from 0 to 2048)
- R/O = read only
- W/O = write only
- R/W = read or write

### Advanced monitoring data types - analog inputs

---

**Note:** The following data types are only recommended for experienced users who are familiar with the terminology and methods associated with the DNP 3.0 protocol.

---

<b>Address</b>	<b>Plant SCADA Type</b>	<b>DNP3 Type</b>	<b>Description</b>
AI<n>.Stat	BYTE	Analog Input Status Status byte Object 30 Variations 1,2,5 Object 32 Var(s) 1,2,3,4,5,7	R/O. Status data related to Value
AI<n>.Stat.Online	DIGITAL	Analog Input Status Online bit Object 30 Variations 1,2,5 Object 32 Var(s) 1,2,3,4,5,7	R/O. Bit 0 of Status byte If Offline, command will not be successful 0=Offline, 1=Online
AI<n>.Stat.Restart	DIGITAL	Analog Input Status Restart bit Object 30 Variations 1,2,5 Object 32 Var(s) 1,2,3,4,5,7	R/O. Bit 1 of Status byte Originating field device has been restarted. 0=normal, 1=Restart
AI<n>.Stat.CommLost	DIGITAL	Analog Input Status Communication Lost bit Object 30 Variations 1,2,5 Object 32 Var(s) 1,2,3,4,5,7	R/O. Bit 2 of Status byte If comms lost, command will not be successful 0=normal, 1=Lost
AI<n>.Stat.RemForced	DIGITAL	Analog Input Status Remote Forced Data bit Object 30 Variations 1,2,5 Object 32 Var(s) 1,2,3,4,5,7	R/O. Bit 3 of Status byte Originating field device is in control 0=normal, 1=Forced
AI<n>.Stat.LocalForced	DIGITAL	Analog Input Status Local Forced Data bit Object 30 Variations 1,2,5 Object 32 Var(s) 1,2,3,4,5,7	R/O. Bit 4 of Status byte This device is in control 0=normal, 1=Forced
AI<n>.Stat.OverRange	DIGITAL	Analog Input Status Over Range bit Object 30 Variations 1,2,5 Object 32 Var(s) 1,2,3,4,5,7	R/O. Bit 5 of Status byte Analog is over/under range and has been clipped 0=normal, 1=Over Range

Address	Plant SCADA Type	DNP3 Type	Description
AI<n>.Stat.RefCheck	DIGITAL	Analog Input Status Reference Check bit Object 30 Variations 1,2,5 Object 32 Var(s) 1,2,3,4,5,7	R/O. Bit 6 of Status byte A/D reference signal unreliable. Value is unreliable 0=normal, 1=Error

**where:**

- n = Point index number (range from 0 to 2048)
- R/O = read only
- W/O = write only
- R/W = read or write

#### Monitoring Data Types - Analog Outputs

This table defines the Plant SCADA variable address required for the specified DNP3 data types.

Address	Plant SCADA Type	DNP3 Type	Description
AO<n>.Val - or - AO<n>.Val.Long	LONG	Analog Output Value (32 bit) Object 40 Variation 1	R/O Current value of Analog Output. (32bit value)
AO<n>.Val	LONG	Analog Output Value (16 bit) Object 40 Variation 2	R/O Current value of Analog Output. (16bit value)
AO<n>.Val.Float	REAL	Analog Output Value (float) Object 40 Variation 3	R/O Current value of Analog Output. (16bit value)
AO<n>.Val.QUAL	LONG	Analog Output Quality	OPC quality of point converted from value of flags.

**where:**

- n = Point index number (range from 0 to 2048)
- R/O = read only
- W/O = write only

- R/W = read or write

## Advanced monitoring data types - analog outputs

**Note:** The following data types are only recommended for experienced users who are familiar with the terminology and methods associated with the DNP 3.0 protocol.

Address	Plant SCADA Type	DNP3 Type	Description
AO<n>.Stat	BYTE	Analog Output Status Status byte Object 40 Variations 1,2,3	R/O. Status data related to Value
AO<n>.Stat.Online	DIGITAL	Analog Output Status Online bit Object 40 Variations 1,2,3	R/O. Bit 0 of Status byte If Offline, command will not be successful 0=Offline, 1=Online
AO<n>.Stat.Restart	DIGITAL	Analog Output Status Restart bit Object 40 Variations 1,2,3	R/O. Bit 1 of Status byte Originating field device has been restarted. 0=normal, 1=Restart
AO<n>.Stat.CommLost	DIGITAL	Analog Output Status Communication Lost bit Object 40 Variations 1,2,3	R/O. Bit 2 of Status byte If comms lost, command will not be successful 0=normal, 1=Lost
AO<n>.Stat.RemForced	DIGITAL	Analog Output Status Remote Forced Data bit Object 40 Variations 1,2,3	R/O. Bit 3 of Status byte Originating field device is in control 0=normal, 1=Forced
AO<n>.Stat.SelPend	DIGITAL	Analog Output Status Plant SCADA – Object Selected in RTU	R/O. Bit 5 of Status byte This device is in control 0=not selected, 1=Selected, waiting on OPERATE
AO<n>.Stat.WrtPend	DIGITAL	Analog Output Status	R/O.

Address	Plant SCADA Type	DNP3 Type	Description
		Plant SCADA – Select Initiated in RTU	Bit 6 of Status byte This device is in control 0=not initiated, 1=SELECT started
AO<n>.Stat.WrtFail	DIGITAL	Analog Output Status Plant SCADA – Problem in SELECT/OPERATE sequence	R/O. Bit 7 of Status byte This device is in control 0=normal, 1=Write unsuccessful
AO<n>.CtrlStat	BYTE	Analog Output Control Status Status byte Object 41 Variations 1,2,3	R/O. Status of Control Operation. 0=Request accepted, initiated or queued 1= Request rejected – OPERATE received after SELECT had already timed-out 2= Request rejected – OPERATE received without receiving matching SELECT 3= Request rejected – Formatting errors in control request (Select, Operate or Doperate) 4= Request rejected – Control Operation not supported for this bit 5= Request rejected – Queue full or point already active 6= Request rejected – Control hardware problems 7-127=Undefined.

where:

- n = Point index number (range from 0 to 2048)
- R/O = read only

- W/O = write only
- R/W = read or write

### Monitoring Data Types - Time and Date

**Note:** The following data types are only recommended for experienced users who are familiar with the terminology and methods associated with the DNP 3.0 protocol.

Address	Plant SCADA Type	DNP3 Type	Description
ReadTime	LONG	RTU Time & Date Object 50 Variation 1	R/W  Read RTU time from driver cache.  Write RTU time to driver cache.  (Forcing a time read request to device and then store the time from the reply to the cache).

where:

- n = Point index number (range from 0 to 2048)
- R/O = read only
- W/O = write only
- R/W = read or write

### Monitoring Data Types - IIN Flags

**Note:** The following data types are only recommended for experienced users who are familiar with the terminology and methods associated with the DNP 3.0 protocol.

Address	Plant SCADA Type	DNP3 Type	Description
IIN	INTEGER	The value of the Internal Indication bits retrieved from the last response (see note 2 below).  No Object	R/O  (see Note 1 below)
IIN.BadFunction	DIGITAL	Bit 0 of byte 2 of the Internal Indication bits (see Note 2 below).  Function code not implemented.  No Object	R/O  (see Note 1 below)

Address	Plant SCADA Type	DNP3 Type	Description
IIN.ObjectUnknown	DIGITAL	Bit 1 of byte 2 of the Internal Indication bits (see Note 2 below). Request object unknown. No Object	R/O (see Note 1 below)
IIN.OutOfRange	DIGITAL	Bit 2 of byte 2 of the Internal Indication bits (see Note 2 below). Parameters in qualifier, range or data fields are not valid or out of range. No Object	R/O (see Note 1 below)
IIN.BufferOvfl	DIGITAL	Bit 3 of byte 2 of the Internal Indication bits (see Note 2 below). Event or other buffers overflowed. No Object	R/O (see Note 1 below)
IIN.ExecutingIIN	DIGITAL	Bit 4 of byte 2 of the Internal Indication bits (see Note 2 below) Request understood but requested operation already executing. No Object	R/O (see Note 1 below)
IIN.ConfigIIN	DIGITAL	Bit 5 of byte 2 of the Internal Indication bits (see Note 2 below) Configuration in outstation corrupt. No Object	R/O (see Note 1 below)
IIN.AllStations	DIGITAL	Bit 0 of byte 1 of the Internal Indication bits (see Note 2 below). All stations message received. No Object	R/O (see Note 1 below)

<b>Address</b>	<b>Plant SCADA Type</b>	<b>DNP3 Type</b>	<b>Description</b>
IIN.Class1	DIGITAL	Bit 1 of byte 1 of the Internal Indication bits (see Note 2 below). Class 1 data available. No Object	R/O (see Note 1 below)
IIN.Class2	DIGITAL	Bit 2 of byte 1 of the Internal Indication bits (see Note 2 below). Class 2 data available. No Object	R/O (see Note 1 below)
IIN.Class3	DIGITAL	Bit 3 of byte 1 of the Internal Indication bits (see Note 2 below). Class 3 data available. No Object	R/O (see Note 1 below)
IIN.TimeIIN	DIGITAL	Bit 4 of byte 1 of the Internal Indication bits (see Note 2 below). Time synchronization required from the master. No Object	R/O (see Note 1 below)
IIN.LocalIIN	DIGITAL	Bit 5 of byte 1 of the Internal Indication bits (see Note 2 below). Some or all of the outstations digital output points are in local state. No Object	R/O (see Note 1 below)
IIN.TroubleIIN	DIGITAL	Bit 6 of byte 1 of the Internal Indication bits (see Note 2 below) Abnormal condition exists in the outstation. No Object	R/O (see Note 1 below)
IIN.Restart	DIGITAL	Bit 7 of byte 1 of the Internal Indication bits	R/O (see Note 1 below)

Address	Plant SCADA Type	DNP3 Type	Description
		(see Note 2 below). Device restart. No Object	

**Where:**

- n = Point index number (range from 0 to 2048)
- R/O = read only
- W/O = write only
- R/W = read or write

**Note:**

1. This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.
2. Not every transition of the IIN will be visible using this tag since the driver reacts to the IIN bits. Also, IIN error consistent reflect the response to a single request therefore may only be briefly stored.  
For instance, if the IIN bits indicate time action is required, and the driver is configured to do so, then the action will occur, and the time action bit become zero before it can be displayed.  
The IIN tag is useful for viewing IIN conditions that are global to the device (not specific to a request) and are not being responded to by the driver (for instance, the Local bit).

**Control Data Types - Binary Outputs**

This table defines the Plant SCADA variable address required for the specified DNP3 data types.

Address	Plant SCADA Type	DNP3 Type	Description
BO<n>.Select.Latch	DIGITAL	Binary Output Control Select (Latch Mode) Object 12 Variation 1	W/O. Selects point and mode of operation (the driver will automatically send out the corresponding operate command). Maintains output in specified state.
BO<n>.Select.Pulse	DIGITAL	Binary Output Control Select (Pulse Mode) Object 12 Variation 1	W/O. Selects point and mode of operation (the driver will automatically send out the corresponding operate command). Only Pulse ON supported.
BO<n>.Select.TC	DIGITAL	Binary Output Control	W/O.

Address	Plant SCADA Type	DNP3 Type	Description
		Select (TC Mode) Object 12 Variation 1	Selects point and mode of operation (the driver will automatically send out the corresponding operate command). Trip and Close both use the ONTIME parameter. 0=Trip breaker, 1=Close breaker.
BO<n>.Operate.Latch	DIGITAL	Binary Output Control Operate (Latch Mode) Object 12 Variation 1	W/O. Activates previously selected operation. Maintains output in specified state.
BO<n>.Operate.Pulse	DIGITAL	Binary Output Control Operate (Pulse Mode) Object 12 Variation 1	W/O. Activates previously selected operation. Only Pulse ON supported
BO<n>.Operate.TC	DIGITAL	Binary Output Control Operate (TC Mode) Object 12 Variation 1	W/O. Activates previously selected operation. Trip and Close both use the ONTIME parameter. 1=Close breaker, 0=Trip breaker.
BO<n>.SelectOnly.Latch	DIGITAL	Binary Output Control Select (Latch Mode) Object 12 Variation 1	W/O. Selects point and mode of operation but does not operate. Maintains output in specified state.
BO<n>.SelectOnly.Pulse	DIGITAL	Binary Output Control Select (Pulse Mode) Object 12 Variation 1	W/O. Selects point and mode of operation but does not operate. Only Pulse ON supported. Pulse OFF may be supported in future release.

Address	Plant SCADA Type	DNP3 Type	Description
BO<n>.SelectOnly.TC	DIGITAL	Binary Output Control Select (TC Mode) Object 12 Variation 1	W/O. Selects point and mode of operation but does not operate. Trip and Close both use the ONTIME parameter. 0=Trip breaker, 1=Close breaker.
BO<n>.DOperate.Latch (See Note below)	DIGITAL	Binary Output Control Direct Operate (Latch Mode) Object 12 Variation 1	W/O. Selects and activates point operation. Maintains output in specified state.
BO<n>.DOperate.Pulse (See Note below)	DIGITAL	Binary Output Control Direct Operate (Pulse Mode) Object 12 Variation 1	W/O. Selects and activates point operation. Only Pulse ON supported.
BO<n>.DOperate.TC (See Note below)	DIGITAL	Binary Output Control Direct Operate (TC Mode) Object 12 Variation 1	W/O. Selects and activates point operation. Trip and Close both use the ONTIME parameter. 1=Close breaker, 0=Trip breaker.
BO<n>.Configure.Ontime	LONG	Binary Output Control Configure Ontime Object 12 Variation 1	W/O. Time in milliseconds of momentary contact closure. (Used in Pulse ON, Trip and Close modes).
BO<n>.CancelSel	DIGITAL	Binary Output Control Cancel Current SelectOnly	W/O. Clear OPERATE status bits and cancel the SELECT operation to the RTU.

**where:**

- n = Point index number (range from 0 to 2048)
- R/O = read only
- W/O = write only

- R/W = read or write

---

**Note:** DNP (Subset level 1) supports a ‘Direct Operate without acknowledgment’, but as this does not verify the success of the command, only ‘Direct Operate’ is currently implemented.

---

### Control Data Types - Counters

This table defines the Plant SCADA variable address required for the specified DNP3 data types.

Address	Plant SCADA Type	DNP3 Type	Description
C.Freeze (See Note 1 below)	DIGITAL	Counter Freeze Command Object 20 Variations 1..8	W/O. Copy all counters to a freeze buffer.
C.FreezeClear (See Note 2 below)	DIGITAL	Counter Freeze Command Object 20 Variations 1..8	W/O. Copy all counter to a freeze buffer, and then clear all counters to 0.

**where:**

- n = Point index number (range from 0 to 2048)
- R/O = read only
- W/O = write only
- R/W = read or write

---

**Note:**

1. DNP (Subset level 2) supports an ‘Immediate Freeze without acknowledgment’, but as this does not verify the success of the command, only ‘Immediate Freeze’ is currently implemented.
  2. DNP (Subset level 2) supports a ‘Freeze and Clear without acknowledgment’, but as this does not verify the success of the command, only ‘Freeze and Clear’ is currently implemented.
- 

### Control Data Types - Analog Outputs

This table defines the Plant SCADA variable address required for the specified DNP3 data types.

Address	Plant SCADA Type	DNP3 Type	Description
AO<n>.Select.Long	LONG	Analog Output Control (32bit) Select Object 41 Variation 1	W/O. Selects point to be controlled (the driver will automatically send out the corresponding operate command). (32bit value).
AO<n>.Select	INTEGER	Analog Output Control	W/O.

Address	Plant SCADA Type	DNP3 Type	Description
		(16bit) Select Object 41 Variation 2	Selects point to be controlled (the driver will automatically send out the corresponding operate command). (16bit value).
AO<n>.Select.Float	REAL	Analog Output Control (Float) Select Object 41 Variation 3	W/O. Selects point to be controlled (the driver will automatically send out the corresponding operate command). (float value).
AO<n>.SelectOnly.Long	LONG	Analog Output Control (32bit) Select Object 41 Variation 1	W/O. Selects point to be controlled but does not operate. (32bit value).
AO<n>.SelectOnly	INTEGER	Analog Output Control (16bit) Select Object 41 Variation 2	W/O. Selects point to be controlled but does not operate. (16bit value).
AO<n>.SelectOnly.Float	REAL	Analog Output Control (Float) Select Object 41 Variation 3	W/O. Selects point to be controlled but does not operate. (float value).
AO<n>.Operate.Long	LONG	Analog Output Control (32bit) Operate Object 41 Variation 1	W/O. Activates control operation on previously selected point. (32bit value).
AO<n>.Operate	INTEGER	Analog Output Control (16bit) Operate Object 41 Variation 2	W/O. Activates control operation on previously selected point. (16bit value).

Address	Plant SCADA Type	DNP3 Type	Description
AO<n>.Operate.Float	REAL	Analog Output Control (Float) Operate Object 41 Variation 3	W/O. Activates control operation on previously selected point. (float value).
AO<n>.DOperate.Long (See Note below)	LONG	Analog Output Control (32bit) Direct Operate Object 41 Variation 1	W/O. Selects and activates control operation on point. (32bit value).
AO<n>.DOperate (See Note below)	INTEGER	Analog Output Control (16bit) Direct Operate Object 41 Variation 2	W/O. Selects and activates control operation on point. (16bit value).
AO<n>.DOperate.Float (See Note below)	REAL	Analog Output Control (Float) Direct Operate Object 41 Variation 3	W/O. Selects and activates control operation on point. (float value).
AO<n>.CancelSel	DIGITAL	Analog Output Control Cancel Current . SelectOnly	W/O. Clear OPERATE status bits and cancel the SELECT operation to the RTU.

where:

- n = Point index number (range from 0 to 2048)
- R/O = read only
- W/O = write only
- R/W = read or write

---

**Note:** DNP (Subset level 1) supports a ‘Direct Operate without acknowledgment’, but as this does not verify the success of the command, only ‘Direct Operate’ is currently implemented.

---

#### Control Data Types - Time and Date

---

**Note:** The following data types are only recommended for experienced users who are familiar with the terminology and methods associated with the DNP 3.0 protocol.

---

Address	Plant SCADA Type	DNP3 Type	Description
WriteTime	DIGITAL	RTU Time & Date Object 50 Variation 1	W/O. Write '1' to synchronise RTU time with Plant SCADA time.

where:

- n = Point index number (range from 0 to 2048)
- R/O = read only
- W/O = write only
- R/W = read or write

## Control Data Types - Utilities

---

**Note:** The following data types are only recommended for experienced users who are familiar with the terminology and methods associated with the DNP 3.0 protocol.

Address	Plant SCADA Type	DNP3 Type	Description
ColdRestart	DIGITAL	Cold Restart Command No Object	W/O. Instruct the Outstation to perform a complete restart of the user application. The only valid value to write is 1. This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.

where:

- n = Point index number (range from 0 to 2048)
- R/O = read only
- W/O = write only
- R/W = read or write

## Global Data Types

---

**Note:** The following data types are only recommended for experienced users who are familiar with the terminology and methods associated with the DNP 3.0 protocol.

Address	Plant SCADA Type	DNP3 Type	Description
EventQueSize	LONG	N/A. No Object	R/O Current size of the event queue.

where:

- n = Point index number (range from 0 to 2048)
- R/O = read only
- W/O = write only
- R/W = read or write

### Polling Regime Data Types

**Note:** The following data types are only recommended for experienced users who are familiar with the terminology and methods associated with the DNP 3.0 protocol.

Address	Plant SCADA Type	DNP3 Type	Description
PollPeriod	LONG	Adjust the Polling Period  No Object	R/W  If the Citect.ini parameter 'EnablePollPeriodWrites' is set to TRUE (1), then this tag can be used to adjust the Event Polling Period.  This tag can be used to display the current Event Polling Period regardless of the state of 'EnablePollPeriodWrites'.  This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.
EnablePoll	INTEGER	Returns if Polling enabled for reads  No Object	R/W  Returns if the unit has polling enabled. A write of '0' will turn polling off, '1' will re-enable polling.  This address does not relate to I/O data internal to the device, but relates

<b>Address</b>	<b>Plant SCADA Type</b>	<b>DNP3 Type</b>	<b>Description</b>
			to data internal to the driver, or an action to be performed by the driver.
ReinitPollSequence	DIGITAL	Force the re-initialization of the Polls sequence.  No Object	W/O  Writing a '1' to this tag will force the driver to re-initialize the poll sequence of all devices. The poll sequence will restart from the Integrity poll when this command is received.  This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.
ForceIntegrityPoll	DIGITAL	Force an integrity poll  Object 60 Variation 1 Object 60 Variation 2 Object 60 Variation 3 Object 60 Variation 4	W/O.  Writing a '1' to this tag will force the driver to execute an Integrity poll of the device (in addition to the routine polling that it automatically undertakes).  This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.
ForceEventPoll	DIGITAL	Force an integrity poll  Object 60 Variation 2 Object 60 Variation 3 Object 60 Variation 4	W/O.  Writing a '1' to this tag will force the driver to execute an Event poll of the device (in addition to the routine polling that it automatically undertakes).  This address does not relate to I/O data internal

Address	Plant SCADA Type	DNP3 Type	Description
			to the device, but relates to data internal to the driver, or an action to be performed by the driver.
ForceClass1Poll	DIGITAL	Force an integrity poll Object 60 Variation 2	W/O. Writing a '1' to this tag will force the driver to execute a poll for class 1 data from the device (in addition to the routine polling that it automatically undertakes).
ForceClass2Poll	DIGITAL	Force an integrity poll Object 60 Variation 3	W/O. Writing a '1' to this tag will force the driver to execute a poll for class 2 data from the device (in addition to the routine polling that it automatically undertakes).
ForceClass3Poll	DIGITAL	Force an integrity poll Object 60 Variation 4	W/O. Writing a '1' to this tag will force the driver to execute a poll for class 3 data from the device (in addition to the routine polling that it automatically undertakes).
DisableUnsolicited	DIGITAL	Disable all Unsoliciteds Object 60 Variation 2 Object 60 Variation 3 Object 60 Variation 4	W/O. Writing a '1' to this tag will instruct the unit not to broadcast any more unsolicited responses. It is W/O, as there is no way of determining if unsoliciteds were disabled before Plant SCADA startup. This address does not

Address	Plant SCADA Type	DNP3 Type	Description
			<p>relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.</p> <p><b>Note:</b> This a Level 3 feature.</p>
EnableUnsolicited	DIGITAL	Enable all Unsoliciteds Object 60 Variation 2 Object 60 Variation 3 Object 60 Variation 4	<p>W/O.</p> <p>Writing a '1' to this tag will allow the unit to broadcast unsolicited responses. The Classes enabled are determined by the INI parameter [DNPR]AutoUnsolicitedEnableDefault or [&lt;unit&gt;] AutoUnsolicitedEnable. It is W/O, as there is no way of determining if unsoliciteds were enabled before Plant SCADA startup.</p> <p>This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.</p> <p><b>Note:</b> This a Level 3 feature.</p>
TimeToNextPoll	LONG	Time to go to next Integrity poll No Object	<p>R/O Seconds.</p> <p>Will count down from the set Integrity poll time, and may go -ve if the Integrity poll has been delayed.</p> <p>This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.</p>
TimeToNextClass1Poll	LONG	Time to go to next class 1	R/O Seconds.

Address	Plant SCADA Type	DNP3 Type	Description
		poll No Object	Will count down from the set class 1 poll time and may go –ve if the class 1 poll has been delayed. This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.
TimeToNextClass2Poll	LONG	Time to go to next class 1 poll No Object	R/O Seconds. Will count down from the set class 2 poll time and may go –ve if the class 2 poll has been delayed. This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.
TimeToNextClass3Poll	LONG	Time to go to next class 1 poll No Object	R/O Seconds. Will count down from the set class 3 poll time and may go –ve if the class 3 poll has been delayed. This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.
Polls	INTEGER	Count of all successful polls (Forced and periodic). No Object	R/W Count of successful Integrity, Event, class 1, class 2 and class 3 polls of the device. Write ‘1’ to reset counter. This address does not relate to I/O data internal to the device, but relates to data internal to the

<b>Address</b>	<b>Plant SCADA Type</b>	<b>DNP3 Type</b>	<b>Description</b>
			driver, or an action to be performed by the driver.
FailedPolls	INTEGER	Count of all unsuccessful polls (Forced and periodic). No Object	R/W Count of unsuccessful Integrity, Event, class 1, class 2 and class 3 polls of the device (ie failure of full timeout sequence). Write '1' to reset counter. This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.
Ipolls	INTEGER	Count of successful Integrity polls (Forced and periodic). No Object	R/W Count of successful Integrity polls of the device. Write '1' to reset counter. This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.
FailedIPolls	INTEGER	Count of unsuccessful Integrity polls (Forced and periodic). No Object	R/W Count of unsuccessful Integrity polls of the device (i.e. failure of full timeout sequence). Write '1' to reset counter. This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.
Epolls	INTEGER	Count of successful Event polls (Forced and periodic).	R/W Count of successful Event polls of the device. Write

Address	Plant SCADA Type	DNP3 Type	Description
		No Object	'1' to reset counter. This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.
FailedEpolls	INTEGER	Count of unsuccessful Event polls (Forced and periodic). No Object	R/W Count of unsuccessful Event polls of the device (i.e. failure of full timeout sequence). Write '1' to reset counter. This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.
UnsolicitedRxd	INTEGER	Count of Unsoliciteds received. No Object	R/W Count of valid Unsolicited Responses received by the device. Write '1' to reset counter. This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.
LateRefresh	DIGITAL	Late cache refresh for device No Object	R/O Indicates when a device poll has been delayed, resulting in a late cache refresh. Refer to Citect.ini parameter DataLag for further details. This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be

Address	Plant SCADA Type	DNP3 Type	Description
			performed by the driver.
RequestEventRefresh	INTEGER	Force Event Refresh for device No Object	R/W  Writing 1 will cause the unit to refresh all event data the next integrity poll. A read reads this state.  <b>Note:</b> This value will be set if the [dnpr]RefreshEventsOnStartup=1 was set.  This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.
RTUEvents	LONG	RTU Events received No Object	R/O  RTU events PER PORT received from the field device.  This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.
RTUStatus	DIGITAL	RTU Online status No Object	R/O  Internal online status of a unit. Of limited use as a tag on a unit as if the unit was offline, you could not read the tag anyway.  This tag has been superceded by the UnitActiveState.X tags.  This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.

**where:**

- n = Point index number (range from 0 to 2048)
- R/O = read only
- W/O = write only
- R/W = read or write

## Miscellaneous Data Types

**Note:** The following data types are only recommended for experienced users who are familiar with the terminology and methods associated with the DNP 3.0 protocol.

Address	Plant SCADA Type	DNP3 Type	Description
DebugReport	INTEGER	Generate a debug report for the device. No Object	W/O The debug info are written in the driver log file. This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.

**where:**

- n = Point index number (range from 0 to 2048)
- R/O = read only
- W/O = write only
- R/W = read or write

## Projects Using Super Genies

To use Super Genies with digital tags, you will need to modify your project settings to allow blocking of requests up to 16 bits (default is 8 bits). To do this, go to the topic [Data Point and Cache Parameters](#) and make the modifications outlined in the description of the [DNPR]IsItemisedRequest parameter.

### **WARNING**

#### **UNINTENDED EQUIPMENT OPERATION**

- Do not under any circumstances change or remove any of the undocumented citect.ini parameters.
- Before deleting sections of the citect.ini file, confirm that no undocumented parameters will be deleted.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

You will also need to:

1. Add the following to your Citect.ini file (in the [DNPR] section):
  - Block = 2
  - MaxBits = 16
  - IsItemisedRequest = 0
2. Modify the protodir.db file from BIT\_BLOCK=8, MAX\_LENGTH=8 to BIT\_BLOCK=16, MAX\_LENGTH=16 and copy to the Include, System and your project directory (exists under the User directory of your Plant SCADA installation).
3. Recompile your project (with the incremental compile option disabled).

---

**Note:** The MAX\_LENGTH value above is adjustable by the user to 2048 bits

---

## Hints and Tips

### Startup considerations

In a site with many RTUs, it is useful to consider staggering port startup using the parameter [DNPR]StartupStaggerDelay to spread out the load.

Also, it is a good idea to use the [<unit>]PollPeriodOffset parameter to stagger when periodic polls are issued, especially where many units are coming through one port. For example:

- Unit 1: 5
- Unit 2: 10
- Unit 3: 15

This would send polls five seconds after the default time for Unit 1, 10 seconds after for Unit 2, and 15 seconds after for Unit 3.

### Resource release at shutdown

If StopUnit() and Stop/CloseChannel() code is not executed when a unit or channel is offline, the system may become inoperable.

To avoid this, set the following Citect.ini parameters:

```
[IoServer]
AlwaysCallStopChannel=1
AlwaysCallStopUnit=1
```

### Unit online/offline

The following Citect.ini parameter settings are recommended to address unit online/offline issues:

```
[DNPR] DebugCategory = PROT|STATE|DCB
```

[DNPR] DebugLevel =ALL

Also use drivertraces with a mask of c0f, (e.g. "drivertrace mask=c0f").

## Data integrity

- If repeatable, then make the page refresh time artificially long (using page properties), for example, every 5 seconds (5000). This will minimize the trace storm if a page has many tags.
- Disable alarms and trends to isolate a trace to just one source of logic, i.e. a page refresh or alarm scan.
- A kernel "probe" window will show tag requests to and from the client, but not necessarily to the driver. Probe results may come from the I/O server cache or an I/O server on another PC. This is only for Plant SCADA v6.10 and before.
- A kernel "probe" window will show tag requests to and from the client, but not necessarily to the driver. Probe results may come from the I/O server cache or an I/O server on another PC. This is only for Plant SCADA v6.10 and before.
- Kernel "drivertrace xxxx" will show requests to/from the driver on the local I/O server. These traces will also show the returned RAW value from the driver. Remember that the client will scale this value if engineering units are defined.
- Useful INIs for data issues are [DNPR] DebugCategory = PROT|CACHE|DCB|MISC, [DNPR] DebugLevel =ALL or DriverTraces.

## Maintenance Page

With more complex systems, it is recommended you have a maintenance page that allows you to enable or disable units and force integrity polls.

This page could display poll counts and have a couple of sample data points per unit. Thus during commissioning or later, allowing you to test the data path to various units. This is particularly true in a multidrop situation. Verifying field communications is very helpful when serial links exist.

## Advanced Configuration and Maintenance

This section of the DNPR Driver Help covers areas that are recommended for experienced users who are familiar with the terminology and methods associated with the DNP 3.0 protocol.

- [Customize a Project using Citect.ini Parameters](#)
- [DNPR Redundancy](#)
- [Data Acquisition within DNP3](#)
- [Device Polling Regime](#)

### Customize a Project using Citect.ini Parameters

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

- Do not under any circumstances change or remove any citect.ini parameters without an informed understanding of the possible implications of your actions.
- Do not delete sections of the citect.ini file without an informed understanding of the possible implications of your actions.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** At times during the life cycle of a driver, circumstances may call for the creation of specific citect.ini parameters that remain undocumented. Always seek the advice of Technical Support regarding the possible implementation of undocumented parameters before you make any changes to a citect.ini file.

The DNPr parameters are grouped into the following categories:

- [Basic Parameters](#)  
The standard set of protocol parameters.
- [Logging/Diagnostic Parameters](#)  
Parameters that can assist with troubleshooting.
- [Driver-specific Parameters](#)  
Parameters specific to the DNPr driver.
- [Peer Redundancy Parameters](#)  
These parameters need only be set if you are using a redundant DNPr system.
- [Port-based Parameters](#)  
These parameters are used to manipulate port control.
- [Event Processing Parameters](#)  
These parameters control how events are handled.
- [Polling Regime Parameters](#)  
These parameters are used to manipulate polling.
- [Communication Parameters](#)  
These parameters configure the data link to devices.
- [Data Point and Cache Parameters](#)  
These parameters control variations of behavior to some data types, as well as data cache behavior.
- [Miscellaneous Parameters](#)

**Note:** Some parameters can be used to configure behavior that will only apply to units within the same device group. These are represented in the following lists using [<unit>] as the defined Citect.ini section. See [Device Group Parameters](#) for more information.

**Basic Parameters**

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

The DNPR driver supports the following basic parameters:

Parameter	Allowable values	Default value	Description
[DNPR]Block	1-256	1	Dynamic I/O server blocking is adjustable by the user up to 256 bytes. e.g. [DNPR]Block=256 This allows DCBs to be blocked together in the I/O server and make fewer requests down to the driver.
[DNPR]ConnectionTimeout	1000 to 65534 (ms)	8000	The maximum amount of time to allow the low level transport for the driver to attempt a connection.
[DNPR]Delay	0-300 (ms)	0	The period (in milliseconds) to wait between receiving a response and sending the next command.
[DNPR]EventPollPeriodDefault	0 to 4,000,000 (seconds)	60 Sec	Default period to poll devices for event class data. Integrity poll will poll for all classes (event and static data), and occurs after every EventPollRatioDefault event polls.  If the value is set to zero then the polling mode in the Citect.ini parameter [DNPR]ResponseModeDefault will be disabled. The

Parameter	Allowable values	Default value	Description
			<p>device will stay offline until an integrity poll is forced out or an unsolicited message from the device is coming in.</p> <p>See "Device Polling Regime" for an example.</p> <p>This parameter can be over-written by the parameter [&lt;unit&gt;]EventPollPeriod.</p> <p><b>Note:</b> This INI parameter can be overwritten if the "Minimum Update Time" field for the I/O Device is greater than 0. (This option is only available with Plant SCADA from version 7.20.)</p>
[DNPR]MaxPending	0-32	16	The maximum number of pending commands that the driver holds ready for immediate execution.
[DNPR]Poltime	50-1000 (ms)	200	<p>The frequency with which messages are processed to/from the driver to the RTUs.</p> <p>It is recommended this value not be changed.</p>
[DNPR]Retry	0-8	1	<p>Default number of application layer retries for all I/O devices as well as physical transport writes allowed before a channel is placed offline.</p> <p>This parameter can be over-written by the parameter [&lt;unit&gt;]Retry.</p>

Parameter	Allowable values	Default value	Description
[DNPR]SCADAAddress	0-65534	3	Defines the DNP Address for Plant SCADA. If a value for this parameter is not provided, a popup box will appear at startup. This parameter can be over-written by the parameter [<unit>]SCADAAddress.
[DNPR]Timeout	500-32767 (ms)	5000	Default application layer timeout (in milliseconds) for all I/O devices. This parameter can be over-written by the parameter [<unit>]Timeout.
[DNPR]WatchTime	5-128 Sec	10	The frequency (in seconds) with which the I/O server checks the communications link to an I/O device if the device is offline.

## Logging/Diagnostic Parameters

### **WARNING**

#### **UNINTENDED EQUIPMENT OPERATION**

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

These parameters are read every few seconds by the driver. This means the values can be changed in real time, for example, you can turn logging on or off.

Parameter	Allowable values	Default value	Description
[DNPR]DebugLevel	Any combination of the following, separated by a pipe character ( ):  WARN	Empty string (no logging)	The trace level used for the log file.

Parameter	Allowable values	Default value	Description
	ERROR TRACE DEBUG ALL See <a href="#">Logging</a> for examples.		
[DNPR]DebugCategory	Any combination of the following, separated by a pipe character ( ): PROT = protocol level debug CACHE = tag cache data STATE = unit state transitions EVENT = events cache data DCB = front end debug (that is, the I/O server) BEND = peer communication MISC = any other debugging ALL = all of the above See <a href="#">Logging</a> for examples.	Empty string (no logging)	The categories used for the log file:

[Debugging Messages](#)

## Driver-specific Parameters

### UNINTENDED EQUIPMENT OPERATION

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

Parameter	Allowable values	Default value	Description
[<unit>]SCADAAddress	0-65534	[DNPR]SCADAAddress	This parameter has the same functionality as the

Parameter	Allowable values	Default value	Description
			driver-level DNPR parameter [DNPR]SCADAAddress, but only applies to units in this device group. It allows you to specify multiple master devices, instead of only one (e.g. Plant SCADA).
[<unit>]Timeout	500-32767 ms	5000	Default application layer timeout (in milliseconds) for the specified I/O device group. This parameter has the same functionality as the driver-level DNPR parameter [DNPR]Timeout.
[<unit>]Retry	0 - 8	1	Default number of application layer retries for the specified device group, as well as physical transport writes allowed before a channel is placed offline. This parameter has the same functionality as the driver-level DNPR parameter [DNPR]Retry.
[DNPR] TimeoutExtensionDefault [<unit>] TimeoutExtension	0-2,000,000,000 ms	0	Default extension to be added to the standard 'timeout' parameter. This extension is only required if a timeout greater than 32000 milliseconds is needed.
[DNPR] OnTimeBODNPDefault [<unit>] OnTimeBODDeviceDefault	0-2,000,000,000 ms	1000	Default value to be used by theOnTimeBODDeviceDefault device level .ini parameters. The

Parameter	Allowable values	Default value	Description
			OnTimeBODDeviceDefault in turn defines the default value for momentary Binary Output closure times for that device (unit). Each Binary Output can have its closure time individually configured.

## Peer Redundancy Parameters

### WARNING

#### UNINTENDED EQUIPMENT OPERATION

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

The following [DNPR] parameters need only be set if you are using a redundant system:

Parameter	Allowable values	Default value	Description
[DNPR] ActivateIfPeerIsActiveOffline <unit> ActivateIfPeerIsActiveOffline	0 – Disable 1 – Enable	1	This parameter is used in a scenario where one of the redundant I/O devices is active and can open the TCPIP connection to the RTU, but stays offline as the driver does not get any response for the DNP3 messages it sends to the RTU.  If this is the case and the parameter is set to 1, the driver performs the switchover to the redundant I/O device peer and makes it active giving that I/O device a chance to communicate to the RTU.  If this behavior is not required, this parameter should be set to 0.

[DNPR] EnablePeerRedundancy	0 – Disable peer driver redundancy. 1 – Enable peer driver redundancy.	0	Enable the peer redundancy process. Only 1 peer driver is supported.
[DNPR]LocalAddress	Valid IP address.	127.0.0.1	The IP address of yourself for listening on.
[DNPR]LocalPort	Port.	5000	Valid Port you want to listen on.
[DNPR]MaxPeerOutQueueSize	1 to 100,000	10,000	If DNPR redundancy is configured, the driver replicates the value updates received from the device to the redundant peer. This provides the peer driver with the latest values in case a switchover occurs.  This parameter controls the maximum number of value updates which the driver stores in the queue before sending them to the peer. Limiting the queue size may be required if the driver receives more values updates than it can replicate.  <b>Note:</b> If the parameter value is greater than 100,000, it will be reset to 100,000.
[DNPR]PeerAddress	Valid IP address.	None	The IP address of your peer driver.
[DNPR]PeerPort	Port	5200	Any Valid Peer Destination Port.
[IOSERVER] WatchdogPrimary	0 – Disable 1 – Enable	0	Should be set when peer redundancy is in use. This helps ensure that the check that your unit is still online occurs for every unit.

			Not only does this enable the unit's offline to be noticed if NO reads are happening to that unit, but enables the driver to minimize #COMs on changeover by reporting offline in this check, and not on actual read requests.
[DNPR] MaxMsgPerPollTime	1 to 4294967295	500	The maximum number of peer cache updates to be processed per call to Cpu() which is controlled by the "PollTime" parameter.
[DNPR] PeerCommRetryCount	1 to 10	3	Retries allowed on peer messages before the peer communications are considered down.
[DNPR] PeerKeepAliveTime	1 to 65535	30000	Ping time between pairs to check "they are there".
[DNPR]PeerTimeout	1 to 65535 ms	4000 ms	Timeout time in getting a response back from your peer.
[DNPR] UnitUsrpModeDefault [<unit>]UnitUsrpMode	0 means that an integrity poll will be issued  1 means that an RTU time read will be issued.  2 means nothing will be done.  3 means that a static (Class0) Poll will be issued.	3	Defines the default behavior on usurp of a unit.  The online status of the RTU is replicated between servers. So regardless of what the value is set to, the unit will initially have the same status as it had on the other server.  The polling sequence is also replicated, so the next periodic poll on the unit will occur at the same time it would have if the usurp had not occurred (unless a value of 0 is used, which results in the poll period being

			reset).
			<b>Note:</b> No event will be generated if the usurp mode is 3 (Static Poll) and the value in the device is different than the value in the driver cache.

## Port-based Parameters

### WARNING

#### UNINTENDED EQUIPMENT OPERATION

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

This parameters are used to manipulate port control.

Parameter	Allowable Values	Default Values	Description
[DNPR_<Port>] Exclusive Access	0 – Non-exclusive access 1 – Exclusive access	0	When set, the port and units adopt exclusive access mode. In this mode, only one server is physically connected to the port.  When a unit is usurped, the other port connects after the originating port disconnects.

## Event Processing Parameters

### WARNING

#### UNINTENDED EQUIPMENT OPERATION

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

These parameters are used to manipulate the handling of events.

Parameter	Allowable Values	Default Values	Description
[DNPR]	0 – Disable the digital/	1	Enables/disables event

EventProcessingEnable	<p>analog events to be pushed to the alarm/trend server.</p> <p>1 – Enable the digital/analog events to be pushed to the alarm/trend server.</p>		<p>processing.</p> <p>May be useful during testing.</p>
[DNPR] EventAtStartupDisable	<p>0 – Events are generated on the initial integrity poll.</p> <p>1 – Stop the initial integrity poll from generating events.</p>	0	<p>Help prevent an event that is not initialized from cache coming through summary system.</p>
[DNPR] PushIntegrityStaticsAsEvents	<p>0 - Do not enable generation of alarm/trend events from static data.</p> <p>1 - Enable generation of alarm/trend events from static data.</p>	1	<p>Enables generation of alarm/trend events from static data (with the timestamp set to the current time on the SCADA machine).</p> <p>It is recommended that this parameter is turned off (set to 0) when the DNP slave should be solely responsible for event generation. This may be desired when there is a time disparity between when the RTU acquires data and when it is received by SCADA, in which case the event timestamps would be incorrect.</p>
[DNPR] UTCTimeSyncDefault  [<unit>] UTCTimeSync	<p>0 – Local time used</p> <p>1 – UTC time used</p>	0	<p>Indicate if the stamp time of the events sent by the device is whether UTC or local time.</p> <p>The default is local time.</p>
[DNPR] RefreshEventsOnStartup	<p>0 – No events refresh</p> <p>1 – Event refresh</p>	0	<p>This Citect.ini parameter should only be set on one server - not on both peer sides. When this server is restarted, it will set the refresh tag. If this server</p>

			<p>is the active server for a unit, it will regenerate events.</p> <p>If another server is the active server for a unit, it asks the redundant server to regenerate events. So it is consistent that only active unit will generate events.</p> <p>This may be needed in some systems to force fresh alarms or trends on all data points to help ensure that the system starts in the correct state. The events are generated when receiving a response to an integrity poll or static poll.</p> <p>This parameter should not be set to 1 if the parameters [DNPR]IssueIntegrityPollOnUnitRecovery or [&lt;unit&gt;]IssueIntegrityPollOnUnitRecovery are set to 0. Otherwise, the events that were time-stamped before the timestamp of the events generated by the static poll will be ignored.</p>
--	--	--	--

## Communication Parameters

### UNINTENDED EQUIPMENT OPERATION

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

The DNPR driver supports the following communication parameters.

Parameter	Allowable Values	Default Values	Description
[DNPR]StartupStaggerDelay	0 to 30000 ms	0	Time between allowing the first unit on each port to come online at startup. This is to avoid large amounts of startup traffic.
[DNPR]MaxDNPTimeOuts [<unit>]MaxTimeOuts	0 to 65535	1	Number of unit timeouts before returning a ‘unit offline’ reply.  Unit timeouts can result from both the I/O server requests and driver polls (timeouts may result from the I/O server request or driver poll). Refer also to parameter [DNPR]RapidOfflineDetectionDefault.
[DNPR] RapidOfflineDetectionDefault [<unit>]RapidOfflineDetection	0 – Rapid detection is disable 1 – Rapid detection is enable	1	If RapidOfflineDetectionDefault is set to 0 (false), then a unit will only be placed offline due to a detected communication breakdown during regular polling requests.  Unsuccessful I/O server requests (e.g. Tag Writes), will not be taken into account when determining a units online status.  This parameter allows the driver to be configured to either provide rapid detection of offline status, or to provide a consistent interval of time before a unit is marked as offline.
[DNPR]MinorIINSelectErrorFilter	Refer to description	0x0000	This parameter allows the user to turn on the ability of the driver to generate a driver error (CDNP_ERR_IIN_ERROR)

			<p>to notify the user of several IIN (Internal indications bits) errors. These IIN errors are normally not considered serious, however in some circumstances, the IIN errors may need to be treated as if the unit is not operating correctly. Any combination of the following IIN errors can be detected by OR-ing the selected IIN error bits together to create the MinorIINSelectErrorFilter value.</p> <p>It should be noted that the errors are only notified under certain conditions. The conditions are noted in the Driver Specific errors section.</p> <p>The IIN bit errors that can be OR-ed together for selection purposes are shown below. The meanings of the terms are also described in the Driver-specific errors section.</p> <p>BAD_FUNCTION_IIN 0x0001 OBJECT_UNKNOWN_IIN 0x0002 OUT_OF_RANGE_IIN 0x0004 BUFFER_OVFL 0x0008 EXECUTING_IIN 0x0010 CONFIG_IIN 0x0020 LOCAL_IIN 0x2000 TROUBLE_IIN 0x4000 0x0000 means the error filter is off.</p> <p>Be reminded that the user can define tags to determine the status of</p>
--	--	--	--

			<p>the IIN flags returned from the device. Be reminded also that CDNP_ERR_IIN_ERROR is a severe level driver error and will force the unit offline and generate #COMs on the screen.</p>
[DNPR]MinorIINSelectFilter	Refer to description	0xFFFF	<p>This parameter allows the user to turn on the ability of the driver to generate a driver error (CDNP_WARN_IIN_ERROR) to notify the user of several IIN (Internal indications bits) errors. These IIN errors are normally not considered serious. Any combination of the following IIN errors can be detected by OR-ing the selected IIN error bits together to create the MinorIINSelectFilter value.</p> <p>It should be noted that the errors are only notified under certain conditions. The conditions are noted in the Driver Specific errors section. The IIN bit errors that can be OR-ed together for selection purposes are shown below. The meanings of the terms are also described in the Driver-specific Errors section.</p> <p>BAD_FUNCTION_IIN 0x0001 OBJECT_UNKNOWN_IIN 0x0002 OUT_OF_RANGE_IIN 0x0004 BUFFER_OVFL 0x0008 EXECUTING_IIN 0x0010</p>

			<p>CONFIG_IIN 0x0020 LOCAL_IIN 0x2000 TROUBLE_IIN 0x4000</p> <p>Note that the user can define tags to determine the status of the IIN flags returned from the device. Note also that CDNP_WARN_IIN_ERROR will not generate any #COMs on the screen.</p>
[DNPR]DataLinkConfirmDefault  [<unit>]DataLinkConfirm	0 - Off 1 - Sometimes (Multiframe only) 2 - On	0	Default Data Link Confirm mode.
[DNPR]DataLinkNoRetriesOnControlsDefault  [<unit>]DataLinkNoRetriesOnControls	1 - There are no data link layer retries when sending control messages such as direct operate, or select/operate.  0 - Normal retries apply.	0	Data Link retries on controls. Note: The data link layer will only retry if data link layer confirmations are used, see DataLinkConfirmDefault.
[DNPR]DataLinkRetriesDefault  [<unit>]DataLinkRetries	0 to 255	3	<p>Default number of attempts to retransmit after a data link timeout. This parameter is only relevant if Data Link confirmation is enabled (see parameter [DNPR] DataLinkConfirmDefault).</p> <p>Note: This parameter is ignored if the application function code is from 2 to 6 (Control requests) and data link retries are disabled for these function codes (see parameter [DNPR]DataLinkNoRetriesOnControlsDefault).</p>
[DNPR]DataLinkTimeOutDefault	0 to 65,535 (ms)	2000 ms	Default waiting period since last frame for a data link confirm –only if

[<unit>]DataLinkTimeOut			confirm requested.
[DNPR]DataLinkFrameSize	28 to 292	292	<p>For DNP devices that have small data link layer frames, then for the same size application layer buffer, more data link layer frames will be produced.</p> <p>The library that the DNPR driver utilizes was previously assuming that the DNP device would have a maximum data link layer frame size of 292 bytes, and an application layer fragment maximum size of 2048 bytes. This combination would result in a maximum of 9 frames per fragment.</p> <p>The library has been modified such that it will allow up to 64 frames per fragment, however the main practical restriction introduced is that the resulting application layer data from the combined frames will not overflow the application layer buffer.</p> <p>Now DNP devices with maximum data link layer frame size of less than 292 bytes are also supported.</p> <p>Similarly, the INI parameter [DNPR]DataLinkFrameSize allows the specification of the Max data link layer transmit frame size.</p> <p>The default value is 292 bytes. The parameter value is upper limited to 292 bytes, and lower</p>

			limited to 28 bytes.
[DNPR]TransDelay	0 to 65,535 (ms)	0 ms	Transmission Delay for use in RS485 networks.
<unit>]AppLayerTimeOut	0 to 2,000,000,000 (ms)	[<unit>]Timeout + [<unit>]TimeoutExtension (ms)	<p>Waiting period for application layer response.</p> <p>It is recommended that this should be set to approximately 10 times the DataLinkTimeOut to allow for confirms and link layer resets that may happen as part of a successful application layer transaction.</p> <p>There is no need to allow for the number of frames or fragments that are sent as part of an integrity poll, as the timeout gets reset when each frame of each response fragment is received.</p> <p>The timer is also reset when a data link layer transaction times out.</p>

## Polling Regime Parameters

### WARNING

#### UNINTENDED EQUIPMENT OPERATION

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

These parameters are used to manipulate polling.

Parameter	Allowable values	Default value	Description
[<unit>]EventPollPeriod	0 to 4,000,000 (seconds)	The current value for [DNPR] EventPollPeriodDefault	<p>Period to poll device for event class data.</p> <p>Integrity poll will poll for all classes (event and static data) after every</p>

Parameter	Allowable values	Default value	Description
			<p>EventPollRatio event polls.</p> <p>If the value is set to zero then the polling mode in the Citect.ini parameter [DNPR]ResponseModeDefault will be disabled. The device will stay offline until an integrity poll is forced out or an unsolicited message from the device is coming in.</p> <p>See <a href="#">Device Polling Regime</a> for an example.</p> <p><b>Note:</b> This Citect.ini parameter can be overwritten if the "Minimum Update Time" field for the I/O Device is greater than 0. (This option is only available with Plant SCADA from version 7.20.)</p>
[<unit>]PollPeriodOffset	0 to 2,000,000,000 (seconds)	0	<p>The amount of time in seconds before the first periodic poll occurs for this unit.</p> <p>A common start time is used for all units for this calculation. Subsequent polls occur every EventPollPeriod after the first poll, thus the offset is maintained between units for all subsequent polls.</p>
[DNPR] EventPollRatioClass1Default  [<unit>] EventPollRatioClass1	0 to 65,535	1	<p>How many class 1 event polls to be issued.</p> <p>A value of 2 would mean that this event class happens every n second poll period.</p> <p>0 will turn class 1 polls off (Note: The integrity poll</p>

Parameter	Allowable values	Default value	Description
			will still ask for class 1 static data). See <a href="#">Device Polling Regime</a> for an example.
[DNPR] EventPollRatioClass2Default [<unit>] EventPollRatioClass2	0 to 65,535	1	How many class 2 event polls to be issued. A value of 2 would mean that this event class happens every n second poll period. 0 will turn class 2 polls off. (NB: The integrity poll will still ask for class 2 static data). See <a href="#">Device Polling Regime</a> for an example.
[DNPR] EventPollRatioClass3Default [<unit>] EventPollRatioClass3	0 to 65,535	1	How many Class3 event polls to be issued. A value of 2 would mean that this event class happens every n second poll period. 0 will turn Class3 polls off. (NB: The integrity poll will still ask for class 3 static data). See <a href="#">Device Polling Regime</a> for an example.
[DNPR]EventPollRatioDefault [<unit>]EventPollRatio	0 to 65,535	10	Default number of event class polls for every integrity poll. Integrity poll will poll for all classes (event and static data). Be reminded that a value of zero implies that only integrity polls are conducted. See <a href="#">Device Polling Regime</a> for an example.
[DNPR] IssueIntegrityPollOnUnitR	0 – Unit recovery carried out with a static poll	0	Enable this setting if the driver should recover a

Parameter	Allowable values	Default value	Description
eccovery [<unit>] IssueIntegrityPollOnUnitR ecoverystatic	1 – unit recovered using integrity poll		device by issuing integrity (static class and event class) poll. static (static class) polls are issued to recover a device if this setting is disabled (default)
[DNPR] AutoUnsolicitedEnableDef ault [<unit>]AutoUnsolicitedE nable	1 for class 1 2 for class 2 4 for class 3 (or any combination thereof)  A value of zero (0) will result in NO classes being enabled for unsolicited responses.  The default value of 7 enables all classes.	7	This provides the ability to explicitly specify the classes to be enabled for unsolicited responses at start-up.  Currently when a device is brought on-line, the driver will send a command to enable unsolicited responses for all classes. This command is only sent if the "Restart" bit is set in the IIN flags.  This parameter will only take effect if the parameter "[DNPR]ResponseModeDefault" has "unsolicited msg" enabled.  Be reminded that the driver also has a 'virtual' data type for enabling/disabling unsolicited responses in a unit. The classes enabled will be as specified by this parameter.
[DNPR] IntegrityPollOnUnsolicited Default [<unit>] IntegrityPollOnUnsolicited	0 – No integrity polls are issued when receiving unsolicited data from an offline device  1 – Unsolicited data from the device causes an integrity poll when the device is offline, in order	0	Send an integrity poll when receiving an unsolicited message for an offline device.

Parameter	Allowable values	Default value	Description
	to bring the device online if possible.		
[DNPR] IPonECPModeDefault [<unit>]IPonECPMode	0 – For any response, immediately send an Event Poll  1 – For any response, immediately send an integrity poll  2 – For an integrity poll response, immediately send another integrity poll, for any other response immediately issue an Event Poll  3 – Disables any polls being sent on IIN bits set except the Overflow bit  4 – Disables any polls being sent on IIN bits including the overflow bit.	2	Defines the follow-up action to be taken when a response is received with any of the class 1, 2, or 3 IIN bits set.
[DNPR] EnableRestartIINDefault [<unit>]EnableRestartIIN	0 – Unit restart sequence is not carried out when restart IIN flag is detected  1 – Unit restart sequence is carried out when restart IIN flag is detected	1	Only disable if all devices are not able to clear their restart IIN flag (as required for DNP compliance). When disabled, the driver will not perform a unit restart sequence (clear restart flag, integrity poll and Enable Unsolicited messages) when a restart IIN flag is detected in a response.
[DNPR] EnablePollPeriodWritesDefault [<unit>] EnablePollPeriodWrites	0 – Disable 1 – Enable	0	Enable the adjustment of the device's poll period via writing to a tag of address 'PollPeriod'.  This is a security feature to help ensure that an operator is not inadvertently given access to adjust the poll period.

Parameter	Allowable values	Default value	Description
[DNPR] IssueClassPollOnUnitRecover [<unit>] IssueClassPollOnUnitRecover	0 – Unit will recover based on the INI parameter "IssueIntegrity PollOnUnitRecovery"  1 – Unit recovered using Class 1 poll  2 – Unit recovered using Class 2 poll  3 – Unit recovered using Class 3 poll	0	Enable this setting if the driver should recover a device by issuing Class 1, Class 2, or Class 3 poll.  Note: The driver will not issue any polls if we configure this parameter along with the INI parameter "EventPollPeriodDefault" with the value Zero.
[DNPR] MaxOperateDelayDefault [<unit>]MaxOperateDelay	1000 to 60000 ms	5000 ms	The RTU configured max delay between a SELECT to OPERATE command in ms.  This is used in the driver to freeze any polling for up to this period to allow the OPERATE command to work.
[DNPR] ChannelTransmissionsPerCpuCount	0 to 20	0	During each poltime, the waiting messages are sent to each RTU. The default behavior is to send these messages out in the order they exist in the driver (when set to 0).  However, some RTUs prefer the messages to go out on one COMs channel, then the next etc.  Setting this value allows this behavior to happen, e.g. if set to 2 (and data was waiting for Ports 0,1,2,3), then the first poltime scan would send data out on Port 0, then Port 1, then wait until the next poltime scan, and send data out to Port 2, then Port 3.

## Data Point and Cache Parameters

### WARNING

#### UNINTENDED EQUIPMENT OPERATION

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

The DNPR driver supports the following data point and cache parameters. These parameters control variations of behavior for some data types, as well as data cache behavior.

Parameter	Allowable values	Default value	Description
[DNPR]UseFeedBackPoll [<unit>]UseFeedBackPoll	0 - 3 (See description.)	1	Sets the FeedBack mode. 0=Use Integrity poll instead of Feedback Poll to update cache after control action or counter freeze action. 1=Use Feedback poll to update cache after counter freeze or analogue or binary writes (Feedback Poll requires devices to support reads to Binary Output Status, Analogue Output Status, Binary Inputs, Analogue Inputs, Counters and Frozen Counters). The following reads are carried out if the operation is a counter freeze write: class 1, class 2, class 3, Counters and Frozen Counters reads. The following reads are carried out if the operation is an analogue or binary write: Binary Output Status, Analogue Output Status, class 1, class 2, class 3, Binary Inputs and Analogue Inputs reads. This mode requires Level 3 DNP support in the RTU.

Parameter	Allowable values	Default value	Description
			2= Do not perform any type of immediate poll after a control write. This mode will be implemented for devices that can provide an unsolicited update of any feedback changes (caused by control writes). 3= Use an individual point read to update the cache after analogue or binary writesSee "Allowable Values" for more details.
[DNPR]UseSelectClear	0 – Time read request is used to cancel a SELECT request. 1 – An OPERATE with the CLEAR bit set is used to cancel a SELECT request.	0	Default way to handle a cancel of select operation. This is to send an OPERATE with the CLEAR bit set. If your RTU hardware does not support that then setting this parameter to 0 will send a dummy time read instruction to cancel the SELECT operation (that is because the OPERATE command has to be the next sequence number and a dummy command will force the cancel the SELECT request.)
[DNPR]FailOnTagFlagSet	0 - Check quality disabled 1 - Check quality enabled	0	Enable quality check in tag read when the tag flag is set. Fail tag on tag read if the quality is not GOOD (#com will be shown on client display). Note:This parameter is only valid when the driver is running on SCADA 7.10 or early.
[DNPR]DataLagDefault	0 to 2,000,000,000	0	Data in cache is only

Parameter	Allowable values	Default value	Description
[<unit>]DataLag	(seconds)		<p>considered fresh if it is no older than the combined periods of:</p> <ul style="list-style-type: none"> <li>Period between integrity polls</li> <li>AND Period of complete timeout sequence (ie initial and retried timeouts)</li> <li>AND DataLagDefault period (tolerated poll delay).</li> </ul> <p>The first time data is retrieved from cache for a unit and the data is not fresh, error 0x61 is generated and a tag read with virtual address LateRefresh will return TRUE.</p> <p>This condition is reset when the late poll for the device is eventually received.</p>
[DNPR] DataInvalidationFactorDefault  [<unit>] DataInvalidationFactor	0 to 65535.	2	<p>As explained in DataLagDefault, data in cache is only considered to be fresh for a certain amount of time. After this time has been exceeded, the data is considered to be valid, but not fresh.</p> <p>If the data in cache is still not refreshed after a further 'n' Event periods of time (where 'n' = DataInvalidationFactorDefault), then the data in cache is no longer considered valid, and data retrieved from cache in this state will be marked with error 0x54.</p>
[DNPR]	0 – An error is returned if	0	Indicate if errors of read

Parameter	Allowable values	Default value	Description
IgnoreReadErrorsOnWrite	trying to read "write only" tags. 1 – 0000 data with no error is returned when reading "write only" tags.		requests on "write only" tags are to be ignored. This is needed when using dialup devices as SCADA reads ALL tags at connect time.
[DNPR] IgnoreWarnIfOneOK	0 – A bad Quality is returned if there is missing or stale data in a read block. 1 – Bad Quality is not returned when there is missing or stale data in a read block provided at least one item in the block is OK. This is useful when points are not configured in the RTU and the read block is requesting these, but SCADA does not use them.	0	Bad Quality should be indicated or not if at least one item is valid in a block read request. This parameter applies to digital points as well as other points.
[DNPR] RetZeroOnCROBInvalid	0=Test validity of Binary Output Control Status data. 1= Do not test validity of Binary Output Control Status data.	0	Flag indicating whether Binary Output Control Status data is to be tested for validity (before a Binary Output Control Status point can be valid, the corresponding binary point requires a written value). If not tested for validity, then if an invalid Binary Output Control Status point is read, then a zero will be displayed.  If the type IS to be tested for validity, then if any point within a I/O server multiple point request is invalid, then the response to the request indicate an error condition. A solution in this case might be to write to all Binary points at startup.

Parameter	Allowable values	Default value	Description
[DNPR] RetZeroOnAOOBInvalid	0=Test validity of Analog Output Control Status data  1= Do not test validity of Analog Output Control Status data.	0	Flag indicating whether Analog Output Control Status data is to be tested for validity in the same manner as for RetZeroOnCROBInvalid above.
[DNPR]Commissioning	0= Treat non-polled points as irrelevant  1= Force non-polled points to #COM (default applies to all devices)	0	A device may have digital types as a non-contiguous list, and may start or end on points not on an 8 bit boundary. As Plant SCADA will block a minimum of 8 bits for digitals, and enforce an 8 bit boundary, requests may include points that are not received by the device or that are invalid for the device. For this reason, the driver assumes that bits that are not updated by the polling sequence are irrelevant and not configured as tags by the user.  These points will return 0 and NO_ERROR to avoid forcing the valid points in the same DCB into error. The driver waits until the first successful data acquisition poll, before determining if a point as irrelevant.  Commission all points of the project to ensure that every tag does indeed refer to a point that is refreshed by the polling routine. The flag commissioning tests for invalid BI points, by not forcing the point to 0 and NO_ERROR. This will then

Parameter	Allowable values	Default value	Description
			#COM all points in the DCB containing the invalid digital point.  Also when this INI is set, the event system will log to "dnpr_logger.txt" the name of tags which are considered irrelevant, e.g. "#TRACE,Irrelevant_point, BI023, in,Unit_035".
[DNPR] IsItemisedRequest	1=Individual I/O server-to-Driver Non-digital requests (RECOMMENDED)  0= I/O server-to-Driver requests are blocked (default applies to all devices).	1	Requests for a basic DNP poll do not use a blocking (grouping) algorithm as applies to a lot of protocols. Instead the required points are predefined in the device (as Class 0), and are requested during an integrity poll.  The DNPR driver can support requests of up to 2048 bits in one request from The I/O server, but this is for contiguous data. The data available in the driver cache will not be contiguous if the predefined points in Class 0 are not contiguous.  The I/O server request will be flagged as bad quality (#COM) if any one of the points in the requested block are not defined in Class 0.  To prevent this situation from occurring, non-digital data is not blocked by default. Requests from The I/O server to the driver, for non-digital data, are for individual points. Be reminded that

Parameter	Allowable values	Default value	Description
			<p>this does not affect the data acquisition algorithm between the driver and the device, only between the I/O server and the driver. Digital types still will be optimized together. A device may have digital types as a non-contiguous list, and may start or end on points not on an 8 bit boundary. As the I/O server will block a minimum of 8 bits for digitals, and enforce an 8 bit boundary, the driver assumes that bits that are not updated by the polling sequence are irrelevant and not configured as tags by the user. These points will return 0 and NO_ERROR to avoid forcing the valid points in the same DCB into error.</p> <p>The flag commissioning tests for invalid BI points. The default should provide the solution for a DNP project, however, if it is decided by a Plant SCADA representative that blocking is required between the driver and the I/O server, set IsItemisedRequest to zero.</p> <p>Change MAX_LENGTH and BIT_BLOCK fields for the DNP protocol (in the \BIN\PROTDIR.DBF file) to the required blocking length in bits, and copy the PROTDIR file to your Plant SCADA project</p>

Parameter	Allowable values	Default value	Description
			<p>directory.</p> <p>Modify the Citect.ini file to configure the 'Block' parameter to the required value in bytes, and also the 'MaxBits' parameter to the required value in bits. Disable the incremental compile option and then recompile your project.</p> <p>Note: If you reinstall Plant SCADA, the PROTDIR.DBF file is overwritten, so repeat the change.</p>
[DNPR]MaxBits	1 to 2048 (bits)	2048	<p>Max Block Size constant (only applies when IsItemisedRequest is set to zero).</p> <p>This value should be left at default unless modifying IsItemisedRequest parameter to block read requests to a specific value. Refer to description of IsItemisedRequest.</p> <p>Note: This field only applies to read requests; writes will be allowed to the maximum that will result in one application layer fragment, but cannot be greater than 2048 bits.</p> <p>Write blocking can be disabled by setting the INI parameter [&lt;IOServer&gt;] 'Blockwrites' to 0.</p>
[DNPR]ReqDelay	0 to 65535 (ms)	20	Delay used when servicing a read request by reading from cache.

## Miscellaneous Parameters

### **WARNING**

#### **UNINTENDED EQUIPMENT OPERATION**

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

Parameter	Allowable values	Default value	Description
[DNPR] ResponseModeDefault [<unit>]ResponseMode	0 to 15	11 (Polled, Unsolicited enabled, Perform time synch when requested)	Default response mode, composed from a combination of:  1 = Polled (Must be set to enable device polling for event class data)  2 = Unsolicited enabled (Must be set to enable unsolicited value updates)  4 = Use Delay Measurement (By default, the driver will use the Record Current Time command (Function Code 24) when performing time synchronization. When this bit is set, it will use Delay Measurement command (Function Code 23))  8 = perform time synch when requested (When set, the driver performs time synchronization after receiving IIN1.4 bit from the device)  In the case where "Use Delay Measurement" is selected, then the parameter [DNPR]ReqDelay should also be set.
[DNPR]StartupDelay	0 to 'WatchTime' (seconds)	0	Allows the unit initialization (and subsequent online check) to be delayed.  This Citect.ini parameter can be used, in conjunction with a Cicode IODeviceControl() call at start-up to disable units

Parameter	Allowable values	Default value	Description
			<p>before they transmit an online check for unit initialization.</p> <p>A delay of a couple of seconds should suffice. Do not delay more than the setting for WatchTime.</p>

## Device Group Parameters

### WARNING

#### UNINTENDED EQUIPMENT OPERATION

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

For the following parameters, [<unit>] represents the Citect.ini section name that is defined with the following precedence:

- *Device group*: as defined in the Address field of the I/O Device. (This section is not recommended. You should choose the next section instead.)
- *Protocol.DeviceGroup*: Protocol is DNPR, DeviceGroup defined in the ‘Address’ field of the I/O Device.
- *Protocol.PortName*: Protocol is DNPR, PortName is defined in the ‘Port Name’ field of the Port.
- *Unit\_x* where x is the value in the Number field on the I/O Device. (This section is not recommended. You should choose the next section instead.)
- *Protocol.PortName.UnitName*: Protocol is DNPR, PortName is defined in the ‘Port Name’ field of the Port, UnitName is defined in the ‘Unit Name’ field of the IODevice.

## Example:

- ‘Address’ field of the IODevice: 128 SITERTU
- ‘Number’ field of the IODevice: 10
- ‘Unit Name’ field of the IODevice: PrimaryIODev128
- ‘Port Name’ field of the Port: PrimaryPort1

## INI section names:

- [SITERTU] (Not recommended anymore)
- [DNPR.SITERTU]
- [DNPR.PrimaryPort1]
- [Unit\_10] (Not recommended anymore)

- [DNPR. PrimaryPort1. PrimaryIODev128]

These parameters are used to configure behavior that will only apply to units with the same device group, in the Citect.ini section called <unit>.

They are as follows:

## Driver-specific Parameters

- [<unit>]SCADAAddress
- [<unit>]Timeout
- [<unit>]Retry
- [<unit>]TimeoutExtension
- [<unit>]OnTimeBODeviceDefault

## Peer Redundancy Parameters

- [<unit>]ActivateIfPeerIsActiveOffline
- [<unit>]UnitUsurpMode
- [<unit>]SyncReplication

## Event Processing Parameters

- [<unit>]UTCTimeSync

## Polling Regime Parameters

- [<unit>]EventPollPeriod
- [<unit>]PollPeriodOffset
- [<unit>]EventPollRatioClass1
- [<unit>]EventPollRatioClass2
- [<unit>]EventPollRatioClass3
- [<unit>]EventPollRatio
- [<unit>]IssueIntegrityPollOnUnitRecovery
- [<unit>]AutoUnsolicitedEnable
- [<unit>]IntegrityPollOnUnsolicited
- [<unit>]IPonECPMode
- [<unit>]EnableRestartIIN
- [<unit>]EnablePollPeriodWrites
- [<unit>]MaxOperateDelay

## Communication Parameters

- [<unit>]MaxTimeOuts
- [<unit>]RapidOfflineDetection
- [<unit>]DataLinkConfirm
- [<unit>]DataLinkNoRetriesOnControls
- [<unit>]DataLinkRetries
- [<unit>]DataLinkTimeOut
- [<unit>]AppLayerTimeOut

## Data Point and Cache Parameters

- [<unit>]UseFeedBackPoll
- [<unit>]DataLag
- [<unit>]DataInvalidationFactor

## Miscellaneous Parameters

- [<unit>]ResponseMode

## DNPR Redundancy

In other Plant SCADA drivers, the I/O Server controls the redundancy switchover based on the redundant I/O Devices state (online/offline) and configured I/O Device priorities. The DNPR driver redundancy support is different. It performs the redundancy switchover (makes either the primary or the standby I/O device active and usurps the connection) by itself, or you can do it manually by using the virtual unit control tags.

In normal driver redundancy, if both primary and standby units (the representation of the I/O device in the driver software) are connected to the device, communication happens via the primary unit. If the connection to the primary unit is lost, the I/O Server switches communication to the standby unit. If the connection to the primary unit is restored, the I/O Server switches communication back to the primary unit.

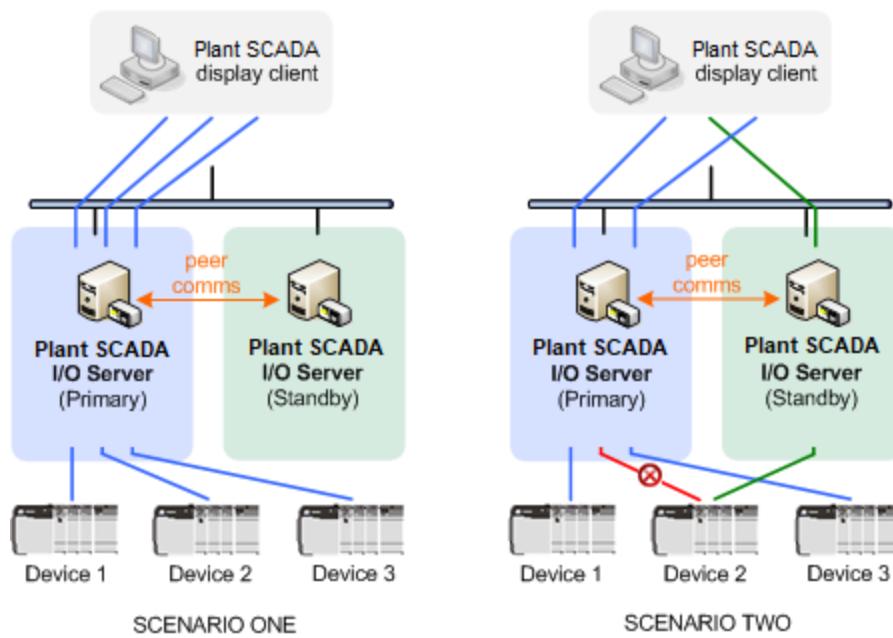

In DNPR driver, the priority for unit use is not based on the primary unit when a driver is started. The unit that is in use continues in service. If both drivers become active (that is, peer connection lost) then the priority for unit use is based on the primary unit when the peer connection is reestablished.

In the redundant configuration, the primary and standby I/O Device pair is configured on different I/O Servers. The DNPR drivers on these servers communicate to each other to synchronize the redundant unit states, the tag and the event/trend cache data.

The driver only communicates with a device if the unit is in the active state. The unit is active only on one peer driver at one time, except for the case when the communication between the redundant I/O Servers is lost and both units go into the active state.

When a unit is active, the driver reports the current online/offline state to Plant SCADA. If the unit is not active, it appears as offline to Plant SCADA. The driver does not communicate to the device if the unit is not active. It does not send any DNP3 frames to the device, or process any frames received from the device.

The following diagram illustrates a typical redundancy configuration showing a pair of redundant I/O servers and a network of DNP3 devices:

**SCENARIO ONE:**

Normal operation, with devices communicating via the primary server.

**SCENARIO TWO:**

Redundancy switchover due to an interruption to the communication channel between the primary I/O server and device two. Even after the communication channel to the primary I/O Server is restored, communication to device two continues via the standby I/O Server.

## Redundancy Configuration

The driver supports single level redundancy only, so a unit can only have one peer (redundant) unit. Configure this unit on a separate I/O server. A unit cannot have a redundant unit within the same I/O server.

The ini parameters required for setting up the peer redundancy are described in [Peer Redundancy Parameters](#).

The following example shows the minimum number of parameters required to set on primary and standby I/O Servers:

**Primary I/O Server:**

```
[DNPR]
EnablePeerRedundancy = 1
LocalAddress = 10.176.234.11
LocalPort = 5200
PeerAddress = 10.176.232.61
PeerPort = 5200
```

```
[IOMServer]
WatchDogPrimary = 1
```

**Standby I/O Server:**

```
[DNPR]
EnablePeerRedundancy = 1
LocalAddress = 10.176.232.61
LocalPort = 5200
```

```
PeerAddress = 10.176.234.11
PeerPort = 5200
[IOServer]
WatchDogPrimary = 1
```

### Manual Redundancy Switchover (Usurping)

To choose the peer driver (I/O server) on which a unit will be active, use the following tags:

#### Primary request tags:

- Unit<n>.RequestUnitActive.Primary

Writing 1 to a primary request tag causes the unit to be active on the driver on the primary I/O server. Writing 0 causes the unit to be active on the driver on the standby I/O server.

#### Standby request tags:

- Unit<n>.RequestUnitActive.Standby

Writing 1 to a standby request tag causes the unit to be active on the driver on the standby I/O server. Writing 0 causes the unit to be active on the driver on the primary I/O server.

The request tags can be read at any time, and return the value last written to the tag.

The user can monitor which peer driver (I/O server) has an active unit, using the following tags:

- Unit<n>.UnitActiveState.Primary
- Unit<n>.UnitActiveState.Standby

If the unit is active on the primary I/O server driver, then the primary tags return 1 and the standby tags return 0. If the unit is active on the standby I/O server driver, then the standby tags return 1 and the primary tags return 0.

You can also use the following addresses to determine a port's online status for diagnostic purposes.

- Unit<n>.UnitPortState.Primary
- Unit<n>.UnitPortState.Standby

This online status is the TRUE online status. Be aware of this when using ExclusiveAccess mode for ports.

Remember that the port that is reported on is the one which matches your tag. If required, you can have units on one port that are PRIMARY, STANDBY, PRIMARY, and so on.

### Automatic Redundancy Switchover (Usurping)

When either primary or standby I/O Server unit starts up, it establishes a connection with a configured peer unit if available. If the peer unit is active, the driver puts the local unit to inactive state and leaves the peer driver to communicate with the device.

Both units become active when communication is inoperable between the I/O Servers. The DNPR drivers exchange states when the communication is reestablished. As both units are active, the driver sets the standby

I/O unit inactive and communication to the device continues via the primary unit.

Only the active unit sends DNP3 frames to the device and processes the frames received from the device.

A unit becomes active when:

- There is no redundant unit. (It is not configured or disabled.)
- The driver finds that its peer is deactivating or is in an inactive state.
- The communication between the I/O Servers is lost. After the connection re-establishes, the standby unit sets to inactive.
- Forcing it to be active by writing to one of the virtual unit control tags.

The automatic switchover (usurping) of units can also happen when the unit port is set offline. The driver reports "CHANNEL\_OFFLINE": driver error 20 (0x14) and generic error 21 (0x15).

The port is set offline when:

- The TCP/IP connection is closed or cannot be opened.
- There is an error report from one of the low-level communication functions.
- There is a request to disconnect the internal port. For example, an I/O Server shutdown, or scheduled use of I/O Server.

The lack of an RTU reply does not mean that a TCP/IP connection is dropped. For example, the removal of a cable at a router is unlikely to close a connection. The specific situation and redundancy control of a site is unique to the site.

That is why usurp control is available via driver tags. Users need to engineer the control (via Cicode) if the default driver handling does not match their needs. It is recommended to make the override usurp control available via an engineering screen to cover any unusual circumstances. An active server has its DNPr units usurped across to the other server before the server is shutdown.

Also, configure the field communication hardware to drop the connections if regular updates does not occur. It helps to ensure that the communications can be reinstated. When gateways are used, and availability of a RTU unit is hidden, then some active update counter should be used and Cicode added to check on count changes. That is, if counter is not incrementing then do X.

## Port-level Redundancy

Normally, Plant SCADA port control involves opening a port at startup and closing it at shutdown (except when used in a scheduled device or dialup situation). However, if an RTU supports multiple IP connections, it will normally get a connection from the primary AND secondary port (normal Plant SCADA redundancy). This may not be acceptable for an RTU.

To help resolve this, ExclusiveAccess mode was introduced in to the DNPR driver (see [Port-based Parameters](#)).

## Exclusive Port Access

When you connect to devices like terminal servers, which only support one connection at a time, port control is required.

An Citect.ini parameter has been provided to set a port's mode to "ExclusiveAccess". In this mode, when any unit on a port is usurped (moved from one state to another) from being active to inactive, the port connection is

dropped. This will allow the port on the redundant server to have access to the device(s), bringing any associated units into action.

When using ExclusiveAccess mode, ports on both sides need to have the Citect.ini parameter set. Additionally, the virtual unit on the port needs to follow the active port, as the physical port may not be online (e.g. the RTU is offline).

Hardware which only allows one connection should have an "inactivity timer" set, so the connection is dropped if it is not used. For example, a terminal server needs to drop its connection if no communication has occurred after "x" seconds. This allows access to the unit from another server if the current connection is broken.

If the hardware doesn't support this, you may want to consider using the -K option on the TCP/IP driver combined with registry "Keep Alive" changes.

## Driver Cache Replication

The driver maintains a database of values received from devices known as the cache.

The cache is updated by both event and static data. When updating this cache with values received from the device, the active unit replicates these values to the non-active unit on a peer driver over the TCP link between the peer drivers.

To send the DNP3 acknowledge to the device after all received values have been replicated to the peer, use the Citect.ini parameters SyncReplicationDefault and SyncReplication.

This behavior is preferable (but not default) as it helps ensure that no data will be lost in case the active server dies in the instant straight after it acknowledges the transaction to the RTU but before the values are replicated to the peer. Also, the DNP3 acknowledge will be sent straight away if the peer TCP link is lost.

On cold start-up, if there is a running peer driver, the cache is synchronized from the running peer's cache prior to the unit, on the starting driver, being allowed to become active. If no peer driver is found, or there is no redundant unit, the cache is cleared.

The cache value replication throughput is faster than 100 values per second provided that the underlying Windows operating system and TCP network does not introduce delays. This rate can be expected on a 10Mbit network that is not congested.

There is no disk file image of the driver cache. On cold start after a total system shutdown (shutdown of both peer drivers) the cache is empty.

## Trend and Alarm Backfilling

The trend and alarm backfilling use event queues that hold events until they are back filled into the Plant SCADA trend and alarm systems. The queue of events waiting to be processed for backfilling will be replicated between the drivers using the same TCP communications link that the cache replication uses.

The event queues in peer drivers are kept synchronized in the same manner as the driver cache is kept synchronized. That is, the image is copied on unit start-up, if there is a peer, and is kept synchronized by replication on queue state change.

There is no disk file image of the event queue. On cold start after a total system shutdown (shutdown of both peer drivers) the queue is empty.

---

**Note:** If some events have not been pushed to the alarm/trend servers and both I/O servers shutdown then the events and trend data will be lost.

---

## Example

A device generates an event and sends it to the active I/O server. The active I/O server will then send the event to the peer I/O server. When it receives the event, the peer I/O server will add the event into its internal queue. Then the active I/O server then adds the event to its internal queue before sending it to the alarm/trend server. The alarm/trend server sends an acknowledgement to the active server on receiving the event. The active I/O server sends a message to the peer to remove the event from its internal queue. The event is then removed from the internal queue of the active I/O server.

### Value Writes

Tag writes (such as controls) which result in a DNP3 transaction, are not replicated between peer drivers.

The 'Write Fail' and 'Write Pending' flags are zero in an inactive peer driver's database. Therefore, if a usurp occurs during a control write, then the WritePending and WriteFail flags will both be zero regardless of whether or not the write was completed.

### Action on Becoming Active

The driver is configurable to perform the following action when a unit becomes active:

- Send DNP3 link reset and then an integrity poll to the device. The polling sequence is reset to start from the time the unit became active.
- Send DNP3 link reset and then read the RTU time. The polling sequence is not changed and continues as if nothing happened.

---

**Note:** The driver may perform additional DNP3 transactions depending on the states of the IIN bits. In particular if the IIN restart bit is set, the driver will perform an integrity poll. If any of the class 1, 2, or 3 event flags are set the driver will perform an event poll if the reset bit is not set.

---

- Send DNP3 link reset and then a Class0 (Static) poll to the device. The polling sequence is reset to start from the time the unit became active.

### Data Acquisition within DNP3

DNP3 offers an array of methods for data acquisition from DNP3 devices, but not all devices will support all methods of data acquisition. The simplest form of data acquisition, and the one that all DNP3 devices support, is the acquisition of a group of points that have been pre-defined in the device. This is known as a class request.

DNP3 devices have four definable groups (classes) of I/O points:

- Class 0 lists the I/O points that are to have their current value sent back to Plant SCADA, when Plant SCADA sends a Class 0 request.
- Class 1 lists the I/O points that are to have their events sent back to Plant SCADA, when Plant SCADA sends a class 1 request.
- Class 2 and class 3 are conceptually the same as class 1 but are separate groups to allow prioritizing of event data.

To summarize, class 0 requests will result in a reply containing the current value of all of the predefined I/O points, whereas class 1, class 2, and class 3 requests will result in a reply containing all of the buffered events that have occurred for all of the predefined I/O points in class 1, class 2, or class 3.

The DNP3 protocol ensures that if a request is made to a device for Class 0, class 1, class 2, and class 3 data, then the device will reply with all of the buffered events (with the most recent event received last), and then reply with the current data. The order in which the data arrives guarantees the most recent value is held in the driver cache, and the inclusion of Class 0 static data assures that data acquisition is not overly dependent on the report-by-exception mechanism. This form of all-classes poll is termed an integrity poll.

The device may automatically send event data to Plant SCADA (this is termed an Unsolicited Response), or it may wait until Plant SCADA requests class 1, class 2, or class 3 data. In either case the driver will update its cache with the value received in the event data, and also check if the event is related to an alarm tag or a trend tag that needs processing.

Citect.ini parameters exist that allow event polls to be isolated into classes. The default behavior is that all event classes are polled on each event poll. The following Citect.ini parameters control the ratio for each class to the event poll (see [Polling Regime Parameters](#)):

- [DNPR]EventPollRatioClass1Default
- [DNPR]EventPollRatioClass2Default
- [DNPR]EventPollRatioClass3Default
- [<unit>]EventPollRatioClass1
- [<unit>]EventPollRatioClass2
- [<unit>]EventPollRatioClass3

A value of zero will turn event polls off for that class. A value of 2 would mean that this event class happens every n second poll period. Be reminded that the integrity poll always asks for the static data for all event classes.

The default DNP3 master address for Plant SCADA is defined by the parameter [DNPR]SCADAAddress. Define this master address in the slave device, if the slave is to send unsolicited responses to Plant SCADA. A different master address can be specified in each unit, using the device-level parameter [<unit>]SCADAAddress.

If the device does support unsolicited responses, then having all I/O points report through exception (send events on change of data) will allow Plant SCADA to poll (with an integrity poll) the device infrequently. This data acquisition algorithm requires very low traffic throughput on the network.

If the device does not support unsolicited responses, then more frequent Plant SCADA polling (with event polls for all classes) will keep its cache up-to-date. After every *n* event polls, Plant SCADA sends an integrity poll to ensure the data integrity of the driver cache. The period between polls for a device is defined by [DNPR]EventPollPeriodDefault and [<unit>]EventPollPeriod, and the ratio of Event Polls for every integrity poll for a device, is defined by [DNPR]EventPollRatioDefault and [<unit>]EventPollRatio.

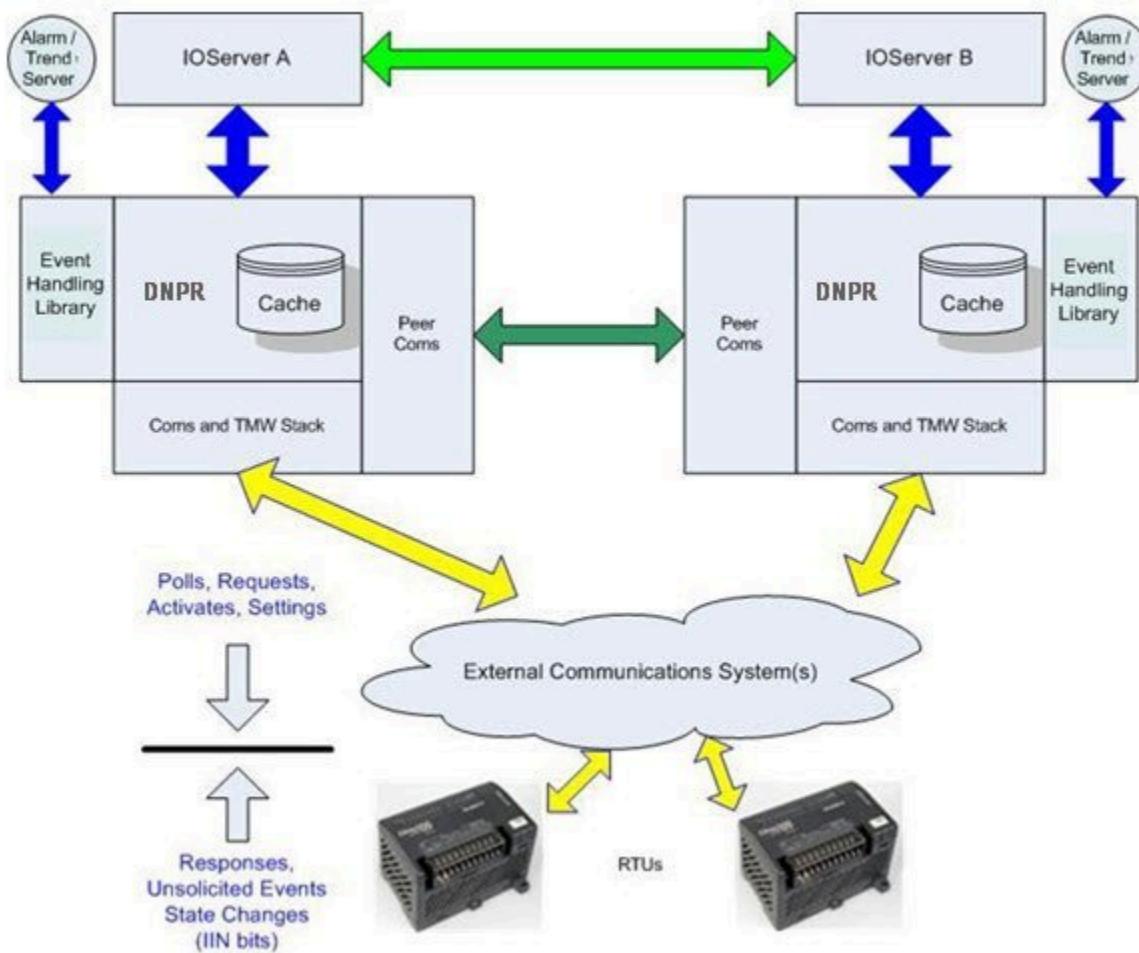

If the device does not support report-by-exception (i.e. it does not buffer event data but will only reply with current data) then the EventPollRatio should be set to zero so that only integrity polls are issued, and the EventPollPeriod should be set to a low value in order to keep the driver cache up-to-date.

The DNP3 protocol also offers other data acquisition algorithms in which the device master (Plant SCADA) can request points that are defined by the master, not by the slave. There are numerous methods, each offering varying levels of control the master has in determining which points it can request. As the level of support for these data acquisition algorithms differs from device to device, and some devices do not support these data acquisition algorithms, Plant SCADA will only implement the Class read data acquisition algorithm described above.

In summary, all of the I/O points in a device that are required by Plant SCADA should be allocated to Class 0 in the device. If the device supports report-by-exception (which is strongly recommended), then also allocate each point to one of the event classes.

## Example

The following diagram gives an overview of the DNPR functional blocks. Debug options are also along these functional block lines.

## Blocking

Requests for a basic DNP3 poll do not use a blocking (grouping) algorithm as applies to a lot of protocols. Instead, the required points are predefined in the device (as Class 0), and are requested during an integrity poll. The DNPR driver can support requests of up to 2048 bits in one request from Plant SCADA, but this is for contiguous data. The data available in the driver cache will not be contiguous if the predefined points in Class 0 are not contiguous. If any of the points in the requested block is not defined in Class 0, all points in a Plant SCADA request will be flagged as bad quality (#COM).

To avoid this situation, non-digital data is not blocked by default. All requests from Plant SCADA to the driver for non-digital data are for individual points. This does not affect the data acquisition algorithm between the driver and the device, only between Plant SCADA and the driver. Digital types will still be optimized together. A device may have digital types as a non-contiguous list, and may start or end on points not on an 8-bit boundary.

As Plant SCADA will block a minimum of 8 bits for digitals, and enforce an 8-bit boundary, the driver assumes that bits not updated by the polling sequence are irrelevant and not configured as tags by the user. These points

will return 0 and NO\_ERROR to avoid forcing the valid points in the same DCB into error. The [DNPR]Commissioning Parameter tests for invalid BI points.

Digital Reads are blocked by Plant SCADA to a minimum of 8 bits. A DNP device can configure points in a non continuous fashion, for example, points 0 to 4, then 10 to 14, and so on. Therefore, non-digital Plant SCADA requests are not blocked so as to avoid the situation where a blocked request may also include a point in cache that is not part of the pre-defined DNP3 group. This is why the default protdir.dbf entries are 8 & 8 bits.

If you know your RTU devices have continuous point allocations, then the compile time value can be increased. For example, if 32 digitals are configured then the value could be set to 32 & 32 in protdir.dbf.

Runtime blocking is controlled by the [DNPR]Block=x, the [DNPR]IsItemisedRequest=y parameter, and the [DNPR]MaxBits=z parameters. This allows you to block together several read requests in the IOServer.

Block = MaxBits / 8, IsItemisedRequest=0

Set the runtime values at least equal the compile time settings. They can however be larger than compile time settings.

If you wish to remove any residual block errors, then you can use the [DNPR]IgnoreWarnIfOneOK parameter. This should be done only after you are happy that all points are configured correctly.

## Device Polling Regime

The DNPR driver has Citect.ini parameters that allow event polls to be isolated into classes.

The default behavior is that all event classes are polled each event poll. The EventPollRatioClassx parameters control the ratio for each class to the event poll. A value of zero will turn event polls off for the specified class. A value of 2 would mean an event class happens every 2nd poll period.

---

**Note:** The integrity poll asks for the static data for all event classes.

The diagram below shows the relationship between the following [Polling Regime Parameters](#):

EventPollPeriod=60 (seconds)

EventPollRatio=10

Integrity polls are issued every 660 seconds (11 mins)

((EventPollRatio+1)\* EventPollPeriod) ----> (10+1)\*60 == 660.

EventPollRatioClass1=2

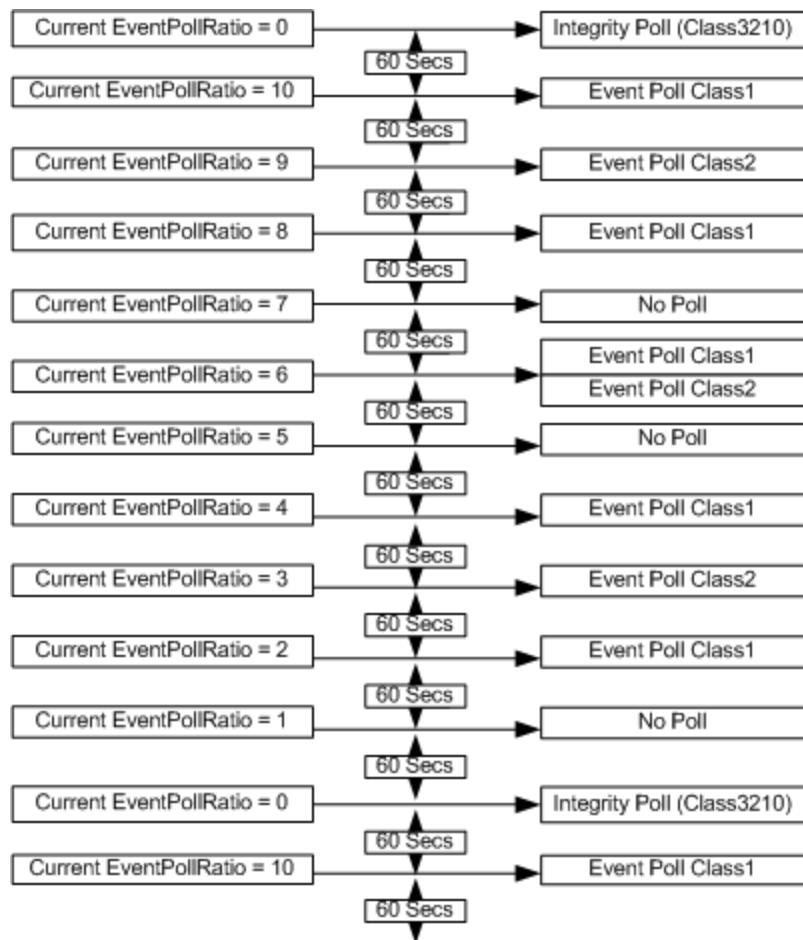

Class 1 polls are issued every second EventPollPeriod from the first module after the integrity poll (poll every EventPollPeriod\* EventPollRatioClass1: 60\*2 == 120 seconds).

EventPollRatioClass2=3

Class 2 polls are issued every third EventPollPeriod from the first module after the integrity poll (poll every EventPollPeriod\* EventPollRatioClass2: 60\*3 == 180 seconds).

EventPollRatioClass3=0

No class 3 polls will be issued.

## Device Recovery

Device recovery refers to the process that occurs when a device goes offline (due to interrupted communication) or the system is starting.

There are two modes to recover a device:

- [Device Recovery - Normal](#)
- [Device Recovery - Fast](#).

The first two attempts to recover a device will place the integrity/static polls with high priority in the DNP3 transmission queue. This means that these polls will be transmitted before any other requests in the exception of write time, delay measurement and control requests. If the device is still not recovered after the first two attempts, then the priority of the subsequent integrity/static polls is the same as the periodic polls of online device. This is to give the chance to online device to be polled.

Once a device is recovered then the periodic polls will be staggered if the Citect.ini parameter "[<unit>]  
PollPeriodOffset" is set.

The Citect.ini parameter to enable one or the other mode (integrity/static polls) is called  
"[DNPR]IssueIntegrityPollOnUnitRecovery" or "[<unit> IssueIntegrityPollOnUnitRecovery". If set to 0 (default) then static polls are issued otherwise integrity polls are issued.

It is also possible to issue Class 1, Class 2, or Class 3 poll on the device recovery. You can enable this behaviour by

the Citect.ini parameter "[DNPR] IssueClassPollOnUnitRecovery" or "[<unit>] IssueClassPollOnUnitRecovery". By default, these parameters remain in disable mode. So the unit will recover based on the "IssueIntegrityPollOnUnitRecovery" ini parameter.

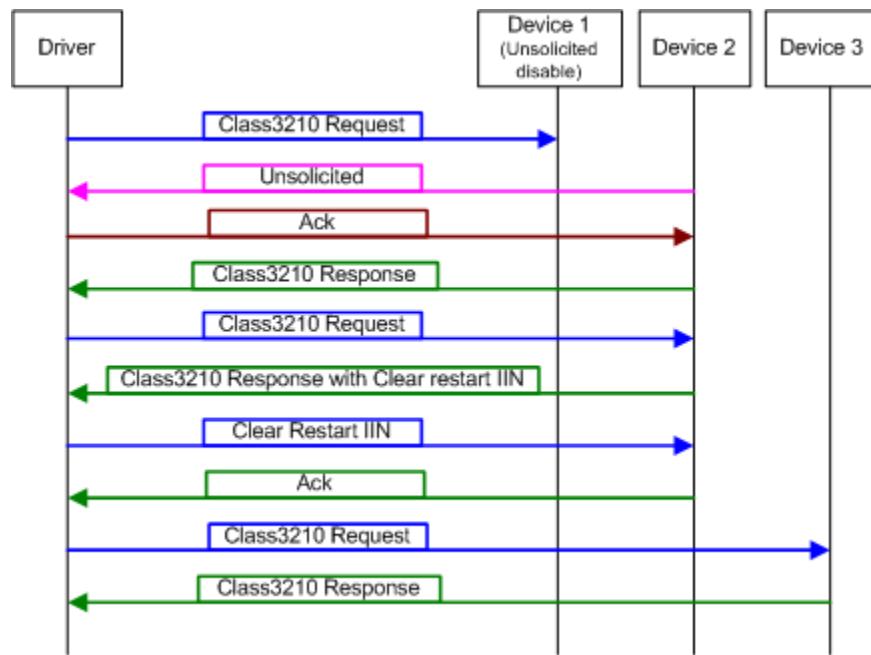

## See Also

[Device Recovery - Startup Considerations](#)

### Device Recovery - Normal

An integrity (Class 0123) poll is issued. This mode will take a long time to bring the device online in the case the device has a lot of events stored. The integrity polls are staggered if the Citect.ini parameter "[<unit>] PollPeriodOffset" is set.

This mode might have less interaction between the driver and the devices than the fast recovery mode but the responses to integrity poll request will take a much longer time if the devices have a lot of events. Also unsolicited messages will slow the responses to the driver's requests.

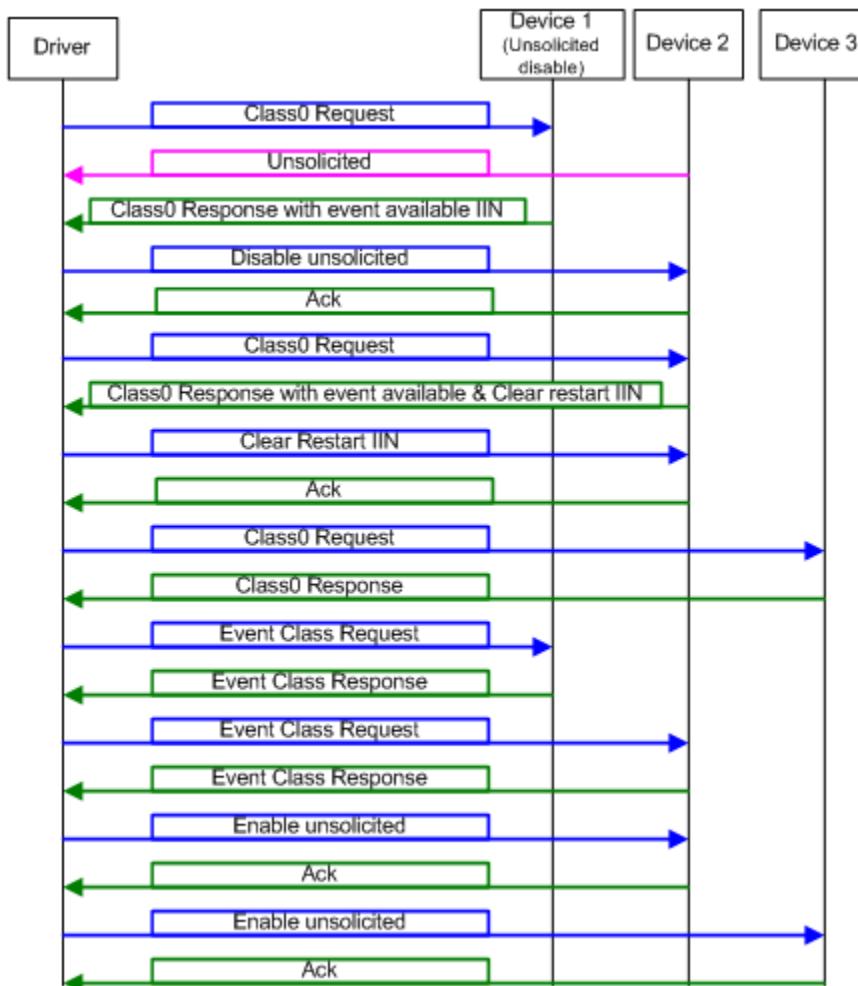

## See Also

[Device Recovery - Fast](#)

### Device Recovery - Fast

A static (Class 0) poll is issued. The IIN flags from the response to the static poll will determine if event needs to be retrieved. Also unsolicited message will not be processed, and a disable unsolicited request will be sent to the device upon receiving unsolicited messages during the device recovery. Unsolicited messages will be re-enabled when the device is recovered if unsolicited message were enabled in the first place. This mode allows to bring the device online quickly in the case the devices have a lot of events stored.

This mode might require more interaction than the normal recovery mode but the response to the static poll requests will be very quick. Therefore, the devices will become online faster than the normal recovery mode.

## See Also

[Device Recovery - Normal](#)

### Device Recovery - Startup Considerations

In a site with many RTUs, it may be useful to consider port startup staggering to spread the load out. This is configured using the Citect.ini parameter [DNPR]StartupStaggerDelay.

It may also be a good idea to use the Citect.ini parameter [<unit>]PollPeriodOffset to stagger when polls are issued, especially where many units are coming through one port.

For example, unit 1 – 5, unit 2 – 10, unit 3 – 15, would send polls 5 seconds after the default time for unit 1, 10 seconds after unit 2, and 15 seconds after unit 3.

---

**Note:** The static polls, which are used to recover a device (after interrupted communications or system startup), will NOT be staggered. This is because the driver will try to bring the devices online as soon as possible and static (class 0) polls will not load the system too much. Subsequent periodic polls will be staggered using the parameter [<unit>] PollPeriodOffset.

[Device Recovery](#)

### SELECT and OPERATE

It is possible to have separate SELECT and OPERATE operations for binary outputs (BO) and analog outputs (AO).

The timeout value for how soon an OPERATE is needed after a SELECT is set in the RTU. Therefore, the default Citect.ini parameters MaxOperateDelayDefault and MaxOperateDelay (per unit) need to be changed to match this time.

Because this time is used to stall any polls for the unit while a SELECT[\_ONLY] is pending. This is because the DNP protocol requires that the next request after a SELECT[\_ONLY] is an OPERATE.

Be reminded that only one SELECT/OPERATE sequence can be done at a time on a single RTU. Multiple SELECTs cannot be done at once. This is a DNP3 limitation.

Users should display the WRITE PENDING bit and the WRITE FAIL bit to verify correct operation. Typically, if you send an OPERATE after the max. delay time, you will see the WRITE FAIL tag light up.

A SELECT can be manually canceled by writing to the BO/AOx.CancelSel tag. This will clear all other status bits for SELECT/OPERATE.

Forced Integrity or Event polls should not occur while a SELECT[\_ONLY] command is pending. The software will automatically delay regular scheduled polling help ensure no poll occurs while a SELECT[\_ONLY] is pending.

Status bits BO/AOx.<WrtPend,WrtFail,SelPend> are available to provide user feedback on the SELECT/OPERATE sequence.

---

**Note:** In an earlier version of the DNPR driver, the SELECT command was effectively a SELECT and OPERATE (automatic). This remains unchanged. Where you see an address with ".Select.", this will be a SELECT and OPERATE. For a pure select only, the address needs to be ".SelectOnly".

---

### Virtual Units

Virtual units allow to monitor and control the physical units which are connected to the real device. As Plant SCADA does not allow you to read or write data for an offline unit, it needs virtual unit support to overcome this limitation.

There are two types of virtual unit supported by Plant SCADA:

- Global virtual units
- Local virtual units.

The global virtual units are configured on a separate port and remain online. The local virtual units are configured on the same port as the physical units and are online only if the port is online.

---

**Note:** It is recommended that only global virtual devices are used, as it can be difficult to determine on which I/O Server a virtual device is active. Also, global virtual devices are easier to use.

---

The virtual unit has an address of 65534. It does not send any DNP3 frames, and the driver does not process any frames received from a device with an address of 65534.

A global virtual unit has an address of 65535. A global virtual until allows you to access globally over all channels. It allows you to define a dummy port which does not go offline and add a virtual unit with the number 65535.

---

**Note:** Each virtual unit must be configured as a primary I/O Device and not included into a redundant pair as the driver can only access the unit information on the I/O Server local to the virtual unit.

---

### Virtual Units Example

The following example shows the implementation of virtual devices on a primary and standby server.

The primary server, which hosts the virtual device "Virtual DevP", has the following Citect.ini parameter settings:

```
[DNPR]
EnablePeerRedundancy = 1
LocalAddress = 10.176.234.11
LocalPort = 5200
PeerAddress = 10.176.232.61
PeerPort = 5200
```

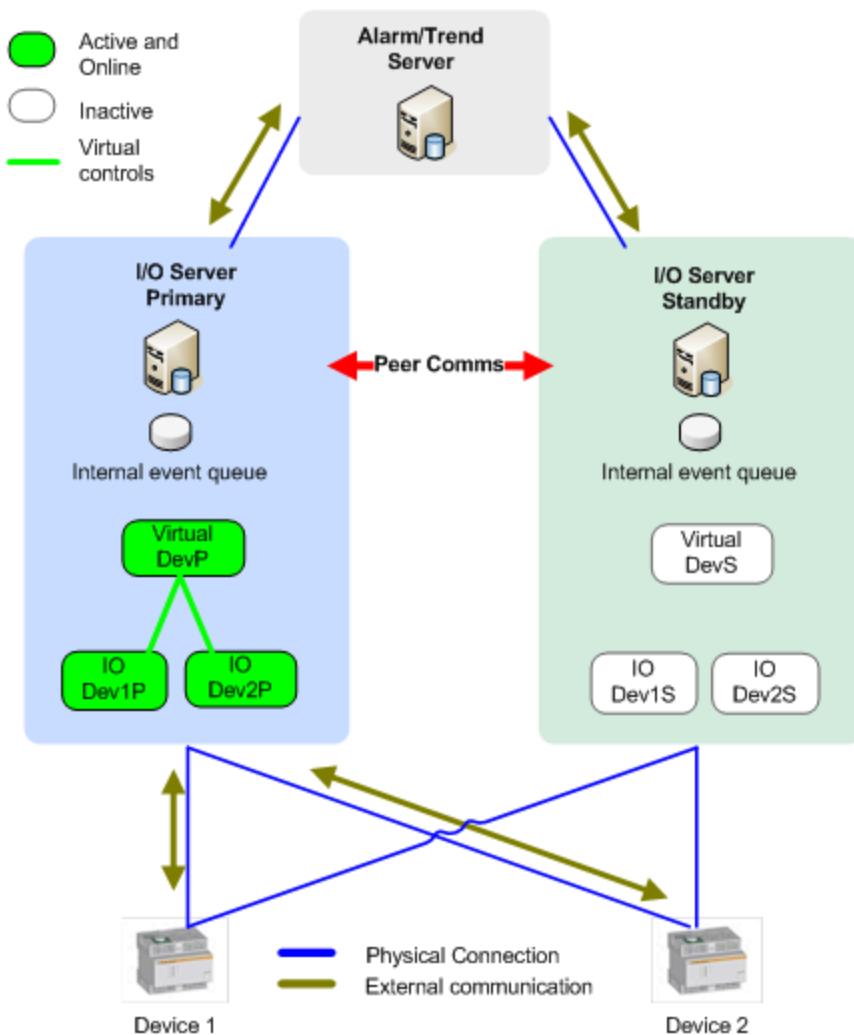

```
[IOServer]
WatchDogPrimary = 1
```

The standby server, which hosts the virtual device "Virtual DevS", has the following Citect.ini parameter settings:

```
[DNPR]
EnablePeerRedundancy = 1
LocalAddress = 10.176.232.61
LocalPort = 5200
PeerAddress = 10.176.234.11
PeerPort = 5200
```

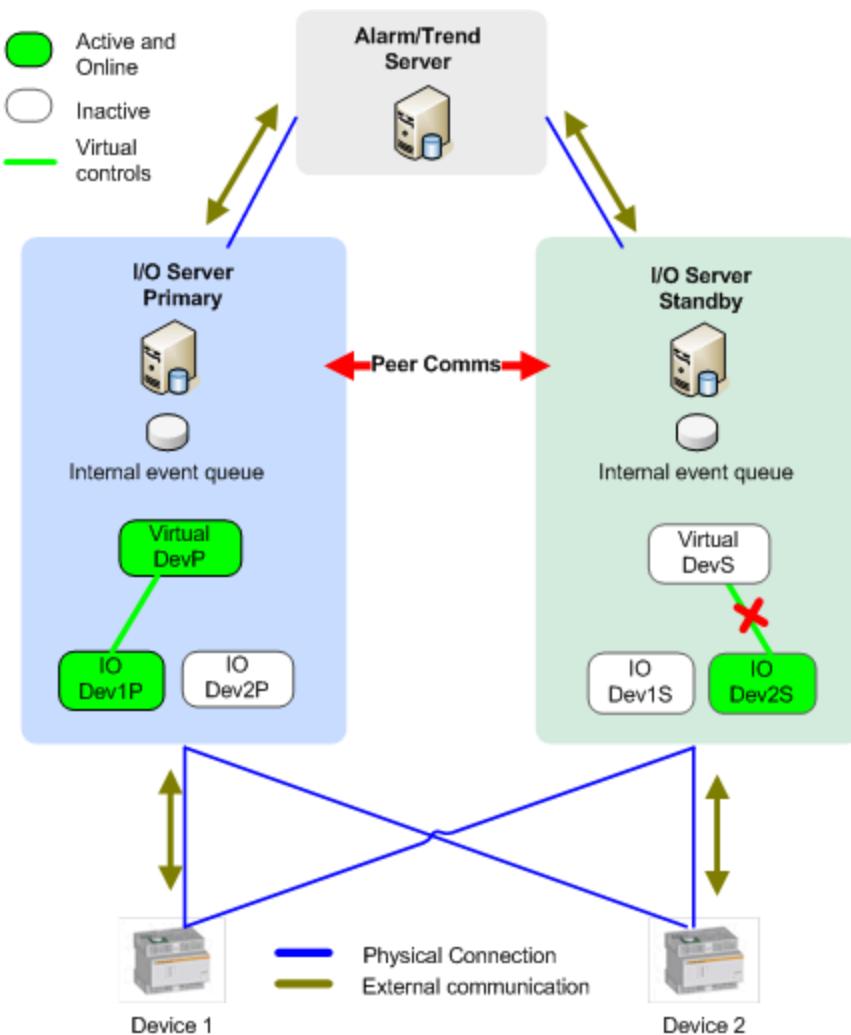

```
[IOServer]
WatchDogPrimary = 1
```

In the following diagram, the virtual device and the I/O devices are communicating on the same port. The three devices are active and online on the primary I/O server. The 3 devices are inactive on the standby I/O server. The I/O devices can be controlled by the virtual device.

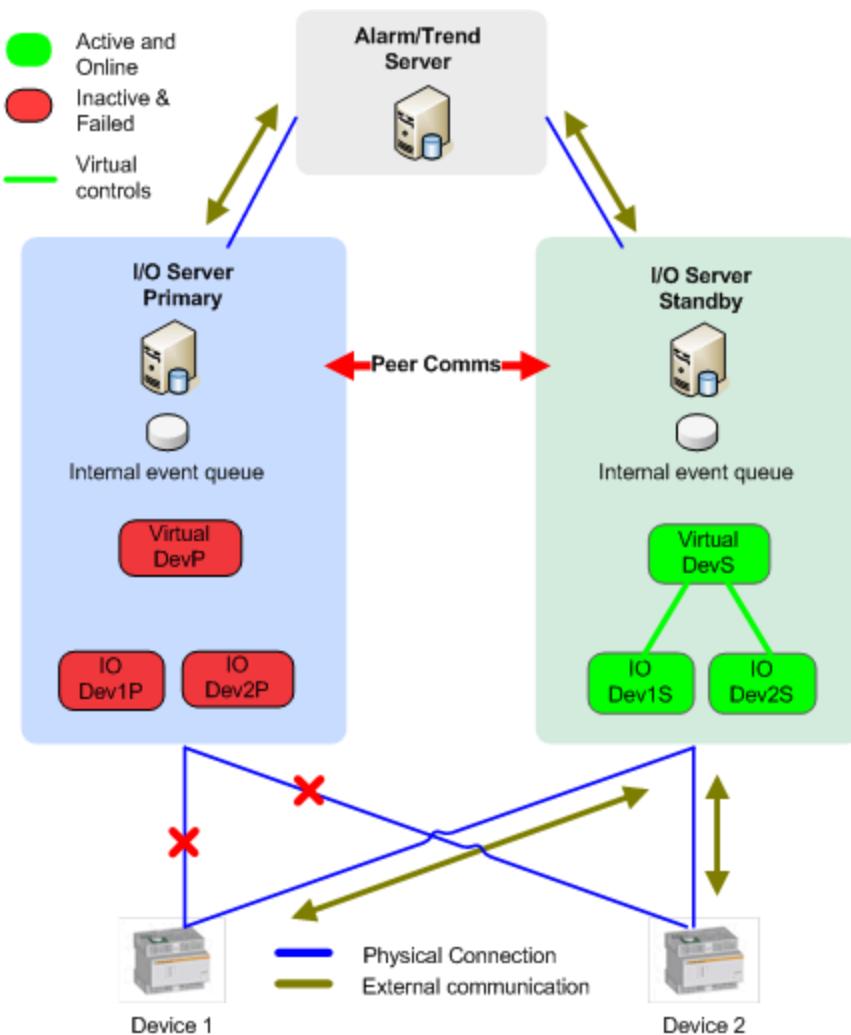

In the diagram below, the virtual device and the I/O devices are communicating on the same port. The I/O device was usurped onto the standby I/O server. The virtual device and I/O device 1 are active and online on the primary I/O server. I/O device 1 can be controlled using the virtual device.

I/O device 2 is active and online on the standby I/O server. The I/O device 2 cannot be controlled with the virtual device because they are not active on the same I/O server.

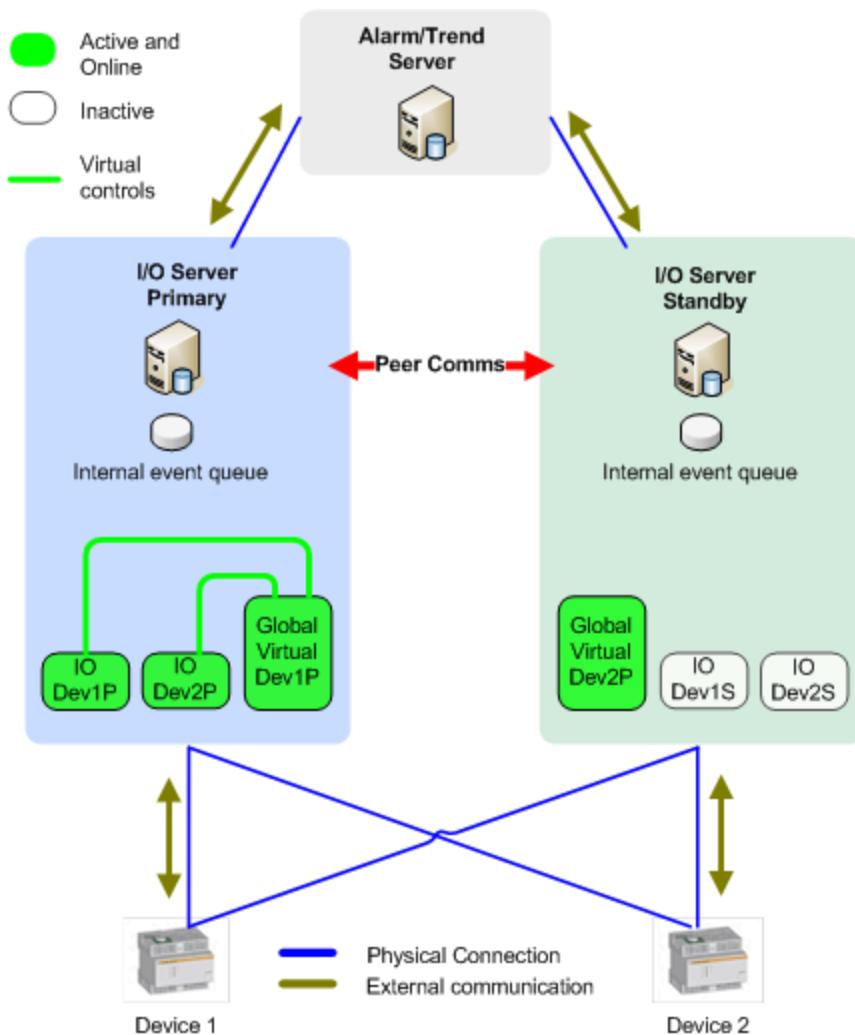

In the next diagram, the virtual device and the I/O devices are communicating on the same port. The connection of the port has been interrupted and the devices are automatically usurped onto the standby I/O server. The three devices are active and online on the standby I/O server. Both I/O devices can be controlled by the virtual device.

In the diagram below, both I/O devices are communicating on the same port. The global virtual devices are on a different port than the I/O devices, and both global devices are primary devices.

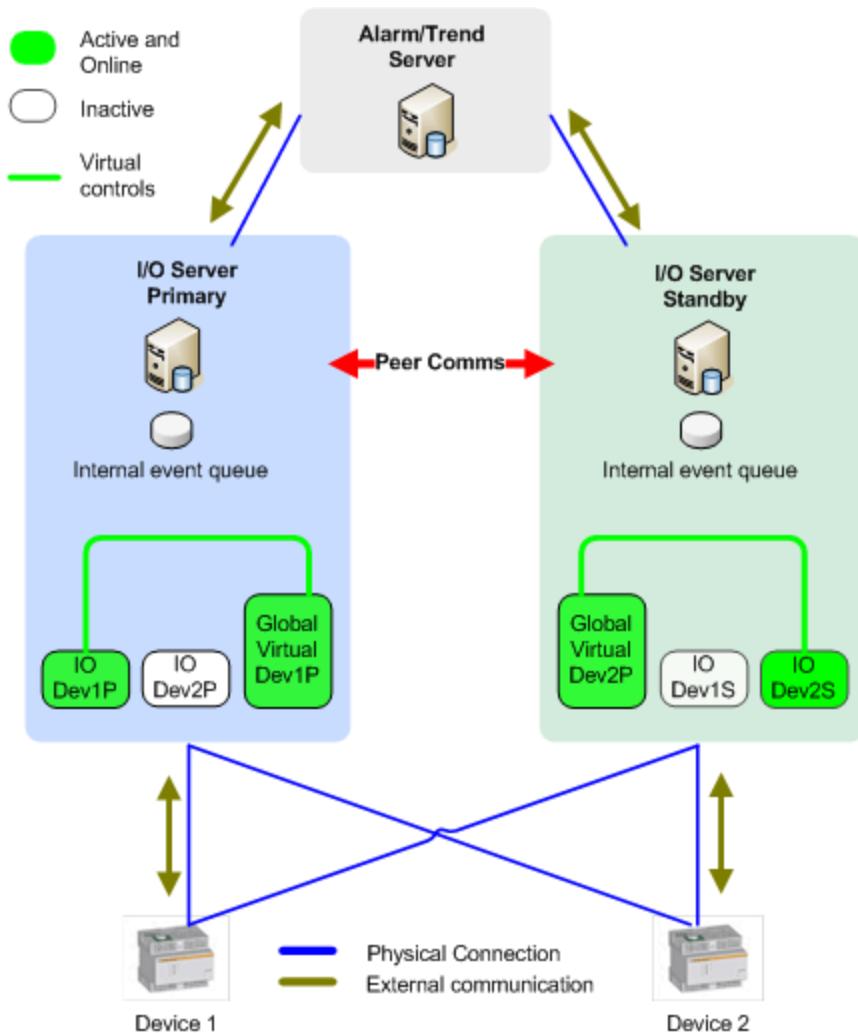

The primary global virtual device 1 is active and online on the primary I/O server. The primary global virtual device 2 is active and online on the standby I/O server. Both I/O devices are active and online on the primary I/O server and can be controlled by the global virtual device 1 on the primary I/O server.

In the last example, both I/O devices are communicating on the same port. The global virtual devices are on different ports to the I/O devices and both global devices are primary devices.

The primary global virtual device 1 is active and online on the primary I/O server. The primary global virtual device 2 is active and online on the standby I/O server. I/O device 2 was usurped onto the standby I/O server. I/O device 1 is active and online on the primary I/O server and can be controlled by the global virtual device 1 on the primary I/O server.

I/O device 2 is active and online on the standby I/O server and can be controlled by the global virtual device 2 on the standby I/O server.

## Configuring Variables for Virtual Units

### Configuring Variables for Virtual Units

The Plant SCADA I/O server does not write to any tags if a unit is offline. Virtual units are useful to implement virtual tags that write to other units on the same port. They provide a way to write to some tags on units regardless of whether the unit is online or offline.

For example, consider the following project units and tags:

#### Unit 42

Tag1 address: *ForceIntegrityPoll*

#### Virtual unit (65534)

Tag2 address: *UNIT42. ForceIntegrityPoll*

If unit 42 is offline, it is not possible to write to Tag1. If the virtual unit stays online, then it is possible to write to the virtual tag Tag2. This causes the driver to do an integrity poll to unit 42 even if unit 42 is offline.

The virtual unit can only access the physical unit information on the I/O Server local to the virtual unit. To monitor or control the primary and standby units via virtual tags, configure a virtual unit on the primary unit I/O Server, a virtual unit on the standby I/O Server and then define two virtual tags on these virtual units.

For example, to monitor the time to the next poll, define a tag with address "*Unit<x>.TimeToNextPoll*" for one virtual unit and a tag with address "*Unit<x>.TimeToNextPoll*" for another virtual unit. At runtime only one of these tags shows data. The tag configured on a virtual unit is located on the same I/O Server as the active physical unit. The other tag sets to 0.

If a switchover happens, the physical unit on this I/O Server becomes active, and the tag on the second virtual unit starts showing data. Use *UnitActiveState.Primary* and *UnitActiveState.Standby* virtual tags to find out the active redundant unit and the virtual tag that is currently showing the data.

For the usurp virtual tags, configure the following only on one virtual unit, as the driver replicates this information between the redundant units.

- *RequestUnitActive.Primary*
- *RequestUnitActive.Standby*
- *UnitActiveState.Primary*
- *UnitActiveState.Standby*
- *UnitPortState.Primary*
- *UnitPortState.Standby*.

# Virtual Units - Polling Regime Data Types

**Note:** The following data types are only recommended for experienced users who are familiar with the terminology and methods associated with the DNP 3.0 protocol.

Address	Plant SCADA Type	DNP3 Type	Description
Unit<x>.PollPeriod	LONG	Adjust the Polling Period  No Object	R/W. If the Citect.ini parameter 'EnablePollPeriodWrites' is set to TRUE (1), then this tag can be used to adjust the Event Polling Period. This tag can be used to display the current Event Polling Period regardless of the state of 'EnablePollPeriodWrites'. This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.
Unit<x>.EnablePoll	INTEGER	Returns if Polling enabled for reads  No Object	R/W. Returns if the unit has enabled polling. A write of '0' will turn polling off, '1' will re-enable polling. <b>Note:</b> The driver schedules regular integrity/event poll intervals from the time the unit comes online. When the polling is re-enabled, the next integrity/event poll executes at the next regular poll time. For example, if the unit EventPollPeriod is set to 60 sec and the unit comes online at 1.00.00 AM, the polls schedule at 1.01.00,

Address	Plant SCADA Type	DNP3 Type	Description
			<p>1.02.00, etc. If the polling gets disabled at 1.00.30 and re-enabled at 1.00.45, the next poll happens at 1.01.00, but if polling gets disabled at 1.01.20, the next polling happens at 1.02.00.</p> <p>This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.</p>
Unit<x>.ForceIntegrityPoll	DIGITAL	Force an integrity poll Object 60 Variation 1 Object 60 Variation 2 Object 60 Variation 3 Object 60 Variation 4	<p>W/O.</p> <p>Writing a '1' to this tag forces the driver to execute an Integrity poll of the device (in addition to the routine polling that it automatically undertakes).</p> <p><b>Note:</b> When the forced integrity poll is completed, the driver checks the next scheduled regular integrity/event poll time. If the time until the next scheduled poll time is less than 33% of the unit EventPollPeriod, the driver increases the next scheduled integrity/ event poll time by the EventPollPeriod value.</p> <p>This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.</p>
Unit<x>.ForceEventPoll	DIGITAL	Force an integrity poll Object 60 Variation 2	<p>W/O.</p> <p>Writing a '1' to this tag</p>

Address	Plant SCADA Type	DNP3 Type	Description
		Object 60 Variation 3 Object 60 Variation 4	will force the driver to execute an Event poll of the device (in addition to the routine polling that it automatically undertakes).  This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.
Unit< x >.TimeToNextPoll	LONG	Time to go to next Integrity poll No Object	R/O Seconds. Will count down from the set Integrity poll time, and may become negative if the Integrity poll has been delayed.  This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.
Unit< x >.TimeToNextClass1 Poll	LONG	Time to go to next class 1 poll No Object	R/O Seconds. Will count down from the set class 1 poll time and may become negative if the class 1 poll has been delayed. This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.
Unit< x >.TimeToNextClass2 Poll	LONG	Time to go to next class 1 poll No Object	R/O Seconds. Will count down from the set class 2 poll time and may become negative if the class 2 poll has been delayed.

Address	Plant SCADA Type	DNP3 Type	Description
			This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.
Unit<x>.TimeToNextClass3Poll	LONG	Time to go to next class 1 poll No Object	R/O Seconds. Will count down from the set class 3 poll time and may become negative if the class 3 poll has been delayed. This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.
Unit<x>.Polls	INTEGER	Count of successful polls (Forced and periodic). No Object	R/W. Count of successful Integrity, Event, class 1, class 2 and class 3 polls of the device. Write '1' to reset counter. This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.
Unit<x>.FailedPolls	INTEGER	Count of unsuccessful polls (Forced and periodic). No Object	R/W. Count of unsuccessful Integrity, Event, class 1, class 2 and class 3 polls of the device (i.e. incomplete full timeout sequence). Write '1' to reset counter. This address does not relate to I/O data internal to the device, but relates to data internal to the driver.

Address	Plant SCADA Type	DNP3 Type	Description
			driver, or an action to be performed by the driver. Note that this counter is incremented only after the poll message and the following retry requests have timed out. The number of retry requests is configured using the "Retry" parameter.
Unit<x>.Ipolls	INTEGER	Count of successful Integrity polls (Forced and periodic). No Object	R/W. Count of successful Integrity polls of the device. Write '1' to reset counter. This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.
Unit<x>.FailedIPolls	INTEGER	Count of unsuccessful integrity polls (Forced and periodic). No Object	R/W. Count of unsuccessful Integrity polls of the device (i.e. failure of full timeout sequence). Write '1' to reset counter. This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver. Note that this counter is incremented only after the poll message and the following retry requests have timed out. The number of retry requests is configured using the "Retry" parameter.
Unit<x>.Epolls	INTEGER	Count of successful Event	R/W.

Address	Plant SCADA Type	DNP3 Type	Description
		polls (Forced and periodic). No Object	Count of successful Event polls of the device. Write '1' to reset counter.  This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.
Unit<x>.FailedEpolls	INTEGER	Count of unsuccessful Event polls (Forced and periodic). No Object	R/W.  Count of unsuccessful Event polls of the device (i.e. failure of full timeout sequence). Write '1' to reset counter.  This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.  Note that this counter is incremented only after the poll message and the following retry requests have timed out. The number of retry requests is configured using the "Retry" parameter.
Unit<x>.UnsolicitedRxd	INTEGER	Count of Unsoliciteds received. No Object	R/W  Count of valid Unsolicited Responses received by the device. Write '1' to reset counter.  This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.
Unit<x>.RequestEventRefresh	INTEGER	Force Event Refresh for device	R/W.  Writing 1 will cause the

Address	Plant SCADA Type	DNP3 Type	Description
		No Object	<p>unit to refresh all event data the next integrity poll. A read reads this state.</p> <p><b>Note:</b> This value will be set if [DNPR]RefreshEventsOnStartup=1 was set.</p> <p>This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.</p>
Unit<x>.RTUEvents	LONG	RTU Events received No Object	R/O. RTU events PER PORT received from the field device. This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.

**Where:**

- x = device address of the real device as specified in the I/O Device's **Address** field
- R/O = read only
- W/O = write only
- R/W = read or write

## Virtual Units - Usurp Data Types

---

**Note:** The following data types are only recommended for experienced users who are familiar with the terminology and methods associated with the DNP 3.0 protocol.

---

Address	Plant SCADA Type	DNP3 Type	Description
Unit< x >.RequestUnitActive.Primary	INTEGER	Request unit active on primary. No Object	R/W Writing a '1' to this tag will force the unit be active on the primary I/O server. Writing '0' will force the unit be active on the standby I/O server. A read returns the last value written to the tag. This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.
Unit< x >.RequestUnitActive.Standby	INTEGER	Request unit active on standby. No Object	R/W Writing a '1' to this tag will force the unit be active on the standby I/O server. Writing '0' will force the unit be active on the primary I/O server. A read returns the last value written to the tag. This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.
Unit< x >.UnitActiveState.Primary	INTEGER	Unit active state on primary. No Object	R/O Returns 1 if the unit is active on the primary I/O server and 0 if active on the standby I/O server. This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.
Unit< x >.	INTEGER	Unit active state on	R/O

Address	Plant SCADA Type	DNP3 Type	Description
UnitActiveState.Standby		standby. No Object	Returns 1 if the unit is active on the standby I/O server and 0 if active on the primary I/O server.  This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.
Unit< x >.UnitPortState.Primary	INTEGER	True port connection state of primary unit. No Object	R/O Useful to check if the port, a unit is on, is connected. -1 No peer update 0 Port not connected 1 Port connected.  This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.
Unit< x >.UnitPortState.Standby	INTEGER	True port connection state of standby unit. No Object	R/O Useful to check if the port, a unit is on, is connected. -1 No peer update 0 Port not connected 1 Port connected.  This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.

**Where:**

- x = device address of the real device as specified in the I/O Device's **Address** field
- R/O = read only
- W/O = write only
- R/W = read or write

# Virtual Units - Control Data Types

**Note:** The following data types are only recommended for experienced users who are familiar with the terminology and methods associated with the DNP 3.0 protocol.

Address	Plant SCADA Type	DNP3 Type	Description
Unit<x>.DisableUnsolicited	DIGITAL	Disable all Unsoliciteds Object 60 Variation 2 Object 60 Variation 3 Object 60 Variation 4	W/O. Writing a '1' to this tag will instruct the unit not to broadcast any more unsolicited responses. Need to be W/O, as there is no way of determining if unsoliciteds were disabled before Plant SCADA startup. This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver. <b>Note:</b> This a Level 3 feature.
Unit<x>.EnableUnsolicited	DIGITAL	Enable all Unsoliciteds Object 60 Variation 2 Object 60 Variation 3 Object 60 Variation 4	W/O. Writing a '1' to this tag will allow the unit to broadcast unsolicited responses. The Classes enabled are determined by the Citect.ini parameter [DNPR]AutoUnsolicitedEnableDefault or [<unit>] AutoUnsolicitedEnable. Need to be W/O, as there is no way of determining if unsoliciteds were enabled before Plant

Address	Plant SCADA Type	DNP3 Type	Description
			<p>SCADA startup.</p> <p>This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.</p> <p><b>Note:</b> This a Level 3 feature.</p>

**Where:**

- x = device address of the real device as specified in the I/O Device's **Address** field
- R/O = read only
- W/O = write only
- R/W = read or write

## Virtual Units - Monitoring Data Types

**Note:** The following data types are only recommended for experienced users who are familiar with the terminology and methods associated with the DNP 3.0 protocol.

Address	Plant SCADA Type	DNP3 Type	Description
Unit<x>.RTUStatus	DIGITAL	RTU Online status No Object	<p>R/O</p> <p>Internal online status of a unit. Of limited use as a tag on a unit as if the unit was offline, you could not read the tag anyway. This tag has been superseded by the UnitActiveState.X tags.</p> <p>This address does not</p>

Address	Plant SCADA Type	DNP3 Type	Description
			relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.
Unit<x>.LateRefresh	DIGITAL	Late cache refresh for device No Object	R/O Indicates when a device poll has been delayed, resulting in a late cache refresh. Refer to Citect.ini parameter DataLag for further details.  This address does not relate to I/O data internal to the device, but relates to data internal to the driver, or an action to be performed by the driver.

**Where:**

- x = device address of the real device as specified in the I/O Device's **Address** field
- R/O = read only
- W/O = write only
- R/W = read or write

**Troubleshooting**

The section of the help contains troubleshooting information for the DNPR driver.

- [DNPR Driver-specific Errors](#)
- [Driver Statistics](#)
- [Logging](#)
- [Debugging Messages](#)

**DNPR Driver-specific Errors**

When a hardware error occurs, Plant SCADA generates an alarm, and displays the alarm on the hardware alarm page (in the alarm description of the hardware alarm). To see the error number, make sure you have Alarm

Category 255 defined with a display format that includes {ErrDesc,15} {ErrPage,10}.

There are a number of generic errors that are common to protocols. In some cases only the generic error is available, though often both the generic error and a specific error are given.

The following errors, listed in (hexadecimal) sequence, are specific to this protocol. Plant SCADA displays the error number and description for common protocol-specific errors. Uncommon errors are not contained in the Plant SCADA error database, in which case only the error number will be displayed.

You may require additional information to enable you to rectify an error. This information should be detailed in the documentation that accompanied the I/O Device (or network). If, after reviewing the documentation, you cannot rectify an error, contact Technical Support for this product. Due to the complex nature of this protocol, technical support is only available at hourly rates. Please contact Technical Support for further details.

**0x00050GENERIC\_SOFTWARE\_ERROR**

Software driver error

**0x00051GENERIC\_SOFTWARE\_ERROR**

Memory could not be allocated for cache

**0x00052GENERIC\_TOO\_MANY\_COMMANDS**

Could not insert request to lower API layer because of existing duplicate request

**0x00053GENERIC\_ADDRESS\_RANGE\_ERROR**

A point used in a write request is invalid

**0x00054GENERIC\_INVALID\_DATA**

Point(s) in a read request are not yet valid because they are older than poltime

**0x00055GENERIC\_BAD\_PARAMETER**

User has set poltime to zero

**0x00056GENERIC\_INVALID\_COMMAND**

This type is write only

**0x00057GENERIC\_ADDRESS\_RANGE\_ERROR**

More points were requested than defined by the user

**0x00058GENERIC\_SOFTWARE\_ERROR**

Invalid Object read tag object sub field. Check for the correct DNPR.dbf file

**0x00059GENERIC\_SOFTWARE\_ERROR**

No matching entry in tag object table can be found. Check for the correct DNPR.dbf file

**0x0005AGENERIC\_INVALID\_DATA**

A point or points in read request not valid

**0x0005BGENERIC\_SOFTWARE\_ERROR**

Cannot find a matching dcb for a write response

**0X0005CGENERIC\_ADDRESS\_RANGE\_ERROR**

Data does not exist in cache

**0x0005DGENERIC\_GENERAL\_ERROR**

Unable to complete write command

**0x0005EGERERIC\_UNIT\_WARNING**

IIN Error detected that will generate an alarm. The ability of the driver to detect any individual member of this

group of alarm conditions can be turned on and off using the Citect.ini parameter MinorIINSelectFilter. The default for the driver is to turn each of these alarms ON.

This Plant SCADA error will only be returned under the following circumstances:

On Plant SCADA write requests for Analog Outputs, CROBs, Counter Freeze and Restart requests. The error will only be returned when there are no other errors considered more serious for that request (e.g. Analog Output/CROB status errors described above).

On a front-end read request (e.g. a tag is displayed) following a back-end periodic poll where the error was detected. This error will only be returned when there are no other errors considered more serious resulting from the back-end poll (low level API application errors have precedence).

If this occurs, it indicates one or more of the selected minor IIN errors have occurred under the circumstances described above. The error code cannot differentiate which of the enabled IIN flag(s) has caused the IIN error. To accomplish this, a "Debug \* ALL" command should be issued in the kernel, and the individual IIN flags will be reported in the syslog through the protocol diagnostic reporting.

IIN flags that can be detected are:

**LOCAL\_IIN**: Bit 5 in byte 1 of IIN - Outstation Digital Output(s) are in Local mode (driver cannot control)

**TROUBLE\_IIN**: Bit 6 in byte 1 of IIN - Abnormal condition flagged in Outstation (refer to device profile).

**BUFFER\_OVFL**: Bit 3 in byte 2 of IIN - Outstation lost data from overflow of event buffers

**EXECUTING\_IIN**: Bit 4 in byte 2 of IIN - Request understood but operation already executing

**CONFIG\_IIN**: Bit 5 in byte 2 of IIN - Current configuration in Outstation is corrupt.

#### **0x0005F GENERIC\_GENERAL\_ERROR**

Cannot open database - Plant SCADA form may be open

#### **0x00060 GENERIC\_GENERAL\_ERROR**

Error detected in queue

#### **0x00061 GENERIC\_GENERAL\_ERROR**

Cache refresh late due to poll delays

#### **0x00062 GENERIC\_INVALID\_DATA\_TYPE**

Requested raw type invalid for native type

#### **0x00063 GENERIC\_UNIT\_WARNING**

An error has occurred in a device using a virtual unit tag

#### **0x00064 GENERIC\_UNIT\_WARNING**

General **null pointer** issue, e.g. a request has occurred internally for a device no longer installed

#### **0x00065 GENERIC\_UNIT\_OFFLINE**

A unit's Startup mode has not been configured (for example, "Primary" or "Standby") for the I/O Device, and peer redundancy is in use.

#### **0x00068 GENERIC\_UNIT\_OFFLINE**

IIN error detected that will generate an error alarm. The ability of the driver to detect any individual member of this group of alarm conditions can be turned on and off using the Citect INI parameter MinorIINSelectErrorFilter. Note: the default for the driver is to turn each of these alarms OFF. See error 0.x0005E for the conditions that trigger this error.

#### **0x00069 GENERIC\_UNIT\_REMOTE**

We have done another SELECT while one is in progress.

**0x0006AGENERIC\_UNIT\_REMOTE**

Waiting for an RTU response before coming online

**0x0006B GENERIC\_GENERAL\_ERROR**

Port level indication that transport is unavailable

**0x0006C GENERIC\_UNIT\_WARNING**

Unit is offline for valid reasons, for example, its pair unit is active

**0x0006D GENERIC\_CHANNEL\_OFFLINE**

Still trying to connect to a port and have been prompted to do it again

**0x10002GENERIC\_GENERAL\_ERROR**

Low Level API Application Layer error code 2 - Function code in response not supported

**0x10003GENERIC\_GENERAL\_ERROR**

Low Level API Application Layer error code 3 - Response sequence number does not match the latest request

**0x10004GENERIC\_GENERAL\_ERROR**

Low Level API Application Layer error code 4 - Response fragment received with no active request

**0x10005GENERIC\_GENERAL\_ERROR**

Low Level API Application Layer error code 5 - Object/Variation not supported

**0x10006GENERIC\_GENERAL\_ERROR**

Low Level API Application Layer error code 6 - Object/Qualifier combination not supported

**0x10007GENERIC\_GENERAL\_ERROR**

Low Level API Application Layer error code 7 - Response qualifier code not supported

**0x10008GENERIC\_GENERAL\_ERROR**

Low Level API Application Layer error code 8 - Timeout waiting for application layer response fragment or restart

**0x10009GENERIC\_GENERAL\_ERROR**

Low Level API Application Layer error code 9 - Object/Variation not supported in read response

**0x1000AGENERIC\_GENERAL\_ERROR**

Low Level API Application Layer error code 10 - Object/Variation not supported in operate response

**0x1000BGENERIC\_GENERAL\_ERROR**

Low Level API Application Layer error code 11 - Error considered serious by low level API. Internal indications bits relating to remote device parsing of last request indicate either:

Device does not recognize requested objects (Bit 1 in byte 2 of IIN).

Outstation rejected application request as invalid or out of range due to formatting errors (Bit 2 in byte 2 of IIN).

Function code not implemented (Bit 0 in byte 2 of IIN).

**0x1000CGENERIC\_GENERAL\_ERROR**

Low Level API Application Layer error code 12 - Response does not match request for 'Select before Operate'

**0x1000DGENERIC\_GENERAL\_ERROR**

Low Level API Application Layer error code 13 - Response to Restart message does not include time object

**0x1000EGERIC\_GENERAL\_ERROR**

Low Level API Application Layer error code 14 - Object/Variation not supported in write response

**0x1000FGENERIC\_GENERAL\_ERROR**

Low Level API Application Layer error code 15 - Invalid device number (index) in application layer transmit queue

**0x10010GENERIC\_GENERAL\_ERROR**

Low Level API Application Layer error code 16 - Response to Delay measurement does not include time object

**0x10011GENERIC\_GENERAL\_ERROR**

Low Level API Application Layer error code 17 - Message not processed as unsolicited responses disabled

**0x10012 GENERIC\_GENERAL\_ERROR**

Low Level API Application Layer error code 18 - Invalid application layer frame received

**0x20001GENERIC\_GENERAL\_ERROR**

Analog Output/CROB Status Value 1 - Bad control request - OPERATE received after SELECT timeout (This Plant SCADA error will only be returned on Plant SCADA Write requests)

**0x20002GENERIC\_GENERAL\_ERROR**

Analog Output/CROB Status Value 2 - Bad control request - OPERATE received without prior SELECT (This Plant SCADA error will only be returned on Plant SCADA Write requests)

**0x20003GENERIC\_GENERAL\_ERROR**

Analog Output/CROB Status Value 3 - Bad control request - formatting errors in control request (This Plant SCADA error will only be returned on Plant SCADA Write requests)

**0x20004GENERIC\_GENERAL\_ERROR**

Analog Output/CROB Status Value 4 - Bad control request - control request not supported for point (This Plant SCADA error will only be returned on Plant SCADA Write requests)

**0x20005GENERIC\_GENERAL\_ERROR**

Analog Output/CROB Status Value 5 - Bad control request - control queue full or point already active (This Plant SCADA error will only be returned on Plant SCADA Write requests)

**0x20006GENERIC\_HARDWARE\_ERROR**

Analog Output/CROB Status Value 6 - Bad control request - not accepted due to hardware problems (This Plant SCADA error will only be returned on Plant SCADA Write requests)

## Driver Statistics

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

- Do not use the kernel for normal Plant SCADA operation. The kernel is only for diagnostics and debugging purposes.
- Configure your security so that only approved personnel can view or use the kernel.
- Do not view or use the kernel unless you are an expert user of Plant SCADA and Cicode, or are under the direct guidance of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:**

Items will update on a per Port basis. Non " \* " items (14 on) are global to the driver.

---

Items B14 to B19 appear on the second port.

---

Items 14 & 15 will NOT be reset when driver stats are cleared. These stats are for actual counts which cannot be cleared.

---

## Logging

The DNPR driver can log combinations of trace levels across different categories. This is achieved by setting the following INI parameters.

### [DNPR]DebugLevel

This parameter allows you to define the trace level. The options include:

Option	Description
WARN	Output warning messages.
ERROR	Output error messages.
TRACE	Output trace messages.
DEBUG	Output debug messages.
ALL	All of the above.

### [DNPR]DebugCategory

This parameter allows you to enable logging for a particular category of trace. The options include:

Option	Description
PROT	Protocol level debug.
CACHE	Cache debug.
STATE	Unit state transitions.
EVENT	Events cache data.
DCB	Front end driver trace.
BEND	Backend trace.
MISC	Any other debugging.
ALL	All of the above.

In both cases, you can use any combination of the available options separated by a pipe character ( | ).

## Example

```
[DNPR]
DebugLevel=WARN | ERROR | TRACE
DebugCategory=ALL
```

In most cases, you can set the DebugLevel and DebugCategory parameters to ALL. If this results in a large, cumbersome log file that causes older data to be overwritten, you can consider refining the debug options.

**Note:** These parameters do not have a value specified by default. To enable logging for this driver, you need to manually configure these parameters in your INI file.

The events generated by the DNPR driver are logged in the following Plant SCADA syslog file:

```
syslog.IOServer.<Cluster name>.<IO Server name>.dat
```

This file is located in the directory specified by the Citect.ini parameter **[CtEdit]Logs**. By default, this location will be:

```
%PROGRAMDATA%\AVEVA Plant SCADA <VersionNumber>\Logs
```

The size of the syslog file and its rollover process is configured via the **[Debug]SysLogSize** and **[Debug]SysLogArchive** INI parameters. For more information, see the topic *Debug Parameters* in the Plant SCADA documentation.

**Note:** If the number of messages being processed for a driver exceeds the value specified by the Plant SCADA parameter **[Kernel]ErrorBuffers**, the pending messages will not be logged. If this occurs, you can increase the value of this parameter so that all the messages generated by the driver are reported. The number of messages that are not logged can be monitored via the Kernel's General window under the item "Lost Errors". If you adjust **[Kernel]ErrorBuffers** and Lost Errors are still occurring, you may need to adjust the level of system logging.

## See Also

[Logging/Diagnostic Parameters](#)

[Debugging Messages](#)

## Debugging Messages

### DriverTrace command

The DriverTrace command is still useful to check the communication (DCB requests and replies) between the IOServer and the driver.

Generally speaking, have this turned on with a [debug]drivertracemask of 21c0f. This setting traces things down to the unit level (not data) and allows to understand what state the I/O server thinks a driver is in.

When the issue is data integrity, then the higher volume traces may be needed to confirm the actual error or data value being returned to the I/O server. This mask will be something like fffe (this excludes the CPU calls which you normally don't need).

Drivertrace allows either all ports or a single port to be traced. If the issue is isolated to a single port, then just trace this port. [debug]drivertraceport=PortABC

## Syslog Size

To minimize the chance of missing something, [debug]syslogsize=32000 should be set and the syslog.dat's

deleted or renamed prior to capturing fresh traces.

## DCB Debugging

When the INI parameter DebugCategory is set to DCB, then trace statements will be produced in the driver log file. The trace statements detail the actions undertaken by the driver in order to process requests received by I/O server.

The following legend describes the symbol abbreviations used in the trace statements:

Symbol	Description
ad	I/O point address
ua	Unit address
ut	Unit type
uc	Unit count

## GENERIC Driver

The GENERIC driver is a special pseudo-protocol supported by Memory I/O Devices and Disk I/O Devices. GENERIC is not a real protocol, and does not communicate with any physical I/O device.

The GENERIC driver supports the basic data types, providing a convenient and consistent way to represent memory and disk data.

---

**Note:** There are no communication specific errors associated with the GENERIC driver. Although you cannot use the GENERIC protocol to communicate with a physical I/O device, memory and disk devices can use other protocols.

---

### See Also

[GENERIC Driver Communications Settings](#)

[GENERIC Driver Data Types](#)

## GENERIC Driver Communications Settings

To establish communication with a device, configure the associated **Board**, **Port** and **I/O Device** in Plant SCADA Studio's **Topology** activity.

### Boards

You do not need to complete any board settings.

## Ports

You do not need to complete any port settings.

## I/O Devices

Complete the I/O Devices settings as follows.

- **I/O Device Name**

A name for your Disk I/O Device, for example: DISK\_PLC or MEMORY\_PLC.

Each I/O Device must have a unique name in the Plant SCADA system.

- **I/O Device Number**

A unique number for the Disk I/O Device (1-4095)

Each I/O Device must have a unique number in the Plant SCADA system.

- **I/O Device Address**

Leave this property blank if you are using a memory device. If you are using a disk device, enter the path and file name of the disk file, for example: [RUN]:DSKDRV.DSK

If you are using redundant Disk I/O Devices, you must specify the path to both the primary file and the Standby file in the configuration of both disk I/O Devices.

For example, if this is the Primary Disk I/O Device enter:

**Primary\_File, Standby\_File**

If this is the Standby Disk I/O Device enter:

**Standby\_File, Primary\_File**

Where:

**Primary\_File** is the name (and path) of the Primary Disk I/O Device file. You may use path substitution in this part of the field.

**Standby\_File** is the name (and path) of the Standby Disk I/O Device file. You may use path substitution in this part of the field.

---

**Note:**

1. If the specified Disk I/O Device file is not found, Plant SCADA will create a new (empty) file with the specified file name.

2. To use redundant Disk I/O Devices, you must be using a network that supports peer-to-peer communication.

3. Disk files must have write permission (on both Primary and Standby servers).

4. If a corrupt file is detected during a read or write, Plant SCADA will change the mode to read only, and display an error message.

5. The frequency with which Plant SCADA writes data to the Disk I/O Device(s) is determined by the **[DiskDrv]UpDateTime** parameter.

---

- **I/O Device Protocol**

Enter GENERIC.

- **I/O Device Port Name**

If you are creating a disk device, you must enter DISK.

If you are creating a memory device, you must enter MEMORY.

- **I/O Device Startup Mode**

If you are not using redundant Disk I/O Devices, leave this property blank.

If you are using redundant Disk I/O Devices, use either:

**PrimaryEnable** immediate use of this Disk I/O Device

**StandbyWrite** This Disk I/O Device will remain unused until the computer with the primary Disk I/O Device configured becomes inoperable. All write requests sent to the primary Disk I/O Device are also sent to this Disk I/O Device.

---

**Note:** To use StandbyWrite mode, you must also configure an I/O Disk Device in the primary server. Both I/O Devices must have the same I/O Device name and number.

- **I/O Device Log Write, Log Read, Cache and Cache Time**

Leave these properties blank.

[GENERIC Driver Data Types](#)

## GENERIC Driver Data Types

The following is a list of data types for the Generic Driver:

Data Type	Address Format	Short Format	where # is	Range
DIGITAL	Digital#	D#	0 to 64000	0 or 1
INTEGER	Int#	I#	0 to 32752	-32,768 to 32,767
LONG	Long#	L#	0 to 16376	-2,147,483,648 to 2,147,483,647
REAL	Real#	R#	0 to 16376	-3.4E38 to 3.4E38
STRING	String#	S#	0 to 510	128 bytes

**Note:** Cicode INT types are 32 bit (4 bytes), whereas PLC INT types are only 16 bit (2 bytes).

**STRING Handling** - Plant SCADA by default supports 8 bit characters (a byte). Though the GENERIC driver supports the read and write of 8 bit characters, the PLC based devices support depends on the format of the data in the end device, it might be a 7 bit character.

On multi byte operating systems, then 2 byte character use means that only 64 characters could be displayed per string for the GENERIC driver.

## GETCP Driver

The GETCP protocols supports communication with the GE Fanuc series [90-30 ,90-70](#) and RX3i PLCs.

The network communication layer is Ethernet and requires an Ethernet board installed in your computer.

---

**Note:** Plant SCADA is not restricted to using Ethernet. Other network standards, such as Token Ring or FDDI, may

---

be adopted if supported by the PLC.

The maximum request length for the GETCP protocols is 2048 bits.

## Setting Up the Ethernet Board

It is recommended you setup your specific Ethernet card as required and confirm basic network communications before proceeding with the communications configuration for the GETCP driver. Refer to the documentation accompanying your hardware for instruction.

---

**Note:** The same Ethernet card that is being used for Plant SCADA communication can be used for PLC communication

The GE Ethernet interface manual should be consulted for details of installation of the PLC Ethernet unit and options. We recommend using Thin Ethernet (10base2) and using a transceiver at the PLC.

## Setting Up the Software

TCP/IP software must be properly installed before configuring this driver. In particular, the correct values for IP address, subnet mask and default gateway must be set before proceeding.

## Safety Information

### Hazard categories and special symbols

The following symbols and special messages may appear in this manual or on the product to warn of potential hazards or to call attention to information that clarifies or simplifies a procedure.

Symbol	Description
 or 	The addition of either symbol to a "Danger" or "Warning" safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.
	This is the safety alert symbol. It is used to alert you to personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.

### DANGER

DANGER indicates an imminently hazardous situation, which, if not avoided, will result in death or serious injury.

**⚠ WARNING**

**WARNING** indicates a potentially hazardous situation, which, if not avoided, can result in death or serious injury.

**⚠ CAUTION**

**CAUTION** indicates a potentially hazardous situation which, if not avoided, can result in minor or moderate injury.

**NOTICE**

**NOTICE** used without a safety alert symbol, indicates a potentially hazardous situation which, if not avoided, can result in property or equipment damage.

**Please Note**

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by AVEVA for any consequences arising out of the use of this material.

**Before You Begin**

Plant SCADA is a Supervisory Control and Data Acquisition (SCADA) solution. It facilitates the creation of software to manage and monitor industrial systems and processes. Due to Plant SCADA's central role in controlling systems and processes, you must appropriately design, commission, and test your Plant SCADA project before implementing it in an operational setting. Observe the following:

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not use Plant SCADA or other SCADA software as a replacement for PLC-based control programs. SCADA software is not designed for direct, high-speed system control.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**⚠ WARNING****LOSS OF CONTROL**

- The designer of any control scheme must consider the potential failure modes of control paths and, for certain critical control functions, provide a means to achieve a safe state during and after a path failure. Examples of critical control functions are emergency stop and overtravel stop, power outage and restart.
- Separate or redundant control paths must be provided for critical control functions.
- System control paths may include communication links. Consideration must be given to the implications of unanticipated transmission delays or failures of the link.
- Observe all accident prevention regulations and local safety guidelines.<sup>1</sup>
- Each implementation of a control system created using Plant SCADA must be individually and thoroughly tested for proper operation before being placed into service.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

1. For additional information, refer to NEMA ICS 1.1 (latest edition) "Safety Guidelines for the Application, Installation, and Maintenance of Solid State Control", and to NEMA ICS 7.1 (latest edition) "Safety Standards for Construction and Guide for Selection, Installation and Operation of Adjustable-Speed Drive Systems" or their equivalent governing your particular location.

## Supported Devices

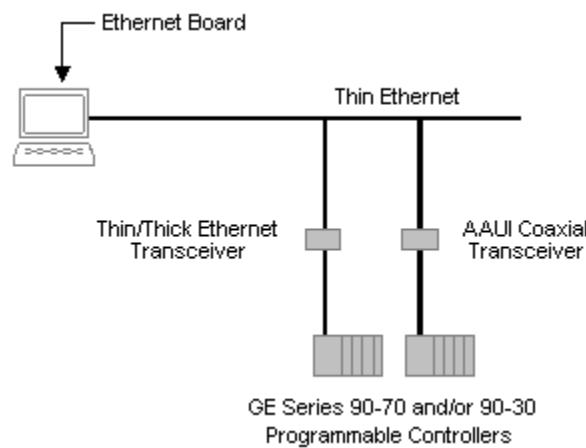

The GETCP driver supports communication with the following devices via Ethernet:

- GE Fanuc 9030 PLCs
- GE Fanuc 9070 PLCs
- GE Fanuc GERx3i via TCP/IP

### GE Fanuc GE9030 via TCP/IP

The GETCP Driver enables TCP/IP communication with GE Fanuc 90-30 PLCs over Ethernet.

Using this method, you can connect to single PLCs or to multiple PLCs as in the following diagram:

## GE Fanuc GE9030 via TCP/IP - Device Address

The information you enter here will be placed in the Special Options field of Plant SCADA's Port settings, with the following format:

-la -Pn -T

Where:

- *a* = the destination IP address in standard Internet dot format. (For example 192.9.2.60)
- *n* = the destination Port number. Often one physical port has several virtual ports, used for different purposes. The default is 18245.
- -T = forces the driver to use TCP (the default), rather than UDP (-U).

See the [GE9030 TCP/IP Overview](#) for more information about this setup.

## GE Fanuc GE9030 via TCP/IP - Hardware Setup

Set up the IP address on the 9030 Ethernet module.

## Hints and Tips

- The 9030 PLCs have an AAUI (Apple Attachment Unit Interface). A transceiver will be needed to connect to other standards (such as Thin Ethernet).
- The transceiver module requires a Signal Quality Error (SQE) test - also known as a heartbeat. Make sure your Ethernet transceiver is set with the SQE test enabled.
- The 9030 PLC CPU can support only one incoming network reference through the Ethernet Interface at a time. Also, the 9030 PLC CPU can support only one programmer connection at a time through either the Ethernet interface or the serial ports. These restrictions will be removed in future upgrades of the PLC and/or Ethernet Interface.

## Plant SCADA Computer Setup

It is recommended that you setup your specific Ethernet card as required and confirm basic network communications before proceeding with the communications configuration for the TCPIP driver. Refer to the documentation accompanying your hardware for instructions.

**Note:** You must also setup the TCP/IP protocol on your Plant SCADA computer.

## GE Fanuc GE9030 via TCP/IP - Communication Settings

To establish communication with a device, the associated Board, Port and I/O Device need to be correctly configured in Plant SCADA Studio's **Topology** activity.

If you use the Express Communications Wizard to connect to a device, these settings will be automatically configured for you. However, if you need to manually configure them, use the settings outlined below.

## Boards

Typically, you would use a normal Ethernet card for this communication. Complete the Board settings with the following specific information.

Field	Value
Board Name	Enter TCPIP.
Address	Enter zero (0).
I/O Port	Leave this field blank.
Interrupt	Leave this field blank.
Special Options	Leave this field blank.

## Ports

Field	Value
Port Name	Any unique number
Baud Rate	Leave this field blank.
Data Bits	Leave this field blank.
Stop Bits	Leave this field blank.
Parity	Leave this field blank.
Special Options	<p>Enter the destination IP address of Ethernet module. Use the following format:</p> <p><b>-la -Pn -T</b></p> <p>where:</p> <p><b>a</b> = the destination IP address in standard Internet dot format. (For example 192.9.2.60)</p> <p><b>n</b> = the destination Port number. Often one physical port has several virtual ports, used for different purposes. Use this option only if you want to override the default of 18245.</p> <p><b>-T</b> = forces the driver to use TCP (the default), rather than UDP (-U).</p>

## I/O Devices

Field	Value
Address	Leave this field blank.
Protocol	Enter GETCP30.

**GE Fanuc GE9030 via TCP/IP - Data Types**

Data Types	Address Format	Plant SCADA Data Type
Discrete Input	Ia	DIGITAL
Discrete Output	Qa	DIGITAL
System Register	Rf	INT, LONG, REAL, BCD, LONGBCD, STRING

#### GE Fanuc GE9070 via TCP/IP

The GETCP Driver enables TCP/IP communication with GE Fanuc 90-70 PLCs over Ethernet.

Using this method, you can connect to single PLCs or to multiple PLCs as in the following diagram:

## GE Fanuc GE9070 via TCP/IP - Device Address

The information you enter here will be placed in the Special Options field of Plant SCADA's Port settings, with the following format:

-la -Pn -T

where:

- *a* = the destination IP address in standard Internet dot format. (For example, 192.9.2.60)
- *n* = the destination Port number. Often one physical port has several virtual ports, used for different purposes. The default is 18245.
- -T = forces the driver to use TCP (the default), rather than UDP (-U).

See the [GE9070 TCP/IP Overview](#) for more information about this setup.

## GE Fanuc GE9070 via TCP/IP - Hardware Setup

Set up the IP address on the 9070 Ethernet module.

## Hints and Tips

The 9070 PLC has a Thick Ethernet port. A transceiver will be needed to connect to other standards (such as Thin Ethernet).

- The transceiver module requires a Signal Quality Error (SQE) test - also known as a heartbeat. Make sure your Ethernet transceiver is set with the SQE test enabled.

## Plant SCADA Computer Setup

It is recommended that you setup your specific Ethernet card as required and confirm basic network communications before proceeding with the communications configuration for the TCPIP driver. Refer to the documentation accompanying your hardware for instruction.

---

**Note:** You must also setup the TCP/IP protocol on your Plant SCADA computer.

---

## GE Fanuc GE9070 via TCP/IP - Communication Settings

To establish communication with a device, the associated Board, Port and I/O Device need to be correctly configured in Plant SCADA Studio's **Topology** activity.

If you use the Express Communications Wizard to connect to a device, these settings will be automatically configured for you. However, if you need to manually configure them, use the settings outlined below.

## Boards

Typically, you would use a normal Ethernet card for this communication. Complete the Board settings with the following information.

Field	Value
Board Name	Enter TCPIP.
Address	Enter zero (0).
I/O Port	Leave this field blank.
Interrupt	Leave this field blank.
Special Options	Leave this field blank.

### GE Fanuc GERx3i via TCP/IP

The GETCP Driver enables TCP/IP communication with GE Fanuc RX3i PLCs over Ethernet.

Using this method, you can connect to single PLCs or to multiple PLCs.

#### GE Fanuc GERx3i via TCP/IP - Device Address

The information you enter here will be placed in the Special Options field of Plant SCADA's Port settings, with the following format:

-la -Pn -T

where:

- *a* = the destination IP address in standard Internet dot format. (For example 192.9.2.60)
- *n* = the destination Port number. Often one physical port has several virtual ports, used for different purposes. The default is 18245.
- -T = forces the driver to use TCP (the default), rather than UDP (-U).

#### GE Fanuc GERx3i via TCP/IP - Hardware Setup

Set up the IP address on the Rx3i Ethernet module.

## Hints and Tips

- The Rx3i PLC has a Thick Ethernet port. A transceiver will be needed to connect to other standards (such as Thin Ethernet).
- The transceiver module requires a Signal Quality Error (SQE) test - also known as a heartbeat. Make sure your Ethernet transceiver is set with the SQE test enabled.

## Plant SCADA Computer Setup

It is recommended that you setup your specific Ethernet card as required and confirm basic network communications before proceeding with the communications configuration for the TCPIP driver. Refer to the documentation accompanying your hardware for instruction.

**Note:** You must also setup the TCP/IP protocol on your Plant SCADA computer.

### GE Fanuc GERx3i via TCP/IP - Communication Settings

To establish communication with a device, the associated Board, Port and I/O Device need to be correctly configured in Plant SCADA Studio's **Topology** activity.

If you use the Express Communications Wizard to connect to a device, these settings will be automatically configured for you. However, if you need to manually configure them, use the settings outlined below.

## Boards

Typically, you would use a normal Ethernet card for this communication. Complete the Board settings with the following information.

Field	Value
Board Name	Enter TCPIP.
Address	Enter zero (0).
I/O Port	Leave this field blank.
Interrupt	Leave this field blank.

## GETCP Driver Parameters

### WARNING

#### UNINTENDED EQUIPMENT OPERATION

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support for this product regarding undocumented features.

### [GETCP]Block

A value (bytes) used by the I/O Server to determine if two or more packets can be blocked into one data request before being sent to the I/O Device. For example, if you set the value to 10, and the I/O Server receives two simultaneous data requests - one for byte 3, and another for byte 8 - the two requests will be blocked into a single physical data request packet. This single request packet is then sent to the I/O Device, saving on bandwidth and processing.

**Allowable Values** 5 to 256

**Default Value** 256

### [GETCP]Delay

The period (in milliseconds) to wait between receiving a response and sending the next command.

**Allowable Values** 0 to 300 (milliseconds)

**Default Value** 0

### [GETCP]MaxPending

The maximum number of pending commands that the driver holds ready for immediate execution.

**Allowable Values** 1 to 32

**Default Value** 15

### [GETCP]PollTime

The interrupt or polling service time (in milliseconds). Setting the polling time to 0 puts the driver in interrupt mode.

**Allowable Values** 0 to 300 (milliseconds)

**Default Value** 0

### [GETCP]Retry

The number of times to retry a command after a timeout.

**Allowable Values** 0 to 8

**Default Value** 1

### [GETCP]Timeout

Specifies how many milliseconds to wait for a response before displaying an error message.

**Allowable Values** 0 to 32000 (milliseconds)

**Default Value** 1000

### [GETCP]WatchTime

The frequency (in seconds) that the driver uses to check the communications link to the I/O Device.

**Allowable Values** 0 to 128 (seconds)

**Default Value** 30

## GETCP Driver Specific Errors

When a hardware error occurs, Plant SCADA generates an alarm, and displays the alarm on the hardware alarm page (in the alarm description of the hardware alarm). To see the error number, make sure you have Alarm Category 255 defined with a display format that includes {ErrDesc,15} {ErrPage,10}.

There are a number of generic errors that are common to all protocols. In some cases only the generic error is available, though often both the generic error and a specific error are given.

The following errors, listed in (hexadecimal) sequence, are specific to this protocol. Plant SCADA displays the error number and description for common protocol-specific errors. Uncommon errors are not contained in the Plant SCADA error database, in which case Plant SCADA will only display the error number.

You may require additional information to enable you to rectify an error. This information should be detailed in the documentation that accompanied the I/O Device (or network). If, after reviewing all documentation, you cannot rectify an error, contact Technical Support.

#### 0x05F4

Invalid input parameters in request.

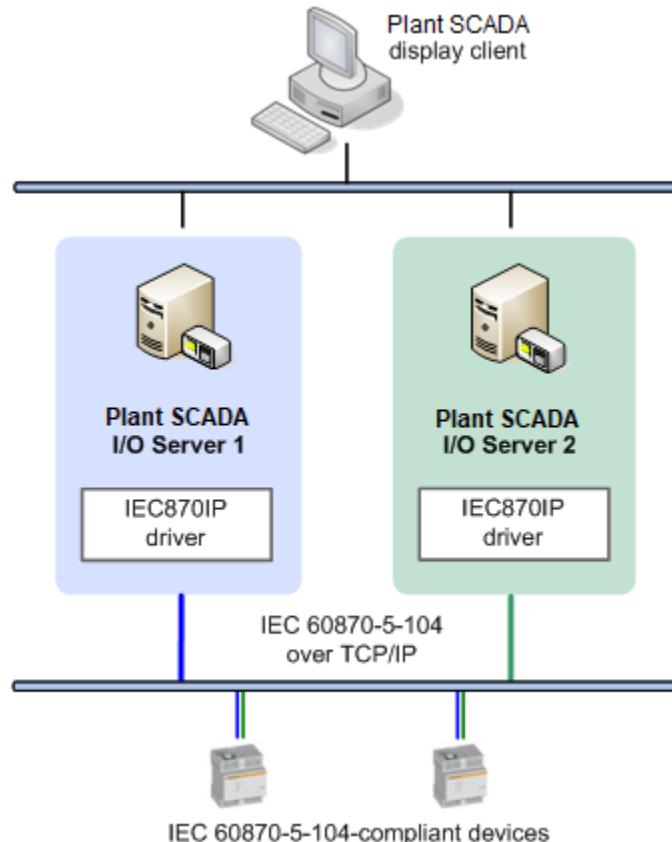

#### 0x05C3

Text length does not match traffic type.

## IEC870IP Driver

The IEC870IP driver enables Plant SCADA to communicate via TCP/IP with devices that use the IEC 60870-5-104 communication protocol.

The following diagram demonstrates a simple system configuration, with Plant SCADA connected to IEC 60870-5-104 devices via the IEC870IP driver hosted on a single pair of redundant I/O servers.

### The Driver Runtime Interface (DRI)

With the release of version 7.20, Citect SCADA supported the retrieval of time-stamped data directly from field devices. This capability is enabled by the Driver Runtime Interface (DRI), a component of Plant SCADA that is used by the IEC870IP driver to directly update time-stamped digital alarms, time-stamped analog alarms and event-based trends. For more information, see the topic *Retrieving time-stamped data from field devices* in the main Plant SCADA help.

---

**Note:**

- As version 4.05.01.0 (or later) of the IEC870IP driver relies on the DRI, it requires Citect SCADA version 7.20 (or later) to operate successfully.
  - This documentation was created to support version 4.05.01.0 (or later) of the IEC870IP driver. Due to significant changes to the driver with this release, this documentation should not be used with an earlier version of the driver.

## Safety Information

### Hazard categories and special symbols

The following symbols and special messages may appear in this manual or on the product to warn of potential hazards or to call attention to information that clarifies or simplifies a procedure.

Symbol	Description
 or 	The addition of either symbol to a "Danger" or "Warning" safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.
	This is the safety alert symbol. It is used to alert you to personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.

#### DANGER

**DANGER** indicates an imminently hazardous situation, which, if not avoided, will result in death or serious injury.

#### WARNING

**WARNING** indicates a potentially hazardous situation, which, if not avoided, can result in death or serious injury.

#### CAUTION

**CAUTION** indicates a potentially hazardous situation which, if not avoided, can result in minor or moderate injury.

**NOTICE**

NOTICE used without a safety alert symbol, indicates a potentially hazardous situation which, if not avoided, can result in property or equipment damage.

**Please Note**

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by AVEVA for any consequences arising out of the use of this material.

**Before You Begin**

Plant SCADA is a Supervisory Control and Data Acquisition (SCADA) solution. It facilitates the creation of software to manage and monitor industrial systems and processes. Due to Plant SCADA's central role in controlling systems and processes, you must appropriately design, commission, and test your Plant SCADA project before implementing it in an operational setting. Observe the following:

** WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not use Plant SCADA or other SCADA software as a replacement for PLC-based control programs. SCADA software is not designed for direct, high-speed system control.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

** WARNING****LOSS OF CONTROL**

- The designer of any control scheme must consider the potential failure modes of control paths and, for certain critical control functions, provide a means to achieve a safe state during and after a path failure. Examples of critical control functions are emergency stop and overtravel stop, power outage and restart.
- Separate or redundant control paths must be provided for critical control functions.
- System control paths may include communication links. Consideration must be given to the implications of unanticipated transmission delays or failures of the link.
- Observe all accident prevention regulations and local safety guidelines.<sup>1</sup>
- Each implementation of a control system created using Plant SCADA must be individually and thoroughly tested for proper operation before being placed into service.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

1. For additional information, refer to NEMA ICS 1.1 (latest edition) "Safety Guidelines for the Application, Installation, and Maintenance of Solid State Control", and to NEMA ICS 7.1 (latest edition) "Safety Standards for Construction and Guide for Selection, Installation and

Operation of Adjustable-Speed Drive Systems" or their equivalent governing your particular location.

## Supported Devices

The IEC870IP driver allows Plant SCADA to communicate with devices that use the IEC 60870-5-104 communication protocol. The driver is limited to the 104 extension of the protocol, as it uses TCP/IP as its network interface.

---

**Note:** The driver can only support up to 256 devices per I/O server. If you configure more than this amount, the 257th device will not come online, and a hardware alarm will be raised.

---

### Interoperability

The IEC 60870-5-104 standard defines a set of parameters and alternatives it can support, compared against those used by the 101 standard. This is outlined in the standard in the interoperability list.

Any telecontrol equipment or systems that are designed to adhere to the standard can implement a subset of the alternatives defined in this list, based on specific requirements. To view the subset of options used by the IEC870IP driver, see the appendix [IEC 870-5-104 Interoperability List](#).

## See Also

[Setting up Device Communications](#)

## Setting up Device Communications

The information included in the following topics is required to establish communication between Plant SCADA and an IEC60870-5-104 device connected via the IEC870IP driver.

- [Using the Express Communications Wizard](#) - the information you will need if you are using the Express Communications Wizard to connect to a device.
- [Communications Settings](#) - the recommended board, port and devices settings for manual configuration.

## Using the Express Communications Wizard

To set up communication using the Plant SCADA Express Communications Wizard, you will need to provide an **Address**, an **IP address** and **Port** number.

- **Address**

The address to use for an IEC 870-5-104 device is the common ADSU address. This value is configured on the device and will be a number between 1 and 65535.

- **IP address**

The IP address of the device.

- **Port**

The default port number for the IEC 870-5-104 protocol is 2404.

---

**Note:** It is recommended you use TCP protocol when setting up an IEC 870-5-104 device.

---

This information is placed in the **Special Options** field of the **Ports** settings by the Express Communications

Wizard using the following format:

—I<device IP address> —P<port number> —<T (TCP)>

For example:

—I192.1.1.182—P2404 —T

## Communications Settings

To establish communication with a device, the associated Board, Port and I/O Device need to be correctly configured in Plant SCADA Studio's **Topology** activity.

If you use the Express Communications Wizard to connect to a device, these settings will be automatically configured for you. However, if you need to configure the settings manually, use the values outlined below.

### Board settings

The Boards view lists boards used in the Plant SCADA project. Each board record defines a separate board within the project.

The IEC870IP driver is a board-level driver, which means it requires a single board configured for each I/O server.

Field	Value
Board Name	Any user-defined name (e.g. "Board1")
Board Type	TCP/IP
Address	0 (zero)
I/O Port	Leave this field blank
Interrupt	Leave this field blank
Special Options	Leave this field blank
Comment	Any useful comment (not required by the driver)

### Port settings

The Ports view lists the ports used in the Plant SCADA project. Each port record defines a separate port within the project.

A separate port should be created for each IEC 870-5-104 device.

Field	Value
Port Name	Any user-defined name (e.g. "Port1")
Port Number	The default port number for the IEC 870-5-104 protocol is 2404.
Board Name	Refers to the board defined in the Boards form

Field	Value
Baud Rate	Leave this field blank
Data Bits	Leave this field blank
Stop Bits	Leave this field blank
Parity	Leave this field blank
Special Options	<p>Use the address for the IEC 870-5-104 device using the following format:</p> <p>—I&lt;device IP address&gt; —P&lt;port number&gt; —&lt;T (TCP)&gt;</p> <p>For example:</p> <p>—I192.1.1.182—P2404 —T</p> <p>The default port number for the IEC 870-5-104 protocol is 2404</p>
Comment	Any useful comment (not required by the driver)

## I/O Device settings

The I/O Devices view lists I/O devices used in the Plant SCADA project. Each device record defines a device within the project.

A Plant SCADA I/O device represents a single IEC 870-5-104 device.

Field	Value
Name	Any user-defined name (e.g. "IODevice1")
Number	I/O device number needs to be unique for each I/O device, but identical for redundant devices.
Address	The address to use for an IEC 870-5-104 device is the common ADSU address. This value is configured on the device and will be a number between 1 and 65535.
Protocol	IEC870IP
Port Name	Refers to the port defined in the Ports form
Comment	Any useful comment. This field is user defined and not required by the driver

## Configuring Variable Tags

The IEC870IP driver supports the following variable tag types:

- [Input Tags](#) - tags that allow process information to be passed to Plant SCADA in a monitoring direction
- [Read Tags](#) - tag that send a read command to request data
- [Output Tags](#) - tag that allow process information to be sent in a control direction
- [Control Tags](#) -tags that can be used to send commands in a control direction
- [Array Tags](#) - tags that represent array elements
- [Virtual Tags](#) - tags that retrieve the status of specific commands.

---

**Note:** The driver supports unstructured tag addresses (e.g. "<IOA>"), as well as structured tag addresses (e.g. "<IOA1>.<IOA2>.<IOA3>"). For more information, see [Structured Tag Addressing](#).

---

### Read Tags

Read tags can be used to retrieve data from IO points that require a read command. See [Using Read Commands to Retrieve Data](#).

<IOA> is used to represent an information object address, defined as a decimal number in the range 0 — 16777215.

**Note:** The tags with the following addresses are only updated when the driver receives a timestamped value directly from a device.

- RSD<IOA>
- RSI<IOA>
- RSL<IOA>
- RSF<IOA>
- RSQD<IOA>

See [Timestamp Handling](#) for more information on the correct syntax to use for your input tags.

Address format	Plant SCADA type	IEC 60870 type	Description
RD<IOA> RSD<IOA>	DIGITAL	Single point Double point	<p>Read command for digital value: Example: RD100</p> <p><b>Note:</b> By default, digital tags report double point states as:</p> <ul style="list-style-type: none"><li>• 1 "On"</li><li>• 0 "Off"</li><li>• 0 "Indeterminate"</li><li>• 0 "Intermediate".</li></ul> <p>This behaviour can be changed to report just the "On" and "Off" states using the INI parameter <a href="#">Data Interrogation</a></p>

Address format	Plant SCADA type	IEC 60870 type	Description	
		<a href="#">Parameters.</a>		
RI<IOA> RSI<IOA>	INTEGER	Measured value: normalized and scaled value Step Position Double Point	Read command for integer value: Example: RI200	
RL<IOA> RSL<IOA>	LONG	Integrated totals	Read command for long value: Example: RL300	
RF<IOA> RSF<IOA>	FLOAT	Short Floating Point	Read command for float value: Example: RF350	
RQD<IOA> RSQD<IOA>	INTEGER	Quality descriptor	Read command for IEC 60870 quality flags and the IEC870IP driver specific flags Example: RQD350	

The address format used in the table above demonstrates unstructured tag addresses (i.e. "<IOA>"). The IEC870IP driver also supports structured tag addresses (e.g. "<IOA1>.<IOA2>.<IOA3>"). For more information, see [Structured Tag Addressing](#).

---

**Note:** Care should be taken when configuring read tags in a system because the read process is less efficient than the usual spontaneous update process. Due to the polling mechanism, read tags will consume more system and network resources than other tags. For example, if you have more than 500 read command tags configured, it may impact the tag value update rate on a page as the driver will have to issue a read command for each tag on a page.

## Output Tags

The driver defines a number of tag addresses which can be used to send process information in a control direction. The output tags are write only.

The following tags are used to perform direct write operations.

<IOA> is used to represent an information object address, defined as a decimal number in the range 0 — 16777215.

---

**Note:** To send the command with the time tag *CP56Time2a*, use the address with a suffix "T".

Address format	Plant SCADA type	IEC 60870 command	Description
C<IOA> CT<IOA>	DIGITAL	Single command Double command	Digital output: Double commands are only ever used for trip/

Address format	Plant SCADA type	IEC 60870 command	Description
		Regulating step command	<p>close operations, so only 2 states are valid. Hence they will be treated as single digital output points by Plant SCADA, and translated in the driver.</p> <ul style="list-style-type: none"> <li>• 0 becomes (0,1) (trip)</li> <li>• 1 becomes (1,0) (close)</li> </ul> <p>Regulating step commands are similar to single commands, except that writing a 0 means "next step lower", and 1 means "next step higher".</p>
CI<IOA> CIT<IOA>	INTEGER	Set point command: normalized and scaled value	Integer output
CF<IOA> CFT<IOA>	FLOAT	Set point command: short floating point number	Float point output

The following tags are used for digital select/execute operations.

Address format	Plant SCADA type	Description
C<IOA>.Sel CT<IOA>.Sel	DIGITAL	Transmits select request
C<IOA>.Desel CT<IOA>.Desel	DIGITAL	Transmits break off command (deselect request)
C<IOA>.Ex CT<IOA>.Ex	DIGITAL	Transmits execute request
CI<IOA>.Sel CIT<IOA>.Sel	INTEGER	Transmits set point command(select request) for normalized or scaled value.
CI<IOA>.Desel CIT<IOA>.Desel	INTEGER	Transmits set point command(deselect request) for normalized or scaled value.
CI<IOA>.Ex CIT<IOA>.Ex	INTEGER	Transmits set point command(execute request) for

Address format	Plant SCADA type	Description
		normalized or scaled value.
CF<IOA>.Sel CFT<IOA>.Sel	FLOAT	Transmits set point command(select request) for short floating point.
CF<IOA>.Desel CFT<IOA>.Desel	FLOAT	Transmits set point command(deselect request) for short floating point.
CF<IOA>.Ex CFT<IOA>.Ex	FLOAT	Transmits set point command(execute request) for short floating point.

**Note:** Double commands, regulating step commands and set-point commands for scaled value are only supported if a tag is configured in the IOA configuration file with the appropriate information. See [Configuring Commands for Individual IOAs](#).

The following tag is used to get a cause of transmission code passed in monitoring direction after completion of single and double commands, regulating step command and set point commands. This tag has read/write access.

Address format	Plant SCADA type	Description
C<IOA>.Conf CT<IOA>.Conf	INTEGER	<p>Confirmation code:</p> <ul style="list-style-type: none"> <li>• 0x7 - activation confirmation</li> <li>• 0x9 - deactivation confirmation</li> <li>• 0x10 - activation termination</li> <li>• 0x44 - unknown type identification</li> <li>• 0x45 - unknown cause of transmission</li> <li>• 0x46 - unknown common address of ASDU</li> <li>• 0x47 - unknown information object address</li> </ul>

**Note:** The address format used in the tables above demonstrates unstructured tag addresses (i.e. "<IOA>"). The IEC870IP driver also supports structured tag addresses (e.g. "<IOA1>.<IOA2>.<IOA3>"). For more information, see [Structured Tag Addressing](#).

## Control Tags

The driver defines a number of tag addresses which can be used to send system information in a control direction. These tags are write-only.

Address format	Plant SCADA type	IEC 60870 command	Description
FORCEGI	DIGITAL	Interrogation command	Writing "1" to this digital

Address format	Plant SCADA type	IEC 60870 command	Description
			register will force a general interrogation of the device.
FORCECS	DIGITAL	Clock synchronization command	Writing "1" to this digital register will force a clock synchronization of the device.
FORCECI	DIGITAL	Counter interrogation command	Writing "1" to this digital register will force a counter interrogation of the device (without freeze or reset of the counters).
COUNTFZ	DIGITAL	Counter interrogation command	Writing "1" to this digital register will perform a counter freeze on the device.
COUNTRS	DIGITAL	Counter interrogation command	Writing "1" to this digital register will perform a counter reset on the device.
COUNTFZRS	DIGITAL	Counter interrogation command	Writing "1" to this digital register will perform a counter freeze and reset on the device.

## Array Tags

You can configure array tags in Plant SCADA for an IEC 60870-5-104 device using the following syntax:

**D<IOA>[array size]**

Be aware, however, that each element of an array is delivered independently. This means Plant SCADA will receive separate array value updates after each array element value changes.

### Example

Assume a user configures an array I100[5], and its initial value is {0,5,0,0,10}.

If the values for the first two elements change to 4 and 10, Plant SCADA will first display {4,5,0,0,10} and then {4,10,0,0,10}.

The quality of the array tag will be equal to the worst quality of the array elements, and the timestamp will be equal to the latest timestamp of the array elements.

---

**Note:** The address format used above demonstrates an unstructured tag address (i.e. "<IOA>"). The IEC870IP driver also supports structured tag addresses (e.g. "<IOA1>.<IOA2>.<IOA3>"). For more information, see [Structured Tag Addressing](#).

## Virtual Tags

The driver defines tag addresses which can be used to retrieve the status of the commands listed in the table below. These tags are read-only.

The driver will update the value of these tags after a command has completed successfully, or failed to complete successfully. If the command completes successfully, the tag value will be set to False otherwise it will be set to True.

Address format	Plant SCADA type	Status for IEC 60870 command
IsGI	DIGITAL	Interrogation command
IsTimeSync	DIGITAL	Clock synchronization command
IsDelayAcq	DIGITAL	Delay acquisition command
IsProtoReset	DIGITAL	Reset command
IsLinkStatus	DIGITAL	Link status command
IsProcessControl	DIGITAL	Control command

## Structured Tag Addressing

The IEC870IP driver supports structured tag addresses using the following format:

<IOA1>.<IOA2>.<IOA3>

When constructing a structured address, each element represents a decimal number in the range 0 — 255. For example:

0.1.126

This can be used instead of an unstructured address (i.e. <IOA>), which represents the information object address as a decimal number in the range 0 — 16777215.

## See Also

[Configuring Variable Tags](#)

## Value Quality Support

The IEC870IP driver can confirm the quality of values received from a device through support for the quality flags implemented by the IEC870-5-101 protocol.

The quality flags are defined by a quality descriptor that is delivered with each value received from a device. The IEC870IP driver then performs a conversion of the quality flags it receives, providing a description of value quality based upon OPC quality.

## See Also

[Quality Descriptors](#)  
[Quality Mapping](#)  
[Value Timestamping](#)

## Quality Descriptors

The IEC870IP driver uses the quality flags implemented by the IEC870-5-101 protocol to determine the quality of a value.

The quality descriptor word that defines these flags has bits defined as follows:

Bit number	Description
0 (least significant)	For Single Points: If the StoreDigitalInQual parameter is 1, this bit contains the current point value  For Double Points: If the StoreDigitalInQual parameter is set this bit contains the lower bit of the point value (DPI)  For Counters: Overflow or counter carry indication
1	Transient for integer inputs  For Double Points (if the StoreDigitalInQual parameter is 0 ): Indeterminate / intermediate state for double digital inputs (DDI)  For Double Points (if the StoreDigitalInQual parameter is 1 ): The upper bit of the point value (DPI)
2	For Double Points (if the StoreDigitalInQual parameter is 0 ): Invalid state for double digital inputs (DDI)
3	Blocked
4	Substituted
5	Not topical
6	Invalid
7	Counter adjusted since last reading
8... 12	Counter Sequence number (number from 0 to 31)

Bit number	Description
13	Quality Descriptor out of date
14	Timestamp was provided by PC, not RTU
15 (most significant)	Timestamp from RTU has "invalid" set. (This bit is undefined if timestamp is provided by PC, i.e. bit 14 is set.)

**Note:** The StoreDigitalInQual parameter can be used to allow the state of a point to be stored within a quality descriptor. However, this will impact the way double point digital values are read by the IEC870IP driver. See [Data Interrogation Parameters](#) for more information.

Once a quality flag is received by the driver, it is mapped to an OPC-based quality value that is presented in the Plant SCADA project.

## See Also

[Quality Mapping](#)

## Quality Mapping

The driver performs a conversion of IEC60870 quality flags into a Plant SCADA quality representation. This conversion is based on OPC quality.

The following table describes the mapping of the IEC 60870 quality flags into Plant SCADA quality. The flags are listed in the order of priority so that if multiple quality flags are set, the driver will push the OPC quality flags for the quality bit with the highest priority:

IEC6870 quality bit	OPC quality flags
Invalid	General: Bad Substatus: Device Failure
Blocked	General: Uncertain Substatus: Last Usable Value
Not topical	General: Uncertain Substatus: Last Usable Value
Substituted	General: Good Substatus: Local Override
Overflow	General: Uncertain Substatus: Engineering Units Exceeded

**Note:** When using TagRead or TagReadEx Cicode functions, the driver is only able to return an error code for conversion to OPC quality in Plant SCADA. This means that the tag quality will only represent the general component of a quality flag.

## Value Timestamping

The IEC780IP driver pushes values to Plant SCADA as they are received via the DRI.

Depending on the device, the driver may receive timestamped or non-timestamped value updates. When a timestamp value is not provided by a device, it can be manufactured by the driver based on the time the update is received. This behavior can be manipulated by the driver parameter [Data Interrogation Parameters](#).

The way Plant SCADA processes timestamp values can also be impacted by the type of input tags you use. See [Timestamp Handling](#) for more information.

The timestamp value the driver pushes to Plant SCADA is a 64-bit value representing the number of 100-nanosecond intervals since January 1, 1601 (UTC).

By default when a timestamped value is received, the values for timestamped and non-timestamped tags will be updated. That behavior can be changed by the [Data Interrogation Parameters](#) ini parameter.

## Timestamp Handling

The IEC60870-5 protocol supports data updates through three types of transmission:

non-timestamped

timestamped

double transmission

Plant SCADA requires a timestamp to be pushed into the I/O server and the rest of the SCADA system for every data update. Where a protocol has not provided a timestamp, a Plant SCADA driver will typically create a timestamp based on the time the data was received.

A special case exists in the IEC870IP driver, where two input tag address options are available:

- "S" prefix addresses are only updated by protocol messages with a timestamp:
  - SD<IOA>
  - SI<IOA>
  - SL<IOA>
  - SF<IOA>
  - SQD<IOA>
- "Non-S" type tags use a driver manufactured timestamp by default:
  - D<IOA>
  - I<IOA>
  - L<IOA>
  - F<IOA>
  - QD<IOA>

For data archiving and event analysis, Plant SCADA offers event trend and timestamped alarm recording options with millisecond accuracy. To avoid superfluous or missing updates due to out of sequence timestamps during startup, active device transitions, or double transmissions, the IEC870IP driver exposes "S" prefix addresses which are only ever updated by protocol messages with a timestamp.

These tags remain #BAD quality at startup until a message with a timestamp arrives. Messages with a value

change but no timestamp will not be pushed to Plant SCADA for these tags.

Double transmission is a IEC60870-5 feature where an RTU will place a high priority value update in its transmit queue as soon as possible after an event. The device will also place a second lower priority message with the same value and also a timestamp.

To capture and action the first high priority data change, a "non-S" tag can be displayed on a page or non-timestamped alarm. Using the "S" prefix tags allows Plant SCADA to archive only the timestamped messages for analysis.

In summary:

- When configuring event trends, timestamped digital or timestamped analog alarms, an "S" prefix tag address should be used.
- When configuring display pages and non-timestamped alarms, the "non-S" tags should be used.

---

**Note:** You need to carefully consider the tag address you use for timestamped alarms and event trends, as the use of a "non-S" tag may cause a delay in the delivery of information to an operator.

---

## The ManufactureTimestamp parameter

The Citect.ini parameter [Data Interrogation Parameters](#) allows one of two options to be selected when configuring "non-S" type tags. The default is to push a driver manufactured timestamp to the I/O server each time for consistency. The alternative option is for the driver to update a tag with a protocol timestamp if one is available. Be aware that this may cause a value displayed on a page to flicker or step backward at times.

## Advanced Configuration and Maintenance

This section provides instructions for advanced configuration and maintenance tasks.

- [Using Read Commands to Retrieve Data](#)
- [Events Handling](#)
- [Configuring Redundancy](#)
- [Customizing a Project using Citect.ini Parameters](#)
- [Configuring Commands for Individual IOAs](#)

### Using Read Commands to Retrieve Data

In some cases, the value for an I/O point can only be retrieved using a read command. For example, a particular I/O point may not support spontaneous events or general interrogation.

Under these circumstances, there are two ways you can read from an I/O point:

- the TagRead function
- the IEC870IP driver's polling engine

In both cases, you will need to configure [Read Tags](#) to successfully retrieve data from field devices. Where a read tag has been used, the driver will send a read command to request data.

#### The TagRead function

The TagRead function will send a read command to the specified IO point and process the response before responding to replying to the function call.

### The polling engine

The IEC870IP driver has an integrated polling engine that allows you to retrieve values for any IO point using regular read command requests sent directly to the device.

The rate at which requests are executed is defined by the subscription rate of the tag. If more than one tag is using the same item, the polling rate will be determined by the highest subscription rate.

The polling engine consists of two main components:

- poll item buckets - which contain the variables that need to be scanned, grouped according to their scan rate.
- the polling manager - which creates the poll item buckets as required, and notifies them if read requests need to be executed.

At start up, all variables are stored in the "not polled" bucket (scan rate is -1). When a subscription is received, the polling manager assigns variables to the poll item buckets according to their scan rate, creating the buckets as required.

If the subscription changes for a tag, the polling rate for any affected item is changed as well and the variables are moved to an appropriate bucket. If the subscription for a variable ends, it is placed back in the "not polled" bucket.

---

**Note:** The polling interval used by the polling manager can be configured using the parameter [Polling Parameters](#). The default value is 100ms.

---

### Events Handling

Spontaneous events are pushed to the relevant servers through the DRIClosed. The IEC870IP driver will confirm with the DRI that events are delivered to the appropriate servers before responding back to the device with acknowledgment. It is possible to change that behavior so that the driver will acknowledge spontaneous events immediately after receiving it from the device by using the parameter DRIGuaranteedEventsDelivery.

If the DRI does not indicate that an event was successfully delivered within the time specified by the parameter DRIResponseTimeout, the driver will still send acknowledgment to the device, though it will also update the driver log with an error message.

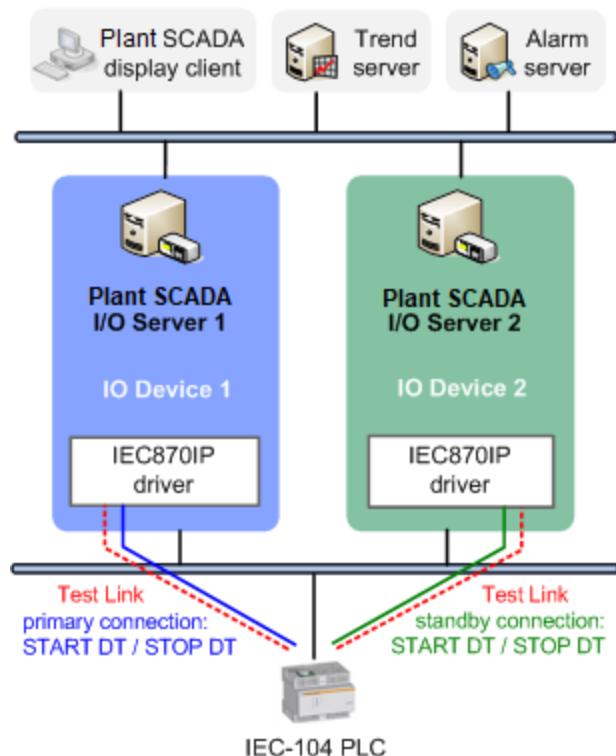

By default, DRIResponseTimeout is set to 1000 milliseconds. This means a response can be sent back to the device to allow acknowledgment to take place in a situation where a destination for an event is not configured in the SCADA system.

See [Communication Parameters](#).

### Configuring Redundancy

The IEC870IP driver supports redundant communication with devices at the I/O server level.

The following diagrams shows the configuration of a simple redundant system with a pair of I/O servers connected to an IEC-60870-5-104 device. The physical device is represented on both I/O servers.

Both I/O servers establish a TCP/IP connection to a device and periodically send test link messages to confirm that it is still online.

As the IEC 60870-5-104 standard specifies that only one master station can perform data interrogation on a device at a time, redundancy is managed through the implementation of START DT/STOP DT requests.

The I/O server with the highest priority connection to the I/O device sends a START DT request to the device to commence data interrogation. If the test link determines the connection to the device has stopped working, the second I/O server assumes highest priority and sends a START DT request.

If the initial server then comes back online, it once again assumes highest priority and issues a START DT request. This will prompt the other server to send a STOP DT request.

---

**Note:** You can adjust the rate of transmission used for test link message via the driver parameter [Communication Parameters](#).

---

## Customizing a Project using Citect.ini Parameters

The IEC870IP driver supports the following parameter categories:

- General Parameters
- Communication Parameters
- Data Interrogation Parameters
- Write Parameters
- Counter Parameters
- Time Synchronization Parameters
- Polling Parameters
- Logging Parameters

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

- Do not under any circumstances change or remove any citect.ini parameters without an informed understanding of the possible implications of your actions.
- Do not delete sections of the citect.ini file without an informed understanding of the possible implications of your actions.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** At times during the life cycle of a driver, circumstances may call for the creation of specific citect.ini parameters that remain undocumented. Always seek the advice of Technical Support regarding the possible implementation of undocumented parameters before you make any changes to a citect.ini file.

Citect.ini parameters are used to tune the performance of the Plant SCADA IEC870IP driver, and to perform runtime maintenance diagnostics.

You can customize the way Plant SCADA communicates with the IEC870IP system (and even individual PLCs) by creating or editing the [IEC870IP] section of the citect.ini file for your project.

When Plant SCADA starts at runtime, it reads configuration values from the citect.ini file that is stored locally. Therefore, any IEC870IP configuration settings need to be included in the citect.ini file located on the computer acting as the I/O server to the IEC870IP system.

By default, Plant SCADA looks for the citect.ini file in the bin directory of the Plant SCADA project. If it can't find the file there, it searches the default Windows directory.

**Note:** The IEC870IP driver can be supported by an IOA configuration file that allows output points to be operated using output commands on a per-IOA basis. See [Configuring Commands for Individual IOAs](#).

You can also set some parameters for every device connected to a specific port. See [Port-specific Parameters](#).

**General Parameters****⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** At times during the life cycle of a driver, circumstances may call for the creation of specific citect.ini parameters that remain undocumented. Always seek the advice of Technical Support regarding the possible implementation of undocumented parameters before you make any changes to a citect.ini file.

[IEC870IP] Parameter	Description	Allowable Values	Default Value
Block	A value (bytes) used by the I/O server to determine if two or more	512	512

	<p>packets can be blocked into one data request before being sent to the I/O device.</p> <p><b>Note:</b> This is a common I/O server parameter that does not impact this driver as blocking is not supported. There is no benefit to changing the value of this parameter.</p>		
Delay	<p>The period (in milliseconds) to wait between receiving a response and sending the next command.</p> <p><b>Note:</b> Do not change this parameter from the default value of 0 (zero), as applying a delay will impact the performance of this driver.</p>	0 (milliseconds)	0
MaxPending	This parameter limits the number of outstanding asynchronous request issued from the I/O server to the driver.	1 - 32	1
Poltime	<p>This parameter is required to clear the receive queue.</p> <p>Each poll time, the driver will check for any entries in the send and receive queue. If any entries are found, the driver will process the data from the queues into the driver's data image. From there, the driver will push into the DRI and SCADA system.</p> <p>The size of the receive queue is governed by the parameter [IEC870IP]ReceiveQueueSi</p>	0 - 300 (milliseconds)	100

	ze (default = 1000)		
Retry	If a DCB command to the driver times out, this parameter determines how many times the command will be tried again before reporting the driver offline.	0 - 8	1
Timeout	This timeout relates to any DCB request issued to the driver.  If a response is not received, this parameter determines how long to wait before the request is issued again.  The driver will be considered offline if no response is received following the number of request attempts specified by the Retry parameter.	0 - 32000 (milliseconds)	2000
Watchtime	The frequency with which the I/O server checks the communications link to an I/O device if the device is determined to be offline.	0 - 128 (seconds)	1

## Communication Parameters

### WARNING

#### UNINTENDED EQUIPMENT OPERATION

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** At times during the life cycle of a driver, circumstances may call for the creation of specific citect.ini parameters that remain undocumented. Always seek the advice of Technical Support regarding the possible implementation of undocumented parameters before you make any changes to a citect.ini file.

[IEC870IP] Parameter	Description	Allowable Values	Default Value
CommandTimeout	Specifies how long the	0 - 32767	15000

	<p>driver will wait for acknowledgment of a command sent to a device.</p> <p><b>Note:</b> You can set this parameter for every device connected to a specific port. See <a href="#">Port-specific Parameters</a>.</p>	(milliseconds)	
ConnectionTimeout	<p>Specifies how long the driver will wait for the TCP/IP connection to be established with a device before setting the device offline.</p> <p><b>Note:</b> You can set this parameter for every device connected to a specific port. See <a href="#">Port-specific Parameters</a>.</p>	0 - 32767 (milliseconds)	30000
DelayChannelOffline	<p>Specifies how long driver should wait before reporting channel offline if TCP/IP connection is closed from device.</p> <p><b>Note:</b> This parameter shouldn't be adjusted without advise from support engineer.</p> <p>You can set this parameter for every device connected to a specific port. See <a href="#">Port-specific Parameters</a>.</p>	0 - 32767 (milliseconds)	5000
DRIGuaranteedEventsDelivery	<p>Specifies how the driver acknowledges spontaneous events received from the device. If the parameter is set to 1, the driver will acknowledge a spontaneous event only after it has been successfully delivered to the appropriate Plant</p>	0 or 1	1

	SCADA servers. Otherwise that event will be acknowledged immediately after receiving it from the device.		
DRIResponseTimeout	<p>Specifies the amount of time the driver will wait for a response from the DRI following delivery of a spontaneous event. Once a response is received, acknowledgment is sent to the device.</p> <p>If a response is not received within the time specified, acknowledgment is still sent to the device, though an error message is logged.</p> <p>See <a href="#">Events Handling</a>.</p> <p><b>Note:</b> You can set this parameter for every device connected to a specific port. See <a href="#">Port-specific Parameters</a>.</p>	1000 - 150000 (milliseconds)	1000
GIPollTimeSec	<p>Specifies how often the driver performs a general interrogation (GI).</p> <p>If the parameter is set to 0, the GI is performed only once when the driver commences data interrogation.</p>	0 - 32767 (seconds)	3600
ReceiveQueueSize	<p>Sets the maximum number of messages supported by the channel receive queue.</p> <p>If the receive queue is full, the driver will replace the oldest message with a new one. If this occurs, an error message will be</p>	100 - 32767	1000

	recorded in the driver log file.		
ResetSendReceiveSequence NumbersOnSwitchover	Specifies whether the driver resets the message send and receive sequence numbers during redundancy switchover.  By default, the I/O device which becomes active resets the send and receive sequence numbers after a STARTDT message.	0 or 1	1
TxTestLink	Specifies how often the driver sends Test Link messages.  Setting this parameter to 0 will disable the periodic sending of Test Link messages.  (See <a href="#">Configuring Redundancy</a> .)	0 - 3600000 (milliseconds)	20000

## Data Interrogation Parameters

### WARNING

#### UNINTENDED EQUIPMENT OPERATION

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** At times during the life cycle of a driver, circumstances may call for the creation of specific citect.ini parameters that remain undocumented. Always seek the advice of Technical Support regarding the possible implementation of undocumented parameters before you make any changes to a citect.ini file.

[IEC870IP] Parameter	Description	Allowable Values	Default Value
ManufacturedIsUTC	Determines if the 56-bit timestamp value received from the device is considered to be UTC time or not.  <b>Note:</b> You can set this parameter for every	0 = timestamp is not UTC 1 = timestamp is UTC	0

	device connected to a specific port. See <a href="#">Port-specific Parameters</a> .		
ManufactureTimestamp	<p>This parameter controls the value timestamp for tags with following addresses:</p> <ul style="list-style-type: none"> <li>• D&lt;IOA&gt;</li> <li>• I&lt;IOA&gt;</li> <li>• L&lt;IOA&gt;</li> <li>• F&lt;IOA&gt;</li> <li>• QD&lt;IOA&gt;</li> </ul> <p>If the parameter is set to 0 (the default), the value timestamp will be equal to the device timestamp, or to the driver manufactured timestamp when the driver receives a value update.</p> <p>If the parameter is set to 1, every value timestamp will be manufactured by the driver.</p> <p><b>Note:</b> You can set this parameter for every device connected to a specific port. See <a href="#">Port-specific Parameters</a>.</p>	0 or 1	0
ReportDoubleDigitalPointOnOffStates	<p>When a double digital point is configured using a digital tag, by default it reports double point states as:</p> <ul style="list-style-type: none"> <li>• 1 "On"</li> <li>• 0 "Off"</li> <li>• 0 "Indeterminate"</li> <li>• 0 "Intermediate".</li> </ul> <p>If this parameter is enabled, the driver will only report a value update when the double point value is set to "On" or "Off" states.</p>	0 or 1	0

StoreDigitalInQual	<p>Determines if the value of a single or double digital point is stored inside the quality descriptor. This allows a single tag to be used for both value and quality information.</p> <p><b>Note:</b> The following information only applies when StoreDigitalInQual is set to 1.</p> <p>The IEC standards specifies the following for a double-point digital DPI field:</p> <ul style="list-style-type: none"> <li>• If DPI=0, the field is "indeterminate or intermediate"</li> <li>• If DPI=1, the field is "valid"</li> <li>• If DPI=2, the field is "valid"</li> <li>• If DPI=3, the field is "indeterminate"</li> </ul> <p>To determine the value of the DPI from a digital tag (D) and the quality descriptor (QD):</p> <ul style="list-style-type: none"> <li>• If QD Bit 1 and Bit 2 are not set and D is 0, then DPI=1</li> <li>• If QD Bit 1 and Bit 2 are not set and D is 1, then DPI=2</li> <li>• If QD Bit 2 is set, then DPI=0</li> <li>• If QD Bit 3 is set, then DPI=3</li> </ul>	<p>0 = do not store the digital point in the quality descriptor.</p> <p>1 = store the digital point in the quality descriptor.</p>	0
UpdateNonTimestampedTagWithTimestampedData	This parameter determines whether the non-timestamped tag value is updated when timestamped data is received. By default when a timestamped value is received, the values for	0 or 1	1

	<p>timestamped and non-timestamped tags will be updated. But in case the parameter is set to 0, only the timestamped tag value be updated.</p> <p><b>Note:</b> You can set this parameter for every device connected to a specific port. See <a href="#">Port-specific Parameters</a>.</p>		
UpdateTimestampedTagWithNonTimestampedData	<p>This parameter determines whether the timestamped tag value is updated with non-timestamped data. If it is set to 1, the timestamped tag will be updated with non-timestamped data until timestamped data is available.</p> <p><b>Note:</b> You can set this parameter for every device connected to a specific port. See <a href="#">Port-specific Parameters</a>.</p>	0 or 1	0

## Write Parameters

### UNINTENDED EQUIPMENT OPERATION

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** At times during the life cycle of a driver, circumstances may call for the creation of specific `citect.ini` parameters that remain undocumented. Always seek the advice of Technical Support regarding the possible implementation of undocumented parameters before you make any changes to a `citect.ini` file.

[IEC870IP] Parameter	Description	Allowable Values	Default Value
AppTimeoutMs	Sets the application-level timeout for the device. This is used for a select confirmation after a	0-32767 (milliseconds)	4000

	<p>control select has been issued.</p> <p><b>Note:</b> You can set this parameter for every device connected to a specific port.</p> <p>See <a href="#">Port-specific Parameters</a>.</p>		
DefaultSetPtType	<p>Determines if the value of the set point defaults to:</p> <ul style="list-style-type: none"> <li>• "normalized value" ("NORM"), or</li> <li>• "scaled value" ("SCALE").</li> </ul> <p><b>Note:</b> You can modify this parameter for an individual output point in the IOA configuration file.</p> <p>Determines the file name and path of the configuration file containing individual IOA parameters.</p> <p>See <a href="#">Configuring Commands for Individual IOAs</a>.</p>	"NORM" or "SCALE"	"NORM"
DefaultSEMode	<p>Determines if the output should default to:</p> <ul style="list-style-type: none"> <li>• "direct execute" (0), or</li> <li>• "select/execute" (1).</li> </ul> <p><b>Note:</b> You can modify this parameter for an individual output point in the IOA configuration file.</p> <p>Determines the file name and path of the configuration file containing individual IOA parameters.</p> <p>See <a href="#">Configuring Commands for Individual IOAs</a>.</p>	0 or 1	0
DefaultDOQual	Sets the default value of output qualifier for digital	0 – Digital controls default to "no additional"	0

	<p>control.</p> <p><b>Note:</b> You can modify this parameter for an individual output point in the IOA configuration file. Determines the file name and path of the configuration file containing individual IOA parameters.</p> <p>See <a href="#">Configuring Commands for Individual IOAs</a>.</p>	<p>definition".</p> <p>1 – Digital controls default to "short duration pulse".</p> <p>2 – Digital controls default to "long duration pulse".</p> <p>3 – Digital controls default to "persistent output".</p>	
IOAConfigFileName	<p>Determines the file name and path of the configuration file containing individual IOA parameters.</p> <p>See <a href="#">Configuring Commands for Individual IOAs</a>.</p>	Any valid path	Plant SCADA\bin
UseIOAConfigFile	<p>Determines whether the IOA configuration file is used.</p> <p>If set to zero (0), the file will not be used.</p> <p>See <a href="#">Configuring Commands for Individual IOAs</a>.</p>	0 or 1	0

## Counter Parameters

### UNINTENDED EQUIPMENT OPERATION

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** At times during the life cycle of a driver, circumstances may call for the creation of specific citect.ini parameters that remain undocumented. Always seek the advice of Technical Support regarding the possible implementation of undocumented parameters before you make any changes to a citect.ini file.

[IEC870IP] Parameter	Description	Allowable Values	Default Value
CounterPollTimeSec	Determines how often a counter interrogation is performed.	0 - 32767 (in seconds)	1800
CounterPollType	Determines the type of counter interrogation message that is sent.	0 – No freeze or reset 1 – Freeze without reset 2 – Freeze with reset 3 – Reset only	1

### Time Synchronization Parameters

#### **WARNING**

##### **UNINTENDED EQUIPMENT OPERATION**

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** At times during the life cycle of a driver, circumstances may call for the creation of specific citect.ini parameters that remain undocumented. Always seek the advice of Technical Support regarding the possible implementation of undocumented parameters before you make any changes to a citect.ini file.

[IEC870IP] Parameter	Description	Allowable Values	Default Value
TimeSyncOnInit	Determines whether or not the time is set for a device as it comes online.  <b>Note:</b> You can set this parameter for every device connected to a specific port. See <a href="#">Port-specific Parameters</a> .	0 - do not set the time for a device as it comes online.  1 - set the time for a device as it comes online.	1
TimeSyncPollTimeSec	Determines how often the time is set for a device (in seconds).	0-32767 (seconds)	1800
TimeSyncDelayAcquire	Determines if a delay acquisition command is sent when a time synchronization response is received.  <b>Note:</b> You can set this parameter for every device connected to a	0 - do not send a delay acquisition command.  1 - send a delay acquisition command.	0

	specific port. See <a href="#">Port-specific Parameters</a> .		
--	---	--	--

## Polling Parameters

### WARNING

#### UNINTENDED EQUIPMENT OPERATION

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** At times during the life cycle of a driver, circumstances may call for the creation of specific citect.ini parameters that remain undocumented. Always seek the advice of Technical Support regarding the possible implementation of undocumented parameters before you make any changes to a citect.ini file.

[IEC870IP] Parameter	Description	Allowable Values	Default Value
ReadPollTimeMs	<p>This parameter controls polling interval used by the polling manager.</p> <p>See <a href="#">Using Read Commands to Retrieve Data</a>.</p> <p><b>Note:</b> You can set this parameter for every device connected to a specific port. See <a href="#">Port-specific Parameters</a>.</p>	50 - 86400000 (milliseconds)	100

## Logging Parameters

### WARNING

#### UNINTENDED EQUIPMENT OPERATION

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** At times during the life cycle of a driver, circumstances may call for the creation of specific citect.ini parameters that remain undocumented. Always seek the advice of Technical Support regarding the possible implementation of undocumented parameters before you make any changes to a citect.ini file.

[IEC870IP] Parameter	Description	Allowable Values	Default Value
DebugLevel	The trace level used for	ALL or any combination of	-

	the log file.	the following, separated by a pipe character ( ): WARN ERROR TRACE DEBUG See <a href="#">Logging</a> for examples.	
DebugCategory	The categories used for the log file.	ALL or any combination of the following, separated by a pipe character ( ): DRI MISC PROT DCB See <a href="#">Logging</a> for examples.	-

**Note:** These parameters do not have a value specified by default. To enable logging for this driver, you need to manually configure these parameters in your INI file.

## See Also

[Logging Messages](#)

## Input Tags

The IEC870IP driver defines a number of tag addresses that allow process information to be passed to Plant SCADA in a monitoring direction. The input tags are read only.

<IOA> is used to represent an information object address, defined as a decimal number in the range 0 — 16777215.

**Note:** Tags with the following addresses are only updated when the driver receives a time-stamped value directly from a device.

- SD<IOA>
- SI<IOA>
- SL<IOA>
- SF<IOA>
- SQD<IOA>

See [Timestamp Handling](#) for more information on the correct syntax to use for your input tags.

Address format	Plant SCADA type	IEC 60870 type	Description
D<IOA> SD<IOA>	DIGITAL	Single point Double point	Digital value: <ul style="list-style-type: none"> <li>• Value: digital value</li> <li>• Quality: value quality</li> <li>• Timestamp: value timestamp</li> </ul>

Address format	Plant SCADA type	IEC 60870 type	Description
			Example: D100
I<IOA> SI<IOA>	INTEGER	Measured value: normalized and scaled value  Step Position  Double Point	Integer value: <ul style="list-style-type: none"><li>• Value: integer value</li><li>• Quality: value quality</li><li>• Timestamp: value timestamp</li></ul> Example: I200
L<IOA> SL<IOA>	LONG	Integrated totals	Long value: <ul style="list-style-type: none"><li>• Value: long value</li><li>• Quality: value quality</li><li>• Timestamp: value timestamp</li></ul> Example: L300
F<IOA> SF<IOA>	FLOAT	Short Floating Point	Float value: <ul style="list-style-type: none"><li>• Value: float value</li><li>• Quality: value quality</li><li>• Timestamp: value timestamp</li></ul> Example: F350
QD<IOA> SQD<IOA>	INTEGER	Quality descriptor	<p>The set of bitflags described in <a href="#">Quality Descriptors</a>.</p> <p>This includes IEC 60870 quality flags and the IEC870IP driver-specific flags:</p> <ul style="list-style-type: none"> <li>• Value: quality descriptor value</li> <li>• Quality: quality good</li> <li>• Timestamp: time when value with this quality descriptor was received</li> </ul> <p>Example: QD350</p>

**Note:** The address format used in the table above demonstrates unstructured tag addresses (i.e. "<IOA>"). The IEC870IP driver also supports structured tag addresses (e.g. "<IOA1>.<IOA2>.<IOA3>"). For more information, see [Structured Tag Addressing](#).

## Port-specific Parameters

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** At times during the life cycle of a driver, circumstances may call for the creation of specific citect.ini parameters that remain undocumented. Always seek the advice of Technical Support regarding the possible implementation of undocumented parameters before you make any changes to a citect.ini file.

Any parameters placed under the [IEC870IP] section of the Citect.ini file will apply globally to every device using the IEC870IP driver. However, you can also set parameters for every device connected to a specified port.

To do this, use the following section name within the Citect.ini file.

[<Protocol>.<PortName>]

Where:

- <Protocol> is IEC870IP
- <PortName> is the 'Port Name' defined for a specified port.

For example, any parameters set within the section [IEC870IP.PrimaryPort1] will impact every device connected to the port defined as "PrimaryPort1".

The following list includes the parameters you can set for all devices on a specific port.

[Data Interrogation Parameters:](#)

- ManufacturedIsUTC
- ManufactureTimestamp
- UpdateNonTimestampedTagWithTimestampedData
- UpdateTimestampedTagWithNonTimestampedData

[Time Synchronization Parameters:](#)

- TimeSyncOnInit
- TimeSyncDelayAcquire
- TimeSyncPollTimeSec

[Communication Parameters:](#)

- CommandTimeout
- ConnectionTimeout
- DelayChannelOffline
- DRIResponseTimeout
- GIPollTimeSec

[Polling Parameters:](#)

- ReadPollTimeMs

[Write Parameters:](#)

- AppTimeoutMs

[Counter Parameters:](#)

- CounterPollTimeSec
- CounterPollType

## Configuring Commands for Individual IOAs

The IEC870IP driver can be supported by an IOA configuration file that enables you to use complex addressing on a per-IOA basis. When implemented, this file allows output points to be individually operated using IEC 60870-5-104 output commands.

For example, a single digital output could be independently configured to "select/execute" or "direct execute". It could be "short pulse", "long pulse", "persistent" or "predefined". Any IOAs not included in the file will continue to use default settings.

## Using the "IECioa.dbf" file

An IOA configuration file (called "IECioa.dbf" by default) is available for modification in the Plant SCADA bin directory. You can use this file as a template to configure your own IOA customizations. To implement the file:

1. Locate the file "IECioa.dbf" in Plant SCADA bin directory.  
**Note:** It is recommended you take a copy of this file and move it to the associated project directory, as this will avoid the file being overwritten if the driver is reinstalled.
2. Configure the parameters UseIOAConfigFile and IOAConfigFileName (see [Write Parameters](#)). These parameters let the driver know an IOA configuration file is available, and confirm the name and location.  
**Note:** If the configuration file specified by these parameters cannot be loaded, the associated unit will go offline.
3. Edit the configuration file as required. It contains one IOA per row, each defining the output qualifiers to use for the specified IO point.

The following table describes the available fields:

Column	Description
CHANNEL	Plant SCADA Port name
COMMADDR	Plant SCADA I/O device address (common address of ASDU)
IOA	Information Object Address for this point
TYPE	For output points only, leave blank for other point

Column	Description
	<p>types:</p> <p>Single or Double Control Output, or Regulating Step Command:</p> <ul style="list-style-type: none"> <li>• "SDO" Single Digital Output (default)</li> <li>• "DDO" Double Digital Output</li> <li>• "RSO" Regulating Step Output Set Point Command</li> <li>• "NORM" Sent as a Normalized Value</li> <li>• "SCALE" Sent as a Scaled Value</li> </ul> <p>The default setpoint is specified by the driver configuration parameter DefaultSetPtType.</p>
QUALIF	<p>Control Qualifier for Output points only, leave blank for other point types.</p> <p>Single or Double Control Output, or Regulating Step Command:</p> <ul style="list-style-type: none"> <li>0 - No additional definition</li> <li>1 - Short Duration Pulse</li> <li>2 - Long Duration Pulse</li> <li>3 - Persistent Output</li> <li>4..31 - Reserved, as per IEC Standard</li> </ul> <p>The default mode is specified by the driver configuration parameter DefaultDOQual.</p> <p>Set Point Command:</p> <ul style="list-style-type: none"> <li>0 - Default</li> <li>1..127 - Reserved, as per IEC Standard</li> </ul>
SELEX	<p>Select/execute mode for output points leave blank for other point types.</p> <ul style="list-style-type: none"> <li>0 - Direct execute (single stage)</li> <li>1 - Select/Execute (three stage).</li> </ul> <p>The default is specified by the driver configuration parameter DefaultSEMode.</p>

**Note:** If a protocol command is set for an IOA that does not support the specified operation, an error will result.

## Troubleshooting

The following topics provide information about the Plant SCADA tools available to diagnose and resolve any unexpected behavior within the runtime system.

- [Driver Statistics](#)
- [Logging](#)

## Driver Statistics

You can use the following driver statistic counters to help you debug the IEC870IPdriver. These statistics can be viewed within the Plant SCADA Kernel using the Page Driver command and then by pressing the 'v' key to select verbose mode.

See the topic *Runtime > Monitor Runtime > The Kernel > Kernel Commands > Page Driver* in the main Plant SCADA help for more information.

Number	Statistic	Description
1	Data CRC Error	The number of messages received that had a bad checksum.
2	Unit Offline	The number of times any device has been made offline.
3	Negative Reply Rx	The number of times a device has indicated in a Command Response that there was something wrong with the command sent to it.
4	NOT IMPL Replies	The number of times the driver has received a NOT IMPLEMENTED message.
5	Busy Replies	The number of times the driver has received a BUSY message.
6	FCB Errors	The number of times the driver has received a message with an incorrect Frame Control Bit (FCB), this indicates that not all messages are being received correctly.
7	Unknown Addr Rx	The number of times the driver has received a message containing invalid address information. Indicates that the slave device may be incorrectly configured.
8	Intercharacter timeouts	The number of times message have been rejected because the time between bytes in a message was too large. This may indicate that communication parameters need to be adjusted.
9	CMD Not Supported	The number of times the driver has received a Command Not Supported message.

Number	Statistic	Description
10	Request Link Count	The number of request link status messages that have been transmitted since the I/O server started.
11	General Int Count	The number of general interrogation messages that have been transmitted since the I/O server started.
12	Time Sync Count	The number of time synchronization messages that have been transmitted since I/O server started.
13	Test Link Count	The number of test link messages that have been transmitted since the I/O server started.

## Logging

The IEC870IP driver can log combinations of trace levels across different categories. This is achieved by setting the following INI parameters.

### [IEC870IP]DebugLevel

This parameter allows you to define the trace level. The options include:

Option	Description
WARN	Output warning messages.
ERROR	Output error messages.
TRACE	Output trace messages.
DEBUG	Output debug messages.
ALL	All of the above.

### [IEC870IP]DebugCategory

This parameter allows you to enable logging for a particular category of trace. The options include:

Option	Description
DRI	Driver Runtime Interface trace.
MIISC	Any other debugging.
PROT	Protocol level debug.
DCB	Front end driver trace.
ALL	All of the above.

In both cases, you can use any combination of the available options separated by a pipe character ( | ).

### Example

```
[IEC870IP]
DebugLevel=WARN | ERROR | TRACE
DebugCategory=ALL
```

In most cases, you can set the DebugLevel and DebugCategory parameters to ALL. If this results in a large, cumbersome log file that causes older data to be overwritten, you can consider refining the debug options.

See [Logging Messages](#) for a list of the error and warning messages supported by the driver.

---

**Note:** These parameters do not have a value specified by default. To enable logging for this driver, you need to manually configure these parameters in your INI file.

The events generated by the IEC870IP driver are logged in the following Plant SCADA syslog file:

```
syslog.IOServer.<Cluster name>.<IO Server name>.dat
```

This file is located in the directory specified by the Citect.ini parameter **[CtEdit]Logs**. By default, this location will be:

```
%PROGRAMDATA%\AVEVA Plant SCADA <VersionNumber>\Logs
```

The size of the syslog file and its rollover process is configured via the **[Debug]SysLogSize** and **[Debug]SysLogArchive** INI parameters. For more information, see the topic *Debug Parameters* in the Plant SCADA documentation.

---

**Note:** If the number of messages being processed for a driver exceeds the value specified by the Plant SCADA parameter **[Kernel]ErrorBuffers**, the pending messages will not be logged. If this occurs, you can increase the value of this parameter so that all the messages generated by the driver are reported. The number of messages that are not logged can be monitored via the Kernel's General window under the item "Lost Errors". If you adjust **[Kernel]ErrorBuffers** and Lost Errors are still occurring, you may need to adjust the level of system logging.

### Logging Messages

The following tables include the error and warning messages that can be logged by the IEC870IP driver.

### LEVEL\_ERROR messages

Debug category	Message
DRI	DRI error message: {error description}
MISC	Cancelling DCB on channel unsuccessful
MISC	Logical Channel Open unsuccessful
MISC	Channel offline
MISC	CreateTimer(OnConnectTimeout) unsuccessful
MISC	COMSetVector(DATA_ALL_EVENTS) returned error message
MISC	COMSetVector(CONN_READY) returned error message
MISC	COMOpenEx returned error message {error description} for channel
MISC	Total number of Channels exceeds the driver maximum
MISC	Opening port {port name} unsuccessful
MISC	Initializing channel {channel} unsuccessful, Channel does not exist
MISC	Stopping channel {channel number} unsuccessful, Channel does not exist
MISC	Closing channel {channel number} unsuccessful, Channel does not exist
MISC	InitUnit unsuccessful {unit name}
MISC	Stopping unit on channel {channel number} unsuccessful
MISC	Performing read on channel {channel number} unsuccessful, Channel does not exist
MISC	Performing write on channel {channel number} unsuccessful, Channel does not exist
MISC	Total number of I/O devices exceeds the driver maximum. Possible mismatch with IECioa.dbf.
MISC	IOAConfig File Open unsuccessful. Filename: {file name } Error message={error}
MISC	AIOConfig Read Num Records unsuccessful. Filename:

	{file name }
MISC	IOAConfig Position to first Rec unsuccessful. Filename: {file name }
MISC	IOAConfig Read of COMMADDR field unsuccessful
MISC	IOAConfig Read of IOA field unsuccessful
MISC	IOAConfig Read of TYPE field unsuccessful
MISC	IOAConfig Read of QUALIF field unsuccessful
MISC	IOAConfig Read of SOEENABL field unsuccessful
MISC	IOAConfig read Event Log Tagname unsuccessful
MISC	IOAConfig read event log Raw Zero Scale unsuccessful
MISC	IOAConfig read event log Raw Full Scale unsuccessful
MISC	IOAConfig read event log Engineering Zero Scale unsuccessful
MISC	IOAConfig read event log Engineering Full Scale unsuccessful
MISC	IOAConfig File Close unsuccessful
PROT	Bad channel number
PROT	Opening port {port } unsuccessful = {error}
PROT	Could not create Command Timeout Timer
PROT	Could not create Intercharacter Timeout
PROT	Invalid Message contains 0 elements
PROT	Invalid timestamp received, using current time.
DCB	Timer creation unsuccessful in Port {port }
DCB	COMConnectEx returned error message {error }
DCB	Total number of I/O devices exceeds the driver maximum.
DCB	Caught protocol Error message in SDA Channel {channel number}, error message = {error}
DCB	Invalid DCB passed to BuildRequest in Port {port}

DCB	CancelDCB unsuccessful
DCB	ProtoReplyError hit default case, proto_err={error}
DCB	ProtoReplyError hit default case, proto_err = {error}

**LEVEL\_WARNING messages**

Debug category	Message
CAT_VALIDATE	AddrConfig Unit has 2 entries, discarding 2nd
DCB	Canceling DCB...
PROT	Receive message for unknown address

DCB	Cancel DCB called

**See Also**[Logging](#)[Logging Parameters](#)**Appendix**

This appendix includes the [IEC 870-5-104 Interoperability List](#), a list of the parameters defined in the IEC 60870-5-101 protocol that shows which options are supported by the Plant SCADA IEC870IP driver.

**IEC 870-5-104 Interoperability List**

This interoperability list refers to section 9 of the IEC 60870-5-104 International Standard (reference number CEI/IEC 60870-5-104:2006).

It is a complete list of the parameters defined in the IEC 60870-5-101 protocol, with the options supported by the IEC870IP driver defined using the following formatting:

<input type="checkbox"/> <description>	This formatting indicates that the described parameter is supported by the 104 variation of the protocol, though it is not supported by this driver.
<input checked="" type="checkbox"/> <description>	A check mark indicates that the described parameter is supported by the 104 variation of the protocol and implemented in this driver.
<input checked="" type="checkbox"/> <description>	This formatting indicates that the described parameter

	is usually not supported by the 104 variation of the protocol, but is implemented in this driver.
<input checked="" type="checkbox"/> <description>	This formatting indicates that the described parameter is not supported by the 104 variation of the protocol and is not supported by the driver.

## 9.1 System or device

<input type="checkbox"/> System definition
<input checked="" type="checkbox"/> Control station definition (master)
<input type="checkbox"/> Control station definition (slave)

## 9.2 Network configuration (network-specific parameters)

<input checked="" type="checkbox"/> Point-to-point	<input checked="" type="checkbox"/> Multipoint party line
<input checked="" type="checkbox"/> Multiple point-to-point	<input checked="" type="checkbox"/> Multipoint star

## 9.3 Physical layer (network-specific parameter)

### Transmission speed (control direction)

Unbalanced interchange circuit V.24/V.28 Standard	Unbalanced interchange circuit V.24/V.28 Recomm. if >1200bit/s	Balanced interchange circuit X.24/X.27	
<input checked="" type="checkbox"/> 100bit/s	<input checked="" type="checkbox"/> 2400 bit/s	<input checked="" type="checkbox"/> 2400 bit/s	<input checked="" type="checkbox"/> 56000bit/s
<input checked="" type="checkbox"/> 200bit/s	<input checked="" type="checkbox"/> 4800 bit/s	<input checked="" type="checkbox"/> 4800 bit/s	<input checked="" type="checkbox"/> 64000bit/s
<input checked="" type="checkbox"/> 300bit/s	<input checked="" type="checkbox"/> 9600 bit/s	<input checked="" type="checkbox"/> 9600 bit/s	
<input checked="" type="checkbox"/> 600bit/s		<input checked="" type="checkbox"/> 19200 bit/s	
<input checked="" type="checkbox"/> 1200bit/s		<input checked="" type="checkbox"/> 38400 bit/s	

### Transmission speed (monitor direction)

Unbalanced interchange circuit V.24/V.28 Standard	Unbalanced interchange circuit V.24/V.28 Recomm. if >1200bit/s	Balanced interchange circuit X.24/X.27	
<input checked="" type="checkbox"/> 100 bit/s	<input checked="" type="checkbox"/> 2400 bit/s	<input checked="" type="checkbox"/> 2400 bit/s	<input checked="" type="checkbox"/> 56000 bit/s

<input type="checkbox"/> 200 bit/s	<input type="checkbox"/> 4800 bit/s	<input type="checkbox"/> 4800 bit/s	<input type="checkbox"/> 64000 bit/s
<input type="checkbox"/> 300 bit/s	<input type="checkbox"/> 9600 bit/s	<input type="checkbox"/> 9600 bit/s	
<input type="checkbox"/> 600 bit/s		<input type="checkbox"/> 19200 bit/s	
<input type="checkbox"/> 1200 bit/s		<input type="checkbox"/> 38400 bit/s	

## 9.4 Link layer

Frame format FT 1.2, single character 1 and the fixed time out interval are used exclusively in this companion standard.

Link Transmission Procedure	Address Field of the Link
<input type="checkbox"/> Balanced transmission	<input type="checkbox"/> Not present (balanced transmission only)
<input type="checkbox"/> Unbalanced transmission	<input type="checkbox"/> One octet
	<input type="checkbox"/> Two octets
<b>Frame Length</b>	<input type="checkbox"/> Structured
<input type="checkbox"/> Max.length L (number of octets)	<input type="checkbox"/> Unstructured

When using an unbalanced link layer, the following ASDU types are returned in class 2 messages (low priority) with the indicated causes of transmission:

<input type="checkbox"/> The standard assignment of ASDUs to class 2 messages is used as follows:	
<b>Type identification</b>	<b>Cause of transmission</b>
9, 11, 13, 21	<1>
<input type="checkbox"/> A special assignment of ASDUs to class 2 messages is used as follows:	
<b>Type identification</b>	<b>Cause of transmission</b>

## 9.5 Application layer

### Transmission Mode for Application Data

Mode 1 (least significant octet first), as defined in clause 4.10 of IEC 870-5-4, is used exclusively in this companion standard.

### Common address of ASDU (System-specific parameter)

<input checked="" type="checkbox"/> One octet	<input type="checkbox"/> Two octets
---	-------------------------------------

### Information Object Address (System-specific parameter)

<input type="checkbox"/> One octet	<input checked="" type="checkbox"/> Structured
<input type="checkbox"/> Two octets	<input checked="" type="checkbox"/> Unstructured
<input checked="" type="checkbox"/> Three octets	

### Cause of Transmission (System-specific parameter)

<input type="checkbox"/> One octet	<input checked="" type="checkbox"/> Two octets (with originator address)
------------------------------------	--

### Length of APDU

<input checked="" type="checkbox"/> 253	Max.length L (number of octets)
---	---------------------------------

### Selection of standard ASDUs

File transfer in monitor direction

 Transparent file Transmission of disturbance data of protection equipment Transmission of sequences of events Transmission of sequences of recorded analog values

File transfer in control direction

 Transparent file**Background scan** (station-specific parameter) Background scan**Acquisition of transmission delay** (object-specific parameter) Acquisition of transmission delay**Definition of timeouts**

Parameter	Default Value	Remarks	Selected Value	Associated Citect.ini parameter
t <sub>0</sub>	30 s	Time-out of connection establishment	5	ConnectionTimeout
t <sub>1</sub>	15 s	Time-out of send or test APDUs	2	CommandTimeout
t <sub>2</sub>	10 s	Time-out for acknowledges in case of no data messages t <sub>2</sub> < t <sub>1</sub>	2	
t <sub>3</sub>	20 s	Time-out for sending test frames in case of a long idle state	5	TxTestLink

**Maximum number of outstanding I format APDUs k and latest acknowledge APDUs (w)**

Parameter	Default Value	Remarks	Selected Value
k	12 APDUs	Maximum difference receive sequence number to send state variable	1
w	8 APDUs	Latest acknowledge after receiving w I format APDUs	1

**Portnumber**

Parameter	Value	Default Value	Remarks
Portnumber	(set in the configuration of the TCP port)	2404	1

**Redundant connections**

The number of redundancy group connections used is dependent on the Plant SCADA project configuration.

## KNX Driver

The KNX driver enables Plant SCADA to communicate with KNX networks and devices using Ethernet and UDP.

KNX is an open standard that has emerged from Europe to service the building and home automation industry. It can be used to control a wide range of equipment and applications associated with building management, including lighting, heating, ventilation, air-conditioning, monitoring systems, alarms, security and load management.

KNX represents an extension of the European Integration Bus (EIB) standard, with additional physical layers and configuration modes built on to the EIB communication stack.

The KNX driver is based on a subset of the standards described in KNX Version 1.1. It is designed for run-time operation only (programming is not supported) for the purpose of reading and writing group address values.

**Note:** The KNX driver has been tested on Citect SCADA v7.20 SP4 and Citect SCADA v7.40 SP2 for backward compatibility.

## Safety Information

### Hazard categories and special symbols

The following symbols and special messages may appear in this manual or on the product to warn of potential hazards or to call attention to information that clarifies or simplifies a procedure.

Symbol	Description
 or 	The addition of either symbol to a "Danger" or "Warning" safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.
	This is the safety alert symbol. It is used to alert you to personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.

#### DANGER

**DANGER** indicates an imminently hazardous situation, which, if not avoided, will result in death or serious injury.

#### WARNING

**WARNING** indicates a potentially hazardous situation, which, if not avoided, can result in death or serious injury.

**⚠ CAUTION**

**CAUTION** indicates a potentially hazardous situation which, if not avoided, can result in minor or moderate injury.

**NOTICE**

NOTICE used without a safety alert symbol, indicates a potentially hazardous situation which, if not avoided, can result in property or equipment damage.

**Please Note**

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by AVEVA for any consequences arising out of the use of this material.

**Before You Begin**

Plant SCADA is a Supervisory Control and Data Acquisition (SCADA) solution. It facilitates the creation of software to manage and monitor industrial systems and processes. Due to Plant SCADA's central role in controlling systems and processes, you must appropriately design, commission, and test your Plant SCADA project before implementing it in an operational setting. Observe the following:

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not use Plant SCADA or other SCADA software as a replacement for PLC-based control programs. SCADA software is not designed for direct, high-speed system control.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**⚠ WARNING****LOSS OF CONTROL**

- The designer of any control scheme must consider the potential failure modes of control paths and, for certain critical control functions, provide a means to achieve a safe state during and after a path failure. Examples of critical control functions are emergency stop and overtravel stop, power outage and restart.
- Separate or redundant control paths must be provided for critical control functions.
- System control paths may include communication links. Consideration must be given to the implications of unanticipated transmission delays or failures of the link.
- Observe all accident prevention regulations and local safety guidelines.<sup>1</sup>
- Each implementation of a control system created using Plant SCADA must be individually and thoroughly tested for proper operation before being placed into service.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

1. For additional information, refer to NEMA ICS 1.1 (latest edition) "Safety Guidelines for the Application, Installation, and Maintenance of Solid State Control", and to NEMA ICS 7.1 (latest edition) "Safety Standards for Construction and Guide for Selection, Installation and Operation of Adjustable-Speed Drive Systems" or their equivalent governing your particular location.

## Communicating with KNX Networks

Plant SCADA KNX driver supports communicating with KNX IP devices via KNXnet/IP routers configured for Unicast or Multicast mode.

The routers need to be properly configured to route messages on to the IP network.

---

**Note:** The KNX driver should be capable of communicating with any KNXnet/IP-based KNX-to-IP router that has the routing specification implemented. However, you should perform specific testing to confirm the driver's ability to communicate effectively with a particular device.

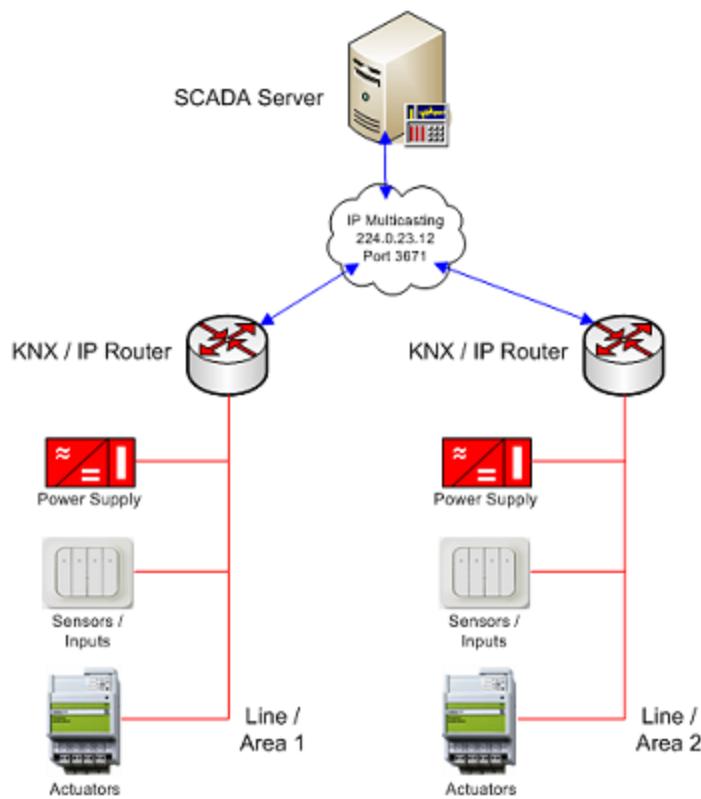

---

When communicating with large and complex configurations it is important to configure the I/O devices appropriately. For example, when multiple floors of a building have identical installation of routers, devices and so on, you need to configure one or more I/O devices for each floor.

### Multicast Mode

In Multicast mode, the driver connects to the router using the Multicast address and multicast port configured for KNX/IP routing. A single device in Plant SCADA can communicate with KNX devices on multiple routers. The routers must be configured for Multicast mode communication.

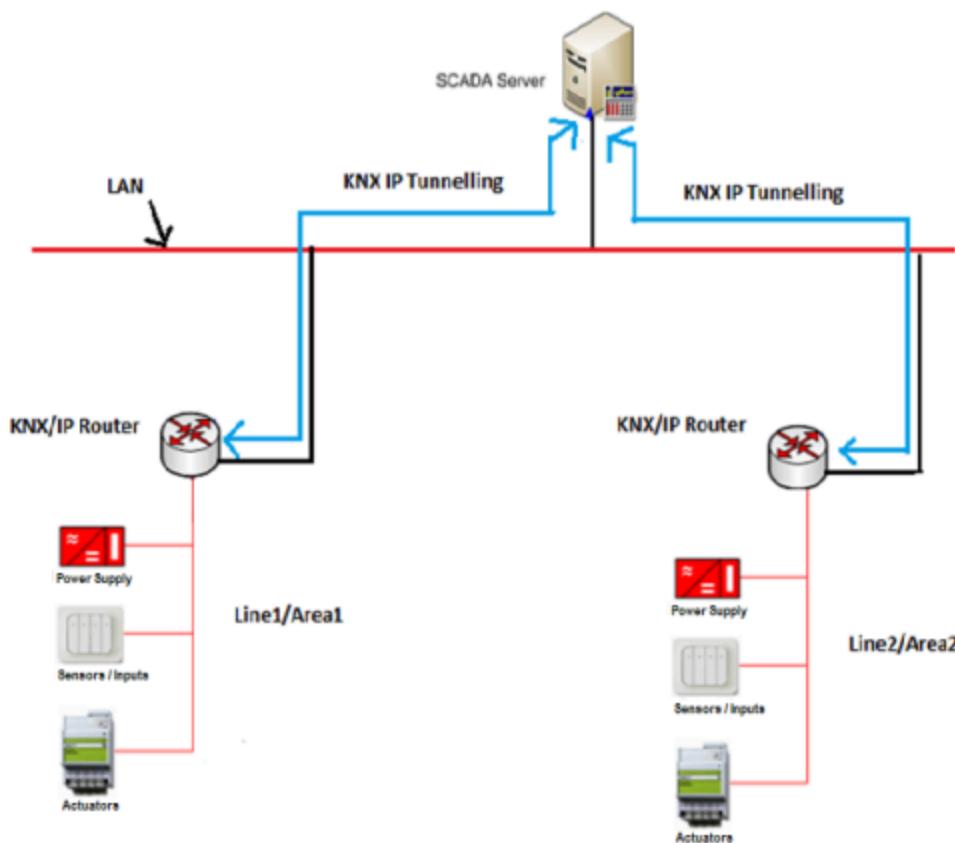

The following diagram illustrates a general layout of the KNX communication in multicast mode.

## Unicast Mode

An entire group of KNX devices is configured as a single device in Plant SCADA. This requires all the devices to be on a single router which is configured for Unicast mode communication.

The following diagram illustrates a general layout of the KNX communication in unicast mode.

#### Connection sequence in Unicast mode:

1. Driver sends a **CONNECT\_REQUEST** to the router.
2. After sending connect request, driver waits for **TunnelConnectionTimeout** to receive a response [**CONNECT\_RESPONSE**] from the router.  
Once the connect response time is ended, any response for the previous connect request will be ignored by the driver and it will request another connection [**CONNECT\_REQUEST**] if there is any pending retries (configured through **TunnelConnectionRetries**), else it makes the device offline.
3. Driver starts sending **TUNNELLING\_REQUEST** packets to the router requesting data for respective group addresses configured in the Plant SCADA project to populate the cache.
4. After the **InitTimeout** time, if at least one tag is good or when all the tags become good whichever occurs first the driver makes the device online and displays the tag values.
5. Driver continuously polls the router status with a **CONNECTSTATE\_REQUEST** to check the connection status with the router. The polling interval can be configured in **TunnelConnectionActive** INI parameter. The router will reply with a **CONNECTSTATE\_RESPONSE** message to confirm the status.
6. The Driver/Router sends the **DISCONNECT\_REQUEST** packet to close the connection if:
  - The device stops
  - The I/O server is stopped
  - The router receives any malformed packet
  - The connection is broken.

[Communications Settings](#)

[Tag Addressing](#)

## Communication Settings

To establish communication with a device, an I/O Device need to be correctly configured in Plant SCADA Studio's **Topology** activity, as well as any associated Boards and Ports. If you use the Express Communications Wizard to connect to a device, the required settings will be automatically configured for you. However, if you need to manually configure these settings, use the values outlined below.

## Boards

Field	Value
Board Name	A unique name (up to 16 alphanumeric characters) per server for the computer board being used to connect with the device. This is used by Plant SCADA in the Ports form.
Board Type	KNX
Address	Set field to 0 (zero).
I/O Port	Leave this field blank.
Interrupt	Leave this field blank.
Special Options	Leave this field blank.
Comment	Any useful comment.

## Ports

Field	Value
Port Name	A unique name (up to 16 alphanumeric character) for the computer port being used to connect with the device. This is used by Plant SCADA in the Devices form.
Port Number	Leave this field blank.
Board Name	The name of the board this port is attached to as defined on the Boards form.
Baud Rate	Leave this field blank.

Field	Value
Data Bits	Leave this field blank.
Stop Bits	Leave this field blank.
Parity	Leave this field blank.
Special Options	<p>Fill this field with IP address of the router and Unicast port number.</p> <p>Use the following format:            -la -Pn            where:            a = the IP address in standard Internet dot format. (For example 192.9.2.60)            n = 3671 (This is the reserved KNX port number for Unicast and Multicast communication)</p> <p><b>Note:</b> Leave this field blank for Multicast communication.</p>
Comment	Any useful comment.

## I/O Devices

Field	Value
Name	A unique name (up to 16 alphanumeric character) for the I/O Device being identified. Assign each I/O Device with a unique name in the Plant SCADA system.
Number	A unique number for the I/O Device (0-16383). Assign each I/O Device a unique number in the Plant SCADA system, (unless redundancy of the I/O Device is being used).
Address	Leave this field blank.
Protocol	KNX
Port Name	Refers to the port defined in the Ports form.
Comment	Any useful comment.

## Tag Addressing

A separate variable tag needs to be added to your Plant SCADA project for each group address within the KNX system you would like Plant SCADA to communicate with.

Variable tag addresses are configured according to the following formats:

**x/y/z:a[!w]**

or

**x/y/z:a.b[!w]**

Where:

- **x** is the main group number [0-31].
- **y** is the sub group number [0-7].
- **z** is the group address [0-255].
- **a** is the main encoding type.
- **b** is the minor encoding type.
- **!w** is an optional flag to define a tag as write only.

The main, sub and group address fields are specified in decimal. The encoding types are specified in decimal, with leading zeros to pad to three characters for the minor encoding type.

The minor encoding type is optional. If the minor encoding is not specified, then an encoding that matches as close as possible to an unscaled memory copy shall be chosen. See [KNX Data Type Mappings](#) for a full list of Plant SCADA data type mappings.

## Tag Ranges

Some data types will not map directly to Plant SCADA data types. In some cases, a tag may not span the entire range of values of a given type. Instead, it uses a reduced set of values that represent the actual values within that range.

For example, 3-bit controlled types are typically used in applications such as opening or closing shades. The controller can be instructed to open or close based on a percentage amount. This is mapped through to an INT tag in Plant SCADA that will take a value in the range -100, -50, -25, -12, -6, -3, -1, 0, 1, 3, 6, 12, 25, 50, 100, representing how much to open or close by.

Plant SCADA will convert a representative value used by a device to reflect the actual value, allowing for more meaningful interpretation.

## Examples

Plant SCADA tag address	Values range
0/0/0:3.007	Values fall within the following range: -100, -50, -25, -12, -6, -3, -1, 0, 1, 3, 6, 12, 25, 50, 100.
0/0/0:3.008	They represent the percentage a value increased or decreased by. If the operator inputs a value other those that appear in this range, the driver will find closest match before sending the command to the device. Example, -44 will become -50, 19 will become 25 and so on.

Plant SCADA tag address	KNX group address
1/1/123:1	Main Group 1, Middle Group 1, Group Address 123 interpreted as a Boolean Switch Plant SCADA type: DIGITAL
1/1/123:1!w	Main Group 1, Middle Group 1, Group Address 123 interpreted as a Boolean Switch Plant SCADA type: DIGITAL <b>Note:</b> This variable is a write only tag.
2/3/44:1.009	Main Group 2, Middle Group 3, Group Address 44 interpreted as a Boolean Open/Close signal Plant SCADA type: DIGITAL
2/3/44:1.009!w	Main Group 2, Middle Group 3, Group Address 44 interpreted as a Boolean Open/Close signal Plant SCADA type: DIGITAL <b>Note:</b> This variable is a write only tag.
1/1/55:5	Main Group 1, Middle Group 1, Group Address 55 interpreted as an 8 bit unsigned relative position Plant SCADA type: INT <b>Note:</b> This variable will have a range of [0..255]. Values outside this range will result in an error.
1/1/55:5.001	Main Group 1, Middle Group 1, Group Address 55 interpreted as an 8 bit unsigned scaling value Plant SCADA type: BYTE <b>Note:</b> This variable will have a range of [0..100]. Values outside this range will result in an error.
7/5/202:16	Main Group 7, Middle Group 5, Group Address 202 interpreted as an 8 bit encoded string Plant SCADA type: STRING <b>Note:</b> The maximum length of the string is 13 characters plus a null char terminator.

## KNX Data Type Mappings

The Date and Time data types will be read and written using the standard Plant SCADA time formats.

The driver will enforce the data ranges as specified for each data type.

When a write is issued to a controlled data type the controlled bit will be set to 1.

Generic KNX Type	Specific KNX Type	Plant SCADA Data Type
Boolean	1 (defaults to 1.001)	DIGITAL
Boolean	1.001	DIGITAL
Boolean	1.002	DIGITAL
Boolean	1.003	DIGITAL
Boolean	1.004	DIGITAL
Boolean	1.005	DIGITAL
Boolean	1.006	DIGITAL
Boolean	1.007	DIGITAL
Boolean	1.008	DIGITAL
Boolean	1.009	DIGITAL
Boolean	1.010	DIGITAL
Boolean	1.011	DIGITAL
Boolean	1.012	DIGITAL
Boolean	1.013	DIGITAL
Boolean	1.014	DIGITAL
2-Bit Controlled	2(defaults to 2.001)	BYTE
2-Bit Controlled	2.001	BYTE
2-Bit Controlled	2.002	BYTE

2-Bit Controlled	2.003	BYTE
2-Bit Controlled	2.004	BYTE
2-Bit Controlled	2.005	BYTE
2-Bit Controlled	2.006	BYTE
2-Bit Controlled	2.007	BYTE
2-Bit Controlled	2.008	BYTE
2-Bit Controlled	2.009	BYTE
2-Bit Controlled	2.010	BYTE
2-Bit Controlled	2.011	BYTE
2-Bit Controlled	2.012	BYTE
3-Bit Controlled	3 (defaults to 3.007)	INT
3-Bit Controlled	3.007	INT
3-Bit Controlled	3.008	INT
3-Bit Controlled	3.009	(currently not supported)
Character Set	4 (defaults to 4.002)	BYTE
Character Set	4.001	BYTE
Character Set	4.002	BYTE

8-Bit Unsigned Value	5 (defaults to 5.010)	INT
8-Bit Unsigned Value	5.001	BYTE
8-Bit Unsigned Value	5.003	INT
8-Bit Unsigned Value	5.004	INT
8-Bit Unsigned Value	5.010	INT
8-Bit Signed Value	6 (defaults to 6.010)	INT
8-Bit Signed Value	6.010	INT
Status with Mode	6.020	(currently not supported)
2-Octet Unsigned Value	7 (defaults to 7.001)	UINT
2-Octet Unsigned Value	7.001	UINT
2-Octet Unsigned Value	7.002	UINT
2-Octet Unsigned Value	7.003	UINT
2-Octet Unsigned Value	7.004	UINT
2-Octet Unsigned Value	7.005	UINT
2-Octet Unsigned Value	7.006	UINT
2-Octet Unsigned Value	7.007	UINT
2-Octet Unsigned Value	7.010	UINT
2-Octet Unsigned Value	7.011	UINT

2-Octet Unsigned Value	7.012	UINT
2-Octet Unsigned Value	7.013	UINT
2-Octet Signed Value	8 (defaults to 8.001)	INT
2-Octet Signed Value	8.001	INT
2-Octet Signed Value	8.002	INT
2-Octet Signed Value	8.003	INT
2-Octet Signed Value	8.004	INT
2-Octet Signed Value	8.005	INT
2-Octet Signed Value	8.006	INT
2-Octet Signed Value	8.007	INT
2-Octet Signed Value	8.010	INT
2-Octet Signed Value	8.011	INT
2-Octet Float Value	9 (defaults to 9.002)	REAL
2-Octet Float Value	9.001	REAL
2-Octet Float Value	9.002	REAL
2-Octet Float Value	9.003	REAL
2-Octet Float Value	9.004	REAL
2-Octet Float Value	9.005	REAL

2-Octet Float Value	9.006	REAL
2-Octet Float Value	9.007	REAL
2-Octet Float Value	9.008	REAL
2-Octet Float Value	9.010	REAL
2-Octet Float Value	9.011	REAL
2-Octet Float Value	9.020	REAL
2-Octet Float Value	9.021	REAL
2-Octet Float Value	9.022	REAL
2-Octet Float Value	9.023	REAL
2-Octet Float Value	9.024	REAL
2-Octet Float Value	9.025	REAL
2-Octet Float Value	9.026	REAL
2-Octet Float Value	9.027	REAL
2-Octet Float Value	9.028	REAL
Time	10 (defaults to 10.001)	(currently not supported)
Date	11 (defaults to 11.001)	(currently not supported)
4-Octet Unsigned Value	12 (defaults to 12.001)	ULONG

4-Octet Signed Value	13 (defaults to 13.001)	LONG
4-Octet Float Value	14 (defaults to 14.005) The range supported for DPT14 is 14.000-14.079	REAL
Access	15 (defaults to 15.001)	LONG
String	16 (defaults to 16.001)	STRING
String	16.001	STRING
8-Bit Unsigned Value	20.102	BYTE
4-Octet Unsigned Value	232.600	LONG
2-Octet Signed Value	237.600	INT
8-Bit Unsigned Value	238.001	BYTE
8-Bit Unsigned Value	238.600	BYTE

## KNX Tag Import

Plant SCADA can automatically generate variable tags for all supported KNX group addresses configured in the KNX Device. Tags are imported per I/O device from an XML file, exported from ETS5. It is important that group addresses exported from ETS5 are for device objects linked to a router, configured for Unicast mode communication with the I/O device.

### To generate variable tags using tag import corresponding to KNX device properties:

1. In ETS5, export the group address to an export file using xml format.

---

**Note:** Make sure that each group address has a data type association.

2. Open Plant SCADA Studio, and select **Import Tags** from the **Topology** activity.
3. The **Import Variable Tags** dialog box opens.
4. In the **Destination** panel, select the **I/O Device**.

---

**Note:** Make sure the I/O device is configured for the KNX protocol. Otherwise you will not be able to

---

configure the device connection. Ensure that the I/O device name does not contain comma, else an error message is displayed saying tags cannot be imported. If I/O device name contains any other special character, then compilation errors will occur.

5. In the **Source** panel, set the **Database type** to KNX.
6. In the **External database** field, click **Browse** button to open KNX Device Configuration dialog box. To configure the KNX device:
  - a. In **Tag Import Options**, identify the required XML file to import in the **XML File Path** field. Click **Browse** button to locate the file.

**Note:** The tag import functionality is available for XML file format generated by ETS5 configuration tool only. XML file format from previous versions such as ETS4 or before does not contain the data type.
  - b. In the **Advanced Options** panel, if you select **Use GroupAddress Name as Tag Name**, variable tags are generated in the following format:

<IODevice>\<GroupAddressName> For example, "IODev1\sensor"

Else, the tags will be generated in the following format:

<IODevice>\<Tag<n>> For example, "IODev1\Tag1", "IODev1\Tag2" and so on.
  - c. Click **OK** to close the KNX Device Configuration dialog box.
7. Click **Import** button from the Import Variable Tags dialog box.

Plant SCADA reads the group addresses and data types from the XML file, and generates the variable tags for the KNX group addresses.

---

**Note:** At present, the tag import functionality is limited to generating the variable tags and the corresponding tag address. Here, the tag address contains a group address and a data type. The description associated with the group address will be copied in to the comment field of the corresponding Plant SCADA tag.

It does not support creating different value ranges for variable tags of a particular data type where the range is defined by minor encoding. For example: 5.001, 5.004. Here 5.001 refers to percentage from 1 to 100 and 5.004 refers to percentage from 1 to 225. If the value ranges are different, you have to configure manually in Plant SCADA.

---

## Tag import log file

Each time a tag import is executed a log file is created in KNXImportLog folder, under the Logs folder, at the location specified in the [CtEdit] section of ini file. The log file will be overwritten each time.

Below are some of the special scenarios of tag import:

- **Group addresses sharing identical name and communicating via same router.**

In each of the following scenario, the XML file will have duplicate group names:

1. If **Use GroupAddress Name as Tag Name** option is selected on the KNX Import File Browser dialog box  
In this case the XML file contains multiple group addresses with duplicate group address name. After import, you need to rename tags created with duplicate names, else compiler errors will occur.
2. If **Use GroupAddress Name as Tag Name** option is not selected on the KNX Import File Browser dialog box  
In this case the XML file contains multiple group addresses with duplicate address name. Tags with separate names will be created for these group addresses.

- **Special characters in group address name.**

Consider an example where a group address name contains special characters and the tag import option **Use GroupAddress Name as Tag Name** is selected. In this case, KNX driver will skip the special characters and generate the tags, as special characters are not allowed in tag names. Hence there is a chance of duplication of tags. In such case, you need to rename the tags, else compiler errors will occur. Refer tag import log file for details of group address names with special characters.

---

**Note:** Backslash and under scores are allowed.

---

- **Group address without a data type.**

Any group address with data type not configured will not be considered during tag import. Refer tag import log for details of group addresses with data type not configured.

## Advanced Configuration and Maintenance

This section provides further information about the implementation of KNX devices within the Plant SCADA.

- [Configuring Redundancy](#)
- [Quality and Timestamps](#)
- [Background Polling](#)
- [Write Requests](#)
- [Data Type Mismatches](#)
- [Maximum Transmission Rate Control](#)
- [Customize a Project using Citect.ini Parameters.](#)

### Configuring Redundancy

Redundancy for the KNX driver in unicast communication supports the traditional redundancy model for Plant SCADA I/O devices as described in the I/O Server Redundancy section of Plant SCADA help.

Redundancy in multicast communication is different from the traditional redundancy model for Plant SCADA I/O devices. In this case one I/O device represents an entire KNX network.

The use of IP multicasting as the communications medium between IP router devices means that only one connection per network interface is possible. In this context, only one I/O device can be defined per I/O server, unless the server supports multiple interfaces and the **LocalIPAddress** parameter is used to bind different I/O devices to different interfaces.

The use of IP multicast, and thus the lack of a direct connection to the KNX IP router devices, means that the I/O server is very limited in the extent to which it can signal a device to be offline.

The KNX driver will only signal a device as offline under the following conditions:

A media disconnect event is received by the socket, i.e. network cable pulled out

All of the group addresses on the device has timeout and become bad

It is possible for two I/O devices on two servers to be configured as a redundant pair. In this case, the two devices will act as a hot-standby, with both servers maintaining a live cache.

### Quality and Timestamps

The KNX driver implements quality and timestamp information, with **GOOD** and **BAD** quality levels used to

reflect the state of a cache value.

A tag will be flagged as bad quality on the basis of either a data type/size mismatch, or for exceeding the cache lifetime.

The quality and timestamp values are used in relation to cache lifetime management. Because no two group addresses can be blocked together, the driver will use the quality value to return #COM for an individual tag.

See [KNX Parameters](#).

## Background Polling

If configured to route telegrams properly, all IP routers on a network will send a message each time a group address is written to by an input device. The driver processes these telegrams and updates the cache value for the group address, thus updating the timestamp, value and quality.

However, the KNX driver does not maintain a continuous connection to each network; there can be multiple KNX to IP routers and it is impossible for Plant SCADA to tell if telegrams from devices have been lost. This means the delivery of on-change notifications can be unreliable.

Because of this, a slow background poll of all group addresses will be conducted. As each group addresses reaches half of the cache life time value a read request will be issued for the group address.

## Write Requests

Write requests issued to KNX IP routers in 'routing' mode are unconfirmed. As such, write requests issued to the driver are delivered in a best-effort manner.

It is not possible for the driver to confirm write requests using a read command because another device may have also written a different value to the group address in the interim.

To improve the accuracy of cache values, a read request for the group address value will be issued immediately after the write request.

## Data Type Mismatches

The configuration between Plant SCADA and the KNX network in regard to group address data types must match. If the KNX driver receives a group address telegram containing data in a format incompatible with the Plant SCADA configuration, the address will be considered bad quality and a read request will return a GENERIC\_INVALID\_DATA\_FORMAT error.

See [KNX Data Type Mappings](#).

## Maximum Transmission Rate Control

By default, the KNX driver uses a bandwidth rate limiting mechanism to restrict outbound traffic to approximately 20 percent of its full capability. This is because KNX uses a 9600 bps serial bus, and there is a possibility the packet buffers of individual IP routers may overflow.

It is possible to set this value higher using the [KNX Parameters](#) parameter, however, this is only recommended for a large KNX network on a single line containing many IP router devices with concise filter tables. If a value other than the default is used, you should monitor and confirm the delivery of telegrams to and from the KNX network.

This parameter only governs outbound traffic, so it should be set at a rate that allows enough bandwidth to accommodate a reply to each read request.

You can also use the [KNX Parameters](#) parameter to adjust the minimum timing delay between successive transmitted frames by the driver.

## Customize a Project using Citect.ini Parameters

The KNX driver supports the following parameter categories:

- [KNX Parameters](#)
- [Logging Parameters](#).

### **WARNING**

#### **UNINTENDED EQUIPMENT OPERATION**

- Do not under any circumstances change or remove any citect.ini parameters without an informed understanding of the possible implications of your actions.
- Do not delete sections of the citect.ini file without an informed understanding of the possible implications of your actions.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** At times during the life cycle of a driver, circumstances may call for the creation of specific citect.ini parameters that remain undocumented. Always seek the advice of Technical Support regarding the possible implementation of undocumented parameters before you make any changes to a citect.ini file.

## KNX Parameters

### **WARNING**

#### **UNINTENDED EQUIPMENT OPERATION**

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

The table describes the KNX driver-specific parameters:

Driver Specific Parameter	Description	Allowable Values	Default Value
CacheLifeTime	The time a cache value will remain active for. Once an item reaches half its cache life time, the driver will process a read	Any positive integer representing number of seconds.	300 (seconds)

Driver Specific Parameter	Description	Allowable Values	Default Value
	request for the group address to refresh the cache value.		
IgnoreRouterDisconnect	When the value of this parameter is set to 1, the driver will not take the I/O device offline if a disconnect request is received from the router.	0 or 1	0
InitTimeout	The maximum time the I/O server is allowed to wait for replies to be received from all group addresses to populate the cache before either aborting the InitUnit or bringing the unit online.	Any positive integer representing number of seconds.	120 (seconds)
InterFrameDelay	The minimum timing delay between successive transmitted frames by the driver. This can be used to avoid flooding the buffers of gateway device.  See <a href="#">Maximum Transmission Rate Control</a> .	Any positive integer representing number of milliseconds.	50 (ms)
LocalIPAddress	Sets the local IP address the I/O server will attempt to bind to.	Any four octet dotted notation IP address. e.g. 192.168.1.1	0.0.0.0 (Instructs the IP stack to bind to any/ all available network interfaces)
LocalPort	Sets the local port number the I/O server will attempt to bind to. For the KNXnetRouter, 3671 is the standard KNXnet/IP Port). If LocalPort is not configured it will default to the MulticastPort only for multicast mode of communication.	Any valid port number	3671

Driver Specific Parameter	Description	Allowable Values	Default Value
MaxTransmitRate	<p>The maximum traffic rate that the driver is allowed to generate in bits per second. The KNX wire protocol is a 9600 bps serial protocol. This parameter allows the maximum traffic rate generated by the KNX driver to be controlled.</p> <p>This only governs outbound traffic. As such it should be set to a lower value than might be expected, as read requests will require bandwidth for a reply.</p> <p>In a large network with many IP router devices with concise filter tables, it may be helpful to set this value much higher than 9600, provided the engineer has tested and confirmed that the packet buffers of any individual IP router will not be overflowed.</p> <p>See <a href="#">Maximum Transmission Rate Control</a>.</p>	Any positive integer representing a number of bits per second. (A value less than 200 is not recommended.)	2000 bps (approx. 20% of maximum bus throughput)
MulticastAddress	Sets the multicast IP address the I/O server will attempt to communicate with.	Any four octet dotted notation IP address within the range of 224.0.0.0 to 239.255.255.255 e.g. 224.168.1.1	224.0.23.12 (Standard KNXnet/IP multicast address)
MulticastPort	Sets the multicast port number the I/O server will attempt to send packets to. For the KNXnetRouter, 3671 is the standard KNXnet/IP Port.	Any valid port number	3671
OfflinePollTime	The polling period (in	Any positive integer	CacheLifeTime/2

Driver Specific Parameter	Description	Allowable Values	Default Value
	seconds) of tags which have bad quality.	representing number of seconds.	
PhysicalAddress	<p>Sets the physical address for the Plant SCADA I/O server in the KNX network. All messages sent from the Plant SCADA I/O server will be sent with this address as the source address.</p> <p>If the value is larger than 65535, it will be masked to only use the lower 16 bits. The value represents Area Number (bits 12-15), Line Number (bits 8-11), Device Number (bits 0-7).</p> <p>The value has to be specified in decimal. If hexadecimal notation is used the address will resolve to 0.</p>	Any 16 bit value	0
Retry	<p>Determines the number of retries the driver should try to send the read request when there is no response from router. After exceeding the number of retries, the driver will set the quality of the tags in the read request to 'Bad' and stop sending read requests for these tags until reaching half of its cache life time.</p> <p><b>Note:</b> Changing the default value of this parameter is only useful to decrease the network traffic between the driver and KNX router caused by unsuccessful read requests.</p>	Any positive integer representing the number of retries.	Zero (0). The driver will not set the tag quality to 'Bad' and will continue sending read requests after exceeding the number of retries.

Driver Specific Parameter	Description	Allowable Values	Default Value
Timeout	Specifies the time delay between each read request.	0 to 32000 (milliseconds)	5000 milliseconds (5 seconds)
TTL	Sets the maximum time-to-live (TTL) on outbound multicast IP packets.  This should only be adjusted on the advice of network administrator. It would only be necessary to control the routing of multicast packets from one IP subnet to another.	Any positive integer	16
UnitType	Determines the type of bus interface unit the device should communicate with. 'KNXnetRouter' represents an KNXnet/IP device configured for routing.	KNXnetRouter	KNXnetRouter

The table describes the KNX INI parameters used specifically for Unicast communication:

INI Parameter	Description	Allowable Values	Default Value
TunnelConnectionRetries 1	Determines the number of retries the driver should try to connect with the router when the initial connection request is unsuccessful.  For example, If the value is 1 then it will retry to send the connect request one more time after the initial connect request is unsuccessful.  Once the number of retries ends, the driver will not make further attempts to connect and will report the unit offline.	0 - 5	3
TunnelConnectionTimeout	Connection related	Any positive integer	10000 (ms)

INI Parameter	Description	Allowable Values	Default Value
t <sup>1</sup>	packets are time bound. If no response received from router within this timeout period, then the driver will ignore any later responses. The timeout option helps driver to determine either to send the packets again or to make the unit offline.	representing number of milliseconds.	
TunnelConnectionActive	Defines the interval to periodically check the connection state with the router. Driver sends a CONNECTSTATE_REQUEST to the router to verify that the connection is active. These parameters can also be configured at unit level. The unit has to be configured for unicast communication.	5 - 100 seconds	60 (seconds)

1. The **InitTimeout** needs to be greater than **TunnelConnectionRetries** x **TunnelConnectionTimeout**.

### Logging Parameters

#### **WARNING**

##### **UNINTENDED EQUIPMENT OPERATION**

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

The table describes the KNX Logging parameters:

Driver Specific Parameter	Description	Allowable Values	Default Value
DebugLevel	Controls which levels of log message are written to the log file.	ALL or any combination of the following values separated by pipe character ( ) :  WARN ERROR	Empty string (no logging).

Driver Specific Parameter	Description	Allowable Values	Default Value
		TRACE DEBUG See <a href="#">Logging</a> for examples.	
DebugCategory	Controls which categories of log message are written to the log file.	ALL or any combination of the following values separated by pipe character ( ) :  PROT DCB THREAD MISC SOCK ENTRY UNIT. See <a href="#">Logging</a> for examples.	Empty string (no logging).

[KNX Parameters](#)

## Troubleshooting

The following topics include information about the Plant SCADA tools provided to help resolve problems with communication and configuration.

- [Logging](#)
- [Specific Errors](#)
- [Frequently Asked Questions.](#)

## Logging

The KNX driver can log combinations of trace levels across different categories. This is achieved by setting the following INI parameters.

## [KNX]DebugLevel

This parameter allows you to define the trace level. The options include:

Option	Description
WARN	Output warning messages.
ERROR	Output error messages.
TRACE	Output trace messages.
DEBUG	Output debug messages.
ALL	All of the above.

## [KNX]DebugCategory

This parameter allows you to enable logging for a particular category of trace. The options include:

Option	Description
PROT	Trace of communication between the driver and the lower level protocol.
DCB	Front end driver trace.
THREAD	Thread trace.
MISC	Any other debugging.
SOCK	Socket trace.
ENTRY	Driver entry trace.
UNIT	I/O device trace.
ALL	All of the above.

In both cases, you can use any combination of the available options separated by a pipe character ( | ).

### Example

```
[KNX]
DebugLevel=WARNING|ERROR|TRACE
DebugCategory=ALL
```

In most cases, you can set the DebugLevel and DebugCategory parameters to ALL. If this results in a large, cumbersome log file that causes older data to be overwritten, you can consider refining the debug options.

---

**Note:** These parameters do not have a value specified by default. To enable logging for this driver, you need to manually configure these parameters in your INI file.

The events generated by the KNX driver are logged in the following Plant SCADA syslog file:

`syslog.IOServer.<Cluster name>.<IO Server name>.dat`

This file is located in the directory specified by the Citect.ini parameter **[CtEdit]Logs**. By default, this location will be:

%PROGRAMDATA%\AVEVA Plant SCADA <VersionNumber>\Logs

The size of the syslog file and its rollover process is configured via the **[Debug]SysLogSize** and **[Debug]SysLogArchive** INI parameters. For more information, see the topic *Debug Parameters* in the Plant SCADA documentation.

**Note:** If the number of messages being processed for a driver exceeds the value specified by the Plant SCADA parameter [Kernel]ErrorBuffers, the pending messages will not be logged. If this occurs, you can increase the value of this parameter so that all the messages generated by the driver are reported. The number of messages that are not logged can be monitored via the Kernel's General window under the item "Lost Errors". If you adjust [Kernel]ErrorBuffers and Lost Errors are still occurring, you may need to adjust the level of system logging.

[Logging Parameters](#)

## Specific Errors

Plant SCADA driver errors can occur when a device:

- does not respond
- is disconnected
- is offline
- returns an error.

Plant SCADA has two kinds of driver errors - generic and specific.

Generic errors are hardware errors 0-31, and are common to all protocols (for more information, see the topic *Error Messages* in the Reference Information section of the main Plant SCADA documentation).

Specific errors are unique to a particular driver, and may not be recognized by the hardware alarm system. The driver converts the specific errors into generic errors so they can be identified by the I/O Server. This means when a driver becomes inoperable, there is often both a specific error and a corresponding generic error.

When a hardware error occurs, Plant SCADA generates an alarm, and displays the alarm on the hardware alarm page (in the alarm description of the hardware alarm). To see the error number, verify that you have Alarm Category 255 defined with a display format that includes {ErrDesc,15} {ErrPage,10}.

## KNX Specific errors

Error value	Error definition	Description
0x20000001	ERR_DEMO_EXPIRED	Unlicensed demo system has timed out
0x20000002	ERR_INIT_UNIT_IN_PROGRESS	Notification only – the unit initialization is still in progress
0x20000003	ERR_INIT_UNIT_TIMEOUT	The unit initialization process has timed out

Error value	Error definition	Description
0x20000004	ERR_INVALID_INTERNAL_STATE	Internal software error
0x20000005	ERR_ALL_TAGS_BAD_QUALITY	The unit has been taken offline because all tags on the unit are in a bad quality state
0x20000006	ERR_TAG_NOT_FOUND	The requested tag could not be found
0x20000007	ERR_TAG_QUALITY_BAD	The tag has a bad quality value

## Frequently Asked Questions

This section addresses problems you might encounter when setting up and operating the KNX driver:

- **Why does it take so long for my KNX IP router to come online?**

At startup, a read request is issued for each group address to initially populate the cache. Ideally, the IP router should come online as soon as a response has been received back from each group address.

However, there is no way for Plant SCADA to determine if a read request has been lost due to an unreliable destination address.

Under these circumstances, you would like any valid addresses to be acknowledged, and for communication to commence. The lost addresses should not hold up communication with the rest of the system.

For this reason, the KNX driver has a initialization timeout period set to 120 seconds. After this period of time, all validated group addresses (a minimum of at least one) will commence communicating; all invalid addresses will be terminated with an error written to the driver log.

Therefore, if your IP router is taking a couple of minutes to come online, it probably means invalid group addresses are forcing the device to the end of the initialization timeout period. You should check the driver log to determine which addresses are causing the problem.

- **Everything is plugged in to the network, but I can't see any packets from Plant SCADA in the bus monitor.**

If this is occurring, check the following:

- If you have multiple network cards (or virtual NICs just from having VMWare installed) you need to confirm that the parameter [KNX]LocalIPAddress is set to the correct out bound interface.
- Confirm that the routers are configured correctly to route messages to and from the KNX network.
- Confirm that all group addresses are configured as readable.

- **When I try to write to a group address, the new value flickers and then reverts to the old address.**

Confirm that the group address is configured to be writable.

- **Unicast mode communication to the KNX network not established. Unit status is offline and all tags show BAD quality**

Make sure the Router is configured for Unicast communication mode. Also check that special option field of port form is configured with the IP address and Unicast port of the router.

## MELSECQ Driver

The MELSECQ driver supports TCP/IP communication with the Mitsubishi Electric [MelsecQ via TCP/IP](#), [MelsecQnA via TCP/IP](#) and [Melsec iQ-R](#) PLCs.

**Note:** The MelsecQ driver supersedes the MelsecQnA driver.

### TCP/IP Protocol Setup

The driver will communicate with the Ethernet card in the SCADA computer using the Plant SCADA TCP/IP driver (TCPPIP.DLL).

This protocol requires Winsock v1.1 TCP/IP software to be installed in your computer. This protocol does not require any software from Mitsubishi Electric.

The software needs to be properly installed before configuring this protocol. In particular, the correct values for IP address, subnet mask and default gateway need to be set before proceeding.

## Safety Information

### Hazard categories and special symbols

The following symbols and special messages may appear in this manual or on the product to warn of potential hazards or to call attention to information that clarifies or simplifies a procedure.

Symbol	Description
 or 	The addition of either symbol to a "Danger" or "Warning" safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.
	This is the safety alert symbol. It is used to alert you to personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.

### **DANGER**

**DANGER** indicates an imminently hazardous situation, which, if not avoided, will result in death or serious injury.

**⚠ WARNING**

**WARNING** indicates a potentially hazardous situation, which, if not avoided, can result in death or serious injury.

**⚠ CAUTION**

**CAUTION** indicates a potentially hazardous situation which, if not avoided, can result in minor or moderate injury.

**NOTICE**

**NOTICE** used without a safety alert symbol, indicates a potentially hazardous situation which, if not avoided, can result in property or equipment damage.

**Please Note**

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by AVEVA for any consequences arising out of the use of this material.

**Before You Begin**

Plant SCADA is a Supervisory Control and Data Acquisition (SCADA) solution. It facilitates the creation of software to manage and monitor industrial systems and processes. Due to Plant SCADA's central role in controlling systems and processes, you must appropriately design, commission, and test your Plant SCADA project before implementing it in an operational setting. Observe the following:

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not use Plant SCADA or other SCADA software as a replacement for PLC-based control programs. SCADA software is not designed for direct, high-speed system control.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**⚠ WARNING****LOSS OF CONTROL**

- The designer of any control scheme must consider the potential failure modes of control paths and, for certain critical control functions, provide a means to achieve a safe state during and after a path failure. Examples of critical control functions are emergency stop and overtravel stop, power outage and restart.
- Separate or redundant control paths must be provided for critical control functions.
- System control paths may include communication links. Consideration must be given to the implications of unanticipated transmission delays or failures of the link.
- Observe all accident prevention regulations and local safety guidelines.<sup>1</sup>
- Each implementation of a control system created using Plant SCADA must be individually and thoroughly tested for proper operation before being placed into service.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

1. For additional information, refer to NEMA ICS 1.1 (latest edition) "Safety Guidelines for the Application, Installation, and Maintenance of Solid State Control", and to NEMA ICS 7.1 (latest edition) "Safety Standards for Construction and Guide for Selection, Installation and Operation of Adjustable-Speed Drive Systems" or their equivalent governing your particular location.

## Supported Devices

- [MelsecQ via TCP/IP](#)

The MELSECQ driver communicates to a Melsec Q PLC through Ethernet interface modules QJ71E71-100, QJ71E71 and QJ71E71-B2.

The Ethernet module is an interface on the PLC side for connecting the Q series PLC with the host system, such as a personal computer and a work station where Plant SCADA is installed, and between PLCs using the TCP/IP or UDP/IP communication protocol via Ethernet (100BASE-TX, 10BASE-T, 10BASE5, 10BASE2).

- [MelsecQnA via TCP/IP](#)

The MELSECQ driver communicates to a Melsec QnA PLC through Ethernet interface modules AJ71QE71-B5, A1SJ71QE71-B2 and A1SJ71QE71-B5.

The Melsec-QnA driver can connect with up to 8 TCP/IP channels per AJ71QE71 interface module. One channel (port) is used to communicate with a primary Melsec-QnA PLC; the other ports can then be used for setting up extra Ethernet communication links to remote I/O modules.

The primary Melsec QnA PLC can also communicate with other PLC CPUs via a MELSECNET network (MELSECNET/10, MELSECNET/II or MELSECNET/B) connected to the primary PLC. The limit of 8 channels per Ethernet AJ71QE71 is set by the number of fixed buffers on this module. The driver itself has an upper limit of 32 communication channels; this driver setting can be changed if necessary.

- [Melsec iQ-R PLC](#)

---

**Note:** The same Ethernet card that is being used for Plant SCADA communication can be used for PLC communication, though this may lower performance.

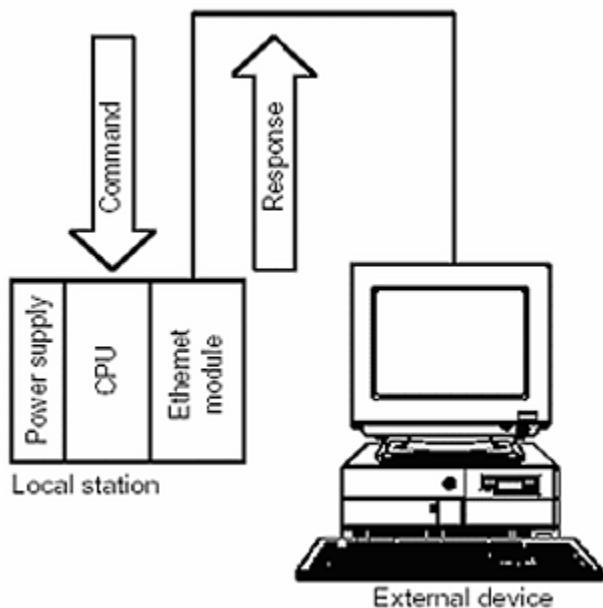

---

The maximum request length for the MELSECQ protocol is 2048 bits (256 bytes).

### MelsecQ via TCP/IP

The Ethernet module (models QJ71E71-100, QJ71E71 and QJ71E71-B2) is an interface module on the PLC side for connecting the Q series PLC with the host system, such as a personal computer and a work station where Plant SCADA is installed, and between PLCs using the TCP/IP or UDP/IP communication protocol via Ethernet (100BASE-TX, 10BASE-T, 10BASE5, 10BASE2).

The following diagram illustrates how the MelsecQ Ethernet module communicates with the external device.

### MelsecQ - Device Address

The information you enter here will be placed in the Special Options field of the Ports settings, with the following format:

-la.b.c.d -Pn -T

where:

- *a.b.c.d* - is the destination IP address using decimal numbers (for example 192.9.2.60).
- *n* - the destination Port number. Often one physical port has several virtual ports, used for different purposes.
- -T - forces the driver to use TCP, rather than UDP (-U).

See the topic [MelsecQ via TCP/IP](#) for setup details.

## MelsecQ - Hardware Setup

Apart from 100BASE-TX, 10BASE-T, 10BASE5, or 10BASE2 Ethernet cabling, no special hardware setup is required for a Plant SCADA interface.

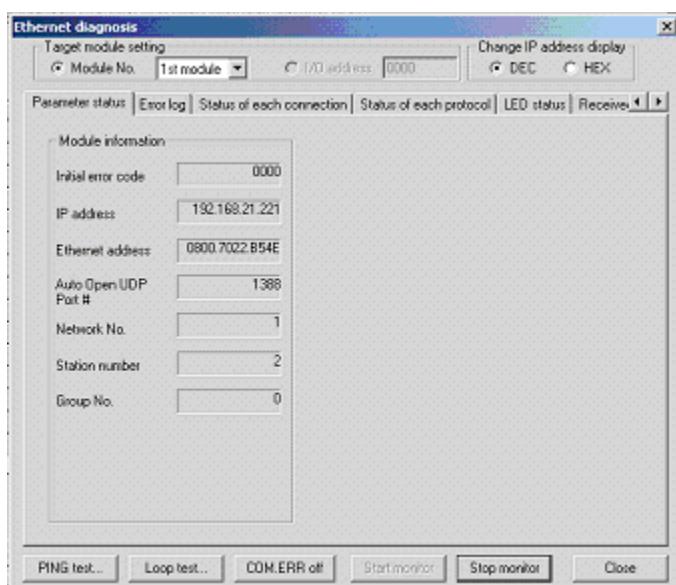

**Note:** MelsecQ devices support an AutoUDP port (port 5001) that opens when a module is initialized with an IP address. Using this port for SCADA communications is not recommended, as other applications may attempt to access the same device via the AutoUDP port.

## Plant SCADA Computer Setup

You should set up your specific Ethernet card as required and confirm basic network communications before proceeding with the communications configuration for the MelsecQ driver. Refer to your hardware documentation for instructions.

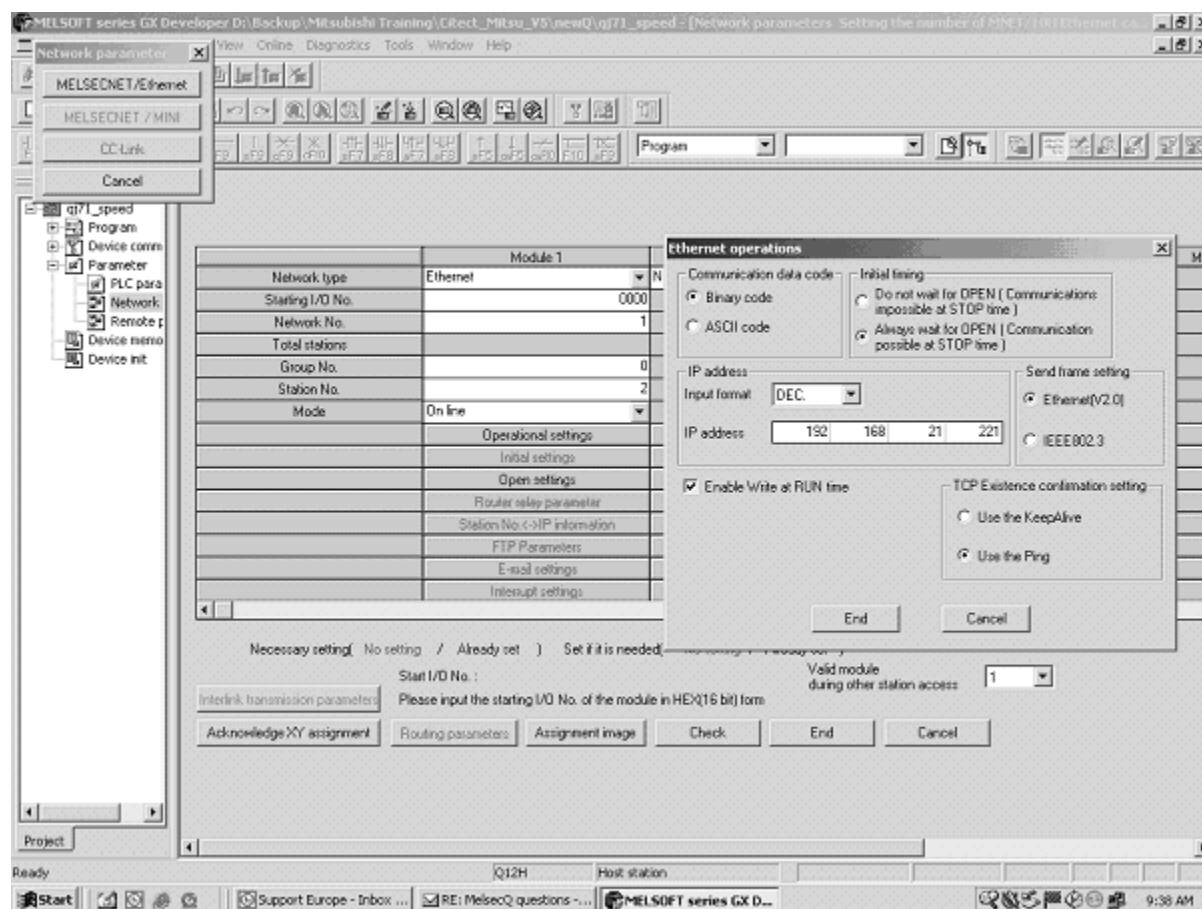

### To set up the MelsecQ software

1. Open Mitsubishi GX Developer, and then double-click Network parameters to display the dialog box.
2. Click MELSECNET/Ethernet . The Ethernet Operations dialog box appears.
3. Enter the parameters in the module listbox.
4. Click Operational Settings .
5. Enter the IP address .
6. Click End .
7. Save and write data to the PLC.
8. Manually reboot the PLC to reset the program memory.
9. Choose Ethernet Diagnostics on the Diagnostics menu to check that IP address is correct. The Ethernet diagnosis dialog box should look like this:

Use the following screenshot of the Mistubishi GX Developer to help you set up the PLC and Ethernet module.

After entering your settings, the dialog boxes should look like this:

## AJ71QE71-B5, A1SJ71QE71-B2 and A1SJ71QE71-B5 Hardware

The B2 has a Coax cable connector for 10Base2 and the B5 has an AUI connector for 10Base5 type connections. Mitsubishi recommend using a Transceiver with SQTEST of HeartBeat functionality if using the B5 model.

There are no switches on the Ethernet module models QJ71E71-100, QJ71E71 and QJ71E71-B2. Configuration is performed via the Mitsubishi GX Developer PLC software.

### Indicators on the front of the module

LED name (QJ71E71-100)	LED name (QJ71E71-B5,QJ71E 71-B2)	Display Description	LED is on	LED is off
RUN	RUN	Normal operation display	Normal	Abnormal
INIT	INIT	Initial processing status display	Normal completion	Not processed
OPEN	OPEN	Open processing status display	Normally opened connection available	Normally opened connection not available

SD	SD	Data sending display	Data being sent	Data is not sent
ERR	ERR	Setting abnormal display	ERR. ERR. Abnormal	Normal setting
COM.ERR.	COM.ERR.	Communication abnormal display	Communication abnormal occurrence	Normal communication in progress
100 M	(Not used)	Transmission speed display	100Mbps	10Mbps/When not connected
RD	RD	Data receiving status display	Data being received	Data not received

The [OPEN] LED turns on/off depending on the open states of user connections 1 to 16.

(The open states of the system connections, for example, automatic open UDP port are not included.)

The [ERR.] LED turns on in the following cases:

- When setting values in GX Developer (mode, station number, and/or network number) are incorrect.
- When an error has occurred in the Ethernet module or PLC CPU and the operation is disabled due to the error.

### MelsecQ - Hints and Tips

If the MELSECQ driver writes a string value to a PLC, it will use a null terminated ASCII value. If a third party driver or application does not correctly read the null character, buffered values may appear as additional junk characters. If this occurs, you may need to use Cicode to pad the values being written to a string tag.

An example of how to do this is provided in the Plant SCADA Knowledge Base article "Q4841: MELSECQ driver writes junk characters".

### MelsecQ - Communication Settings

To establish communication with a device, configure the **Boards**, **Ports** and **I/O Devices** settings in the Plant SCADA Studio's Topology activity. If you use the Express Communications Wizard to connect to a device, these settings will be automatically configured for you. However, if you need to manually configure these, use the information outlined below.

## Boards

Field	Value
Board Type	Enter TCPIP.
Address	Enter 0.
I/O Port	Leave this field blank.

Field	Value
Interrupt	Leave this field blank.
Special Options	This field is not used.

## Ports

For details about initializing the port, see [MelsecQ - Hints and Tips](#).

Field	Value
Port Number	Leave this field blank.
Baud Rate	Leave this field blank.
Data Bits	Leave this field blank.
Stop Bits	Leave this field blank.
Parity	This field is not used.
Special Options	Enter the AJ71QE71 Ethernet module's TCP/IP address of the controller.  See "I/O Device Address" below for details about this option.

## I/O Devices

For details about initializing the I/O Device, see [MelsecQ - Hints and Tips](#).

Field	Value
I/O Device Address	The CPU number (0-64 or 255). You can specify the CPU monitoring time using the optional parameter "/Tt" after the CPU number. It should be possible to specify the network number (0-239 or 255) by using optional parameter "/Nn" after the CPU number (only useful for MELSECNET/10 PLC networks). Finally you can specify the ASCII Mode for data exchange by using optional parameter /A (the default is binary mode).  The address format is: <b>a [/Tt] [/Nn] [/Pp OR /Qq OR /Ss] [/A]</b> Where: <b>a</b> = CPU number 0 to 64 or 255 in decimal <b>t</b> = CPU monitoring time parameter (units 250 ms). The default is 10.

Field	Value
	<p><b>n</b> = Network number 0 to 239 or 255 in decimal. The default network number is 0.</p> <p><b>p</b> = PLC number, default is 0 for control PLC</p> <p><b>s</b> = System CPU</p> <ul style="list-style-type: none"> <li>1 - Control System CPU</li> <li>2 - Standby System CPU</li> <li>3 - System A CPU</li> <li>4 - System B CPU</li> </ul> <p><b>q</b> = External device ID for multidrop Q mode C24 devices.</p> <p>/P, /Q and /S parameters are mutually exclusive. The precedence of them is /P &gt; /Q &gt; /S.</p> <p><b>Note:</b> An in-depth description of the Network and CPU monitoring policy can be found in section 10.1 of the "MELSEC Q series Programmable Controller User's Manual - QnA Ethernet Interface Module type AJ71QE71(B5) - A1SJ71QE71-B2 - A1SJ71QE71-B5". Manual number IB (NA) 66661-C</p>
I/O Device Protocol	Enter MELSECQ.

### MelsecQ - Data Types

Data Types	Plant SCADA Data Format	Plant SCADA Data Type	Descriptions/ Special Usages/ Limitations/ Valid Ranges
Input relay	X<hexno>	DIGITAL	Read / Write
Output relay	Y<hexno>	DIGITAL	Read / Write
Link input	DX<hexno>	DIGITAL	Read / Write
Link output	DY<hexno>	DIGITAL	Read / Write
Internal relay	M<no>	DIGITAL	Read / Write
Link relay	B<hexno>	DIGITAL	Read / Write
Latch relay	L<no>	DIGITAL	Read / Write
Annunciator	F<no>	DIGITAL	Read / Write
Edge relay	V<no>	DIGITAL	Read / Write

Data Types	Plant SCADA Data Format	Plant SCADA Data Type	Descriptions/ Special Usages/ Limitations/ Valid Ranges
Step relay	S<no>	DIGITAL	Read / Write
Special relay	SM<no>	DIGITAL	Read / Write
Special relay for link	SB<hexno>	DIGITAL	Read / Write
Timer (Contact)	TS<no>	DIGITAL	Read / Write
Timer (Coil)	TC<no>	DIGITAL	Read / Write
Integrating Timer (Contact)	SS<no>	DIGITAL	Read / Write
Intergating Timer (Coil)	SC<no>	DIGITAL	Read / Write
Counter (Contact)	CS<no>	DIGITAL	Read / Write
Counter (Coil)	CC<no>	DIGITAL	Read / Write
Timer (Current Value)	TN<no>	INT, LONG, STRING, REAL, BCD, LONGBCD	Read / Write
Integrating Timer (Current Value)	SN<no>	INT, LONG, STRING, REAL, BCD, LONGBCD	Read / Write
Counter (Current value)	CN<no>	INT, LONG, STRING, REAL, BCD, LONGBCD	Read / Write
Data register	D<no>	INT, LONG, STRING, REAL, BCD, LONGBCD	Read / Write
Link register	W<hexno>	INT, LONG, STRING, REAL, BCD, LONGBCD	Read / Write
Special register for link	SW<hexno>	INT, LONG, STRING, REAL, BCD, LONGBCD	Read / Write
Special register	SD<no>	INT, LONG, STRING, REAL, BCD, LONGBCD	Read / Write
File Register (Block Access)	R<no>	INT, LONG, STRING, REAL, BCD, LONGBCD	Read / Write
File Register (Seq. Access)	ZR<hexno>	INT, LONG, STRING, REAL, BCD, LONGBCD	Read / Write
Index register	Z<no>	INT, LONG, STRING, REAL, BCD, LONGBCD	Read / Write

Where:

<no>	decimal number
<hexno>	hexadecimal number

DX & DY are DIRECT read and writes of the I/O values. X & Y are read / written at the end of the scan. Thus the X / DX , Y / DY areas are one of the same.

## EXAMPLES:

Data Type	INTEGER
Address	V77
Comment	Stator current
Data Type	DIGITAL
Address	X107
Comment	Running feedback indicator

## MelsecQnA via TCP/IP

The MELSECQ Driver supports TCP/IP communication to the MelsecQnA PLC, manufactured by Mitsubishi Electric, over Ethernet. Using this method you can connect to single MelsecQnA PLCs or to multiple MelsecQnA PLCs, using 10BASE5 or 10BASE2 Ethernet cabling.

Communication to the MelsecQnA PLC is specifically through the Melsec QnA interface module type AJ71QE71, but AJ71QE71-B5, A1SJ71QE71-B2 and A1SJ71QE71-B5 Ethernet interface modules are also supported. See the section on [MelsecQnA - Hardware Setup](#) for more information on these modules.

The primary MelsecQnA PLC is also able to communicate with other PLC CPUs via a MELSECNET network (MELSECNET/10, MELSECNET/II or MESLCNET/B) connected to the primary PLC.

## MelsecQnA - Device Address

The information you enter here will be placed in the Special Options field of the Ports form, with the following format:

-la.b.c.d -Pn -T

where:

- *a.b.c.d* is the destination IP address using decimal numbers (for example 192.9.2.60).
- *n* The destination Port number. Often one physical port has several virtual ports, used for different purposes.
- -T Forces the driver to use TCP, rather than UDP (-U).

See the topic [MelsecQnA via TCP/IP](#) for details about setting up MelsecQnA PLCs.

## MelsecQnA - Hardware Setup

### MelsecQnA PLC Setup

Apart from 10BASE5 or 10BASE2 Ethernet cabling, no special hardware setup is required for a Plant SCADA interface.

The PLC has to be programmed to operate the AJ71QE71 interface. Following is an example of the ladder logic to enable the TCP/IP port to work. This example uses ports 1020 & 1021. This code needs to exist in the initethet section of the QNA code.

---

**Note:** MelsecQnA devices support an AutoUDP port (port 5001) that opens when a module is initialized with an IP address. Using this port for SCADA communications is not recommended, as other applications may attempt to access the same device via the AutoUDP port.

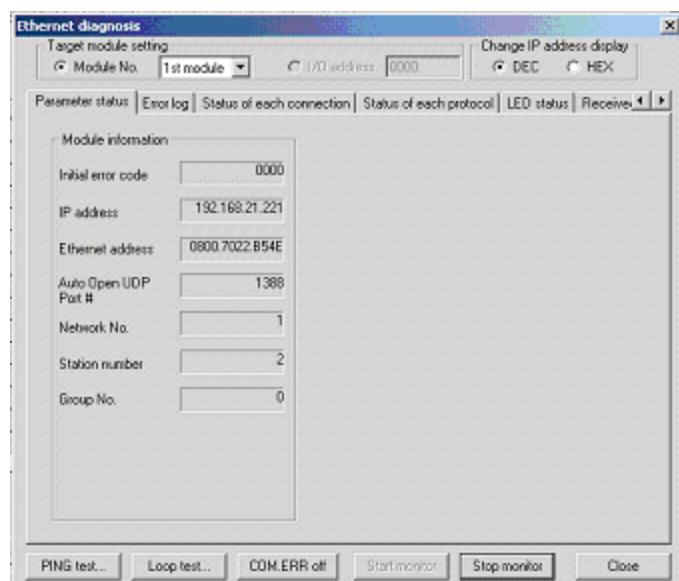

---

### Plant SCADA Computer Setup

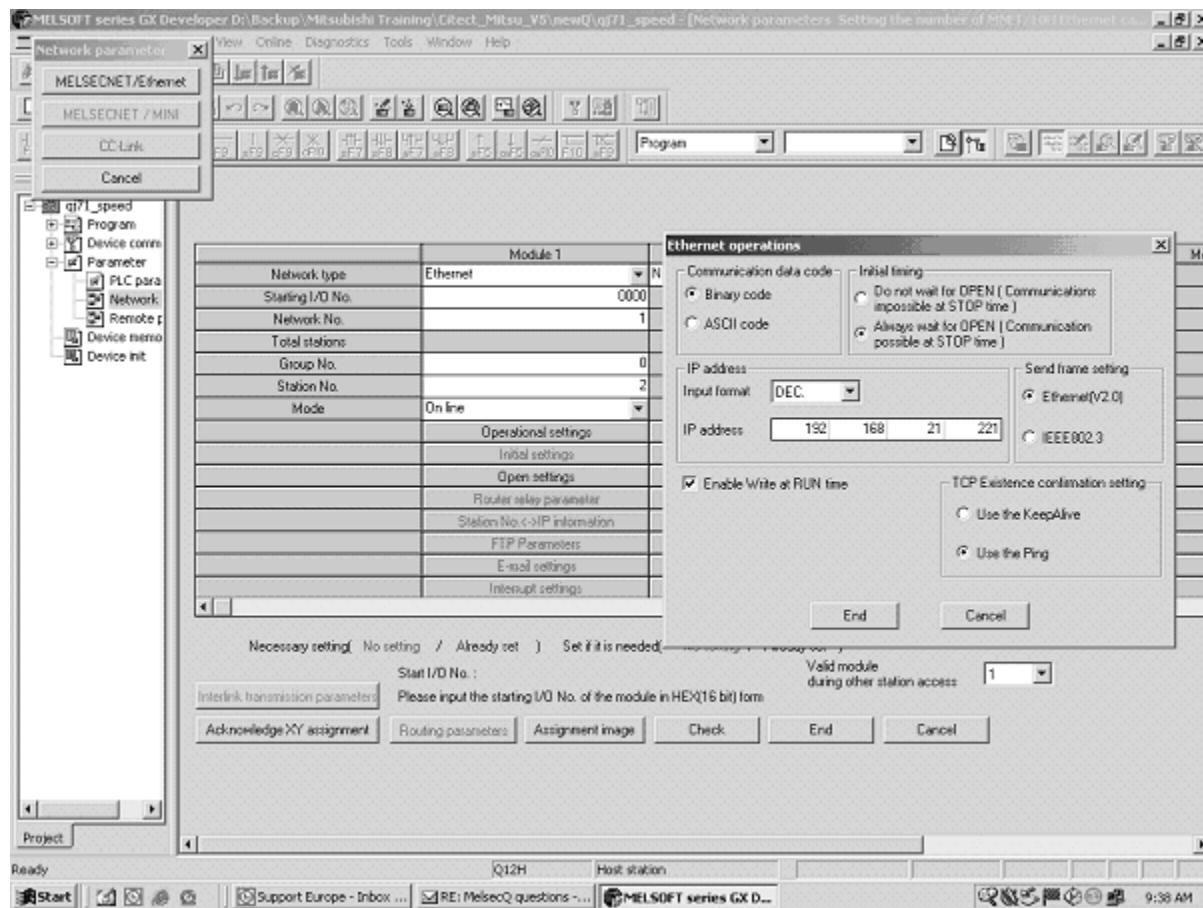

It is recommended that you setup your specific Ethernet card as required and confirm basic network communications before proceeding with the communications configuration for the MELSECQ driver. Refer to the documentation accompanying your hardware for instructions.

#### To set up the MelsecQ software

1. Open Mitsubishi GX Developer, and then double-click Network parameters to display the dialog box.
2. Click MELSECNET/Ethernet . The Ethernet Operations dialog box appears.
3. Enter the parameters in the module listbox.
4. Click Operational Settings .
5. Enter the IP address .
6. Click End.
7. Save and write data to the PLC.
8. Manually reboot the PLC to reset the program memory.
9. Choose Ethernet Diagnostics on the Diagnostics menu to check that IP address is correct. The Ethernet diagnosis dialog box should look like this:

Use the following screenshot of the Mitsubishi GX Developer to help you set up the PLC and Ethernet module. After entering your settings, the dialog boxes should look like this:

## AJ71QE71-B5, A1SJ71QE71-B2 and A1SJ71QE71-B5 Hardware

The B2 has a Coax cable connector for 10Base2 and the B5 has an AUI connector for 10Base5 type connections.

Mitsubishi recommend using a Transceiver with SQTEST or HeartBeat functionality if using the B5 model.

### Indicators on the front of the module

RUN	ON = Normal, OFF = Bad Thing (Normal Operation Display)
RDY	Flashing = On-Line and Good (Standard Display of communication exchange completion)
BSY	ON = Executing, OFF= Not Executing (Display during execution of communication exchange processing)
SW ERR	CPU error, CPU type error, or rotary switch error display ON = Error, OFF= Normal
COM ERR	ON = Communication Exchange Abnormality (Bad Thing)
CPU R/W	ON = Exchanging data with CPU
TRANS.S	ON = Data link command request executing
TRANS.R	ON = Data link RECV command request waiting
FTP	ON = FTP server function operating
B1 - B8	Communication line connection status ON = Open completed, OFF= Closed state
TEST	ON = Self diagnosis executing
TEST.ERR	ON = Error during self diagnosis

### Operation Mode Switch

0	On-line
1	Off-line
2	Execute a self-diagnosis test using a self-loopback test
3	Execute a RAM test
4	Execute a ROM test

5	Execute am EEPROM test
6	F not used

## Communication Exchange Condition Setting Switches

Recommended settings have been marked in blue. See also [MelsecQnA - Hints and Tips](#) for a summary of switch settings.

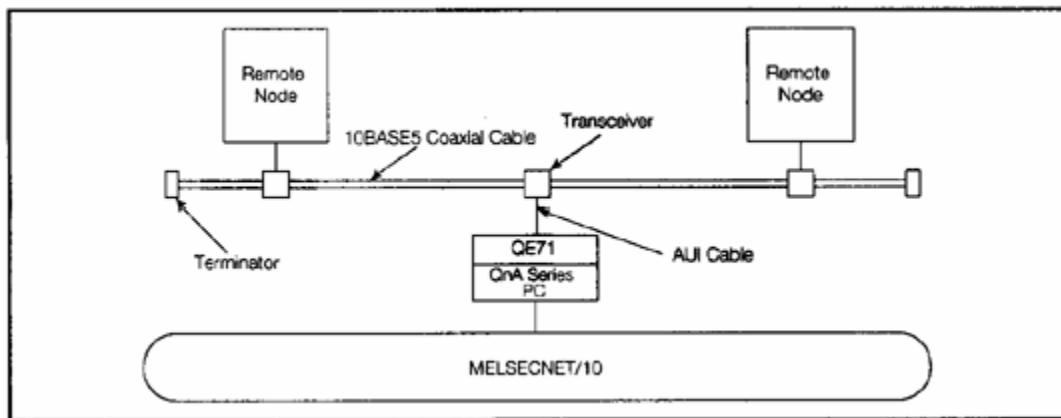

SW1	TCP Timeout error temporary circuit process selection. Selection of Circuit processing at the time of a transmission of a TCP time out error. OFF = Close the circuit ON = Do Not Close the Circuit For Plant SCADA keep it OFF
SW2	Data Code Selection Type of Data Communications supported: OFF= Binary Mode ON = ASCII Mode Mitsubishi has released a Windows version of their programming software that uses ASCII Mode for communicating with the Module. Plant SCADA normally uses Binary Mode, but there is also the ability to use the ASCII Mode.
SW3	Self start mode setting Selects the start mode when the QE71 is booted. OFF= Runs following Y19 (initial processing request signal) ON = Reads the parameters in the EEPROM buffer memory regardless of the Y19 (initial processing request signal) after power has been turned on or the module reset and then conducts initial processing of the contents. This switch should be OFF.
SW4 - SW6	Usage not possible (fixed to OFF).
SW7	CPU communications exchange timing setting Write Protect the PLC. OFF = Writing Prohibited ON = Writing allowed. If you want to write to the PLC then set this to ON.
SW8	Initial Timing Setting Select the Timing which starts Initial Processing. OFF= Quick Start (Start without Delay) when entirely

constructed in a single network.  
OFF = Normal Start (start after a 20 sec delay) when entirely constructed in multiple networks.  
For Plant SCADA, keep it OFF. Select the Timing which starts Initial Processing.  
OFF= Quick Start (Start without Delay) when entirely constructed in a single network.  
OFF = Normal Start (start after a 20 sec delay) when entirely constructed in multiple networks.  
For Plant SCADA, keep it OFF.

### MelsecQnA - Wiring Diagram 1

The following functional/layout diagrams illustrate the connection between Plant SCADA and the Melsec-QnA Ethernet interface module type AJ71QE7. In these configurations, the primary QnA Series PLC itself is connected to a MELSECNET/10 network. The nodes which are marked as remote can be occupied by a Plant SCADA Workstation.

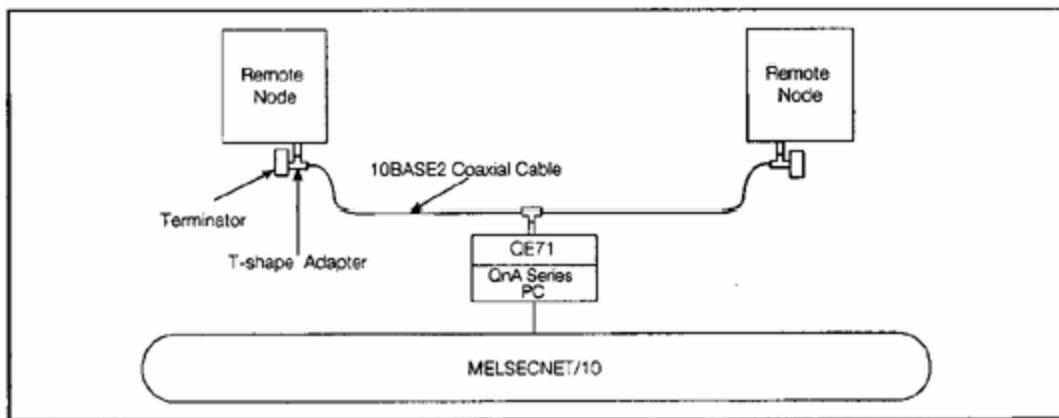

The following diagram shows connection using 10BASE5 Ethernet cabling:

### MelsecQnA - Wiring Diagram 2

The following functional/layout diagrams illustrate the connection between Plant SCADA and the Melsec-QnA Ethernet interface module type AJ71QE7. In these configurations, the primary QnA Series PLC itself is connected to a MELSECNET/10 network. The nodes which are marked as remote can be occupied by a Plant SCADA Workstation.

The following diagram shows connection using 10BASE2 "CheaperNet" cabling:

### MelsecQnA - Hints and Tips

- To initialize the ports, the Melsec-QnA driver will open an Ethernet channel on an AJ71QE71 interface module by using the IP addresses you specify on the Ports Form. You may specify up to 8 TCP/IP ports for one AJ71QE71; this limit is set by the amount of fixed buffers on the Ethernet interface module. Throughput of this driver may be improved by specifying different ports for different remote I/O modules (ie. spread the traffic across several TCP/IP connections, as the driver only supports one pending message per TCP/IP connection). This limit of one pending message per TCP/IP connection finds its roots in the simple request/response protocol used to communicate with PLCs.
- To initialize the I/O Device, Plant SCADA will call CTDRV\_INIT\_UNIT with information from the driver database. This is also the appropriate place to set the data exchange mode (Binary Mode, ASCII Mode) for the IO Device.
- Concerning data exchange, the driver will support both Binary Mode (SW2 on front panel of AJ71QE71 OFF) and ASCII Mode (SW2 on front panel of AJ71QE71 ON).

Normally SW1 and SW8 will be OFF, while SW3 and SW6 will be ON. SW4 - 6 are not used.

SW1 - OFF

SW2 - OFF (ON)

SW3 - OFF

SW7 - ON

SW8 - OFF

Mode = 0

SW1 is TCP Timeout control

SW2 is Communications Type.

Mitsubishi Programming Software MMPlus needs this to be set to ASCII Mode (ON).

Plant SCADA normally uses Binary Mode (OFF), but a parameter allows the selection of ASCII Mode (ON).

SW3 is Self-start enabling/disabling of PLC. OFF = Self-start disabled, ON = Self-start enabled.

SW7 is write protecting the PLC. OFF - Writing prohibited, ON = writing approved.

SW8 is Initial timing setting of PLC. OFF = Quick start, ON = Normal start (start after a delay of 20 seconds).

- If the MELSECQ driver writes a string value to a PLC, it will use a null terminated ASCII value. If a third party driver or application does not correctly read the null character, buffered values may appear as additional junk characters. If this occurs, you may need to use Cicode to pad the values being written to a string tag. An example of how to do this is provided in the Plant SCADA Knowledge Base article "Q4841: MELSECQ driver writes junk characters".

## MelsecQnA - Communication Settings

To establish communication with a device, configure the **Boards**, **Ports** and **I/O Devices** in the Plant SCADA Studio's **Topology** activity. If you use the Express Communications Wizard to connect to a device, these settings will be automatically configured for you. However, if you need to manually configure these, use the information outlined below.

### Boards

Field	Value
Board Type	Enter TCPIP.
Address	Enter 0.
I/O Port	Leave this field blank.
Interrupt	Leave this field blank.
Special Options	This field is not used.

### Ports

For details about initializing the port, see [MelsecQ - Hints and Tips](#).

Field	Value
Port Number	Leave this field blank.
Baud Rate	Leave this field blank.
Data Bits	Leave this field blank.
Stop Bits	Leave this field blank.
Parity	This field is not used.
Special Options	Enter the AJ71QE71 Ethernet module's TCP/IP address of the controller.  See "I/O Device Address" below for details about this option.

### I/O Devices

For details about initializing the I/O Device, see [MelsecQ - Hints and Tips](#).

Field	Value
I/O Device Address	<p>The CPU number (0-64 or 255). You can specify the CPU monitoring time using the optional parameter "/Tt" after the CPU number. It should be possible to specify the network number (0-239 or 255) by using optional parameter "/Nn" after the CPU number (only useful for MELSECNET/10 PLC networks). Finally you can specify the ASCII Mode for data exchange by using optional parameter /A (the default is binary mode).</p> <p>The address format is:</p> <p><b>a [/Tt] [/Nn] [/A]</b></p> <p>Where:</p> <p><b>a</b> = CPU number 1 to 64 or 255 in decimal</p> <p><b>t</b> = CPU monitoring time parameter (units 250 ms). The default is 10.</p> <p><b>n</b> = Network number 0 to 239 or 255 in decimal. The default network number is 0.</p> <p><b>Note:</b> An in-depth description of the Network and CPU monitoring policy can be found in section 10.1 of the "MELSEC Q series Programmable Controller User's Manual - QnA Ethernet Interface Module type AJ71QE71(B5) - A1SJ71QE71-B2 - A1SJ71QE71-B5". Manual number IB (NA) 66661-C</p>
I/O Device Protocol	Enter MELSECQ.

### MelsecQnA - Data Types

Data Types	Plant SCADA Data Format	Plant SCADA Data Type	Descriptions/ Special Usages/ Limitations/ Valid Ranges

## Melsec iQ-R via TCP/IP

The MELSECQ Driver supports TCP/IP communication with the Melsec iQ-R, manufactured by Mitsubishi Electric. The following diagram illustrates how the Melsec iQ-R module communicates with the external device.

### Melsec iQ-R - Device Address

The information you enter here will be placed in the Special Options field of the Ports settings, with the following format:

`-la.b.c.d -Pn -T`

where:

- *a.b.c.d* - is the destination IP address using decimal numbers (for example 192.9.2.60).
- *n* - the destination Port number. Often one physical port has several virtual ports, used for different purposes.
- `-T` - forces the driver to use TCP, rather than UDP (`-U`).

See the topic [Melsec iQ-R via TCP/IP](#) for setup details.

### Melsec iQ-R - Communications Settings

To establish communication with a device, configure the **Boards**, **Ports** and **I/O Devices** settings in the Plant SCADA Studio's Topology activity. If you use the Express Communications Wizard to connect to a device, these settings will be automatically configured for you. However, if you need to manually configure these, use the information outlined below.

## Boards

Field	Value
Board Type	Enter TCPIP.
Address	Enter 0.

Field	Value
I/O Port	Leave this field blank.
Interrupt	Leave this field blank.
Special Options	This field is not used.

## Ports

Field	Value
Port Number	Leave this field blank.
Baud Rate	Leave this field blank.
Data Bits	Leave this field blank.
Stop Bits	Leave this field blank.
Parity	This field is not used.
Special Options	Enter the AJ71QE71 Ethernet module's TCP/IP address of the controller.  See "I/O Device Address" below for details about this option.

## I/O Devices

Field	Value
I/O Device Address	The CPU number (0-64 or 255). You can specify the CPU monitoring time using the optional parameter "/Tt" after the CPU number. It should be possible to specify the network number (0-239 or 255) by using optional parameter "/Nn" after the CPU number (only useful for MELSECNET/10 PLC networks). Finally you can specify the ASCII Mode for data exchange by using optional parameter /A (the default is binary mode).  The address format is: <b>a [/Tt] [/Nn] [/Pp OR /Qq OR /Ss] [/A]</b> Where: <b>a</b> = CPU number 0 to 64 or 255 in decimal

Field	Value
	<p><b>t</b> = CPU monitoring time parameter (units 250 ms). The default is 10.</p> <p><b>n</b> = Network number 0 to 239 or 255 in decimal. The default network number is 0.</p> <p><b>p</b> = PLC number, default is 0 for control PLC</p> <p><b>s</b> = System CPU</p> <ul style="list-style-type: none"> <li>1 - Control System CPU</li> <li>2 - Standby System CPU</li> <li>3 - System A CPU</li> <li>4 - System B CPU</li> </ul> <p><b>q</b> = External device ID for multidrop Q mode C24 devices.</p> <p>/P, /Q and /S parameters are mutually exclusive. The precedence of them is /P &gt; /Q &gt; /S.</p> <p><b>Note:</b> An in-depth description of the Network and CPU monitoring policy can be found in section 10.1 of the "MELSEC Q series Programmable Controller User's Manual - QnA Ethernet Interface Module type AJ71QE71(B5) - A1SJ71QE71-B2 - A1SJ71QE71-B5". Manual number IB (NA) 66661-C</p>
I/O Device Protocol	Enter MELSECQ2.

### Melsec iQ-R - Data Types

## Customize a Project using Citect.ini Parameters

The MELSECQ driver supports the following parameter categories:

- MELSECQ Driver Parameters
- Logging Parameters.

## **WARNING**

### **UNINTENDED EQUIPMENT OPERATION**

- Do not under any circumstances change or remove any citect.ini parameters without an informed understanding of the possible implications of your actions.
- Do not delete sections of the citect.ini file without an informed understanding of the possible implications of your actions.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** At times during the life cycle of a driver, circumstances may call for the creation of specific citect.ini parameters that remain undocumented. Always seek the advice of Technical Support regarding the possible implementation of undocumented parameters before you make any changes to a citect.ini file.

## **MELSECQ Driver Parameters**

## **WARNING**

### **UNINTENDED EQUIPMENT OPERATION**

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

MELSECQ Parameter	Description	Allowable Values	Default Value
Block	A value (bytes) used by the I/O server to determine if two or more packets can be blocked into one data request before being sent to the I/O device.  For example, if you set the value to 10, and the I/O server receives two simultaneous data requests - one for byte 3, and another for byte 8 - the two requests will be blocked into a single	5 to 256	256

	physical data request packet.  This single request packet is then sent to the I/O Device, saving on bandwidth and processing.		
Delay	The period (in milliseconds) to wait between receiving a response and sending the next command.	0 to 300 (milliseconds)	0
MaxPending	The maximum number of pending commands that the driver holds ready for immediate execution.	1 to 32	1
PollTime	The interrupt or polling service time (in milliseconds). Setting the polling time to 0 puts the driver in interrupt mode.	0 to 300 (milliseconds)	0
Retry	The number of times to retry a command after a timeout.	0 to 8	2
Timeout Allowable Values: Default Value:	Specifies how many milliseconds to wait for a response before displaying an error message.	0 to 32 000 (milliseconds)	10000 milliseconds (Mitsubishi recommends this value)
WatchTime	The frequency (in seconds) that the driver uses to check the communications link to the I/O Device.	0 to 128 (seconds)	30 seconds <b>Note:</b> This value should be increased to lower CPU load. Mitsubishi recommends a default value of 3.

## Logging Parameters

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

MELSECQ Parameter	Description	Allowable Values	Default Value
DebugCategory	Controls which categories of log messages are written to the log file.	ALL or any combination of the following values separated by a pipe character (   ):  PROT UNIT MSG ENTRY DCB MISC  See <a href="#">Logging</a> for examples.	Empty string (no logging).
DebugLevel	Controls which levels of log message are written to the log file.	ALL or any combination of the following values separated by a pipe character (   ):  WARN ERROR TRACE DEBUG  See <a href="#">Logging</a> for examples.	Empty string (no logging).

**See Also**

[MELSECQ Driver Parameters](#)

## MELSECQ Driver Specific Errors

When a hardware error occurs, Plant SCADA generates an alarm, and displays the alarm on the hardware alarm page (in the alarm description of the hardware alarm). To see the error number, you need to have Alarm Category 255 defined with a display format that includes {ErrDesc,15} {ErrPage,10} .

There are a number of generic errors that are common to many protocols. In some cases, only the generic error is available, though often both the generic error and a specific error are given.

The following errors, listed in (hexadecimal) sequence, are specific to this protocol. Plant SCADA displays the error number and description for common protocol-specific errors. Uncommon errors are not contained in the

Plant SCADA error database, in which case Plant SCADA will only display the error number.

You may require additional information to enable you to rectify an error. This information should be detailed in the documentation that accompanied the I/O Device (or network). If, after reviewing the documentation, you cannot rectify an error, contact Technical Support for this product.

## 10000H + CODE

Code is the error code. Consult the QnA Ethernet Interface Module User's Manual for details on the error code.

## Logging

The MELSECQ driver can log combinations of trace levels across different categories. This is achieved by setting the following INI parameters.

### [MELSECQ]DebugLevel

This parameter allows you to define the trace level. The options include:

Option	Description
WARN	Output warning messages.
ERROR	Output error messages.
TRACE	Output trace messages.
DEBUG	Output debug messages.
ALL	All of the above.

### [MELSECQ]DebugCategory

This parameter allows you to enable logging for a particular category of trace. The options include:

Option	Description
PROT	Trace of communication between the driver and the lower level protocol.
UNIT	I/O device trace.
ENTRY	Driver entry trace.
DCB	Front end driver trace.
MISC	Any other debugging.
ALL	All of the above.

In both cases, you can use any combination of the available options separated by a pipe character ( | ).

#### Example

```
[MELSECQ]
DebugLevel=WARN|ERROR|TRACE
DebugCategory=ALL
```

In most cases, you can set the DebugLevel and DebugCategory parameters to ALL. If this results in a large, cumbersome log file that causes older data to be overwritten, you can consider refining the debug options.

**Note:** These parameters do not have a value specified by default. To enable logging for this driver, you need to manually configure these parameters in your INI file.

The events generated by the MELSECQ driver are logged in the following Plant SCADA syslog file:

```
syslog.IOServer.<Cluster name>.<IO Server name>.dat
```

This file is located in the directory specified by the Citect.ini parameter **[CtEdit]Logs**. By default, this location will be:

```
%PROGRAMDATA%\AVEVA Plant SCADA <VersionNumber>\Logs
```

The size of the syslog file and its rollover process is configured via the **[Debug]SysLogSize** and **[Debug]SysLogArchive** INI parameters. For more information, see the topic *Debug Parameters* in the Plant SCADA documentation.

**Note:** If the number of messages being processed for a driver exceeds the value specified by the Plant SCADA parameter **[Kernel]ErrorBuffers**, the pending messages will not be logged. If this occurs, you can increase the value of this parameter so that all the messages generated by the driver are reported. The number of messages that are not logged can be monitored via the Kernel's General window under the item "Lost Errors". If you adjust **[Kernel]ErrorBuffers** and Lost Errors are still occurring, you may need to adjust the level of system logging.

## See Also

[Logging Parameters](#)

## MODBUS Driver

The MODBUS Driver supports serial communication with many I/O devices (including the Modicon 484, 584, 884, and 984 programmable controllers, and Moore Products IOExpress).

**Note:** The **MODBUS** and **MODBUSA** drivers are closely related. They only differ from each other in the data framing technique used: MODBUS is RTU-based, while MODBUSA is ASCII-based. You should determine which your system requires and make sure you proceed using the appropriate driver.

The maximum request length for the MODBUS driver is 2000 bits.

## Safety Information

### Hazard categories and special symbols

The following symbols and special messages may appear in this manual or on the product to warn of potential hazards or to call attention to information that clarifies or simplifies a procedure.

Symbol	Description
 or 	The addition of either symbol to a "Danger" or "Warning" safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.
	This is the safety alert symbol. It is used to alert you to personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.
<b> DANGER</b>	
<b>DANGER</b> indicates an imminently hazardous situation, which, if not avoided, will result in death or serious injury.	
<b> WARNING</b>	
<b>WARNING</b> indicates a potentially hazardous situation, which, if not avoided, can result in death or serious injury.	
<b> CAUTION</b>	
<b>CAUTION</b> indicates a potentially hazardous situation which, if not avoided, can result in minor or moderate injury.	
<b>NOTICE</b>	
<b>NOTICE</b> used without a safety alert symbol, indicates a potentially hazardous situation which, if not avoided, can result in property or equipment damage.	

## Please Note

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by AVEVA for any consequences arising out of the use of this material.

## Before You Begin

Plant SCADA is a Supervisory Control and Data Acquisition (SCADA) solution. It facilitates the creation of software to manage and monitor industrial systems and processes. Due to Plant SCADA's central role in controlling systems and processes, you must appropriately design, commission, and test your Plant SCADA project before implementing it in an operational setting. Observe the following:

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not use Plant SCADA or other SCADA software as a replacement for PLC-based control programs. SCADA software is not designed for direct, high-speed system control.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**⚠ WARNING****LOSS OF CONTROL**

- The designer of any control scheme must consider the potential failure modes of control paths and, for certain critical control functions, provide a means to achieve a safe state during and after a path failure. Examples of critical control functions are emergency stop and overtravel stop, power outage and restart.
- Separate or redundant control paths must be provided for critical control functions.
- System control paths may include communication links. Consideration must be given to the implications of unanticipated transmission delays or failures of the link.
- Observe all accident prevention regulations and local safety guidelines.<sup>1</sup>
- Each implementation of a control system created using Plant SCADA must be individually and thoroughly tested for proper operation before being placed into service.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

1. For additional information, refer to NEMA ICS 1.1 (latest edition) "Safety Guidelines for the Application, Installation, and Maintenance of Solid State Control", and to NEMA ICS 7.1 (latest edition) "Safety Standards for Construction and Guide for Selection, Installation and Operation of Adjustable-Speed Drive Systems" or their equivalent governing your particular location.

## Supported Devices

The MODBUS Driver supports serial communication with the following devices:

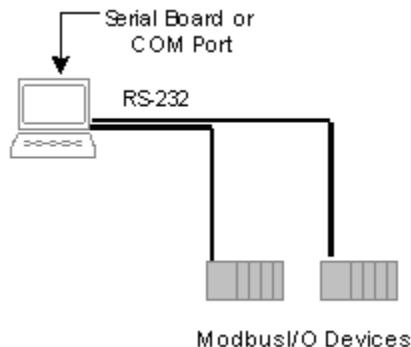

- Generic devices
- Modicon 484 PLCs
- Modicon 884 PLCs
- Modicon 984 PLCs
- Moore Products IOExpress Data Collection Units.

Also see [Working with non-standard devices](#).

## MODBUS Generic Devices

Being an established industry standard, the Modbus protocol supports many I/O devices from a variety of manufacturers. The MODBUS Driver therefore can support communication between Plant SCADA and any generic Modbus devices.

Communication is via a Modbus port on the PLC. Using this method, you can connect to multiple PLCs as in the following diagram:

The following topics provide information required to connect Plant SCADA to a generic Modbus device.

### MODBUS Generic Devices - Device Address

The I/O Device Address for a PLC is its station number. Try 1 to 10.

- **1** specifies station number **1**.
- **9** specifies station number **9**.

### MODBUS Generic Devices - Hardware Setup

Set your PLC to the communication setting you require. The default hardware settings for the device are as follows:

Setting	Value
Baud Rate	19200
Data Bits	8
Stop Bits	1
Parity	2 (Even)

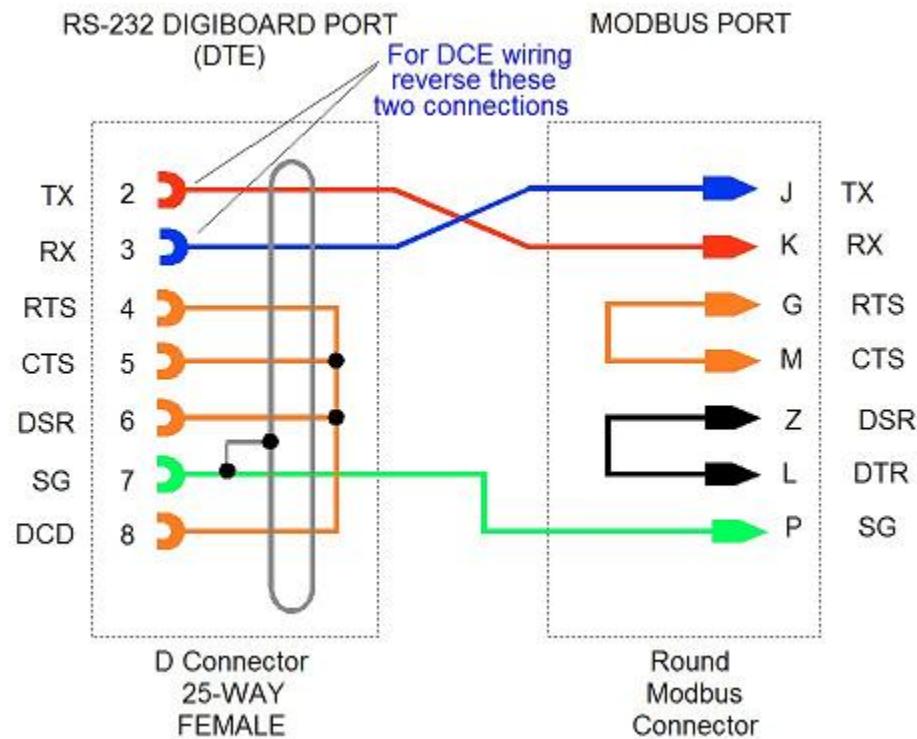

**Note:** These settings are recommendations only. If you use the Communications Express Wizard, these default settings are configured in your project automatically, though your hardware may support other values. If you do set the baud rate, data bits, stop bits or parity to another value, you must manually set the new value(s) in your project.

Set the following configuration options on the Modbus port on the PLC:

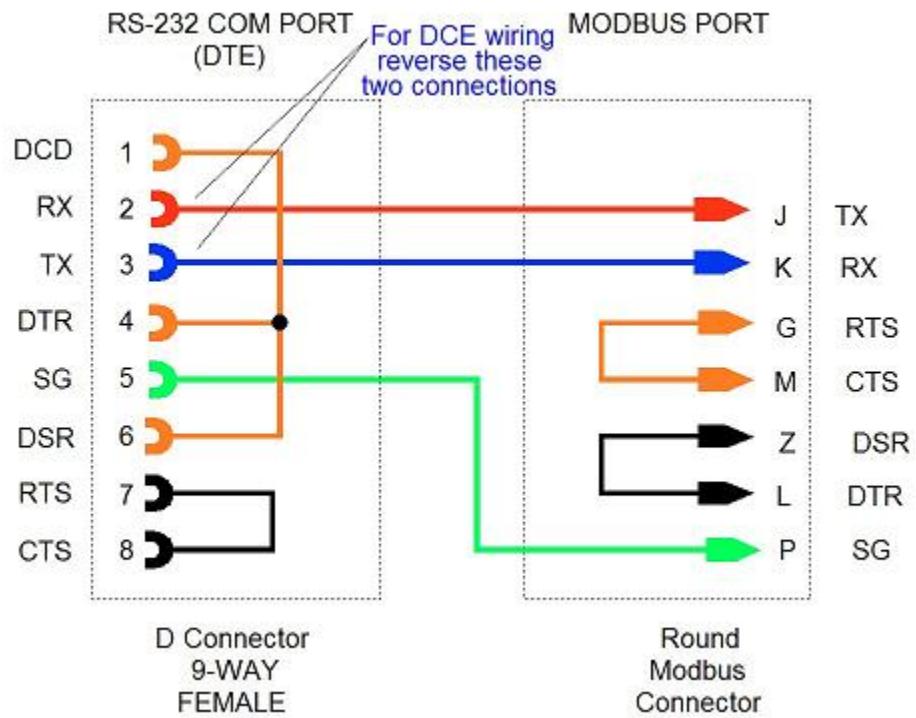

- Station number

- RTU mode (This is not selected if the MODBUSA protocol is being used)
- Delay time to 1

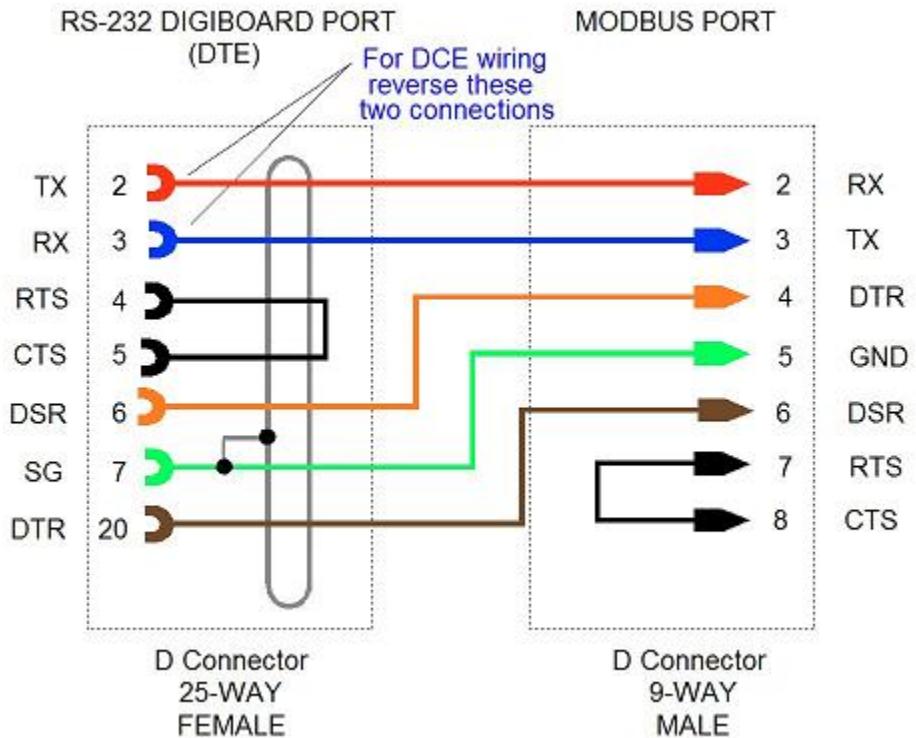

### MODBUS Generic Devices - Wiring Diagram 1

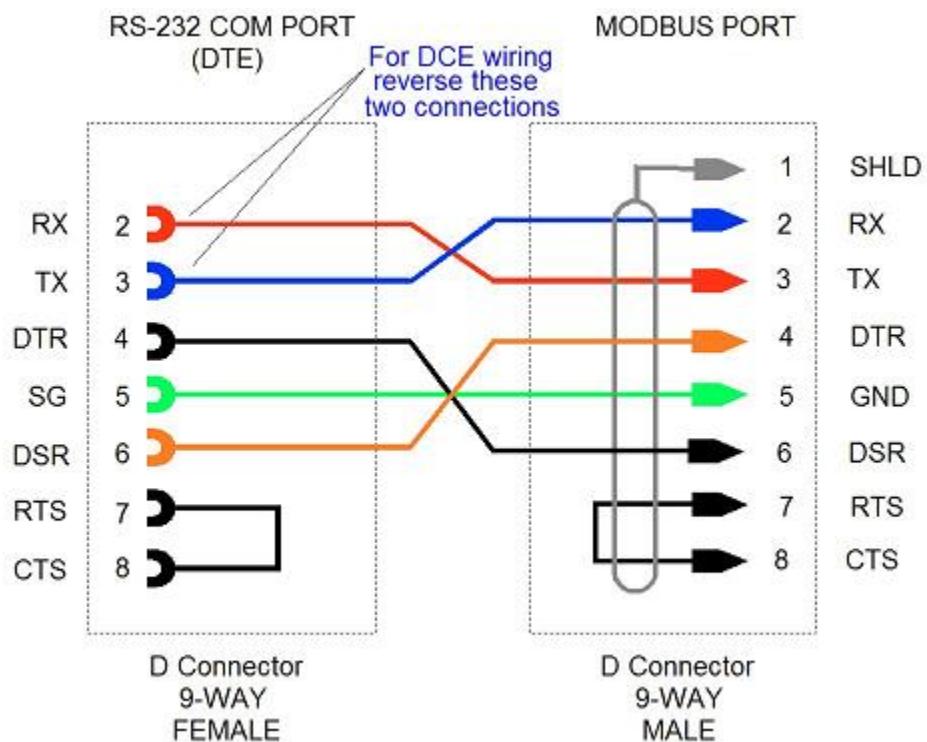

## MODBUS Generic Devices - Wiring Diagram 2

## MODBUS Generic Devices - Wiring Diagram 3

## MODBUS Generic Devices - Wiring Diagram 4

## MODBUS Generic Devices - Communication Settings

To establish communication with a device, configure the Boards, Port and I/O Device in Plant SCADA Studio's **Topology** activity. If you use the Express Communications Wizard to connect to a device, these settings will be automatically configured for you. However, if you need to manually configure these, use the settings outlined below.

### Board Settings

Typically, you would use a serial board or COM port for this communication. Refer to the instructions for setting up and using COM ports or serial boards. Or complete the Board settings with the following specific information.

Field	Value
Board Type	If using a serial board or COM port, enter COMx.
Address	If using a serial board or COM port, enter 0.
I/O Port	Leave this field blank.
Interrupt	Leave this field blank.
Special Options	Leave this field blank.

## Port Settings

Complete the Port settings with the following specific information.

Field	Value
Port Number	This value matches the COM port number. This number is defined in the Ports section of the Control Panel.
Baud Rate	This value matches the setting of the unit - 19200.
Data Bits	Enter 8.
Stop Bits	Enter 1.
Parity	This value matches the setting of the unit - EVEN_P.
Special Options	You may want to use the special options for the COMx Driver if you are using a modem (or similar) and want the driver to perform differently. For more information, see the topic <i>COMx Driver Special Options Reference</i> in the <i>Communicating with I/O Devices</i> chapter of the main help.

## I/O Device Settings

Complete the I/O Device settings with the following specific information.

Field	Value
I/O Device Address	The PLC station number configured on the PLC. Try 1 to 10. 1 specifies station number 1. 9 specifies station number 9 .
I/O Device Protocol	Enter MODBUS if you want to use the Modbus RTU (binary) protocol. Enter MODBUSA if you want to use the Modbus ASCII protocol. (See the topic <a href="#">Protocol Variants</a> to determine if a non-standard protocol variant is required.)

## MODBUS Generic Devices - Data Types

---

**Note:** The address ranges specified in the following table will be appropriate for most generic Modbus devices. However, you should check the capabilities of a device to confirm if it will support the full extent of the ranges suggested.

---

Data Types	Address Format	Plant SCADA Data Type
<b>DIGITAL</b>		
Output Coils	000001 to 065536	DIGITAL ( <b>Note:</b> Leading zero is required.)
Input Status	100001 to 165536	DIGITAL (Read Only)
<b>INTEGER</b>		
Input Registers	300001 to 365536	INT / LONG / STRING / REAL (Read Only)
Output Registers	400001 to 465536	INT / LONG / STRING / REAL
<b>EXTENDED REGISTERS</b>		
(6xxxxx range)	Ef:r.b <i>where:</i> f = file no. (1 - 999) r = register no. (0 - 9999) b = bit no. (1 - 16)	DIGITAL / INT / LONG / STRING / REAL

**Examples**

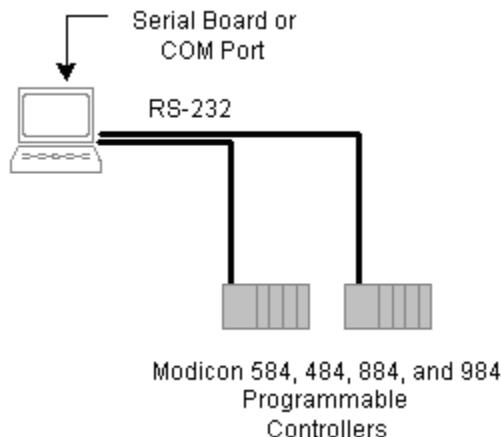

Data Type	DIGITAL
Address	00001
Comment	Output Coil 00001
Data Type	INT
Address	40001
Comment	Output Register 40001
Data Type	INT
Address	E1:00001
Comment	Modbus Address 600001

**Note:** LONG data types default to a simplified implementation, with a shortened range of 0 to 655,359,999. To increase the LONG data type to the full range, set the LongDataType parameter to either 1 or 3.

**Modicon 484 PLCs**

The serial method of communication to Modicon 484 PLCs, uses either the MODBUS or MODBUSA protocol. Communication is via the Modbus port on the PLC. Using this method, you can connect to single or multiple PLCs

as in the following diagram:

### Modicon 484 PLCs - Device Address

The I/O Device Address for a 484 PLC is PLC station number. Try 1 to 10.

- **1** specifies station number **1**.
- **9** specifies station number **9**.

### Modicon 484 PLCs - Hardware Setup

Set your PLC to the communication settings you require. The default hardware settings for the 484 are as follows:

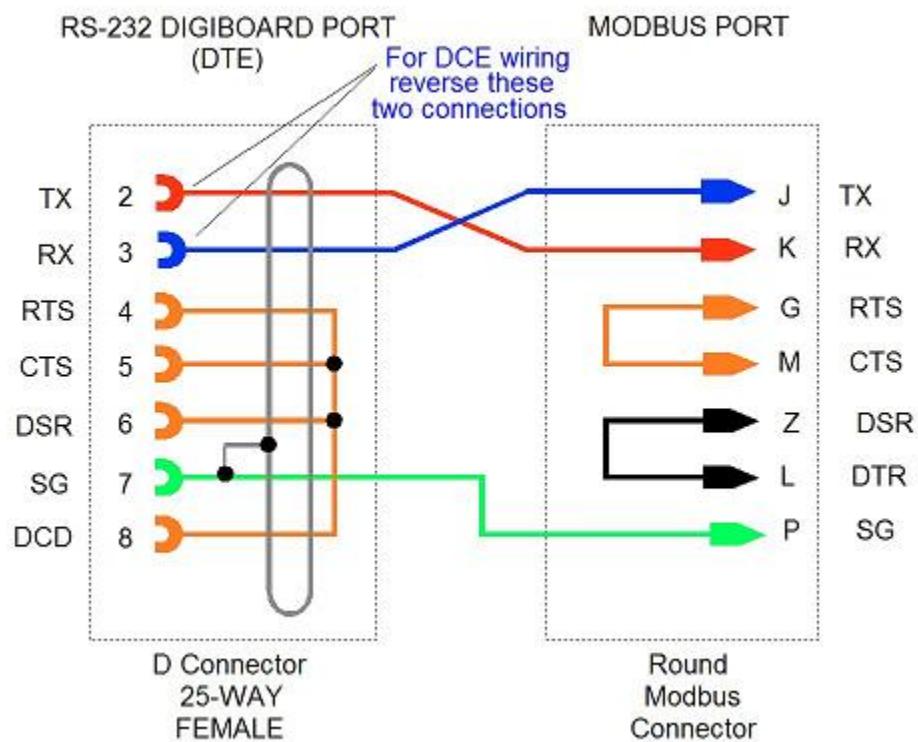

Setting	Value
Baud Rate	19200
Data Bits	8
Stop Bits	1
Parity	2 (Even)

**Note:** These settings are recommendations only. If you use the Communications Express Wizard, these default settings are configured in your project automatically, though your hardware may support other values. If you do set the baud rate, data bits, stop bits or parity to another value, you must manually set the new value(s) in your project.

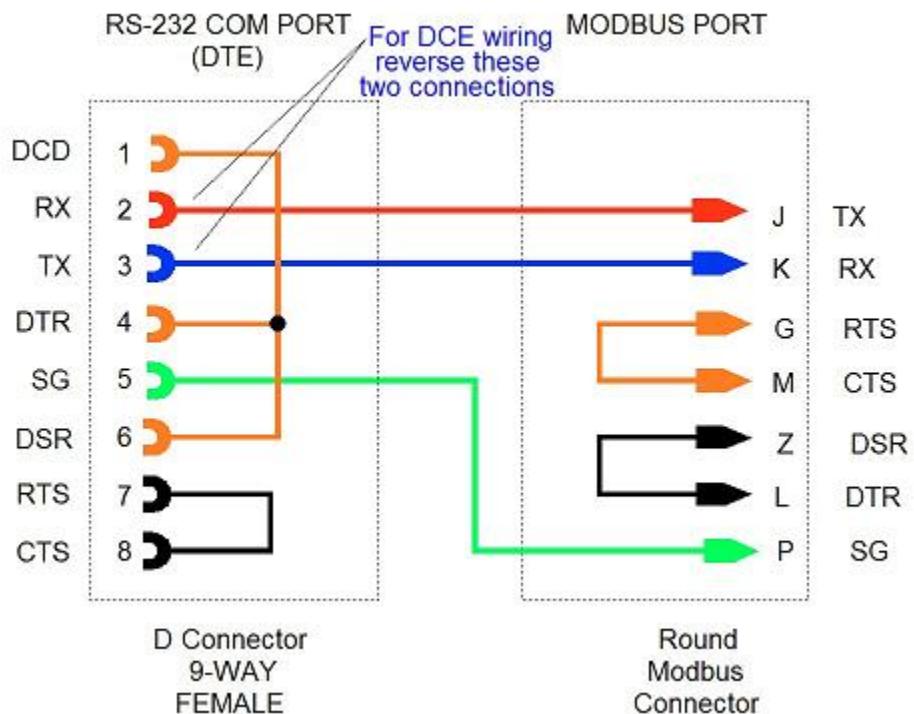

Set the following configuration options on the Modbus port on the Modicon PLC:

- Station number
- RTU mode (If this is not selected then the MODBUSA protocol is used)
- Delay time to 1

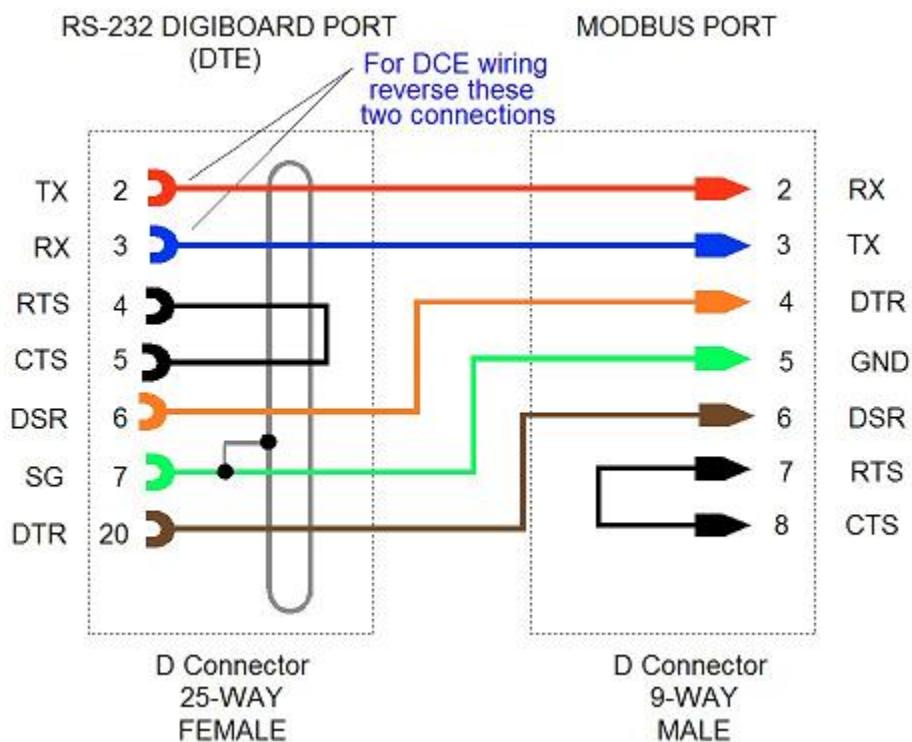

## Modicon 484 PLCs - Wiring Diagram 1

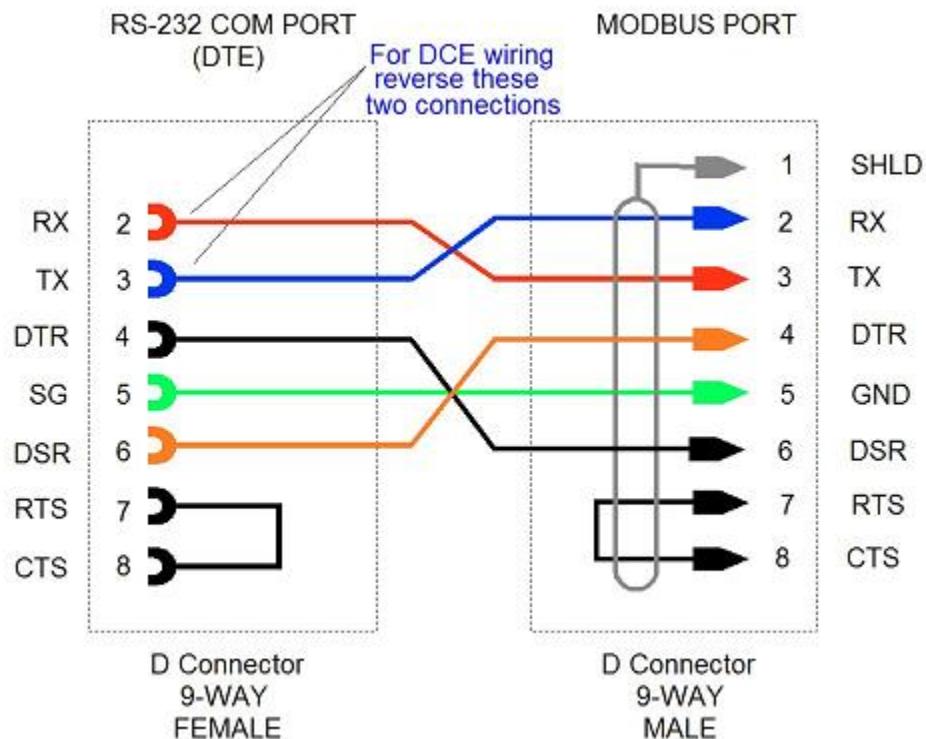

## Modicon 484 PLCs - Wiring Diagram 2

## Modicon 484 PLCs - Wiring Diagram 3

## Modicon 484 PLCs - Wiring Diagram 4

## Modicon 484 PLCs - Communication Settings

To establish communication with a device, configure the Boards, Port and I/O Device in Plant SCADA Studio's **Topology** activity. If you use the Express Communications Wizard to connect to a device, these settings will be automatically configured for you. However, if you need to manually configure these, use the settings outlined below.

### Board Settings

Typically, you would use a serial board or COM port for this communication. Refer to the instructions for setting up and using COM ports or serial boards. Or complete the Board settings with the following specific information.

Field	Value
Board Type	If using a serial board or COM port, enter COMx.
Address	If using a serial board or COM port, enter 0.
I/O Port	Leave this field blank.
Interrupt	Leave this field blank.
Special Options	Leave this field blank.

### Port Settings

Complete the Port settings with the following specific information.

Field	Value
Port Number	This value matches the COM port number. This number is defined in the Ports section of the Control Panel.
Baud Rate	This value matches the setting of the unit - 19200.
Data Bits	Enter 8.
Stop Bits	Enter 1.
Parity	This value matches the setting of the unit - EVEN_P.
Special Options	You may want to use the special options for the COMx Driver if you are using a modem (or similar) and want the driver to perform differently.  For more information, see the topic <i>COMx Driver Special Options Reference</i> in the <i>Communicating with I/O Devices</i> chapter of the main help.

## I/O Device Settings

Complete the I/O Device settings with the following specific information.

Field	Value
I/O Device Address	The PLC station number configured on the PLC. Try 1 to 10. 1 specifies station number 1. 9 specifies station number 9.
I/O Device Protocol	Enter MODBUS if you want to use the Modbus RTU (binary) protocol. Enter MODBUSA if you want to use the Modbus ASCII protocol. (See the topic <a href="#">Protocol Variants</a> to determine if a non-standard protocol variant is required.)

## Modicon 484 PLCs - Data Types

Data Types	Address Format	Plant SCADA Data Type
DIGITAL		
Output Coils	000001 to 065536	DIGITAL ( <b>Note:</b> Leading zero is required.)
Input Status	100001 to 165536	DIGITAL (Read Only)
INTEGER		
Input Registers	300001 to 365536	INT / LONG / STRING / REAL (Read Only)
Output Registers	400001 to 465536	INT / LONG / STRING / REAL

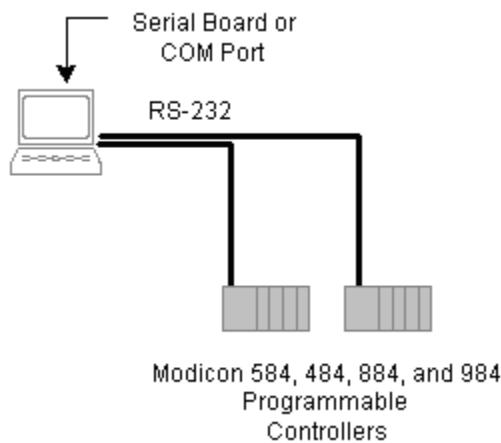

### Examples

Data Type	DIGITAL
Address	00001
Comment	Output Coil 00001
Data Type	INT
Address	40001
Comment	Output Register 40001

**Note:** In the MODBUS protocol, LONG data types default to a simplified implementation, with a shortened range of 0 to 655,359,999. To increase the LONG data type to the full range, set the [MODBUS]LongDataType parameter to either 1 or 3.

## Modicon 584 PLCs

The serial method of communication to Modicon 584 PLCs, uses either the MODBUS or MODBUSUSA protocol. Communication is via the Modbus port on the PLC. Using this method, you can connect to single PLCs or to multiple PLCs as in the following diagram:

## Modicon 584 PLCs - Device Address

The I/O Device Address for a 584 PLC is PLC station number. Try 1 to 10.

- **1** specifies station number **1**.
- **9** specifies station number **9**.

## Modicon 584 PLCs - Hardware Setup

Set your PLC to the communication settings you require. The default hardware settings for the 584 are as follows:

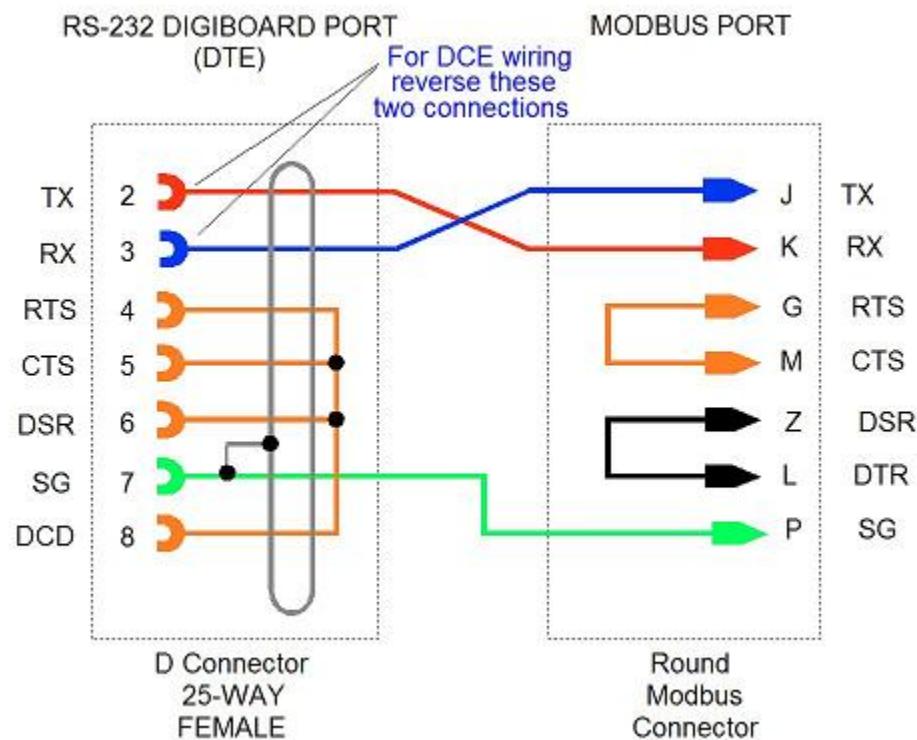

Setting	Value
Baud Rate	19200
Data Bits	8
Stop Bits	1
Parity	2 (Even)

**Note:** These settings are recommendations only. If you use the Communications Express Wizard, these default settings are configured in your project automatically, though your hardware may support other values. If you do set the baud rate, data bits, stop bits or parity to another value, you must manually set the new value(s) in your project.

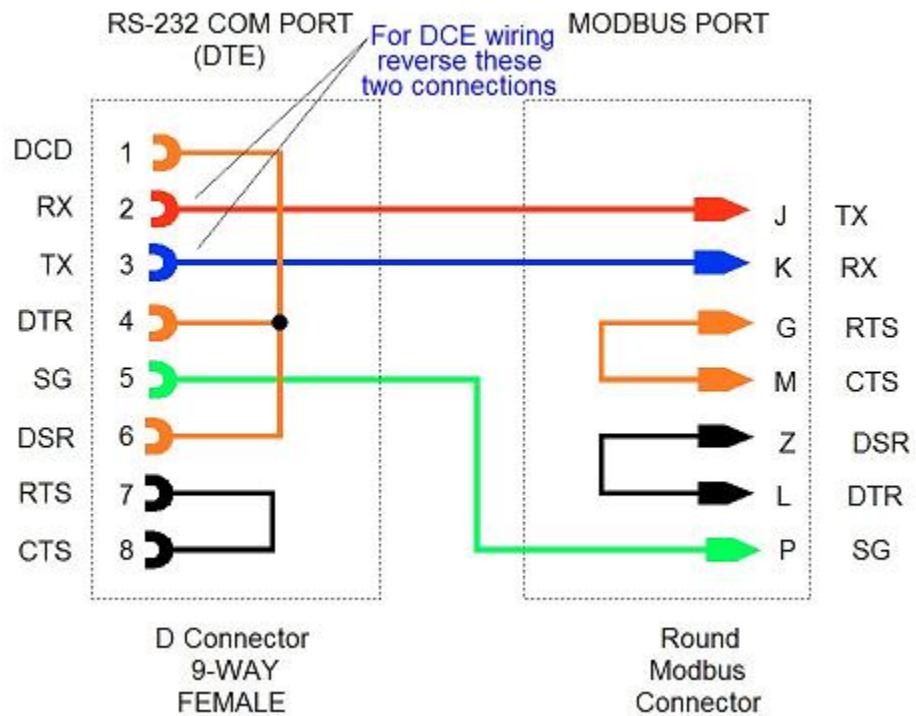

Set the following configuration options on the Modbus port on the Modicon PLC:

- Station number
- RTU mode (If this is not selected then the MODBUSA protocol is used)
- Delay time to 1

## Modicon 584 PLCs - Wiring Diagram 4

## Modicon 584 PLCs - Communication Settings

To establish communication with a device, configure the Boards, Port and I/O Device in Plant SCADA Studio's **Topology** activity. If you use the Express Communications Wizard to connect to a device, these settings will be automatically configured for you. However, if you need to manually configure these, use the settings outlined below.

### Board Settings

Typically, you would use a serial board or COM port for this communication. Refer to the instructions for setting up and using COM ports or serial boards. Or complete the Board settings with the following specific information.

Field	Value
Board Type	If using a serial board or COM port, enter COMx.
Address	If using a serial board or COM port, enter 0.
I/O Port	Leave this field blank.
Interrupt	Leave this field blank.
Special Options	Leave this field blank.

## Port Settings

Complete the Port settings with the following specific information.

Field	Value
Port Number	This value matches the COM port number. This number is defined in the Ports section of the Control Panel.
Baud Rate	This value matches the setting of the unit - 19200.
Data Bits	Enter 8.
Stop Bits	Enter 1.
Parity	This value matches the setting of the unit - EVEN_P.
Special Options	You may want to use the special options for the COMx Driver if you are using a modem (or similar) and want the driver to perform differently. For more information, see the topic <i>COMx Driver Special Options Reference</i> in the <i>Communicating with I/O Devices</i> chapter of the main help.

## I/O Device Settings

Complete the I/O Device settings with the following specific information.

Field	Value
I/O Device Address	The PLC station number configured on the PLC. Try 1 to 10. 1 specifies station number 1. 9 specifies station number 9.
I/O Device Protocol	Enter MODBUS if you want to use the Modbus RTU (binary) protocol. Enter MODBUSA if you want to use the Modbus ASCII protocol. (See the topic <a href="#">Protocol Variants</a> to determine if a non-standard protocol variant is required.)

## Modicon 584 PLCs - Data Types

Data Types	Address Format	Plant SCADA Data Type
<b>DIGITAL</b>		
Output Coils	000001 to 065536	DIGITAL ( <b>Note:</b> Leading zero is required.)
Input Status	100001 to 165536	DIGITAL (Read Only)
<b>INTEGER</b>		
Input Registers	300001 to 365536	INT / LONG / STRING / REAL (Read Only)
Output Registers	400001 to 465536	INT / LONG / STRING / REAL

**Examples**

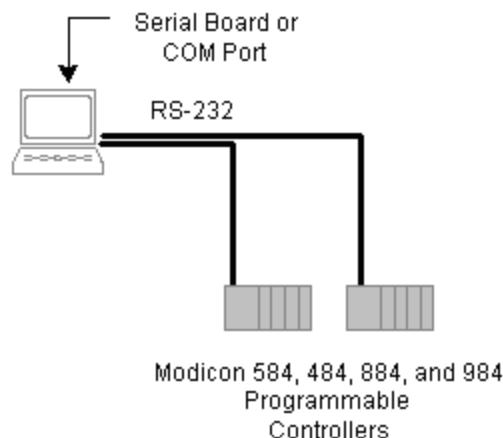

Data Type	DIGITAL
Address	00001
Comment	Output Coil 00001
Data Type	INT
Address	40001
Comment	Output Register 40001

**Note:**

- 1) Modicon 584 PLCs support remapping of both reads and writes.
- 2) In the MODBUS protocol, LONG data types default to a simplified implementation, with a shortened range of 0 to 655,359,999. To increase the LONG data type to the full range, set the [MODBUS]LongDataType parameter to either 1 or 3.

**Modicon 884 PLCs**

The serial method of communication to Modicon 884 PLCs, uses either the MODBUS or MODBUSA protocol. Communication is via the Modbus port on the PLC. Using this method you can connect to single or multiple PLCs as in the following diagram:

### Modicon 884 PLCs - Device Address

The I/O Device Address for a 884 PLC is PLC station number. Try 1 to 10.

- **1** specifies station number **1**.
- **9** specifies station number **9**.

### Modicon 884 PLCs - Hardware Setup

Set your PLC to the communication settings you require. The default hardware settings for the 884 are as follows:

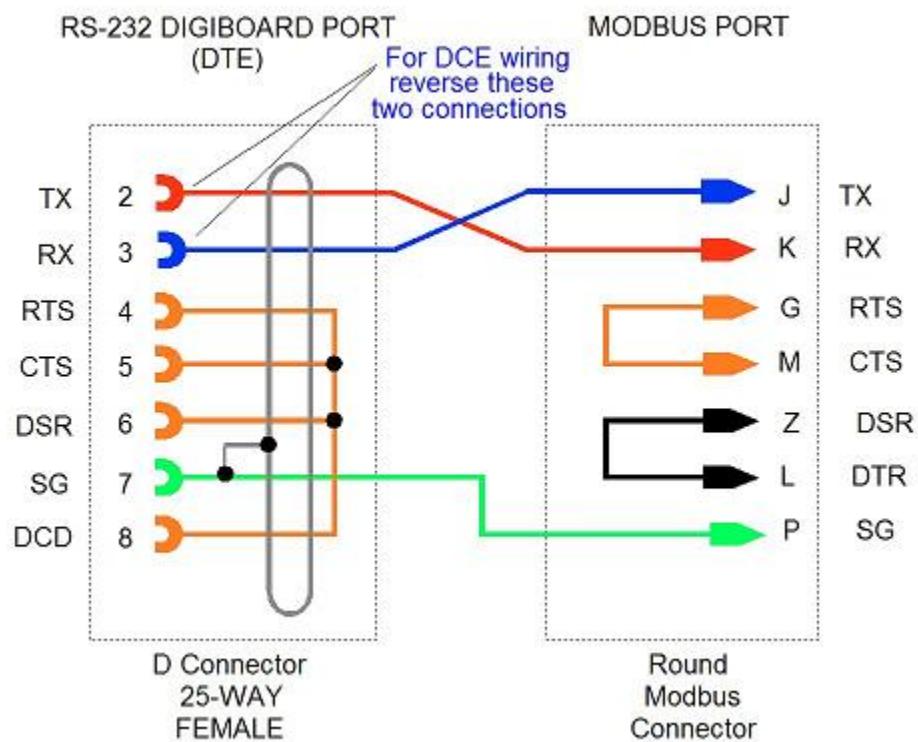

Setting	Value
Baud Rate	19200
Data Bits	8
Stop Bits	1
Parity	2 (Even)

**Note:** These settings are recommendations only. If you use the Communications Express Wizard, these default settings are configured in your project automatically, though your hardware may support other values. If you do set the baud rate, data bits, stop bits or parity to another value, you must manually set the new value(s) in your project.

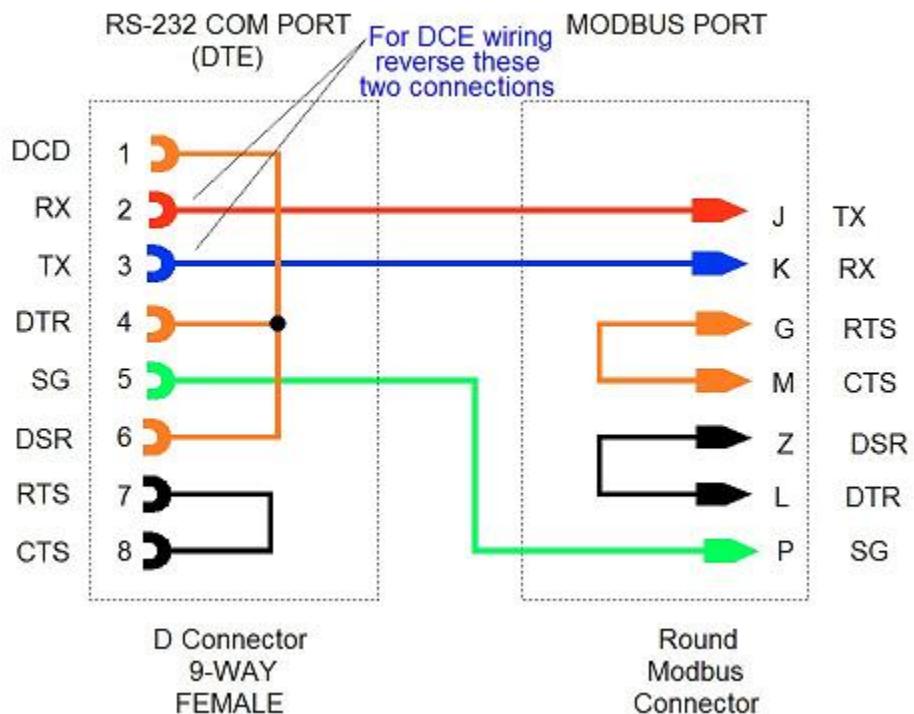

Set the following configuration options on the Modbus port on the Modicon PLC:

- Station number
- RTU mode (If this is not selected then the MODBUSA protocol is used)
- Delay time to 1

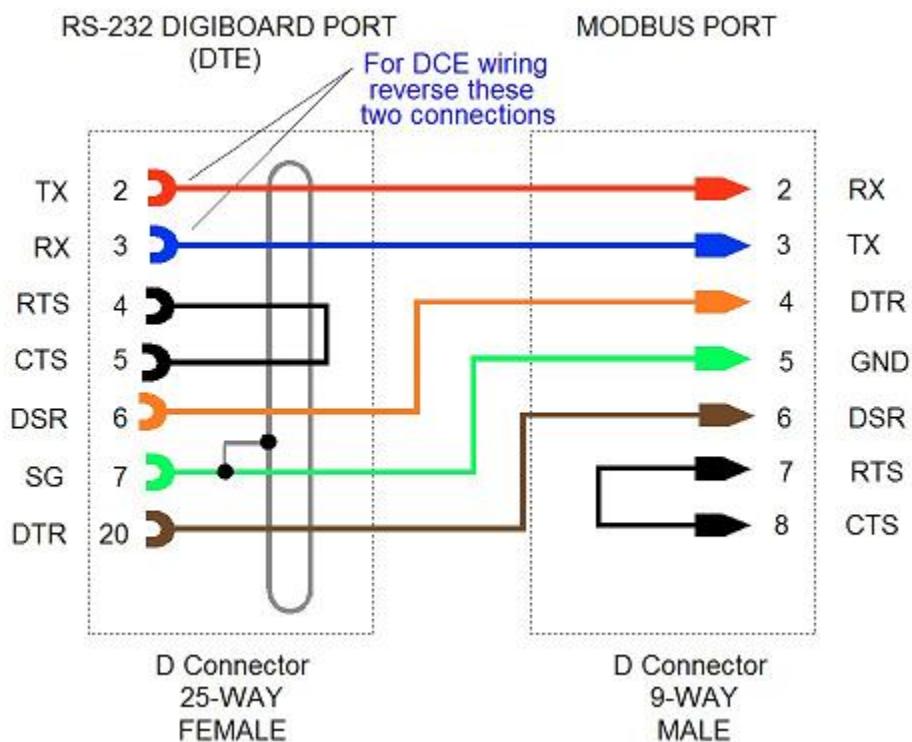

## Modicon 884 PLCs - Wiring Diagram 1

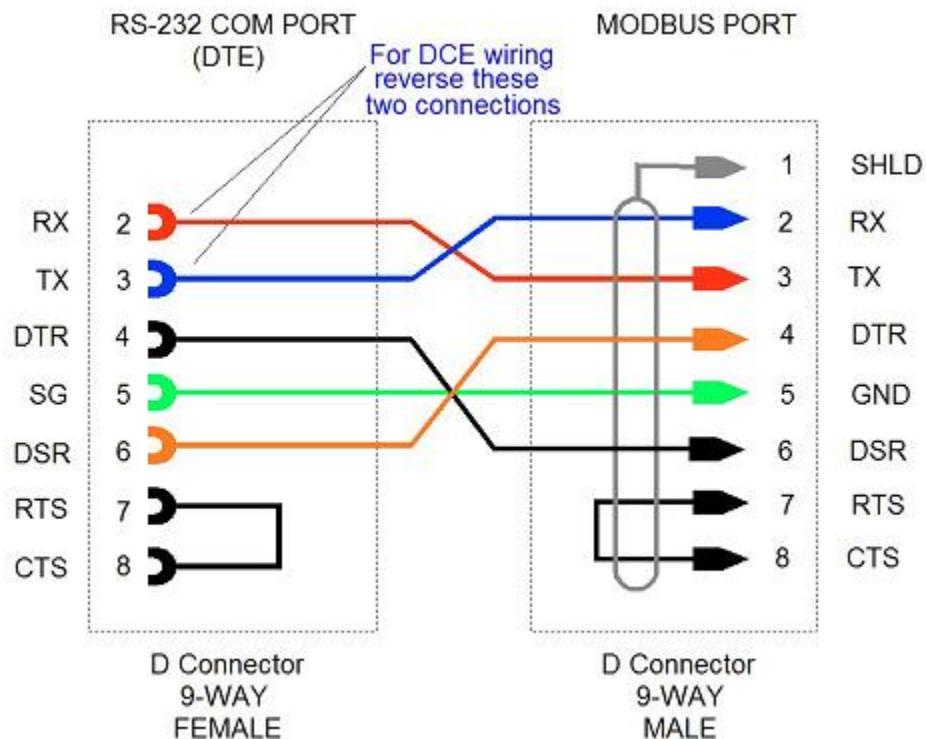

## Modicon 884 PLCs - Wiring Diagram 2

## Modicon 884 PLCs - Wiring Diagram 3

## Modicon 884 PLCs - Wiring Diagram 4

## Modicon 884 PLCs - Communication Settings

To establish communication with a device, configure the Boards, Port and I/O Device in Plant SCADA Studio's **Topology** activity. If you use the Express Communications Wizard to connect to a device, these settings will be automatically configured for you. However, if you need to manually configure these, use the settings outlined below.

### Board Settings

Typically, you would use a serial board or COM port for this communication. Refer to the instructions for setting up and using COM ports or serial boards. Or complete the Board settings as instructed with the following specific information.

Field	Value
Board Type	If using a serial board or COM port, enter COMx.
Address	If using a serial board or COM port, enter 0.
I/O Port	Leave this field blank.
Interrupt	Leave this field blank.
Special Options	Leave this field blank.

### Ports Settings

Complete the Ports settings with the following specific information.

Field	Value
Port Number	This value matches the COM port number. This number is defined in the Ports section of the Control Panel.
Baud Rate	This value matches the setting of the unit - 19200.
Data Bits	Enter 8.
Stop Bits	Enter 1.
Parity	This value matches the setting of the unit - EVEN_P.
Special Options	You may want to use the special options for the COMx Driver if you are using a modem (or similar) and want the driver to perform differently. For more information, see the topic <i>COMx Driver Special Options Reference</i> in the <i>Communicating with I/O Devices</i> chapter of the main help.

## I/O Device Settings

Complete the I/O Device settings with the following specific information.

Field	Value
I/O Device Address	The PLC station number configured on the PLC. Try 1 to 10. 1 specifies station number 1. 9 specifies station number 9.
I/O Device Protocol	Enter MODBUS if you want to use the Modbus RTU (binary) protocol. Enter MODBUSA if you want to use the Modbus ASCII protocol. (See the topic <a href="#">Protocol Variants</a> to determine if a non-standard protocol variant is required.)

## Modicon 884 PLCs - Data Types

Data Types	Address Format	Plant SCADA Data Type
<b>DIGITAL</b>		
Output Coils	000001 to 065536	DIGITAL ( <b>Note:</b> Leading zero is required.)
Input Status	100001 to 165536	DIGITAL (Read Only)
<b>INTEGER</b>		
Input Registers	300001 to 365536	INT / LONG / STRING / REAL (Read Only)
Output Registers	400001 to 465536	INT / LONG / STRING / REAL

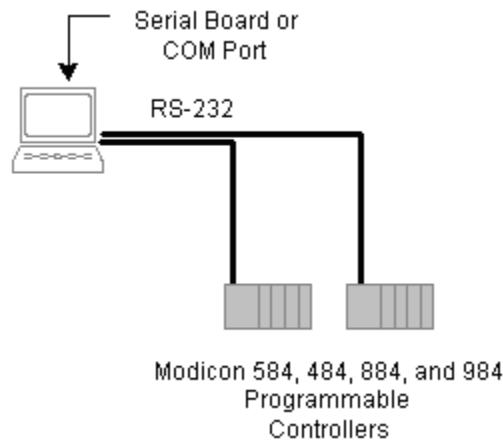

### Examples

Data Type	DIGITAL
Address	00001
Comment	Output Coil 00001
Data Type	INT
Address	40001
Comment	Output Register 40001

**Note:** In the MODBUS protocol, LONG data types default to a simplified implementation, with a shortened range of 0 to 655,359,999. To increase the LONG data type to the full range, set the [MODBUS]LongDataType parameter to either 1 or 3.

## Modicon 984 PLCs

The serial method of communication to Modicon 984 PLCs, uses either the MODBUS or MODBUSUSA protocol. Communication is via the Modbus port on the PLC. Using this method you can connect to single PLCs or to multiple PLCs as in the following diagram:

## Modicon 984 PLCs - Device Address

The I/O Device Address for a 984 PLC is PLC station number. Try 1 to 10.

- **1** specifies station number **1**.
- **9** specifies station number **9**.

## Modicon 984 PLCs - Hardware Setup

Set your PLC to the communication settings you require. The default hardware settings for the 984 are as follows:

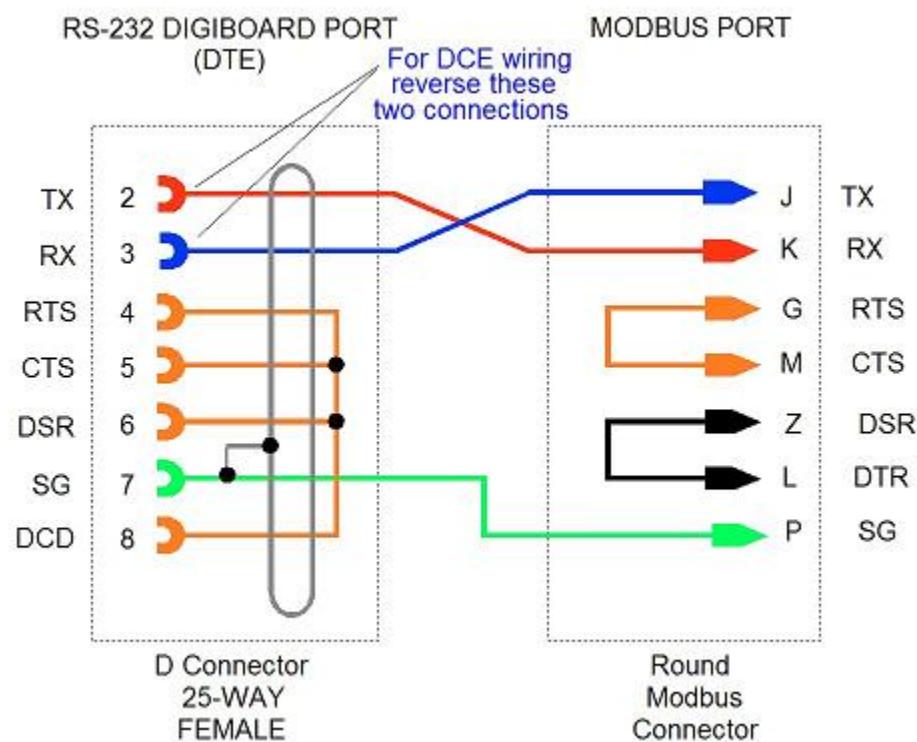

Setting	Value
Baud Rate	19200
Data Bits	8
Stop Bits	1
Parity	2 (Even)

**Note:** These settings are recommendations only. If you use the Communications Express Wizard, these default settings are configured in your project automatically, though your hardware may support other values. If you do set the baud rate, data bits, stop bits or parity to another value, you must manually set the new value(s) in your project.

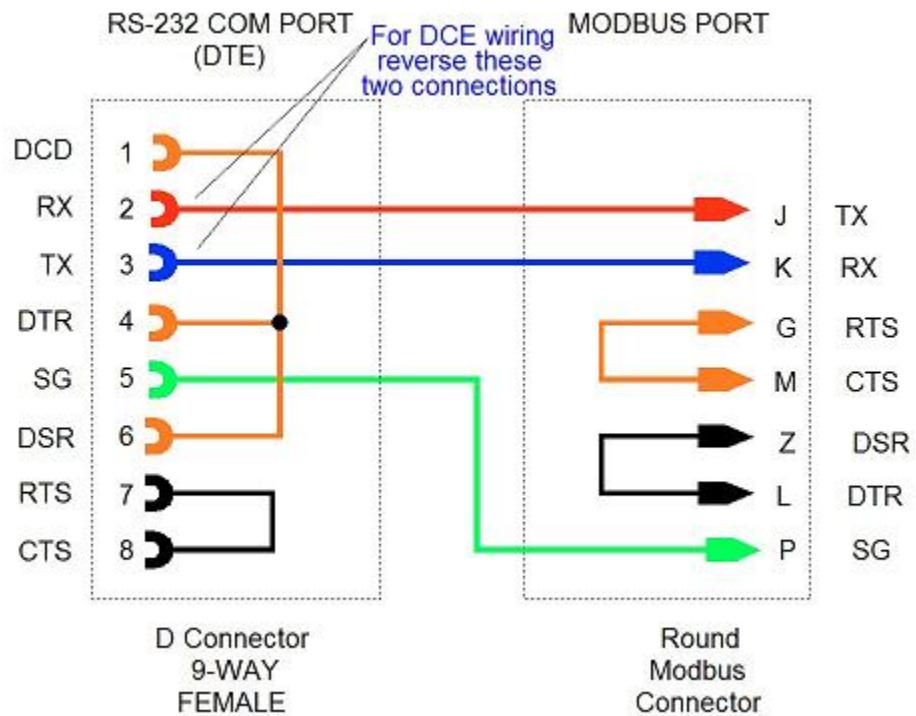

Set the following configuration options on the Modbus port on the Modicon PLC:

- Station number
- RTU mode (If this is not selected then the MODBUSA protocol is used)
- Delay time to 1

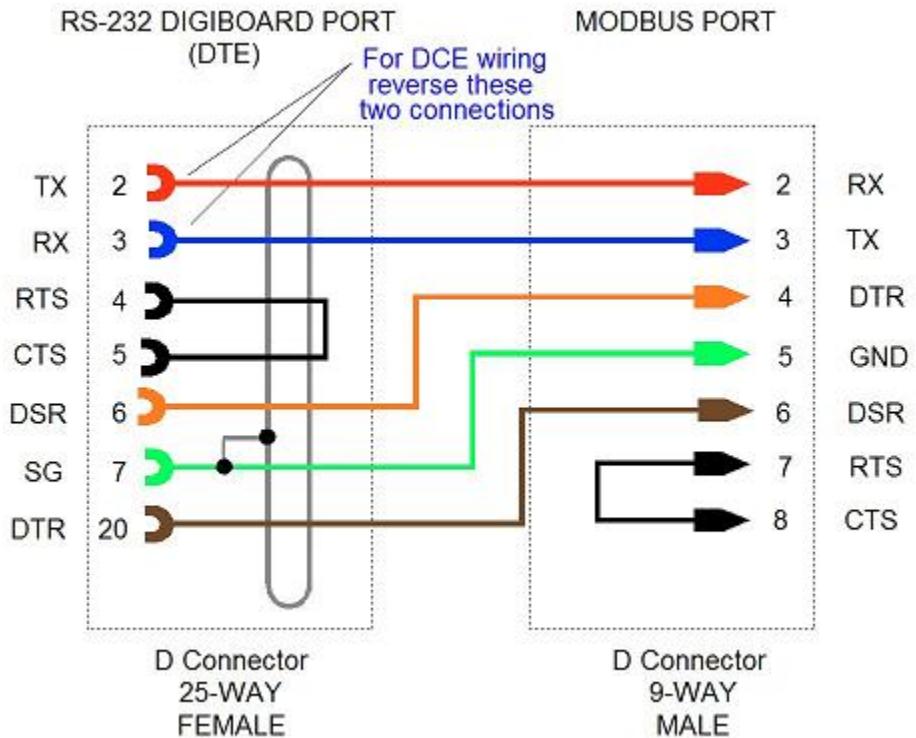

### Modicon 984 PLCs - Wiring Diagram 1

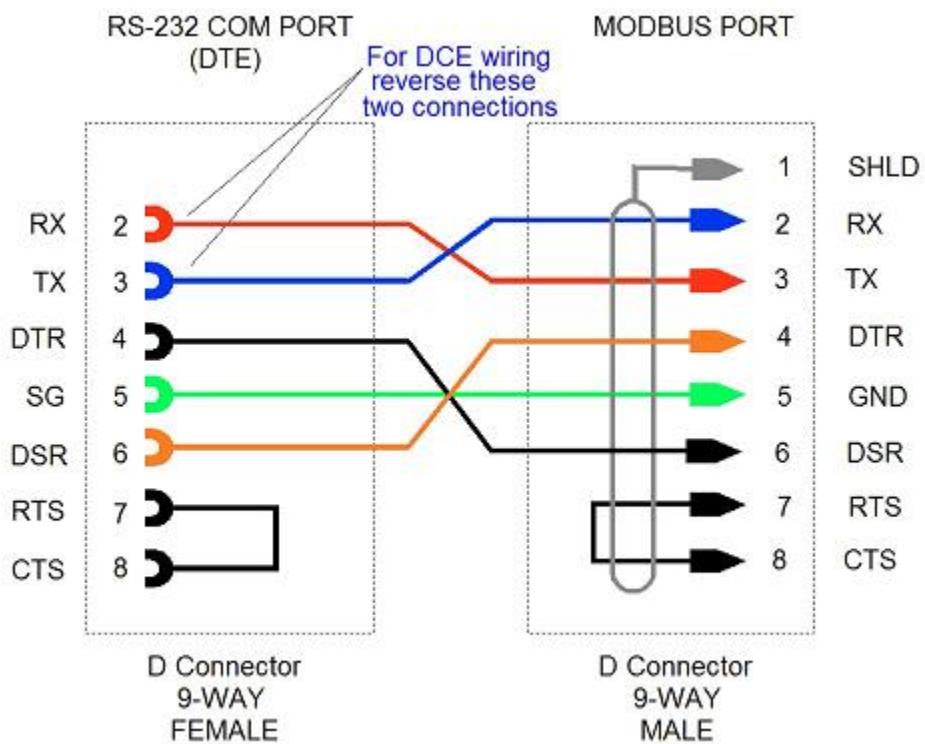

## Modicon 984 PLCs - Wiring Diagram 2

## Modicon 984 PLCs - Wiring Diagram 3

## Modicon 984 PLCs - Wiring Diagram 4

## Modicon 984 PLCs = Communication Settings

To establish communication with a device, configure the Boards, Port and I/O Device in Plant SCADA Studio's **Topology** activity. If you use the Express Communications Wizard to connect to a device, these settings will be automatically configured for you. However, if you need to manually configure these, use the settings outlined below.

**Board Settings**

Typically, you would use a serial board or COM port for this communication. Refer to the instructions for setting up and using COM ports or serial boards. Or complete the Board settings as instructed with the following specific information.

Field	Value
Board Type	If using a serial board or COM port, enter COMx.
Address	If using a serial board or COM port, enter 0.
I/O Port	Leave this field blank.
Interrupt	Leave this field blank.
Special Options	Leave this field blank.

## Port Settings

Complete the Port settings with the following specific information.

Field	Value
Port Number	This value matches the COM port number. This number is defined in the Ports section of the Control Panel.
Baud Rate	This value matches the setting of the unit - 19200.
Data Bits	Enter 8.
Stop Bits	Enter 1.
Parity	This value matches the setting of the unit - EVEN_P.
Special Options	You may want to use the special options for the COMx Driver if you are using a modem (or similar) and want the driver to perform differently. For more information, see the topic <i>COMx Driver Special Options Reference</i> in the <i>Communicating with I/O Devices</i> chapter of the main help.

## I/O Device Settings

Complete the I/O Device settings with the following specific information.

Field	Value
I/O Device Address	The PLC station number configured on the PLC. Try 1 to 10. 1 specifies station number 1. 9 specifies station number 9.
I/O Device Protocol	Enter MODBUS if you want to use the Modbus RTU (binary) protocol. Enter MODBUSA if you want to use the Modbus ASCII protocol. (See the topic <a href="#">Protocol Variants</a> to determine if a non-standard protocol variant is required.)

## Modicon 984 PLCs - Data Types

Data Types	Address Format	Plant SCADA Data Type
<b>DIGITAL</b>		
Output Coils	000001 - 065536	DIGITAL ( <b>Note:</b> Leading zero is required.)
Input Status	100001- 165536	DIGITAL (Read Only)
<b>INTEGER</b>		
Input Registers	300001- 365536	INT / LONG / STRING / REAL (Read Only)
Output Registers	400001- 465536	INT / LONG / STRING / REAL

**Examples**

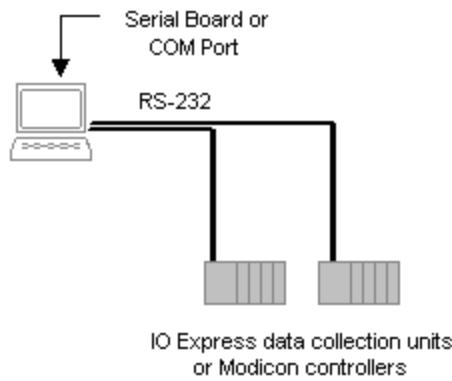

Data Type	DIGITAL
Address	00001
Comment	Output Coil 00001
Data Type	INT
Address	40001
Comment	Output Register 40001

**Note:**

- 1) Modicon 984 PLCs support remapping of both reads and writes.
- 2) In the MODBUS protocol, LONG data types default to a simplified implementation, with a shortened range of 0 to 655,359,999. To increase the LONG data type to the full range, set the [MODBUS]LongDataType parameter to either 1 or 3.

**Moore Products IOExpress**

The serial method of communication to IOExpress data collection units, manufactured by Moore Products, uses the MODBUS protocol. Using this method, you can connect to single units or to multiple units as in the following diagram:

### Moore Products IOExpress - Device Address

The I/O Device Address for a IOExpress unit station address configured on the IOExpress unit. Try 1-10, for example:

- **1** specifies station address **1**.
- **9** specifies station address **9**.

### Moore Products IOExpress - Hardware Setup

Set your unit to the communication settings you require. The default hardware settings for the IOExpress are as follows:

Setting	Value
Baud Rate	19200
Data Bits	8
Stop Bits	1
Parity	2 (Even)

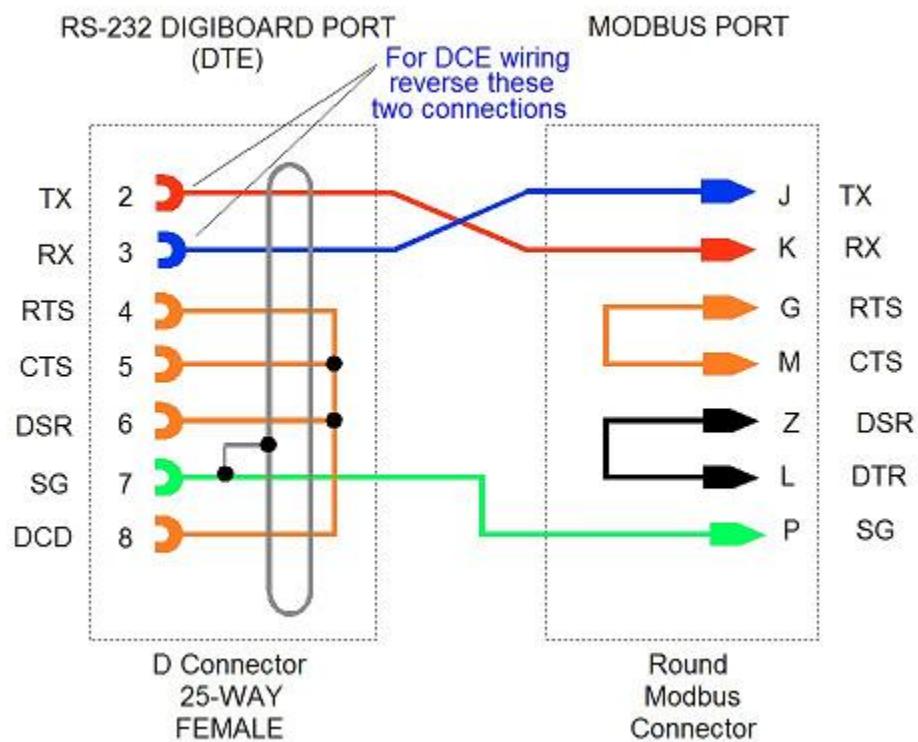

**Note:** These settings are recommendations only. If you use the Communications Express Wizard, these default settings are configured in your project automatically, though your hardware may support other values. If you do set the baud rate, data bits, stop bits or parity to another value, you must manually set the new value(s) in your project.

Set the following configuration options on the unit:

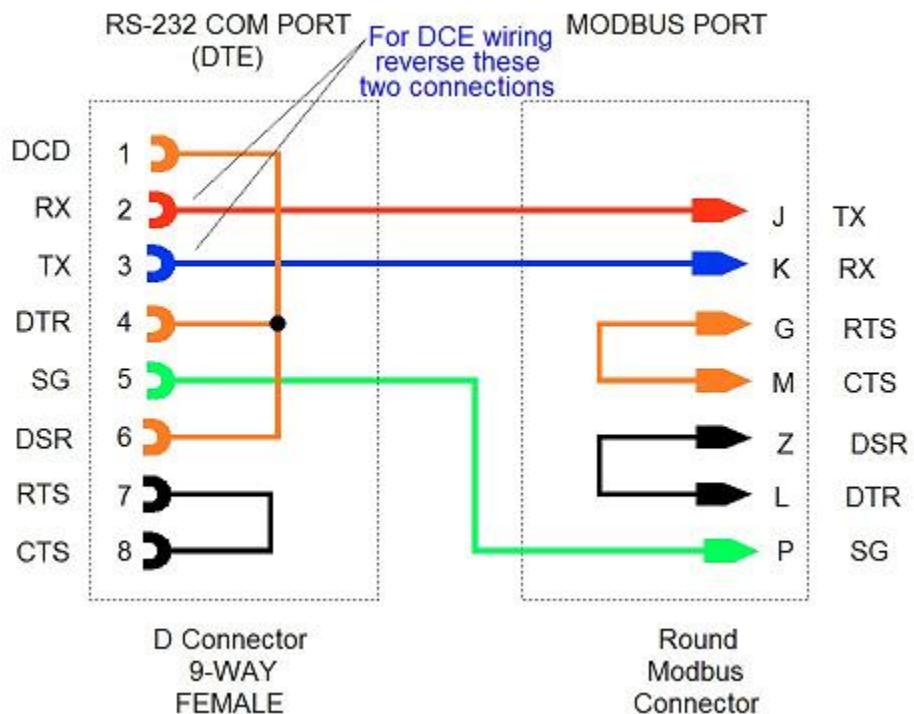

- Station number
- RTU mode (If this is not selected then the MODBUSA protocol must be used)
- Delay time to 1

The IOExpress unit emulates the MODBUS protocol, but has some slight differences. See [Working with Non-standard Devices](#).

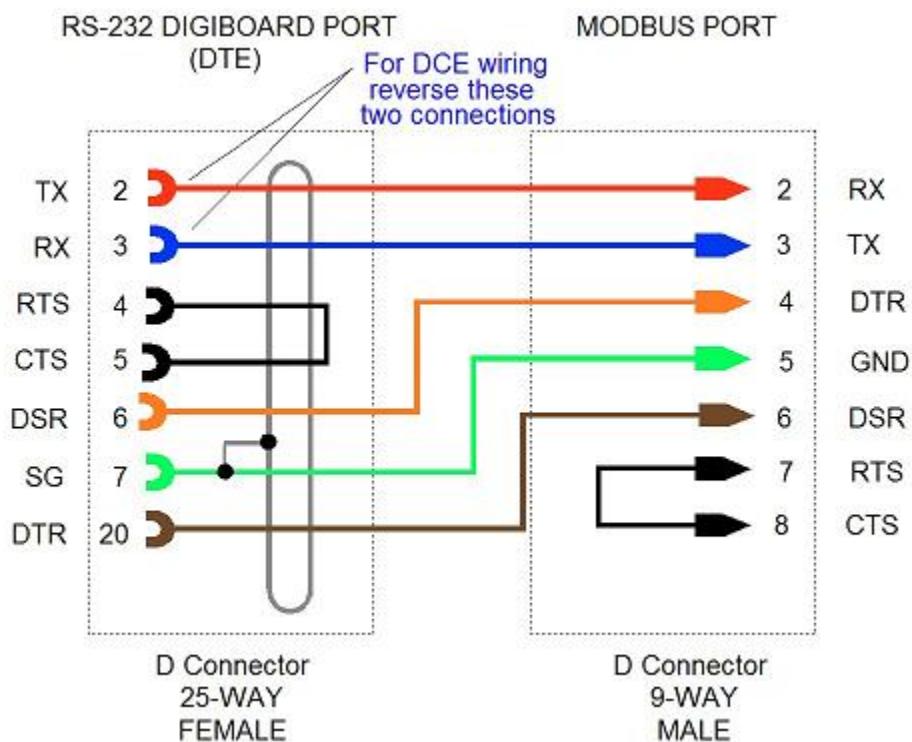

## Moore Products IOExpress - Wiring Diagram 1

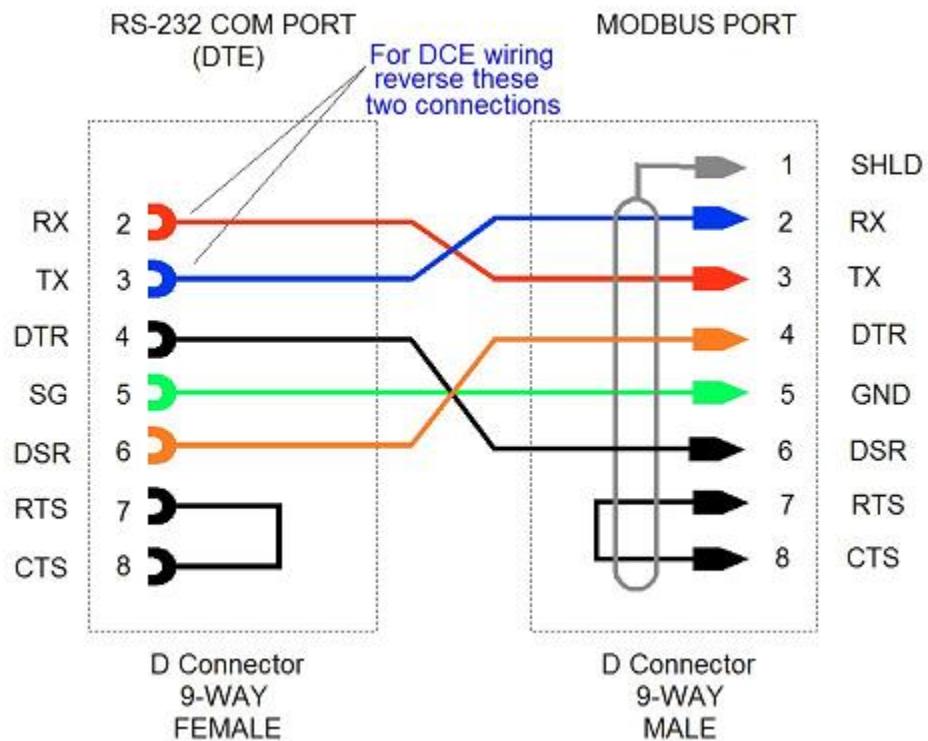

## Moore Products IOExpress - Wiring Diagram 2

## Moore Products IOExpress - Wiring Diagram 3

## Moore Products IOExpress - Communication Settings

To establish communication with a device, configure the Boards, Port and I/O Device in Plant SCADA Studio's **Topology** activity. If you use the Express Communications Wizard to connect to a device, these settings will be automatically configured for you. However, if you need to manually configure these, use the settings outlined below.

### Board Settings

Typically, you would use a serial board or COM port for this communication. Refer to the instructions for setting up and using COM ports or serial boards, or complete the Board settings as instructed with the following specific information.

Field	Value
Board Type	If using a serial board or COM port, enter COMx.
Address	If using a serial board or COM port, enter 0.
I/O Port	Leave this field blank.
Interrupt	Leave this field blank.
Special Options	Leave this field blank.

### Port Settings

Complete the Port settings with the following specific information.

Field	Value
Port Number	This value matches the COM port number. This number is defined in the Ports section of the Control Panel.
Baud Rate	This value matches the setting of the unit - 19200.
Data Bits	Enter 8.
Stop Bits	Enter 1.
Parity	This value matches the setting of the unit - EVEN_P.
Special Options	You may want to use the special options for the COMx Driver if you are using a modem (or similar) and want the driver to perform differently. For more information, see the topic <i>COMx Driver Special Options Reference</i> in the <i>Communicating with I/O Devices</i> chapter of the main help.

## I/O Device Settings

Complete the I/O Device settings with the following specific information.

Field	Value
I/O Device Address	The PLC station number configured on the PLC. Try 1 to 10. 1 specifies station number 1. 9 specifies station number 9.
I/O Device Protocol	Enter MODBUS. (See the topic <a href="#">Protocol Variants</a> to determine if a non-standard protocol variant is required.)

### Moore Products IOExpress - Data Types

Data Types	Address Format	Plant SCADA Data Type
<b>DIGITAL</b>		
Output Coils	000001 to 065536	DIGITAL ( <b>Note:</b> Leading zero is required.)
Input Status	100001 to 165536	DIGITAL (Read Only)
<b>INTEGER</b>		
Input Registers	300001 to 365536	INT / LONG / STRING / REAL (Read Only)
Output Registers	400001 to 465536	INT / LONG / STRING / REAL

#### Examples

Data Type	DIGITAL
Address	00001
Comment	Output Coil 00001
Data Type	INT
Address	40001
Comment	Output Register 40001

## Working With Non-standard Devices

Some non-standard PLCs support the Modbus protocol. However, some of these I/O devices do not support the protocol correctly. When Plant SCADA tries to communicate with these I/O devices, you might get errors on startup or during communication.

To handle these non-standard I/O devices, the Modbus protocol has some special options to change its operation:

1. On startup, Plant SCADA tries to read some digital inputs to verify that the PLC does exist. If Plant SCADA cannot read these bits, it assumes the PLC is bad, and remains off line. Some non-standard I/O devices do not support digital bits, so this command results in an error. With the [\[MODBUS\]InitType](#) parameter, you can change the type of variable the Modbus protocol tries to read on startup, to allow communication to start.
2. The standard MODBUS driver allows reading of 2000 bits in one request. Some non-standard I/O devices do not support such large reads. You can change the maximum read size with the [\[MODBUS\]MaxBits](#) parameter. (The default is 2000.)

Change the MAX\_LENGTH field for the Modbus protocol (in the \Plant SCADA\BIN\PROTDIR.DBF file) to the same value. Re-compile your project after changing this option. Be aware that if you reinstall Plant SCADA, the PROTDIR.DBF file is overwritten and you will need to repeat the change.

3. Some I/O devices that operate over radio modems also require the padding of protocol messages. The padding characters wake the radio modem to allow the rest of the message to be transmitted. Set the [\[MODBUS\]Pad](#) parameter to the number of characters to pad, and the [\[MODBUS\]PadChar](#) parameter to the ASCII code of the character to pad. For example, to pad 20 0xFF characters to the start of the message, set:

```
[MODBUS]
Pad=20
PadChar=255
```

4. In the Modbus protocol, LONG data types default to a simplified implementation, with a shortened range of 0 to 655,359,999. To increase the LONG data type to the full range, set the [\[MODBUS\]LongDataType](#) parameter to either 1 or 3.

As a LONG is composed from two registers, the register order used by Plant SCADA must match the order used by the PLC. Refer to the help accompanying the [\[MODBUS\]LongDataType](#) parameter to determine the appropriate value.

---

**Note:** The MODBUS driver supports a number of variants of the MODBUS protocol to communicate with some non-standard PLCs. See the topic MODBUS protocol variants [MODBUS Protocol Variants](#) to determine which variant you should use when configuring a device.

---

## Protocol Variants

Many devices from different vendors support the Modbus protocol. Unfortunately, addressing structures used by these devices vary. The following information will help you understand which protocol you should select on the I/O devices dialog box to make the addresses you enter into the variables form match those entered into the programming software for your device.

You will need to know the following:

- What is the lowest register / coil number in the device?

Some devices (such as a TSX Quantum or Modicon 948) have register / coil 1 as the lowest register / coil

number. Other devices (such as the TSX Premium) have register / coil 0 as the lowest register / coil number

- When addressing an individual bit from a register, what is the lowest bit number?

Some devices refer to the bits within a register as bits 0-15, others refer to them as bits 1-16.

Based on the above information you can select a protocol using the following table:

Range of bits in a register	Lowest coil / register number	Protocol
1-16	1	MODBUS (default)
1-16	0	MODBUS1
0-15	1	MODBUS2
0-15	0	MODBUS3

If you are using a PLC that supports extended registers (6xxxxx addresses in a TSX Quantum for example) then the following table should be used:

Range of bits in a register	Lowest coil / register number	Protocol
1-16	1	MODBUS10
1-16	0	MODBUS11
0-15	1	MODBUS12
0-15	0	MODBUS13

Two special protocols exist for use with the TSX Quantum and TSX Premium PLC ranges. These protocol options will select the correct addressing modes, select certain INI values and other settings to provide compatibility with these devices without the need to set any other special parameters.

These protocols also allow you to access memory digitals and memory words using %M7 or %MW3 or %MW4.6 style addressing. Select a protocol as follows:

PLC Model	Protocol
TSX Quantum	MODBUS20
TSX Premium	MODBUS30

## Customizing a Project using Citect.ini Parameters

Citect.ini parameters are used to tune the performance of the Plant SCADA MODBUS driver and to perform runtime maintenance diagnostics.

You can customize the way Plant SCADA communicates with the Modbus system (and even individual PLCs) by creating or editing the [MODBUS] section of the citect.ini file for your project.

There are some common Plant SCADA driver settings as well as custom MODBUS driver settings.

When Plant SCADA starts at runtime, it reads configuration values from the citect.ini file that is stored locally. Therefore, any MODBUS configuration settings must be included in the citect.ini file located on the computer

acting as the I/O server to the Modbus system.

By default, Plant SCADA looks for the citect.ini file in the Plant SCADA project \bin directory. If it can't find the file there, it searches the default Windows directory.

## MODBUS Driver Parameters

These parameters default to a value which have shown to be suitable for the majority of circumstances.

### **WARNING**

#### **UNINTENDED EQUIPMENT OPERATION**

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

With certain parameters, the MODBUS driver can apply different initialization parameter values to specific I/O devices or groups of I/O devices. For details see [Device/Group-specific Parameters](#).

## [MODBUS]Block

A value (bytes) used by the I/O server to determine if two or more packets can be blocked into one data request before being sent to the I/O device. For example, if you set the value to 10 and the I/O server receives two simultaneous data requests (one for byte 3 and another for byte 8) the two requests are blocked into a single physical data request packet. This single request packet is then sent to the I/O device, saving on bandwidth and processing.

**Allowable Values:** 5 to 256

**Default Value:** 50

## [MODBUS.<Port\_Name>.<IODevice\_Name>]Broadcast

Sends a write request to a specified device on a Modbus network.

**Note:** This parameter can only be used as a device-specific parameter, for example, [MODBUS.<Port\_Name>.<IODevice\_Name>]Broadcast=1. It should not be used globally. For more details, see [Device/group-specific parameters](#).

To use this feature:

1. Define an I/O device with address 0 (zero) for the Channel of interest.
2. Define the value for the BroadcastDelay parameter in the Citect.ini file (default is 50ms). This parameter defines the amount of time the driver will delay after submitting a broadcast request before it will send another request to the PLCs.
3. Define tags (Coils and Registers) associated with this I/O device.
4. Implement a Plant SCADA application that requests writes to the tags (via Cicode, application display, and so on).

Requests for Variable Tag READs to the I/O device with the address zero (0) will return a Driver Error of Unknown

Command (driver error 15 decimal). Requests for Variable Tag WRITES to the I/O device with the address zero (0) will be issued to ALL controllers on the SAME Channel (port) as the I/O device with the assigned address of zero. The Modbus protocol does not provide a response to broadcast requests so inspect the appropriate coils or registers in each controller to observe completion of the request.

**Allowable Values:**

0 = Broadcast disabled

1 = write request will be issued

**Default Value:** 1

## [MODBUS]BroadcastDelay

Defines the amount of time the driver will delay after submitting a broadcast request before sending another request to the PLCs.

**Allowable Values:** 0 to 300 (milliseconds)**Default Value:** 50

---

**Note:** This parameter is only available at the MODBUS level, i.e. [MODBUS]

---

## [MODBUS]Delay

The period (in milliseconds) to wait between receiving a response and sending the next command.

**Allowable Values:** 0 to 32767 (milliseconds)**Default Value:** 0

## [MODBUS]DoCRC

Enables or disables the Modbus Cyclic Redundancy Check (CRC), a communications check. The MODBUS driver does a CRC on incoming data and provides a CRC remainder in outgoing data blocks. In some limited cases, such as the testing of "slave" drivers, it may be necessary to disable the CRC.

**Allowable Values:** 1 or 0, where:

1 = enable CRC

0 = disable CRC

**Default Value:** 1

The CRC should remain "enabled" under normal circumstances. If the CRC is disabled, no checks are performed on incoming data and the CRC field in the data transmitted by the driver remains 0. This will mean the driver cannot detect lack off communication between itself and the I/O device.

## [MODBUS]FileNumber

If the parameter InitType is set to 20 to implement extended register access, use this parameter to identify the extended memory file number.

**Allowable Values:** 1 to 65535**Default value:** 1

## [MODBUS]FailOnBadData

Used by the MODBUS driver to determine whether or not to force the display of good data within a block read which contains bad tags during tag read.

**Allowable Values:** 1 or 0, where:

1 = A block read which contains a bad tag would result in the whole block returning #BAD

0 = The MODBUS driver will not return "#BAD" for a block of data if at least one valid value is in the read block.

**Default Value:** 1

## [MODBUS]FloatMode

---

**Note:** This parameter is not applicable if you are using the [protocol variant](#) MODBUS20 or MODBUS30 to communicate with a device. Under these circumstances, a value of 0 (zero) will be hardcoded for this parameter.

---

This INI parameter sets the byte order for floating point values (the MODBUS driver supports floating point values). Some systems expect to use a different byte order for their floating point data.

**Allowable Values:** 0 to 3, where:

0 - Byte order = 1 0 3 2

1 - Byte order = 3 2 1 0

2 - Byte order = 0 1 2 3

3 - Byte order = 2 3 0 1

**Default Value:** 0

With this parameter, you can set different values for specific I/O devices or groups of I/O devices. See [Device/group-specific parameters](#).

## [MODBUS]ForceMultiCoilsOnly

Forces the use of only function code 15 (multiple coils) for coil writes.

**Allowable Values:**

0 - (function code 5 and 15)

1 - (function code 15 only)

**Default Value:** 0

## [MODBUS]InitType

The type of variable the MODBUS protocol tries to read on startup, to allow communication to start.

**Allowable Values:** 1 to 4, or 20 (for extended registers access).

InitType	Address	Variable
1	00001 - 00017	Output status
2	10001 - 10017	Input status
3	40001	Output registers

4	30001	Input registers
20		General reference

**Default Value:** 2

If setting this parameter to 20 for extended register access, you will need to adjust the FileNumber parameter to identify the extended memory file number.

With this parameter, you can set different values for specific I/O devices or groups of I/O devices. See [Device/group-specific parameters](#).

**[MODBUS]InitUnitAddress**

The MODBUS driver reads the citect.ini file to determine the correct unit address for initialization of a PLC. InitUnitAddress is the parameter used to set the unit address.

**Allowable Values:** 0 to 65535**Default Value:** 0

With this parameter, you can set different values for specific I/O devices or groups of I/O devices. See [Device/group-specific parameters](#).

**[MODBUS]LongDataType**

---

**Note:** This parameter is not applicable if you are using the [protocol variant](#) MODBUS20 or MODBUS30 to communicate with a device. Under these circumstances, a value of 3 will be hardcoded for this parameter.

---

In the Modbus protocol, LONG data types default to a simplified implementation, with a shortened range of 0 to 99,999,999 - mode 0. Mode 2 has the same range as mode 0, but with the register order swapped. Mode 1 supports the complete LONG range of -2,147,483,648 to +2,147,483,647. Mode 3 has the same range as mode 1, but with the register order swapped.

**Allowable Values:** 0 to 3, where:

- 0 = 10000 x low register + high register
- 1 = 65536 x low register + high register
- 2 = 10000 x high register + low register
- 3 = 65536 x high register + low register

**Default Value:** 3

With this parameter, you can set different values for specific I/O devices or groups of I/O devices. See [Device/group-specific parameters](#).

**[MODBUS]MaxBits**

---

**Note:** This parameter is not applicable if you are using the [protocol variant](#) MODBUS20 or MODBUS30 to communicate with a device. If MODBUS20 is being used, a value of 1904 will be hardcoded for this parameter. If MODBUS30 is being used, a value of 1024 will be hardcoded.

---

The maximum read size in one request. Decrease the value for non-standard I/O devices that do not support large reads.

**Allowable Values:** 8 to 32767

**Default Value:** 1904

### [MODBUS]MaxBitsExt

---

**Note:** This parameter is not applicable if you are using the [protocol variant](#) MODBUS20 or MODBUS30 to communicate with a device. If MODBUS20 is being used, a value of 1904 will be hardcoded for this parameter. If MODBUS30 is being used, a value of 1024 will be hardcoded.

This INI parameter sets the maximum bits blocked for the Quantum PLCs "Ex:y[.z]" address type.

**Allowable Values:** 8 to 32767

**Default Value:** 1904

### [MODBUS]MaxPending

The maximum number of pending commands that the driver holds ready for immediate execution.

**Allowable Values:** 1 to 32

**Default Value:** 2

### [MODBUS]Pad

The number of characters with which to pad protocol messages. The padding characters wake the radio modem to allow the rest of the message to be transmitted. A value of 20 is recommended for non-standard I/O devices that operate over radio modems.

**Allowable Values:** 0 to 65535

**Default Value:** 0

### [MODBUS]PadChar

The ASCII code of the padding character with which to pad protocol messages. The padding characters wake the radio modem to allow the rest of the message to be transmitted.

**Allowable Values:** 0 to 255

**Default Value:** 255

### [MODBUS]PollTime

The interrupt or polling service time (in milliseconds). Setting the polling time to 0 puts the driver in interrupt mode.

**Allowable Values:** 0 to 300 (milliseconds)

**Default Value:** 0

### [MODBUS]PresetMultiRegistersOnly

Forces the use of only function code 16 (multiple registers) for register writes.

**Allowable Values:** 0 or 1:

0 - (function code 6 and 16)  
1 - (function code 16 only)

**Default Value:** 0

## [MODBUS]RegisterBitReverse

---

**Note:** This parameter is not applicable if you are using the [protocol variant](#) MODBUS20 or MODBUS30 to communicate with a device. Under these circumstances, a value of 1 will be hardcoded for this parameter.

This INI parameter allows reverse interpretation of Most Significant Bit (MSB) and Least Significant Bit (LSB) in words. The Modbus specification defines bit 1 of a word as the MSB, and bit16 of the word as the LSB. Some devices use a different order, causing bit 1 of a word to be the LSB and bit 16 to be the MSB.

**Allowable Values:** 0 or 1, where:

1 - Bit 1= LSB, Bit 16 = MSB  
0 - Bit 1 = MSB, Bit 16 = LSB

**Default Value:** 1

With this parameter, you can set different values for specific I/O devices or groups of I/O devices. See [Device/group-specific parameters](#).

## [MODBUS]Retry

The number of times to retry a command after a timeout.

**Allowable Values:** 0 to 8

**Default Value:** 0

## [MODBUS]SendBCDSwap

Reverses the byte order for BCDs on writes (the MODBUS driver supports BCDs). Some systems expect to use a different byte order for their data; in the case of BCDs, this causes "1234" to be written to the device as "3412".

**Allowable Values:** 0 or 1, where:

1 = 1 2 3 4  
0 = 3 4 1 2

**Default Value:** 1

With this parameter, you can set different values for specific I/O devices or groups of I/O devices. See [Device/group-specific parameters](#).

## [MODBUS]Status

Sometimes you can read data from a device even though the processor module is not running. In view of this, it can be useful to detect this situation by monitoring a continuously changing register or a digital. If the register is unable to change in a given period or the digital becomes zero, the processor can be assumed to have stopped running.

If enabled, the MODBUS driver will check on startup and approximately every watchtime the status of a user specified variable in the PLC is changing. If a digital is specified, the value should be on, otherwise the unit is put offline. If an analog is specified, on startup two consecutive reads with an interval of 1000ms (specified by

[MODBUS]Timeout) should return different values before the unit can be put online. At every watchtime, if the digital is off or the analog data does not change from the last value read, the driver returns an error and the unit is put offline.

**Allowable Values:**

RawType

BitWidth

UnitType

UnitAddress

UnitAddress

where:

RawType	BitWidth	UnitType	UnitAddress	UnitCount
0 = Digital	1 = Digital	See variable specification .dbf files	The item number or bit number	1 = analog 16 = digital
1 = Int	16 = Int			
4 = Long	32 = Long			
8 = Byte	8 = Byte			

**Default Value:**

Zero length string

**Examples**

To specify Modbus address 40001 as the analog tag variable which must change to indicate the device is online, use:

```
[MODBUS]
status=1,16,3,0,1
```

To use Modbus address 00001 as the digital tag variable which must remain set to 1 to indicate the device is online, then use:

```
[MODBUS]
status=0,1,1,0,16
```

## [MODBUS]StringReverse

Reverse byte order for strings. The MODBUS driver supports strings. Some systems expect to use a different byte order for their data, which in the case of string variables, causes "ABCD" to appear as "BADC".

**Allowable Values:** 0 or 1

**Default Value:** 0 (do not reverse byte order)

With this parameter, you can set different values for specific I/O devices or groups of I/O devices. See [Device/group-specific parameters](#).

## [MODBUS]Timeout

Specifies how many milliseconds to wait for a response before displaying an error message.

**Allowable Values:** 0 to 32000 (milliseconds)

**Default Value:** 3000

**Note:** This parameter is only available at the MODBUS Portlevel, i.e. [MODBUS.Port] but values are overridden by the default values in theyslog and Kernel page.

## [MODBUS]WatchTime

The frequency (in seconds) that the driver uses to check the communications link to the I/O device.

**Allowable Values:** 0 to 128 (seconds)

**Default Value:** 30

## Device/Group-specific Parameters

The MODBUS driver can apply different initialization parameter values to specific I/O devices or groups of I/O devices. This means the user can specify:

Global parameters that apply to all devices.

Channel- (port-) level parameters that apply to all devices on the specified port.

Group-level parameters that apply to all devices in a specified group.

Device-level parameters that apply only to the specified device.

### **WARNING**

#### **UNINTENDED EQUIPMENT OPERATION**

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

This feature can be implemented in the citect.ini for the following [MODBUS Parameters](#):

- Broadcast
- BroadcastDelay
- FloatMode
- ForceMultiCoilsOnly
- InitType
- InitUnitAddress
- LongDataType
- PresetMultiRegistersOnly
- RegisterBitReverse
- SendBCDSwap

- StringReverse

To set parameters for a particular port, group, or device, you must create a new section in the citect.ini file. Label it with the driver name followed by a period (.) character and the name of the particular port, group, or device you want to specify the parameter setting for.

For example:

- [MODBUS.<Port\_Name>]: applies the parameter settings to the specified port.
- [MODBUS.<Group\_Name>]: applies the parameter settings to the specified group.
- [MODBUS.<Port\_Name>,<IODevice\_Name>]: applies to the specified device.

Any parameters you then define in the following section of the citect.ini file relate only to the specified device or device group.

#### Example

The following citect ini file format is an example of how the InitType parameter could be specified differently for different I/O devices communicating using the Modbus protocol.

Assume that two ports are used: PORT1 and PORT2. PORT1 has three I/O devices attached:

- DEV1A DEV1B EV1C

POR2 also has three devices:

- DEV2A DEV2B DEV2C

Assume that the user has specified that DEV1C and DEV2C belong to GROUPZ. The citect.ini file contains the following entries:

```
[MODBUS]
InitType=1
[MODBUS.PORT1]
InitType=2
[MODBUS.PORT2]
InitType=2
[MODBUS.GROUPZ]
InitType=3
[MODBUS.PORT1.DEV1A]
InitType=1
[MODBUS.PORT2.DEV2B]
InitType=4
```

The resultant InitType for the I/O devices will be as follows:

DEV1A:	1	as a result of [MODBUS.PORT1.DEV1A]
DEV1B:	2	as a result of [MODBUS.PORT1]
DEV1C:	3	as a result of [MODBUS.GROUPZ]
DEV2A:	2	as a result of [MODBUS.PORT2]

DEV2B:	4	as a result of [MODBUS.PORT2.DEV2B]
DEV2C:	3	as a result of [MODBUS.GROUPZ]

As the above example shows, there is a hierarchy that determines the outcome of such settings. In simple terms, specific parameter settings overwrite general level settings. Therefore, parameters written in the scope of I/O devices will overwrite those set for groups; parameters set for groups will overwrite global settings, and so on.

## MODBUS Driver Errors

MODBUS has two kinds of protocol driver errors:

- **Generic errors**, which are hardware errors 0-31 and common to all protocols. Some generic errors are common to all protocols. Sometimes only the generic error is available, though often both the generic error and a specific error are given.
- **Specific errors**, which can be unique and therefore cannot be recognized by the hardware alarm system. The drivers convert their specific errors into generic errors that can be identified by the I/O server. For example, when a driver experiences an error, there is often both a protocol-specific error and a corresponding generic error.

When a hardware error occurs, Plant SCADA generates an alarm and displays the alarm on the Hardware Alarm page (in the alarm description of the hardware alarm). To see the error number, make sure you have Alarm Category 255 defined with a display format that includes {ErrDesc,15} {ErrPage,10}.

## Specific Errors

The following errors, listed in (hexadecimal) sequence, are specific to this driver. Plant SCADA displays the error number and description for common protocol-specific errors. Uncommon errors are not contained in the Plant SCADA error database, in which case Plant SCADA only displays the error number.

You might need additional information to rectify an error. This information should be detailed in the documentation that accompanied the I/O device (or network). If, after reviewing all documentation, you cannot rectify an error, contact Technical Support for this product.

Error (in hex)	Description
0x0101 Illegal function	The message function received is not allowed for the addressed slave.
0x0102 Illegal data address	The address referenced is out of range.
0x0103 Illegal data value	Invalid data is being written to the PLC.
0x0108 Memory parity error	An error has been encountered in the computer's memory.
0x28	Bad response from PLC
0x104	Device inoperative

0x105	Acknowledge
0x106	Busy – rejected
0x107	Negative Acknowledge

## MODBUSA Driver

The MODBUSA Driver supports serial communication with many I/O devices (including the Modicon 484, 584, 884, and 984 programmable controllers, and Moore Products IOExpress).

---

**Note:** The **MODBUS** and **MODBUSA** drivers are closely related. They only differ from each other in the data framing technique used: MODBUS is RTU-based, while MODBUSA is ASCII-based. You should determine which your system requires and make sure you proceed using the appropriate driver.

---

The maximum request length for the MODBUSA driver is 2000 bits.

## Safety Information

### Hazard categories and special symbols

The following symbols and special messages may appear in this manual or on the product to warn of potential hazards or to call attention to information that clarifies or simplifies a procedure.

Symbol	Description
 or 	The addition of either symbol to a "Danger" or "Warning" safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.
	This is the safety alert symbol. It is used to alert you to personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.

#### DANGER

**DANGER** indicates an imminently hazardous situation, which, if not avoided, will result in death or serious injury.

#### WARNING

**WARNING** indicates a potentially hazardous situation, which, if not avoided, can result in death or serious injury.

**⚠ CAUTION**

**CAUTION** indicates a potentially hazardous situation which, if not avoided, can result in minor or moderate injury.

**NOTICE**

NOTICE used without a safety alert symbol, indicates a potentially hazardous situation which, if not avoided, can result in property or equipment damage.

**Please Note**

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by AVEVA for any consequences arising out of the use of this material.

**Before You Begin**

Plant SCADA is a Supervisory Control and Data Acquisition (SCADA) solution. It facilitates the creation of software to manage and monitor industrial systems and processes. Due to Plant SCADA's central role in controlling systems and processes, you must appropriately design, commission, and test your Plant SCADA project before implementing it in an operational setting. Observe the following:

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not use Plant SCADA or other SCADA software as a replacement for PLC-based control programs. SCADA software is not designed for direct, high-speed system control.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**⚠ WARNING****LOSS OF CONTROL**

- The designer of any control scheme must consider the potential failure modes of control paths and, for certain critical control functions, provide a means to achieve a safe state during and after a path failure. Examples of critical control functions are emergency stop and overtravel stop, power outage and restart.
- Separate or redundant control paths must be provided for critical control functions.
- System control paths may include communication links. Consideration must be given to the implications of unanticipated transmission delays or failures of the link.
- Observe all accident prevention regulations and local safety guidelines.<sup>1</sup>
- Each implementation of a control system created using Plant SCADA must be individually and thoroughly tested for proper operation before being placed into service.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

1. For additional information, refer to NEMA ICS 1.1 (latest edition) "Safety Guidelines for the Application, Installation, and Maintenance of Solid State Control", and to NEMA ICS 7.1 (latest edition) "Safety Standards for Construction and Guide for Selection, Installation and Operation of Adjustable-Speed Drive Systems" or their equivalent governing your particular location.

## Supported Devices

The MODBUSA Driver supports serial communication with the following devices:

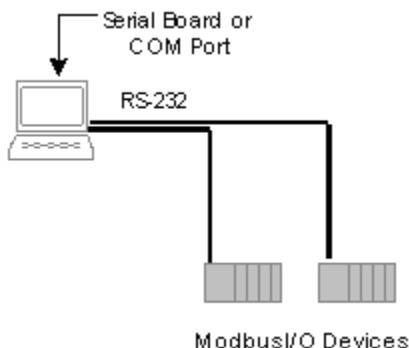

- Generic devices.

Also see [Working with Non-standard Devices](#).

### Generic Devices

Being an established industry standard, the Modbus protocol supports many I/O devices from a variety of manufacturers. The MODBUSA Driver therefore can support communication between Plant SCADA and any generic Modbus devices.

Communication is via a Modbus port on the PLC. Using this method, you can connect to multiple PLCs as in the following diagram:

The following topics provide information required to connect Plant SCADA to a generic Modbus device.

### Generic Devices - Device Address

The I/O Device Address for a PLC is its station number. Try 1 to 10.

- **1** specifies station number **1**.
- **9** specifies station number **9**.

### Generic Devices - Hardware Setup

Set your PLC to the communication setting you want. The default hardware settings for the device are as follows:

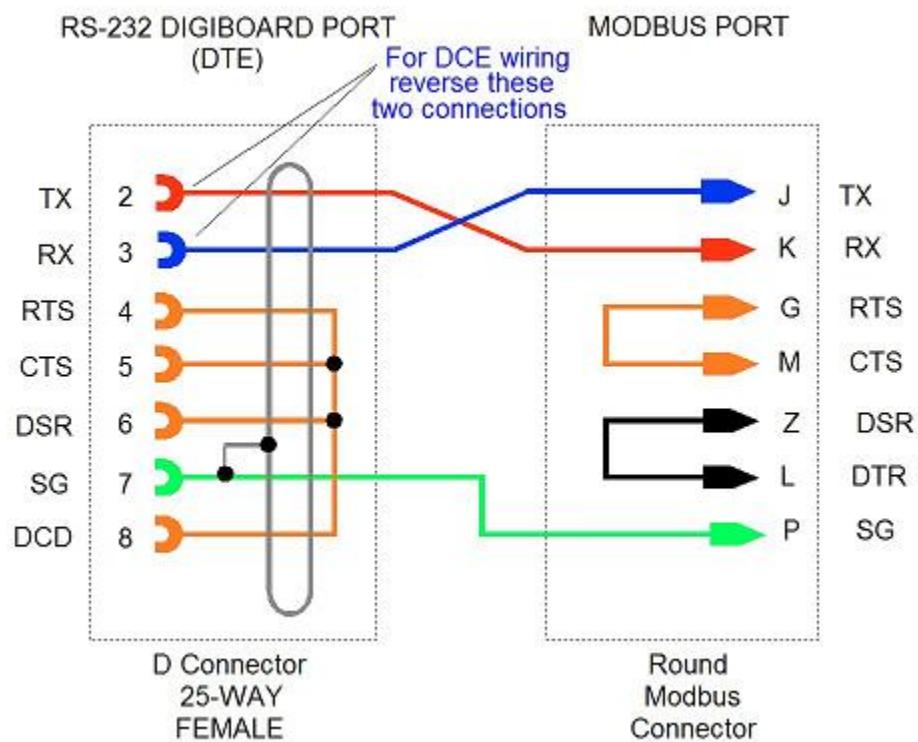

Setting	Value
Baud Rate	19200
Data Bits	8
Stop Bits	1
Parity	2 (Even)

**Note:** These settings are recommendations only. If you use the Communications Express Wizard, these default settings are configured in your project automatically, though your hardware may support other values. If you do set the baud rate, data bits, stop bits or parity to another value, you must manually set the new value(s) in your project.

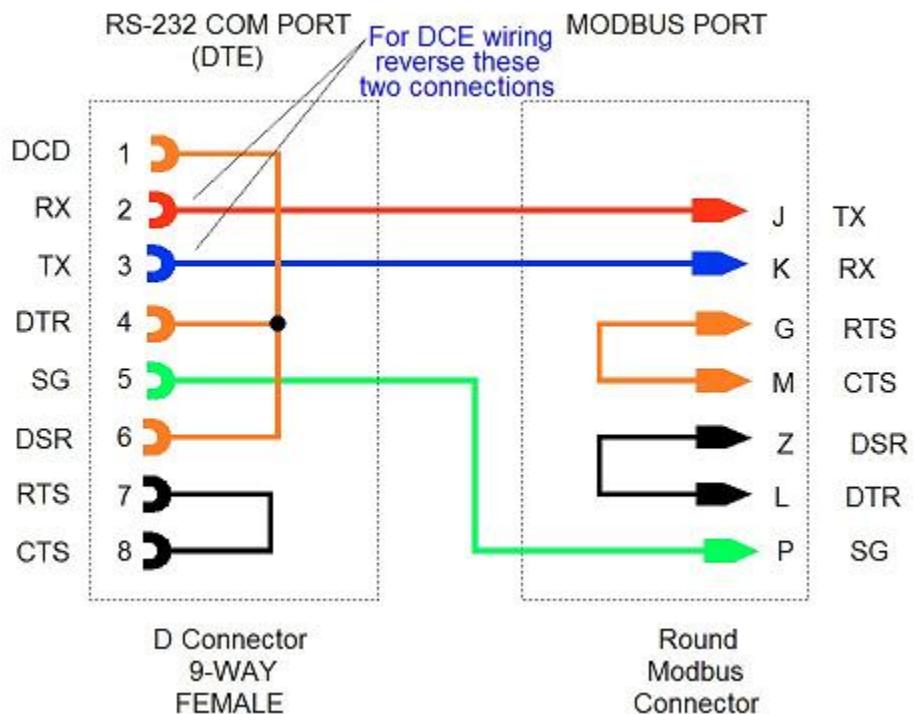

Set the following configuration options on the Modbus port on the PLC:

- Station number
- RTU mode (This is not selected if the MODBUSA protocol is being used)
- Delay time to 1

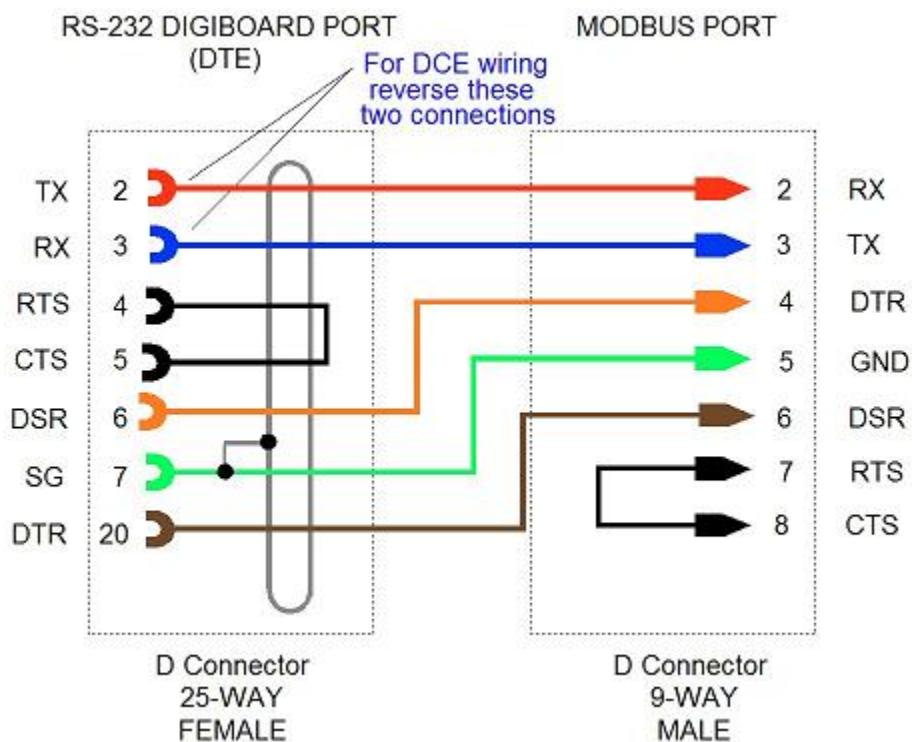

## Generic Devices - Wiring Diagram 1

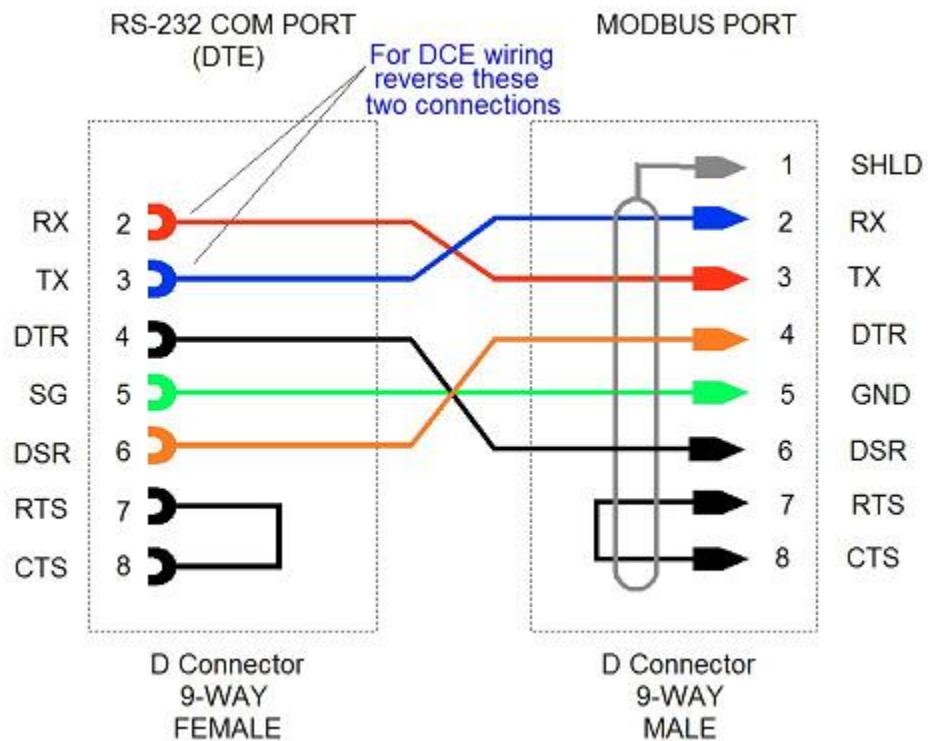

## Generic Devices - Wiring Diagram 2

## Generic Devices - Wiring Diagram 3

## Generic Devices - Wiring Diagram 4

## Generic Devices - Communications Settings

To establish communication with a device, the associated Board, Port and I/O Device need to be correctly configured in Plant SCADA Studio's **Topology** activity.

If you use the Express Communications Wizard to connect to a device, these settings will be automatically configured for you. However, if you need to manually configure them, use the information outlined below.

### Boards

Typically, you would use a serial board or COM port for this communication. Refer to the instructions for setting up and using COM ports or serial boards. Or, complete the Board settings with the following information.

Field	Value
Board Type	If using a serial board or COM port, enter COMx.
Address	If using a serial board or COM port, enter 0.
I/O Port	Leave this field blank.
Interrupt	Leave this field blank.
Special Options	Leave this field blank.

### Ports

Field	Value
Port Number	This value matches the COM port number. This number is defined in the Ports section of the Control Panel.
Baud Rate	This value matches the setting of the unit - 19200.
Data Bits	Enter 8.
Stop Bits	Enter 1.
Parity	This value matches the setting of the unit - EVEN_P.
Special Options	You may want to use the special options for the COMx Driver if you are using a modem (or similar) and want the driver to perform differently. For more information, see the topic <i>COMx Driver Special Options Reference</i> in the <i>Configure I/O Device Communications</i> chapter of the main help.

### I/O Devices

Field	Value
Port Number	This value matches the COM port number. This number is defined in the Ports section of the Control Panel.
Baud Rate	This value matches the setting of the unit - 19200.
Data Bits	Enter 8.
Stop Bits	Enter 1.
Parity	This value matches the setting of the unit - EVEN_P.
Special Options	You may want to use the special options for the COMx Driver if you are using a modem (or similar) and want the driver to perform differently. For more information, see the topic <i>COMx Driver Special Options Reference</i> in the <i>Configure I/O Device Communications</i> chapter of the main help.

## Generic Devices - Data Types

**Note:** The address ranges specified in the following table will be appropriate for most generic Modbus devices. However, you should check the capabilities of a device to confirm if it will support the full extent of the ranges suggested.

Data Types	Address Format	Plant SCADA Data Type
<b>DIGITAL</b>		
Output Coils	000001 to 065536	DIGITAL ( <b>Note:</b> Leading zero is required.)
Input Status	100001 to 165536	DIGITAL (Read Only)
<b>INTEGER</b>		
Input Registers	300001 to 365536	INT / LONG / STRING / REAL (Read Only)
Output Registers	400001 to 465536	INT / LONG / STRING / REAL
<b>EXTENDED REGISTERS</b>		
(6xxxxx range)	Ef:r.b <i>where:</i> f = file no. (1 - 999) r = register no. (0 - 9999) b = bit no. (1 - 16)	DIGITAL / INT / LONG / STRING / REAL

**Examples**

Data Type	DIGITAL
Address	00001
Comment	Output Coil 00001
Data Type	INT
Address	40001
Comment	Output Register 40001
Data Type	INT
Address	E1:00001
Comment	Modbus Address 600001

**Note:** LONG data types default to a simplified implementation, with a shortened range of 0 to 655,359,999. To increase the LONG data type to the full range, set the LongDataType parameter to either 1 or 3.

**Working With Non-standard Devices**

Some non-standard PLCs support the Modbus protocol. However, some of these I/O devices do not support the protocol correctly. When Plant SCADA tries to communicate with these I/O devices, you might get errors on startup or during communication.

To handle these non-standard I/O devices, the Modbus protocol has some special options to change its operation:

1. On startup, Plant SCADA tries to read some digital inputs to verify that the PLC does exist. If Plant SCADA cannot read these bits, it assumes the PLC is bad, and remains off line. Some non-standard I/O devices do not support digital bits, so this command results in an error. With the [MODBUSA]InitType parameter, you can change the type of variable the Modbus protocol tries to read on startup, to allow communication to start.
2. The standard MODBUSA driver allows reading of 2000 bits in one request. Some non-standard I/O devices do not support such large reads. You can change the maximum read size with the [MODBUSA]MaxBits parameter. (The default is 2000.)

Change the MAX\_LENGTH field for the Modbus protocol (in the \Plant SCADA\BIN\PROTDIR.DBF file) to the same value. Re-compile your project after changing this option. Be aware that if you reinstall Plant SCADA, the PROTDIR.DBF file is overwritten and you will need to repeat the change.

3. Some I/O devices that operate over radio modems also require the padding of protocol messages. The padding characters wake the radio modem to allow the rest of the message to be transmitted. Set the [MODBUSA]Pad parameter to the number of characters to pad, and the [MODBUSA]PadChar parameter to the ASCII code of the character to pad. For example, to pad 20 0xFF characters to the start of the message, set:

[MODBUSA]  
Pad=20

PadChar=255

4. In the Modbus protocol, LONG data types default to a simplified implementation, with a shortened range of 0 to 655,359,999. To increase the LONG data type to the full range, set the [MODBUSA]LongDataType parameter to either 1 or 3.

As a LONG is composed from two registers, the register order used by Plant SCADA must match the order used by the PLC. Refer to the help accompanying the [MODBUSA]LongDataType parameter to determine the appropriate value.

**Note:** The MODBUSA driver supports a number of variants of the MODBUS protocol to communicate with some non-standard PLCs. See the topic to determine which variant you should use when configuring a device.

## Protocol Variants

Many devices from different vendors support the Modbus protocol. Unfortunately, addressing structures used by these devices vary. The following information will help you understand which protocol you should select on the I/O devices dialog box to make the addresses you enter into the variables form match those entered into the programming software for your device.

You will need to know the following:

- What is the lowest register / coil number in the device?

Some devices (such as a TSX Quantum or Modicon 948) have register / coil 1 as the lowest register / coil number. Other devices (such as the TSX Premium) have register / coil 0 as the lowest register / coil number

- When addressing an individual bit from a register, what is the lowest bit number?

Some devices refer to the bits within a register as bits 0-15, others refer to them as bits 1-16.

Based on the above information you can select a protocol using the following table:

Range of bits in a register	Lowest coil / register number	Protocol
1-16	1	MODBUS (default)
1-16	0	MODBUS1
0-15	1	MODBUS2
0-15	0	MODBUS3

If you are using a PLC that supports extended registers (6xxxxx addresses in a TSX Quantum for example) then the following table should be used:

Range of bits in a register	Lowest coil / register number	Protocol
1-16	1	MODBUS10
1-16	0	MODBUS11
0-15	1	MODBUS12
0-15	0	MODBUS13

Two special protocols exist for use with the TSX Quantum and TSX Premium PLC ranges. These protocol options will select the correct addressing modes, select certain INI values and other settings to provide compatibility with these devices without the need to set any other special parameters.

These protocols also allow you to access memory digitals and memory words using %M7 or %MW3 or %MW4.6 style addressing. Select a protocol as follows:

PLC Model	Protocol
TSX Quantum	MODBUS20
TSX Premium	MODBUS30

## Customizing a Project using Citect.ini Parameters

Citect.ini parameters are used to tune the performance of the Plant SCADA MODBUSA driver and to perform runtime maintenance diagnostics.

You can customize the way Plant SCADA communicates with the Modbus system (and even individual PLCs) by creating or editing the [MODBUSA] section of the citect.ini file for your project.

There are some common Plant SCADA driver settings as well as custom MODBUSA driver settings.

When Plant SCADA starts at runtime, it reads configuration values from the citect.ini file that is stored locally. Therefore, any MODBUSA configuration settings must be included in the citect.ini file located on the computer acting as the I/O server to the Modbus system.

By default, Plant SCADA looks for the citect.ini file in the Plant SCADA project \bin directory. If it can't find the file there, it searches the default Windows directory.

### MODBUSA Driver Parameters

These parameters default to a value which have shown to be suitable for the majority of circumstances.

#### **WARNING**

##### **UNINTENDED EQUIPMENT OPERATION**

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

With certain parameters, the MODBUSA driver can apply different initialization parameter values to specific I/O devices or groups of I/O devices. For details see Device/group-specific parameters.

### [MODBUSA]Block

A value (bytes) used by the I/O server to determine if two or more packets can be blocked into one data request before being sent to the I/O device. For example, if you set the value to 10 and the I/O server receives two simultaneous data requests (one for byte 3 and another for byte 8) the two requests are blocked into a single physical data request packet. This single request packet is then sent to the I/O device, saving on bandwidth and

processing.

**Allowable Values:** 5 to 256

**Default Value:** 50

## [MODBUSA.<Port\_Name>.<IODevice\_Name>]Broadcast

Sends a write request to a specified device on a Modbus network.

---

**Note:** This parameter can only be used as a device-specific parameter, for example, [MODBUSA.<Port\_Name>.<IODevice\_Name>]Broadcast=1. It should not be used globally. For more details, see [Device/Group-specific Parameters](#).

---

To use this feature:

Define an I/O device with address 0 (zero) for the Channel of interest.

Define the value for the BroadcastDelay parameter in the Citect.ini file (default is 50ms). This parameter defines the amount of time the driver will delay after submitting a broadcast request before it will send another request to the PLCs.

Define tags (Coils and Registers) associated with this I/O device.

Implement a Plant SCADA application that requests writes to the tags (via Cicode, application display, and so on).

Requests for Variable Tag READs to the I/O device with the address zero (0) will return a Driver Error of Unknown Command (driver error 15 decimal). Requests for Variable Tag WRITEs to the I/O device with the address zero (0) will be issued to ALL controllers on the SAME Channel (port) as the I/O device with the assigned address of zero. The Modbus protocol does not provide a response to broadcast requests so inspect the appropriate coils or registers in each controller to observe completion of the request.

**Allowable Values:**

0 = Broadcast disabled

1 = write request will be issued

**Default Value:** 1

## [MODBUSA]BroadcastDelay

Defines the amount of time the driver will delay after submitting a broadcast request before sending another request to the PLCs.

**Allowable Values:** 0 to 300 (milliseconds)

**Default Value:** 50

---

**Note:** This parameter is only available at the MODBUSA level, i.e. [MODBUSA]

---

## [MODBUSA]Delay

The period (in milliseconds) to wait between receiving a response and sending the next command.

**Allowable Values:** 0 to 32767 (milliseconds)

**Default Value:** 0

## [MODBUS]DoCRC

Enables or disables the Modbus Cyclic Redundancy Check (CRC), a communications check. The MODBUSA driver does a CRC on incoming data and provides a CRC remainder in outgoing data blocks. In some limited cases, such as the testing of "slave" drivers, it may be necessary to disable the CRC.

**Allowable Values:** 1 or 0, where:

1 = enable CRC

0 = disable CRC

**Default Value:** 1

The CRC should remain "enabled" under normal circumstances. If the CRC is disabled, no checks are performed on incoming data and the CRC field in the data transmitted by the driver remains 0. This will mean the driver cannot detect lack off communication between itself and the I/O device.

## [MODBUS]FailOnBadData

Used by the MODBUSA driver to determine whether or not to force the display of good data within a block read which contains bad tags during tag read.

**Allowable Values:** 1 or 0, where:

1 = A block read which contains a bad tag would result in the whole block returning #BAD

0 = The MODBUSA driver will not return "#BAD" for a block of data if at least one valid value is in the read block.

**Default Value:** 1

## [MODBUS]FloatMode

---

**Note:** This parameter is not applicable if you are using the protocol variant MODBUS20 or MODBUS30 to communicate with a device. Under these circumstances, a value of 0 (zero) will be hardcoded for this parameter.

This INI parameter sets the byte order for floating point values (the MODBUSA driver supports floating point values). Some systems expect to use a different byte order for their floating point data.

**Allowable Values:** 0 to 3, where:

0 - Byte order = 1 0 3 2

1 - Byte order = 3 2 1 0

2 - Byte order = 0 1 2 3

3 - Byte order = 2 3 0 1

**Default Value:** 0

With this parameter, you can set different values for specific I/O devices or groups of I/O devices. See [Device/Group-specific Parameters](#).

## [MODBUS]ForceMultiCoilsOnly

Forces the use of only function code 15 (multiple coils) for coil writes.

**Allowable Values:**

0 - (function code 5 and 15)

1 - (function code 15 only)

**Default Value:** 0

### [MODBUS]InitType

The type of variable the MODBUSA protocol tries to read on startup, to allow communication to start.

**Allowable Values:** 1 to 4.

InitType	Address	Variable
1	00001 - 00017	Output status
2	10001 - 10017	Input status
3	40001	Output registers
4	30001	Input registers

**Default Value:** 2

With this parameter, you can set different values for specific I/O devices or groups of I/O devices. See [Device/Group-specific parameters](#).

### [MODBUS]InitUnitAddress

The MODBUSA driver reads the citect.ini file to determine the correct unit address for initialization of a PLC. InitUnitAddress is the parameter used to set the unit address.

**Allowable Values:** 0 to 65535

**Default Value:** 0

With this parameter, you can set different values for specific I/O devices or groups of I/O devices. See [Device/Group-specific Parameters](#).

### [MODBUS]LongDataType

**Note:** This parameter is not applicable if you are using the protocol variant MODBUS20 or MODBUS30 to communicate with a device. Under these circumstances, a value of 3 will be hardcoded for this parameter.

In the Modbus protocol, LONG data types default to a simplified implementation, with a shortened range of 0 to 99,999,999 - mode 0. Mode 2 has the same range as mode 0, but with the register order swapped. Mode 1 supports the complete LONG range of -2,147,483,648 to +2,147,483,647. Mode 3 has the same range as mode 1, but with the register order swapped.

**Allowable Values:** 0 to 3, where:

- 0 = 10000 x low register + high register
- 1 = 65536 x low register + high register
- 2 = 10000 x high register + low register
- 3 = 65536 x high register + low register

**Default Value:** 3

With this parameter, you can set different values for specific I/O devices or groups of I/O devices. See [Device/Group-specific Parameters](#).

## [MODBUS]MaxBits

**Note:** This parameter is not applicable if you are using the protocol variant MODBUS20 or MODBUS30 to communicate with a device. If MODBUS20 is being used, a value of 1904 will be hardcoded for this parameter. If MODBUS30 is being used, a value of 1024 will be hardcoded.

The maximum read size in one request. Decrease the value for non-standard I/O devices that do not support large reads.

**Allowable Values:** 8 to 32767

**Default Value:** 1904

## [MODBUS]MaxBitsExt

**Note:** This parameter is not applicable if you are using the protocol variant MODBUS20 or MODBUS30 to communicate with a device. If MODBUS20 is being used, a value of 1904 will be hardcoded for this parameter. If MODBUS30 is being used, a value of 1024 will be hardcoded.

This INI parameter sets the maximum bits blocked for the Quantum PLCs "Ex:y[.z]" address type.

**Allowable Values:** 8 to 32767

**Default Value:** 1904

## [MODBUS]MaxPending

The maximum number of pending commands that the driver holds ready for immediate execution.

**Allowable Values:** 1 to 32

**Default Value:** 2

## [MODBUS]Pad

The number of characters with which to pad protocol messages. The padding characters wake the radio modem to allow the rest of the message to be transmitted. A value of 20 is recommended for non-standard I/O devices that operate over radio modems.

**Allowable Values:** 0 to 65535

**Default Value:** 0

## [MODBUS]PadChar

The ASCII code of the padding character with which to pad protocol messages. The padding characters wake the radio modem to allow the rest of the message to be transmitted.

**Allowable Values:** 0 to 255

**Default Value:** 255

## [MODBUS]PollTime

The interrupt or polling service time (in milliseconds). Setting the polling time to 0 puts the driver in interrupt

mode.

**Allowable Values:** 0 to 300 (milliseconds)

**Default Value:** 0

## [MODBUSA]PresetMultiRegistersOnly

Forces the use of only function code 16 (multiple registers) for register writes.

**Allowable Values:** 0 or 1:

0 - (function code 6 and 16)

1 - (function code 16 only)

**Default Value:** 0

## [MODBUSA]RegisterBitReverse

---

**Note:** This parameter is not applicable if you are using the protocol variant MODBUS20 or MODBUS30 to communicate with a device. Under these circumstances, a value of 1 will be hardcoded for this parameter.

This INI parameter allows reverse interpretation of Most Significant Bit (MSB) and Least Significant Bit (LSB) in words. The Modbus specification defines bit 1 of a word as the MSB, and bit16 of the word as the LSB. Some devices use a different order, causing bit 1 of a word to be the LSB and bit 16 to be the MSB.

**Allowable Values:** 0 or 1, where:

1 - Bit 1= LSB, Bit 16 = MSB

0 - Bit 1 = MSB, Bit 16 = LSB

**Default Value:** 1

With this parameter, you can set different values for specific I/O devices or groups of I/O devices. See [Device/Group-specific Parameters](#).

## [MODBUSA]Retry

The number of times to retry a command after a timeout.

**Allowable Values:** 0 to 8

**Default Value:** 0

## [MODBUSA]SendBCDSwap

Reverses the byte order for BCDs on writes (the MODBUSA driver supports BCDs). Some systems expect to use a different byte order for their data; in the case of BCDs, this causes "1234" to be written to the device as "3412".

**Allowable Values:** 0 or 1, where:

1 = 1 2 3 4

0 = 3 4 1 2

**Default Value:** 1

With this parameter, you can set different values for specific I/O devices or groups of I/O devices. See [Device/Group-specific Parameters](#).

**[MODBUSA]Status**

Sometimes you can read data from a device even though the processor module is not running. In view of this, it can be useful to detect this situation by monitoring a continuously changing register or a digital. If the register is unable to change in a given period or the digital becomes zero, the processor can be assumed to have stopped running.

If enabled, the MODBUSA driver will check on startup and approximately every watchtime the status of a user specified variable in the PLC is changing. If a digital is specified, the value should be on, otherwise the unit is put offline. If an analog is specified, on startup two consecutive reads with an interval of 1000ms (specified by [MODBUSA]Timeout) should return different values before the unit can be put online. At every watchtime, if the digital is off or the analog data does not change from the last value read, the driver returns an error and the unit is put offline.

**Allowable Values:**

RawType

BitWidth

UnitType

UnitAddress

UnitAddress

where:

RawType	BitWidth	UnitType	UnitAddress	UnitCount
0 = Digital	1 = Digital	See variable specification .dbf files	The item number or bit number	1 = analog 16 = digital
1 = Int	16 = Int			
4 = Long	32 = Long			
8 = Byte	8 = Byte			

**Default Value:**

Zero length string

**Examples**

To specify Modbus address 40001 as the analog tag variable which must change to indicate the device is online, use:

```
[MODBUSA]
status=1,16,3,0,1
```

To use Modbus address 00001 as the digital tag variable which must remain set to 1 to indicate the device is online, then use:

```
[MODBUSA]
status=0,1,1,0,16
```

## [MODBUSA]StringReverse

Reverse byte order for strings. The MODBUSA driver supports strings. Some systems expect to use a different byte order for their data, which in the case of string variables, causes "ABCD" to appear as "BADC".

**Allowable Values:** 0 or 1

**Default Value:** 0 (do not reverse byte order)

With this parameter, you can set different values for specific I/O devices or groups of I/O devices. See [Device/Group-specific Parameters](#).

## [MODBUSA]Timeout

Specifies how many milliseconds to wait for a response before displaying an error message.

**Allowable Values:** 0 to 32000 (milliseconds)

**Default Value:** 3000

**Note:** This parameter is only available at the MODBUSA Portlevel, i.e. [MODBUSA.Port] but values are overridden by the default values in the syslog and Kernel page.

## [MODBUSA]WatchTime

The frequency (in seconds) that the driver uses to check the communications link to the I/O device.

**Allowable Values:** 0 to 128 (seconds)

**Default Value:** 30

## Device/group-specific parameters

The MODBUSA driver can apply different initialization parameter values to specific I/O devices or groups of I/O devices. This means the user can specify:

- Global parameters that apply to all devices.
- Channel- (port-) level parameters that apply to all devices on the specified port.
- Group-level parameters that apply to all devices in a specified group.
- Device-level parameters that apply only to the specified device.

### **WARNING**

#### **UNINTENDED EQUIPMENT OPERATION**

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

This feature can be implemented in the citect.ini for the following [MODBUSA Parameters](#):

- Broadcast

- BroadcastDelay
- FloatMode
- ForceMultiCoilsOnly
- InitType
- InitUnitAddress
- LongDataType
- PresetMultiRegistersOnly
- RegisterBitReverse
- SendBCDSwap
- StringReverse

To set parameters for a particular port, group, or device, you must create a new section in the citect.ini file. Label it with the driver name followed by a period (.) character and the name of the particular port, group, or device you want to specify the parameter setting for.

For example:

- [MODBUS.<Port\_Name>]: applies the parameter settings to the specified port.
- [MODBUS.<Group\_Name>]: applies the parameter settings to the specified group.
- [MODBUS.<Port\_Name>.<IODevice\_Name>]: applies to the specified device.

Any parameters you then define in the following section of the citect.ini file relate only to the specified device or device group.

#### Example

The following citect ini file format is an example of how the InitType parameter could be specified differently for different I/O devices communicating using the Modbus protocol.

Assume that two ports are used: PORT1 and PORT2.

PORT1 has three I/O devices attached:

- DEV1A DEV1B EV1C

PORT2 also has three devices:

- DEV2A DEV2B DEV2C

Assume that the user has specified that DEV1C and DEV2C belong to GROUPZ. The citect.ini file contains the following entries:

```
[MODBUS]
InitType=1
[MODBUS.PORT1]
InitType=2
[MODBUS.PORT2]
InitType=2
[MODBUS.GROUPZ]
InitType=3
[MODBUS.PORT1.DEV1A]
```

InitType=1  
[MODBUS.PORT2.DEV2B]  
InitType=4

The resultant InitType for the I/O devices will be as follows:

DEV1A:	1	as a result of [MODBUS.PORT1.DEV1A]
DEV1B:	2	as a result of [MODBUS.PORT1]
DEV1C:	3	as a result of [MODBUS.GROUPZ]
DEV2A:	2	as a result of [MODBUS.PORT2]
DEV2B:	4	as a result of [MODBUS.PORT2.DEV2B]
DEV2C:	3	as a result of [MODBUS.GROUPZ]

As the above example shows, there is a hierarchy that determines the outcome of such settings. In simple terms, specific parameter settings overwrite general level settings. Therefore, parameters written in the scope of I/O devices will overwrite those set for groups; parameters set for groups will overwrite global settings, and so on.

## MODBUSA Driver Errors

MODBUSA has two kinds of protocol driver errors:

- **Generic errors**, which are hardware errors 0-31 and common to all protocols. Some generic errors are common to all protocols. Sometimes only the generic error is available, though often both the generic error and a specific error are given.
- **Specific errors**, which can be unique and therefore cannot be recognized by the hardware alarm system. The drivers convert their specific errors into generic errors that can be identified by the I/O server. For example, when a driver experiences an error, there is often both a protocol-specific error and a corresponding generic error.

When a hardware error occurs, Plant SCADA generates an alarm and displays the alarm on the Hardware Alarm page (in the alarm description of the hardware alarm). To see the error number, make sure you have Alarm Category 255 defined with a display format that includes {ErrDesc,15} {ErrPage,10}.

## Specific Errors

The following errors, listed in (hexadecimal) sequence, are specific to this driver. Plant SCADA displays the error number and description for common protocol-specific errors. Uncommon errors are not contained in the Plant SCADA error database, in which case Plant SCADA only displays the error number.

You might need additional information to rectify an error. This information should be detailed in the documentation that accompanied the I/O device (or network). If, after reviewing all documentation, you cannot rectify an error, contact Technical Support for this product.

Error (in hex)	Description
0x0101 Illegal function	The message function received is not allowed for the addressed slave.
0x0102 Illegal data address	The address referenced is out of range.
0x0103 Illegal data value	Invalid data is being written to the PLC.
0x0108 Memory parity error	An error has been encountered in the computer's memory.
0x28	Bad response from PLC
0x104	Device inoperative
0x105	Acknowledge
0x106	Busy – rejected
0x107	Negative Acknowledge

## MODNET Driver

The MODNET driver supports TCP/IP communication with Modicon™ TSX Quantum™ and Premium™ PLCs, as well as a number of TCP-compatible generic MODBUS devices.

The maximum request length for the MODNET driver is 1920.

## Safety Information

### Hazard categories and special symbols

The following symbols and special messages may appear in this manual or on the product to warn of potential hazards or to call attention to information that clarifies or simplifies a procedure.

Symbol	Description
 or 	The addition of either symbol to a "Danger" or "Warning" safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.
	This is the safety alert symbol. It is used to alert you to personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.
<b>⚠ DANGER</b>	<b>DANGER</b> indicates an imminently hazardous situation, which, if not avoided, will result in death or serious injury.
<b>⚠ WARNING</b>	<b>WARNING</b> indicates a potentially hazardous situation, which, if not avoided, can result in death or serious injury.
<b>⚠ CAUTION</b>	<b>CAUTION</b> indicates a potentially hazardous situation which, if not avoided, can result in minor or moderate injury.
<b>NOTICE</b>	NOTICE used without a safety alert symbol, indicates a potentially hazardous situation which, if not avoided, can result in property or equipment damage.

## Please Note

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by AVEVA for any consequences arising out of the use of this material.

## Before You Begin

Plant SCADA is a Supervisory Control and Data Acquisition (SCADA) solution. It facilitates the creation of software to manage and monitor industrial systems and processes. Due to Plant SCADA's central role in controlling systems and processes, you must appropriately design, commission, and test your Plant SCADA project before implementing it in an operational setting. Observe the following:

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not use Plant SCADA or other SCADA software as a replacement for PLC-based control programs. SCADA software is not designed for direct, high-speed system control.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**⚠ WARNING****LOSS OF CONTROL**

- The designer of any control scheme must consider the potential failure modes of control paths and, for certain critical control functions, provide a means to achieve a safe state during and after a path failure. Examples of critical control functions are emergency stop and overtravel stop, power outage and restart.
- Separate or redundant control paths must be provided for critical control functions.
- System control paths may include communication links. Consideration must be given to the implications of unanticipated transmission delays or failures of the link.
- Observe all accident prevention regulations and local safety guidelines.<sup>1</sup>
- Each implementation of a control system created using Plant SCADA must be individually and thoroughly tested for proper operation before being placed into service.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

1. For additional information, refer to NEMA ICS 1.1 (latest edition) "Safety Guidelines for the Application, Installation, and Maintenance of Solid State Control", and to NEMA ICS 7.1 (latest edition) "Safety Standards for Construction and Guide for Selection, Installation and Operation of Adjustable-Speed Drive Systems" or their equivalent governing your particular location.

## Supported Devices

The MODNET driver supports MODBUS communications via TCP/IP for the following devices:

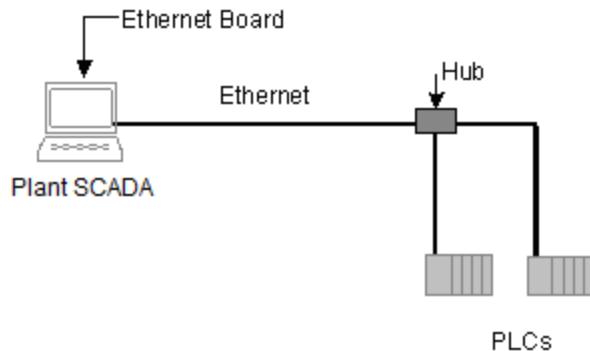

- Generic MODBUS TCP/IP Devices
- Modicon™ M340, TSX Quantum™ and Premium™ PLCs.

---

**Note:** To support a wide range of Modbus/TCP devices, there are a number of variants of the MODNET protocol. See the topic [MODNET Protocol Variants](#) to determine which variant you should use when configuring a device.

### Generic MODBUS TCP/IP Devices

The MODNET Driver supports TCP/IP communication to devices supporting MODBUS/TCP over Ethernet. Using this method you can connect to single or multiple PLCs as in the following diagram:

**Note:** The same Ethernet card that is being used for Plant SCADA communication can be used for PLC communication though this may lower performance.

- [Generic MODBUS TCP/IP Devices - Communication Settings](#)
- [Generic MODBUS TCP/IP Devices - Data Types](#)

### Generic MODBUS TCP/IP Devices - Device Address

The information you enter here will be placed in the Special Options field of the Port settings, with the following format:

-la -Pn -T

where:

a = the IP address in standard Internet dot format. (For example 192.9.2.60)

n = the destination Port number. Often one physical port has several virtual ports, used for different purposes. The default is 502.

-T -- forces the driver to use TCP, rather than UDP (-U).

See [Generic MODBUS TCP/IP Devices](#) for more information about this setup.

### Generic MODBUS TCP/IP Devices - Hardware Setup

## Plant SCADA Computer Setup

It is recommended that you setup your specific Ethernet card as required and confirm basic network communications before proceeding with the communications configuration for the MODNET driver. Refer to the documentation accompanying your hardware for instruction.

### Generic MODBUS TCP/IP Devices - Communication Settings

The following tables show the settings for communication with Generic MODBUS TCP/IP Devices. To establish communication with a device, configure the Boards, Ports and I/O Devices settings in Plant SCADA Studio's

**Topology** activity correctly. If you use the Express Communications Wizard to connect to a device, these will be automatically configured for you. However, if you need to configure them manually, or verify that the fields are correct, use the settings outlined below.

## Boards

Field	Value
Board Type	Enter TCPIP .
Address	Enter 0 .
I/O Port	Leave this field blank .
Interrupt	Leave this field blank.
Special Options	Leave this field blank.

## Ports

Field	Value
Port Number	A valid unique number.
Baud Rate	Leave this field blank.
Data Bits	Leave this field blank.
Stop Bits	Leave this field blank.
Parity	Leave this field blank.
Special Options	<p>Enter the destination IP address of the PLC. Use the following format:</p> <p><b>-Ia -Pn -T</b></p> <p>where:</p> <p><i>a</i> = the IP address in standard Internet dot format. (For example 192.9.2.60)</p> <p><i>n</i> = the destination Port number. Often one physical port has several virtual ports, used for different purposes. Use this option only if you want to override the default of 502.</p> <p><b>-T</b> = forces the driver to use TCP, rather than UDP (-U).</p>

## I/O Devices

Field	Value
I/O Device Address	If the connection to the I/O device is point-to-point using TCP/IP, leave this field blank to assign a default value of 0. Or, you can specify the slave address if the device requires it.  If the connection to the I/O device is through MODBUS/TCP to MODBUS serial line gateway, use the slave address of I/O device.  <b>Note:</b> To enable broadcast through MODBUS/TCP to MODBUS serial line gateway, an I/O device should be created with address value 0. All the broadcast requests should be sent to this I/O device. Refer to the Broadcast and BroadcastDelay parameters for details (see <a href="#">MODNET Driver Parameters</a> ).
I/O Device Protocol	Enter the MODNET protocol variant. (See <a href="#">MODNET Protocol Variants</a> to determine which variant is required.)

### Generic MODBUS TCP/IP Devices - Data Types

**Note:** The address ranges specified in the following table will be appropriate for most generic Modbus devices. However, you should check the capabilities of a device to confirm if it will support the extent of the ranges suggested.

For information on array support, see [Generic MODBUS TCP/IP Devices - Array Support](#).

Data Types	Valid Address Range	Address Format	Plant SCADA Data Type
Output Coils	000001 - 065536	<valid address> (e.g. 001000)	DIGITAL
Input Status	100001 - 165536	<valid address> (e.g. 103000)	DIGITAL
Input Registers	300001 - 365536	<valid address> (e.g. 301350)	INT/ REAL/ LONG/ BCD/ LONGBCD
Input Registers (DIGITAL)	300001 - 365536	<valid address>.b where b is the bit number between 1 and 16 inclusive	DIGITAL

Data Types	Valid Address Range	Address Format	Plant SCADA Data Type
		(e.g. 302300.2)	
Output Registers	400001 - 465536	<valid address> (e.g. 401190)	INT/ REAL/ LONG/ BCD/ LONGBCD
Output Registers (DIGITAL)	400001 - 465536	<valid address>.b where b is the bit number between 1 and 16 inclusive (e.g. 40001.4)	DIGITAL
Extended registers	-	<b>EF:R</b> where: <b>E</b> denotes the extended register. <b>F</b> is the file number between 1 and 16 inclusive <b>R</b> is the register between 0 and 9999 inclusive	INT/ REAL/ LONG/ BCD/ LONGBCD/ STRING
Individual Output Coil Register	000001 – 065536	G<valid address> (e.g. G 001000)	DIGITAL
Individual Input Coil Status	100001 – 165536	G<valid address> (e.g. G103000)	DIGITAL
Individual Input Register	300001 – 365536	G<valid address> (e.g. G 301350)	INT / REAL / LONG / BCD / LONGBCD / STRING
Individual Output Register	400001 – 465536	G<valid address> (e.g. G401190)	INT / REAL / LONG / BCD / LONGBCD / STRING
Individual Extended Register		G<EF:R> where: <b>E</b> denotes the extended register. <b>F</b> is the file number between 1 and 16 inclusive <b>R</b> is the register between 0 and 9999 inclusive	INT/ REAL / LONG / BCD / LONGBCD / STRING

**Note:** When writing DIGITAL variables to Output registers, the individual bits in a register (1..16) can be written to with the format **n .BitPosition** (e.g. 40001.1). Writing to sequential bits requires individual write commands. The user can specify the bit order direction in the INI parameter [MODNET]RegisterBitReverse.

#### EXAMPLES:

Data Type	DIGITAL
Address	000006
Comment	Output Coil
Data Type	LONGBCD
Address	300019
Comment	Input Register

## Generic MODBUS TCP/IP Devices - Array Support

Plant SCADA Data Type	Address	Array size
DIGITAL	[Address][Array size]	1-2032
INT	[Address][Array size]	1-127
LONG	[Address][Array size]	1-63
REAL	[Address][Array size]	1-63
BCD	[Address][Array size]	1-127
LONGBCD	[Address][Array size]	1-63
STRING	[Address][Array size]	1-127 (2-254 characters)

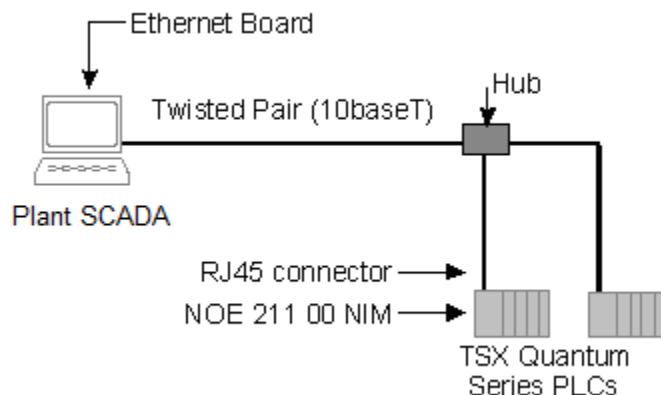

### EXAMPLES:

Data Type	DIGITAL
Address	000006[2000]
Data Type	LONGBCD
Address	300019[5]
Data Type	INT
Address	400001[1]
Data Type	REAL
Address	400100[12]

Data Type	STRING
Address	400001[2]

## M340, TSX Quantum™ and Premium™ PLCs

The MODNET Driver supports TCP/IP method of communication to the Modicon M340, TSX Quantum and Premium PLCs. Using this method you can connect to single or multiple PLCs as in the following diagram:

### Note:

- 1) The same Ethernet card that is being used for Plant SCADA communication can be used for PLC communication though this may lower performance.
- 2) The hub is necessary even if connecting to only one PLC.

- [M340, TSX Quantum™ and Premium™ PLCs - Communication Settings](#)
- [M340, TSX Quantum™ and Premium™ PLCs - Data Types](#)

## M340, TSX Quantum and Premium PLCs - Device Address

The information you enter here will be placed in the Special Options field of the Ports form, with the following format:

-la -Pn -T

where:

a = the IP address in standard Internet dot format. (For example 192.9.2.60)

n = the destination Port number. Often one physical port has several virtual ports, used for different purposes. The default is 502.

-T = forces the driver to use TCP, rather than UDP (-U).

See the topic [M340, TSX Quantum™ and Premium™ PLCs](#) for more information about this setup.

## M340, TSX Quantum and Premium PLCs - Hardware Setup

### Plant SCADA Computer Setup

It is recommended that you setup your specific Ethernet card as required and confirm basic network communications before proceeding with the communications configuration for the MODNET driver. Refer to the documentation accompanying your hardware for instruction.

## M340, TSX Quantum and Premium PLCs - Communication Settings

The following tables show the settings for communication with TSX Quantum™ and Premium™ PLCs. To establish communication with a device, configure the Boards, Ports and I/O Devices settings in Plant SCADA Studio's **Topology** activity. If you use the Express Communications Wizard to connect to a device, these settings will be automatically configured for you. However, if you need to configure them manually, or verify that the fields are correct, use the settings outlined below.

### Boards

Field	Value
Board Type	Enter TCPIP.
Address	Enter 0.
I/O Port	Leave this field blank.
Interrupt	Leave this field blank.
Special Options	Leave this field blank.

### Ports

Field	Value
Port Number	A valid unique number.
Baud Rate	Leave this field blank.
Data Bits	Leave this field blank.
Stop Bits	Leave this field blank.
Parity	Leave this field blank.
Special Options	Enter the destination IP address of the PLC. Use the following format:

Field	Value
	<p><b>-Ia -Pn -T</b></p> <p>where:</p> <p><i>a</i> = the IP address in standard Internet dot format. (For example 192.9.2.60)</p> <p><i>n</i> = the destination Port number. Often one physical port has several virtual ports, used for different purposes. Use this option only if you want to override the default of 502.</p> <p><b>-T</b> = forces the driver to use TCP, rather than UDP (-U).</p>

## I/O Device Settings

Field	Value
I/O Device Address	Leave this field blank. A value of 0 is assigned by default.
I/O Device Protocol	Enter the MODNET protocol variant. (See <a href="#">MODNET Protocol Variants</a> to determine which variant is required.)

## M340, TSX Quantum and Premium PLCs - Data Types

Data Types	Valid Address Range	Address Format	Plant SCADA Data Type
Output Coils	000001 - 065536	<valid address> (e.g. 01000)	DIGITAL
Output Coils (Memory)	000001 – 065536	%M<valid address> (e.g. %M7)	DIGITAL
Input Status	100001 - 165536	<valid address> (e.g. 11001)	DIGITAL
Input Registers	300001 - 365536	<valid address> (e.g. 31350)	INT/ REAL/ LONG/ BCD/ LONGBCD
Input Registers (DIGITAL)	300001 - 365536	<valid address>.b where <b>b</b> is the bit number between 1 and 16 inclusive	DIGITAL

Data Types	Valid Address Range	Address Format	Plant SCADA Data Type
		(e.g. 32300.2)	
Output Holding Registers (ANALOG)	400001 - 465536	<valid address> (e.g. 41190)	INT/ REAL/ LONG/ BCD/ LONGBCD
Output Registers (Memory)	000001 – 065536	%MW<valid address> (e.g. %MW3)	INT/ REAL/ LONG/ BCD/ LONGBCD
Output Holding Registers (DIGITAL)	400001 - 465536	<valid address>.b where b is the bit number between 1 and 16 inclusive (e.g. 40001.4)	DIGITAL
Output Registers (DIGITAL) (Memory)	000001 – 065536	%MW<valid address>.b where b is the bit number between 1 and 16 inclusive (e.g. %MW4.6)	DIGITAL
Extended registers		<b>EF:R</b> where: <b>E</b> denotes the extended register. <b>F</b> is the file number between 1 and 16 inclusive. <b>R</b> is the register between 0 and 9999 inclusive.	INT/ REAL/ LONG/ BCD/ LONGBCD/ STRING
Individual Output Coil Register	000001 – 065536	G<valid address> (e.g. G001000)	DIGITAL
Individual Input Coil Status	100001 – 165536	G<valid address> (e.g. G103000)	DIGITAL
Individual Input Register	300001 – 365536	G<valid address> (e.g. G301350)	INT / REAL / LONG / BCD / LONGBCD / STRING
Individual Output Register	400001 – 465536	G<valid address> (e.g. G401190)	INT / REAL / LONG / BCD / LONGBCD / STRING
Individual Extended Register		G<EF:R> where: <b>E</b> denotes the extended register. <b>F</b> is the file number	INT/ REAL / LONG / BCD / LONGBCD / STRING

Data Types	Valid Address Range	Address Format	Plant SCADA Data Type
		between 1 and 16 inclusive <b>R</b> is the register between 0 and 9999 inclusive	

**Note:** When writing DIGITAL variables to output registers, the individual bits in a register (1..16) can be written to with the format **n.BitPosition** (e.g. 40001.1). Writing to sequential bits requires individual write commands. The user can specify the bit order direction in the INI parameter [MODNET]RegisterBitReverse.

#### EXAMPLES

Data Type	DIGITAL
Address	00036
Comment	Output Coil
Data Type	LONGBCD
Address	30019
Comment	Input Register

## MODNET Protocol Variants

Many devices from different vendors support the Modbus/TCP protocol. Unfortunately addressing structures used by these devices vary. The following information will help you understand which protocol you should select on the I/O devices dialog box to make the addresses you enter into the variables form match those entered into the programming software for your device.

You will need to know the following:

- **What is the lowest register / coil number in the device?**

Some devices (such as a TSX Quantum or Modicon 948) have register / coil 1 as the lowest register / coil number. Other devices (such as the TSX Premium) have register / coil 0 as the lowest register / coil number

- **When addressing an individual bit from a register, what is the lowest bit number?**

Some devices refer to the bits within a register as bits 0-15, others refer to them as bits 1-16.

Based on the above information you can select a protocol using the following table:

Range of bits in a register	Lowest coil / register number	Protocol
1-16	1	MODNET (default)
1-16	0	MODNET1
0-15	1	MODNET2

0-15	0	MODNET3
------	---	---------

If you are using a PLC that supports extended registers (6xxxxx addresses in a TSX Quantum for example) then the following table should be used:

Range of bits in a register	Lowest coil / register number	Protocol
1-16	1	MODNET10
1-16	0	MODNET11
0-15	1	MODNET12
0-15	0	MODNET13

Two special protocols exist for use with the TSX Quantum and TSX Premium PLC ranges. These protocol options will select the correct addressing modes, select certain INI values and other settings to provide compatibility with these devices without the need to set any other special parameters.

These protocols also allow you to access memory digitals and memory words using %M7 or %MW3 or %MW4.6 style addressing. Select a protocol as follows:

PLC Model	Protocol
TSX Quantum	MODNET20
TSX Premium	MODNET30
M340	MODNET30

## MODNET Driver Parameters

### **WARNING**

#### UNINTENDED EQUIPMENT OPERATION

- Do not under any circumstances change or remove any of the undocumented citect.ini parameters.
- Before deleting sections of the citect.ini file, confirm that no undocumented parameters will be deleted.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

[MODNET] Parameter name	Description	Allowable values	Default value
Broadcast	Enables or disables broadcast through a gateway.	1 – Write request will be issued. 0 – Broadcast disabled.	0

[MODNET] Parameter name	Description	Allowable values	Default value
	<p>The 'broadcast' mechanism is designed to allow an I/O Device configured with address '0' to come online and be used to send write requests to the Modbus network through a gateway. Some devices will interpret this address as a 'broadcast' address and accept the write request. Consequently, there will be no acknowledgement of the message.</p> <p>The ini parameter is configured as:</p> <p>[MODNET.&lt;port_name&gt;.&lt;iodevice_name&gt;] Broadcast</p>		
BroadcastDelay	Time delay before replying to broadcast write requests in milliseconds.	1-65535	50
ConnTimeout	Timeout period for channel initialization in milliseconds.	1 - 65535 (milliseconds)	15000
Debug	<p>Allows extra debug information to be displayed in the kernel window and logged into the syslog.dat file.</p> <p><b>Note:</b> This parameter is only applicable if DebugStr parameter is configured.</p>	<p>1 - turn on the extra debug information option 0 - turn off the extra debug information option</p>	0 (zero)
DebugStr	Enables logging of debug information to be displayed in the kernel window and logged into the syslog.dat file.	<p>&lt;port name&gt; ALL – Enables logging for a specific port. * ALL –</p>	Disabled

[MODNET] Parameter name	Description	Allowable values	Default value
	This ini parameter is configured as: [MODNET] DebugStr = <port name> ALL	Enables logging for all the ports configured.	
Delay	The period (in milliseconds) to wait between receiving a response and sending the next command.	0 to 300 (milliseconds)	0 (zero)
FailOnBadData	Controls error reporting when BCD or LONG values received from the device are outside the valid range for that type.	1 – Reports error 0 – No error reported	1
FloatMode	<p>Specifies the order of bytes in REAL variable types.</p> <p><b>Note:</b> This parameter is not applicable if you are using the <a href="#">MODNET Protocol Variants</a> MODNET20 or MODNET30 to communicate with a device. Under these circumstances, a value of 0 (zero) will be hardcoded for this parameter.</p> <p>With this parameter, you can set different values for specific I/O devices or groups of I/O devices.</p> <p>See <a href="#">Device/Group-specific Parameters</a>.</p>	0: Order of bytes = 1 0 3 2 1: Order of bytes = 3 2 1 0 2: Order of bytes = 0 1 2 3 3: Order of bytes = 2 3 0 1	0 (zero)
ForceMultiCoilsOnly	<p>Forces the use of only function code 15 (multiple coils) for coil writes.</p> <p>With this parameter, you can set different values for specific I/O devices or groups of I/O devices.</p>	0 - function code 5 and 15 1 - function code 15 only	0 (zero)

[MODNET] Parameter name	Description	Allowable values	Default value
	See <a href="#">Device/Group-specific Parameters</a> .		
InitVar (With the InitVarType parameter configured.)	<p>Address of the register to read at startup to confirm connections.</p> <p>If the InitVarType parameter is configured, InitVar must have the register address and InitVarType must provide the register type. InitVar will be able to support the values 0-65535.</p> <p>Example:</p> <pre>[Modnet] InitVar = 39000 InitVarType = 4</pre> <p>With this configuration during start-up and re-connection the driver will attempt to read Input Register 39000</p> <p>See <a href="#">Device/Group-specific Parameters</a>.</p>	0 – 65535	40001
InitVar (Without the InitVarType parameter configured.)	<p>Address of the register to read at startup to confirm connections.</p> <p>If the InitVarType parameter is not configured, InitVar must have the complete address including the register type.</p> <p>InitVar should be configured as format FR.</p> <p>F : Register type (range: 1-4, 1-Digital read output, 2-Digital read input, 3-Integer read output, 4-Integer read input)</p> <p>R : Register address</p>	(1-4) (0-65535)	040001

[MODNET] Parameter name	Description	Allowable values	Default value
	<p>(range : 0-65535)</p> <p>Example :</p> <p>[Modnet] InitVar = 12345</p> <p>By default, InitVarType will be assigned value 0.</p> <p>With this configuration during start-up and re-connection the driver will attempt to read Input Coil 2345.</p> <p>With this parameter, you can set different values for specific I/O devices or groups of I/O devices.</p> <p>See <a href="#">Device/Group-specific Parameters</a>.</p>		
InitVarType	<p>The type of register the MODNET driver tries to read on startup to allow communication to start. It is configured with the parameter InitVar.</p> <p>With this parameter, you can set different values for specific I/O devices or groups of I/O devices.</p> <p>See <a href="#">Device/Group-specific Parameters</a>.</p>	0 to 4, or 20 (for extended registers access) 1 - Digital read output 2 - Digital read input 3 - Integer read output 4 - Integer read input 20 – Extended register 0 - the value defined for the parameter InitVar will be considered a complete address, having register type.	0
LongDataType	<p>In the MODNET protocol, LONG data types default to a simplified implementation, with a shortened range of 0 to 99,999,999 for mode 0.</p> <p>Mode 2 has the same range as mode 0, but with the register order swapped.</p>	0 - implies 10,000 * low register + high register 1 - implies 65,536 * low register + high register 2 - implies 10,000 * high register + low register 3 - implies 65,536 * high register + low register	3

[MODNET] Parameter name	Description	Allowable values	Default value
	<p>Mode 1 supports the complete LONG range of -2,147,483,648 to +2,147,483,647.</p> <p>Mode 3 has the same range as mode 1, but with the register order swapped.</p> <p>When using the MODBUS protocol, Plant SCADA combines two registers to store a long data type in a PLC. The way in which it does this is defined by this parameter.</p> <p><b>Note:</b> This parameter is not applicable if you are using the <a href="#">MODNET Protocol Variants</a> MODNET20 or MODNET30 to communicate with a device. Under these circumstances, a value of 3 will be hardcoded for this parameter.</p> <p>With this parameter, you can set different values for specific I/O devices or groups of I/O devices.</p> <p>See <a href="#">Device/Group-specific Parameters</a>.</p>		
MaxBits	<p>Sets the maximum number of bits in a block for dynamic blocking. This is normally the same as the MODNET protdir.dbf "max_bits" setting.</p> <p><b>Note:</b> For <a href="#">MODNET Protocol Variants</a> MODNET20, this parameter is not applicable. The default</p>	8 to 2000	2000

[MODNET] Parameter name	Description	Allowable values	Default value
	<p>value 2000 is used for blocking, ignoring any configured value.</p> <p>For protocol variant MODNET30, this parameter is applicable. The default value is 1024 in this case.</p> <p>With this parameter, you can set different values for specific I/O devices or groups of I/O devices.</p> <p>See <a href="#">Device/Group-specific Parameters</a>.</p>		
MaxBitsExt	<p>This parameter sets the maximum bits blocked for extended registers.</p> <p><b>Note:</b> This parameter is not applicable if you are using the <a href="#">MODNET Protocol Variants</a> MODNET20 or MODNET30 to communicate with a device. If MODNET20 is being used, a value of 1920 will be hardcoded for this parameter. If MODNET30 is being used, a value of 1024 will be hardcoded.</p>	8 to 32767	1920
MaxOutstanding	<p>Specifies the maximum number of outstanding requests (that is, the maximum number of requests allowed to be sent to the PLC at a given time).</p> <p>This parameter should be adjusted to coincide with the number of requests the PLC can process in one scan cycle. The</p>	1 to 32	1

[MODNET] Parameter name	Description	Allowable values	Default value
	<p>appropriate value can be obtained by analysing a "debug * all" dump to determine the number of PLC replies received in one PLC scan. If the PLC is running at short scan rates, the scan time might have to be temporarily stretched to 30 milliseconds in order to identify the different PLC scans easily. Empirical testing indicates that longer PLC scan times allows the PLC to process more requests per scan.</p> <p>Setting the MaxOutstanding parameter unnecessarily high will lower throughput. The number of requests the PLC can process per scan determines the driver's performance. This value is dependent on both the tuning of the PLC scan times and on the PLC's overheads such as Modbus communications.</p> <p><b>Note:</b> MaxPending needs to be greater than MaxOutstanding.</p> <p>If this parameter is placed under the section [MODNET] then all ports in the project will have this parameter set to this number. If this parameter is placed under the following section: [MODNET.&lt;Port_name&gt;] the specified port will have this parameter set to</p>		

[MODNET] Parameter name	Description	Allowable values	Default value
	<p>this number and previous number will be overwritten.</p> <p>A [MODNET.&lt;Port_name&gt;] parameter has the highest precedence.</p> <p>If the MaxOutstanding parameter is missing, the number of the outstanding requests will be set to the default of 1 for all Modnet ports in the project.</p> <p><b>Examples</b></p> <p>[MODNET.TCPPORT1] MaxOutstanding =3 [MODNET.TCPPORT2] MaxOutstanding =4</p> <p>In the above example, TCPPORT1 is set to 3 and port TCPPORT2 is set to 4</p> <p>[MODNET] MaxOutstanding =3 [MODNET. TCPPORT1] MaxOutstanding =5</p> <p>In this example, TCPPORT1 is set to 5 and all other ports in the project (if any) are set to 3.</p>		
MaxPending	<p>The maximum number of pending commands that the driver holds ready for immediate execution.</p> <p><b>Note:</b> MaxPending needs to be greater than MaxOutstanding.</p>	1 to 32	2
NonCriticalExceptionMask	Defines the exceptions to be considered non-critical exception. If a non-critical exception occurs, the	0x1 – 0xFFFFFFFF	0x20 Exception code 6 – Sever busy

[MODNET] Parameter name	Description	Allowable values	Default value
	<p>driver will retry to send the request.</p> <p>Its value is a exception mask, where bit position value maps to exception code.</p> <p>Example:</p> <p>The value 0x20 sets the mask for bit position 6, that represents exception code 6, i.e. server busy.</p>		
OnlineTestExceptionMask	<p>Defines the exceptions to be reported that are received while initializing or checking status of IO Device.</p> <p>Its value is a exception mask, where bit position value maps to exception code.</p> <p>Example:</p> <p>The value 0xFFFFFFF9 sets the mask of bit positions except bit position 2 and 3, that represents exception code 2 (Illegal data address) and 3 (Illegal data value). Hence these exceptions will be ignored to report IO Device online status.</p>	0x1 – 0xFFFFFFFF	0xFFFFFFF9
PollTime	<p>The interrupt or polling service time (in milliseconds). Setting the polling time to 0 puts the driver in interrupt mode.</p> <p><b>Note:</b> It is recommended that you do not modify the PollTime value, which is set to 0 (zero) by default.</p>	0 to 300 (milliseconds)	0
PresetMultiRegistersOnly	Forces the use of only	0 - function code 6 and 16	1

[MODNET] Parameter name	Description	Allowable values	Default value
	<p>function code 16 (multiple registers) for register writes. This function code setting is normal for a Class 0 Modbus TCP/IP device.</p> <p>With this parameter, you can set different values for specific I/O devices or groups of I/O devices.</p> <p>See <a href="#">Device/Group-specific Parameters</a>.</p>	1 - function code 16 only	
ReadMinTwoRegisters	<p>By default, the driver reads a minimum of one register. This parameter allows the driver to check the read request size and make sure the driver reads at least two registers.</p>	0 – The driver reads a minimum of one register. 1 - The driver reads at least two registers.	0
RegisterBitReverse	<p>This parameter defines the order in which bits in a register are individually addressed.</p> <p><b>Note:</b> This parameter is not applicable if you are using the <a href="#">MODNET Protocol Variants</a> MODNET20 or MODNET30 to communicate with a device. Under these circumstances, a value of 1 will be hardcoded for this parameter.</p> <p>With this parameter, you can set different values for specific I/O devices or groups of I/O devices.</p> <p>See <a href="#">Device/Group-specific Parameters</a>.</p>	0 - setting Bit 16 (only) will result in a register value of 1 1 - setting Bit 1 (only) will result in a register value of 1	0
Retry	The number of times to	0 to 8	0

[MODNET] Parameter name	Description	Allowable values	Default value
	<p>retry a command after a timeout.</p> <p>With this parameter, you can set different values for specific I/O devices or groups of I/O devices.</p> <p>See <a href="#">Device/Group-specific Parameters</a>.</p>		
SendBCDSwap	<p>Defines the order of bytes in a written word. This will not affect the order of bytes read.</p> <p><b>Note:</b> This parameter is not applicable to long BCD data types.</p> <p>With this parameter, you can set different values for specific I/O devices or groups of I/O devices.</p> <p>See <a href="#">Device/Group-specific Parameters</a>.</p>	1 - Big Endian format (Motorola or Network format) 0 - Small Endian format (Intel format)	1
SetNRDDDisconnectExceptionErrorAsOffline	<p>Indicates how the non-standard exception error 0x1d is handled.</p> <p>This error occurs when a MODNET device is disconnected from an NRDD Gateway.</p>	0 - The error is treated as a general error 1 - The error will cause the device to go offline	0
StringReverse	<p>Reverses the order of bytes in string variable types, for example, "ABCD" "BADC".</p> <p>With this parameter, you can set different values for specific I/O devices or groups of I/O devices.</p> <p>See <a href="#">Device/Group-specific Parameters</a>.</p>	0 - No reverse 1 - Reverse	0
TransactionExceptionMask	Defines which exception to be considered	0x1 – 0xFFFFFFFF	0x400

[MODNET] Parameter name	Description	Allowable values	Default value
	<p>transaction difficulties. Driver will report unit offline if this exception is received.</p> <p>Its value is a exception mask, where bit position value maps to exception code.</p> <p>Example: The value 0x400 sets the mask for bit position 11, that represent exception code 0xB.</p>		
Timeout	<p>Specifies how many milliseconds to wait for a response before displaying an error message.</p> <p>With this parameter, you can set different values for specific I/O devices or groups of I/O devices.</p> <p>See <a href="#">Device/Group-specific Parameters</a>.</p>	0 to 32000 (milliseconds)	1000
WatchTime	<p>The period (in seconds) with which the driver checks the communications link to the I/O device.</p> <p>With this parameter, you can set different values for specific I/O devices or groups of I/O devices.</p> <p>See <a href="#">Device/Group-specific Parameters</a>.</p>	0 to 128 (seconds)	30

## Device/Group-specific Parameters

The MODNET driver can apply different initialization parameter values to specific I/O devices or groups of I/O devices. This means the user can specify:

Global parameters that apply to devices.

Channel-level (port-level) parameters that apply to devices on the specified port.

Group-level parameters that apply to devices in a specified group.

Device-level parameters that apply only to the specified device.

## **WARNING**

### **UNINTENDED EQUIPMENT OPERATION**

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

This feature can be implemented in the citect.ini for the following MODNET parameters:

- MaxBits
- InitVar
- InitVarType
- StringReverse
- RegisterBitReverse
- FloatMode
- LongDataType
- SendBCDSwap
- ForceMultiCoilsOnly
- PresetMultiRegistersOnly
- Retry
- Timeout

To set parameters for a particular port, group, or device, you need to create a new section in the citect.ini file. Label it with the driver name followed by a period (.) character and the name of the particular port, group, or device you want to specify the parameter setting for.

For example:

[MODNET.<Port\_Name>]: applies the parameter settings to the specified port.

[MODNET.<Group\_Name>]: applies the parameter settings to the specified group.

[MODNET.<Port\_Name>.<IODevice\_Name>]: applies to the specified device.

Any parameters you then define in the following section of the citect.ini file relate only to the specified device or device group.

### **Example**

The following citect ini file format is an example of how the InitVarType parameter could be specified differently for different I/O devices communicating using the MODNET protocol.

Assume that two ports are used: PORT1 and PORT2. PORT1 has three I/O devices attached:

- DEV1A
- DEV1B

- EV1C

PORTE also has three devices:

- DEV2A
- DEV2B
- DEV2C

Assume that the user has specified that DEV1C and DEV2C belong to GROUPZ. The citect.ini file contains the following entries:

```
[MODNET]
InitVarType=1
[MODNET.PORT1]
InitVarType=2
[MODNET.PORT2]
InitVarType=2
[MODNET.GROUPZ]
InitVarType=3
[MODNET.PORT1.DEV1A]
InitVarType=1
[MODNET.PORT2.DEV2B]
InitVarType=4
```

The resultant InitVarType for the I/O devices will be as follows:

DEV1A:	1	as a result of [MODNET.PORT1.DEV1A]
DEV1B:	2	as a result of [MODNET.PORT1]
DEV1C:	3	as a result of [MODNET.GROUPZ]
DEV2A:	2	as a result of [MODNET.PORT2]
DEV2B:	4	as a result of [MODNET.PORT2.DEV2B]
DEV2C:	3	as a result of [MODNET.GROUPZ]

As the above example shows, there is a hierarchy that determines the outcome of such settings. In simple terms, specific parameter settings overwrite general level settings. Therefore, parameters written in the scope of I/O devices will overwrite those set for groups; parameters set for groups will overwrite global settings, and so on.

## MODNET Driver Specific Errors

The following errors, listed in (hexadecimal) sequence, are specific to this protocol. Plant SCADA displays the error number and description for common protocol-specific errors. Uncommon errors are not contained in the Plant SCADA error database, in which case Plant SCADA only displays the error number.

You might need additional information to rectify an error. This information should be detailed in the documentation that accompanied the I/O device (or network). If, after reviewing the documentation, you cannot

rectify an error, contact Technical Support for this product.

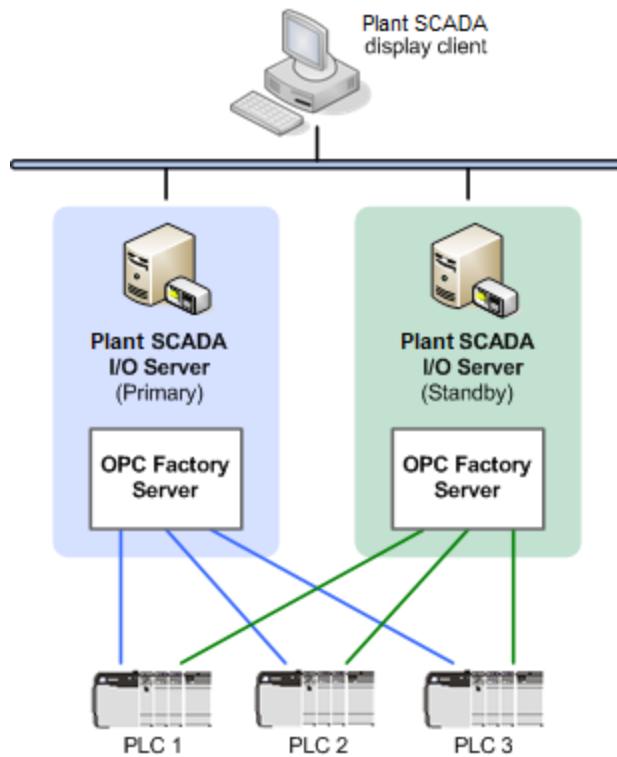

Error (in hex)	Description
0x0101 Illegal function	The message function received is not allowed for the addressed slave.
0x0102 Illegal data address	The address referenced is out of range.
0x0103 Illegal data value	Invalid data is being written to the PLC.
0x0108 Memory parity error	An error has been encountered in the computer's memory.
0x28	Bad response from PLC.
0x104	Device inoperative.
0x105	Acknowledge.
0x106	Busy – rejected.
0x107	Negative Acknowledge.
0x2100	Function Code Mismatch.
0x2101	Invalid Command.
0x100	Point-To-Point and gateway units are on the same port.

## OFSOPC Driver

The OFSOPC Driver enables Plant SCADA to communicate with OPC Factory Server (OFS), providing a gateway to a network of OFS-compatible devices.

For each Plant SCADA I/O server, a single connection to a local instance of OFS is established, allowing tight integration between the driver and the OFS configuration environment. Individual devices are addressed within a Plant SCADA project using OFS alias names.

The following diagram demonstrates a simple system installation using I/O server and PLC network redundancy.

**Note:** With the release of version 7.20, Plant SCADA supports the retrieval of time-stamped data directly from field devices. This capability is enabled by the Driver Runtime Interface (DRI), a component of Plant SCADA that is used by the OFSOPC driver to directly update time-stamped digital alarms, time-stamped analog alarms and event-based trends. For more information, see the topic *Retrieving Time-stamped Data from Field Devices* in the main Plant SCADA help.

## Safety Information

### Hazard categories and special symbols

The following symbols and special messages may appear in this manual or on the product to warn of potential hazards or to call attention to information that clarifies or simplifies a procedure.

Symbol	Description
 or 	The addition of either symbol to a "Danger" or "Warning" safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.
	This is the safety alert symbol. It is used to alert you to personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.
<b> DANGER</b>	
<b>DANGER</b> indicates an imminently hazardous situation, which, if not avoided, will result in death or serious injury.	
<b> WARNING</b>	
<b>WARNING</b> indicates a potentially hazardous situation, which, if not avoided, can result in death or serious injury.	
<b> CAUTION</b>	
<b>CAUTION</b> indicates a potentially hazardous situation which, if not avoided, can result in minor or moderate injury.	
<b>NOTICE</b>	
<b>NOTICE</b> used without a safety alert symbol, indicates a potentially hazardous situation which, if not avoided, can result in property or equipment damage.	

## Please Note

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by AVEVA for any consequences arising out of the use of this material.

## Before You Begin

Plant SCADA is a Supervisory Control and Data Acquisition (SCADA) solution. It facilitates the creation of software to manage and monitor industrial systems and processes. Due to Plant SCADA's central role in controlling systems and processes, you must appropriately design, commission, and test your Plant SCADA project before implementing it in an operational setting. Observe the following:

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not use Plant SCADA or other SCADA software as a replacement for PLC-based control programs. SCADA software is not designed for direct, high-speed system control.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**⚠ WARNING****LOSS OF CONTROL**

- The designer of any control scheme must consider the potential failure modes of control paths and, for certain critical control functions, provide a means to achieve a safe state during and after a path failure. Examples of critical control functions are emergency stop and overtravel stop, power outage and restart.
- Separate or redundant control paths must be provided for critical control functions.
- System control paths may include communication links. Consideration must be given to the implications of unanticipated transmission delays or failures of the link.
- Observe all accident prevention regulations and local safety guidelines.<sup>1</sup>
- Each implementation of a control system created using Plant SCADA must be individually and thoroughly tested for proper operation before being placed into service.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

1. For additional information, refer to NEMA ICS 1.1 (latest edition) "Safety Guidelines for the Application, Installation, and Maintenance of Solid State Control", and to NEMA ICS 7.1 (latest edition) "Safety Standards for Construction and Guide for Selection, Installation and Operation of Adjustable-Speed Drive Systems" or their equivalent governing your particular location.

**⚠ WARNING****INTENDED USAGE**

The integration of diagnostic buffer support into Plant SCADA is provided as a supplementary source of alarm information and should not be used to monitor critical alarms for a live production system.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

Alarms generated by PLCs set to different date and time values will be sorted according to their time information, but the resulting order may not reflect their real chronological order of appearance (i.e. as defined per a shared clock). Depending on the synchronization accuracy required at system level, different synchronization methods should be used.

**⚠ WARNING****ALARMS NOT DISPLAYED IN TRUE CHRONOLOGICAL ORDER**

Set Plant SCADA and all PLCs to the same system date and time.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

## System Requirements

Each Plant SCADA I/O server needs to have a local installation of OPC Factory Server (OFS) version 3.33 or later. Version 1.02.12.001 (or later) of the OFSOPC driver will only use the **#PLCQualStatus** tag to determine the status of a device.

## OFS configuration file locations

At startup, the OFSOPC driver might need to access the OFS configuration file **DeviceConfig.xml** to gather push data information.

Once OFS has been installed, this file can be found in the following directory:

%PROGRAMDATA%\AVEVA Plant SCADA 2020 R2\OFS\<ver>

Where <ver> is the version of OFS installed.

## Setting up Device Communication

The OFSOPC driver handles device communication through the integration of OPC Factory Server (OFS) on the I/O Server. Individual devices are addressed through the use of OFS alias names in the configuration of your Plant SCADA variable tags.

Setting up communication within a Plant SCADA project is therefore a straightforward process of connecting to OFS locally on each I/O server.

See [Communication Settings](#) for the default settings used by the Express Communication Wizard when configuring the connection to OFS as a device.

---

**Note:** If you want to use the OFSOPC driver on an I/O server that is running as a Windows® service, you need to make some additional configuration settings on the I/O server.

## See Also

[Device Address](#)

[Data Dictionary Support](#)

## Device Address

The address to use for a device using the OFSOPC driver is the alias name configured in the OFS configuration for the remote PLC.

## See Also

[Communication Settings](#)

## Communication Settings

To establish communication with a device, the associated **Board**, **Port** and **I/O Device** need to be correctly configured in Plant SCADA Studio's **Topology** activity.

If you use the Express Communications Wizard to connect to a device, these settings will be automatically configured for you. However, if you need to manually configure them, use the settings outlined below.

### Boards

Field	Value
Board Name	This field is user defined (e.g. 'Board1').
Board Type	Enter <b>OFSOPC</b> .
Address	Enter zero (0)
I/O Port	Leave this field blank.
Interrupt	Leave this field blank.
Special Options	Leave this field blank.
Comment	Any useful comment. This field is user defined and not required by the driver.

### Ports

Field	Value
Port Name	This field is user defined.
Port Number	Leave this field blank.
Board Name	Refers to the board previously defined in Board settings (e.g. 'Board1').
Baud Rate	Leave this field blank.
Data Bits	Leave this field blank.
Stop Bits	Leave this field blank.
Parity	Leave this field blank.
Special Options	Leave this field blank.

Comment	Any useful comment. This field is user defined and not required by the driver.

## I/O Devices

Field	Value
Name	This field is user defined.
Number	I/O device number which needs to be unique for each logical device, but identical for redundant devices.
Address	The alias name configured in the OFS configuration for the remote PLC.
Protocol	Enter OFSOPC.
Port Name	Refers to the port previously defined in the Port settings.
Comment	Any useful comment. This field is user defined and not required by the driver.

## Data Dictionary Support

To support OFS Data Dictionary, OFS version 3.6 (or later) needs to be installed.

OFS version 3.6 introduced a new specific item, #PLCDaDataDicReady, which provides the status of Data Dictionary in OFS for each device alias.

The #PLCDaDataDicReady item can be equal to the following values:

- **0:** indicates that the PLC Data Dictionary is not configured for this alias (in the OFS configuration tool).
- **1:** indicates that the PLC Data Dictionary is not available. This may occur if OFS is still in the process of loading the Data Dictionary, or the Data Dictionary is not set in the UnityPro application (which means it is not embedded in the PLC).
- **2:** indicates that the PLC Data Dictionary is available.

The driver checks the status of the #PLCDaDataDicReady item. If the value of the item is equal to **0** (data dictionary is not enabled in OFS configuration tool), or **2** (data dictionary is loaded), it adds the OPC items and sets the I/O device online.

**Note:** Data Dictionary must be either enabled or disabled in both the OFS configuration tool and the UnityPro application, otherwise the value of #PLCDaDataDicReady will be equal to 1 and the driver will not put the I/O device online.

## Configuring Variable Tags

Variable tags are addressed using the alias names defined in OPC Factory Server (OFS). The following table demonstrates the variable tag address formats you can use to read values.

When specifying a data type, consider whether the server will be able to convert data to the requested type.

Address	Plant SCADA type	OFS Type	Example
[<alias>!]<item_id>	digital	vt_bool	bool_symbol or plc1!bool_symbol
[<alias>!]<item_id>	byte	vt_ui1	byte_symbol or plc1!byte_symbol
[<alias>!]<item_id>	int	vt_i2	int_symbol or plc1!int_symbol
[<alias>!]<item_id>	long	vt_i4	long_symbol or plc1!long_symbol
[<alias>!]<item_id>	real	vt_r4	real_symbol or plc1!real_symbol
[<alias>!]<item_id>	string	VT_ARRAY of VT_UI1	string_symbol or plc1!string_symbol

Plant SCADA also allows a collection of variables to be associated with an OFS array tag. The following table demonstrates the variable tag address formats used to read values from OFS array tags.

See also [Array Tag Support](#).

Address	Plant SCADA type	OFS Type	Example
[<alias>!]<item_id>!a[size]	digital	array of vt_bool	dig_array!a[32] or plc1!dig_array!a[32]
[<alias>!]<item_id>!a[size]	byte	array of vt_ui1	byte_array!a[10] or plc1!byte_array!a[10]
[<alias>!]<item_id>!a[size]	int	array of vt_i2	int_array!a[10] or plc1!int_array!a[10]
[<alias>!]<item_id>!a[size]	long	array of vt_i4	long_array!a[10] or plc1!long_array!a[10]
[<alias>!]<item_id>!a[size]	real	array of vt_r4	real_array!a[10] or plc1!real_array!a[10]

## Tag addressing for bits

The following table defines the syntax for configuring the tag that represents the bit of a WORD or INT UnityPro

data type.

Address	Plant SCADA type	UnityPro Type	Example
[<alias>!]<item_ID>.<bit number>	digital	INT or WORD	MyInt.0 Or PLC!MyInt.1

The item\_id above can be either a symbolic or direct address.

The direct address syntax is shown below:

- Single variable: [<alias>!]<direct\_address>  
For example: PLC1!%MW1
- Array of variables: [<alias>!]<direct\_address>:<size>!A[<size>]  
For example: PLC1!%MW1:10!A[10]

---

**Note:** The driver will poll some of the OFS special items instead of subscribing to the item value updates. For more information, refer to [Poll Engine for #Specific Tags](#).

---

## See Also

[Timestamp and Quality Support](#)

[Tag Addressing for Derived Data Types \(DDT\)](#)

## Array Support

The OFSOPC driver allows you to write to an individual array item without updating the whole array. This operation is performed by creating a temporary subscription to the individual sub-item and issuing a write to that item.

For example, the following expression indicates to the OFSOPC driver to assign a value of 8 to the fifth element of the "MyArray" tag in OFS:

MyArray [5] = 8

---

**Note:** Plant SCADA indexes an array starting from zero, while some OFS applications allow you to specify an array's lower bound (as a positive or negative value). The OFSOPC driver will dynamically determine an array's lower bound and map the Plant SCADA array to it.

---

## Large array support

The maximum size of an array tag is limited to 256 bytes due to the underlying infrastructure of Plant SCADA. For example, if the type is integer (2 bytes), Plant SCADA only allows the array tag to be configured with 128 elements.

However, special array offset syntax can be used to address multiple array tags configured with the same address as sub-arrays. A variable tag can therefore represent a sub-array with the particular offset and range within a large array.

The following demonstrates the variable tag address syntax used to facilitate this:

[<alias>!]<ITEM\_ID>\<OFFSET>!A[SIZE]

#### Example

The following provides an example of how sub-arrays can be used to map to a large array in an OFS system.

To address **IntArray[17]** in OFS, you would use the variable tag address **LargeArrayPart1[17]**.

To address **IntArray[193]**, you would use **LargeArrayPart2[65]** (as  $65 = 193 - 128$ ).

## Timestamp and Quality Support

When used with Plant SCADA version 7.0 or later, the OFSOPC driver supports the use of additional variable tags to obtain quality and timestamp values. Quality or timestamp tags are duplicates of a variable tag, with an appended "!Q" or "!T" or "!M" in the address field to define their purpose.

For example:

Address	Plant SCADA Type	Description
[<alias>!]<item_ID>!Q	INT	The quality reported for the item
[<alias>!]<item_ID>!T	LONG	The seconds component of the timestamp reported for the item (in UTC seconds)
[<alias>!]<item_ID>!M	LONG	The milliseconds component of the timestamp reported for the item

## Tag Addressing for Derived Data Types (DDT)

The following table defines the syntax for configuring the tag that represents the field of a structure.

Address	Example
[<alias>!]<item_ID>.<field>	MyStruct.MyField1 or PLC1!MyStruct.MyField1

For example, if the Derived Data Type (DDT) "MyStruct" is defined in UnityPro as the following:

Field Name	UnityPro Type
MyField1	INT
MyField2	INT
MyField3	INT

And **MyStructInstance** is configured as an instance of **MyStruct** in UnityPro®, then you would need to configure the following tags to access the fields of **MyStructInstance**:

Tag Name	Tag Address	Plant SCADA Type
MyStructInstance_MyField1	MyStructInstance.MyField1	INT
MyStructInstance_MyField2	MyStructInstance.MyField2	INT
MyStructInstance_MyField3	MyStructInstance.MyField3	INT

## Poll Engine for #Specific Tags

Generally, the OFSOPC driver activates the item specified in the tag address and relies on the value updates from OFS, but some special OFS items do not provide value updates via subscription. The driver needs to poll these items for the value updates. If the tag address contains any of the following strings, the driver will poll it for value updates:

- #AppliName
- #AppliVersion
- #NbrRequest
- #RefreshDevice
- #AppliOMC
- <>system>#!ClientAlive
- #TSEventSynchro
- #DeviceIdentity

---

**Note:** The OFSOPC driver will poll for value updates only if these tags are subscribed in Plant SCADA. The Plant SCADA tag subscription rate defines the poll rate.

---

## Advanced Configuration and Maintenance

This section provides advanced configuration instructions.

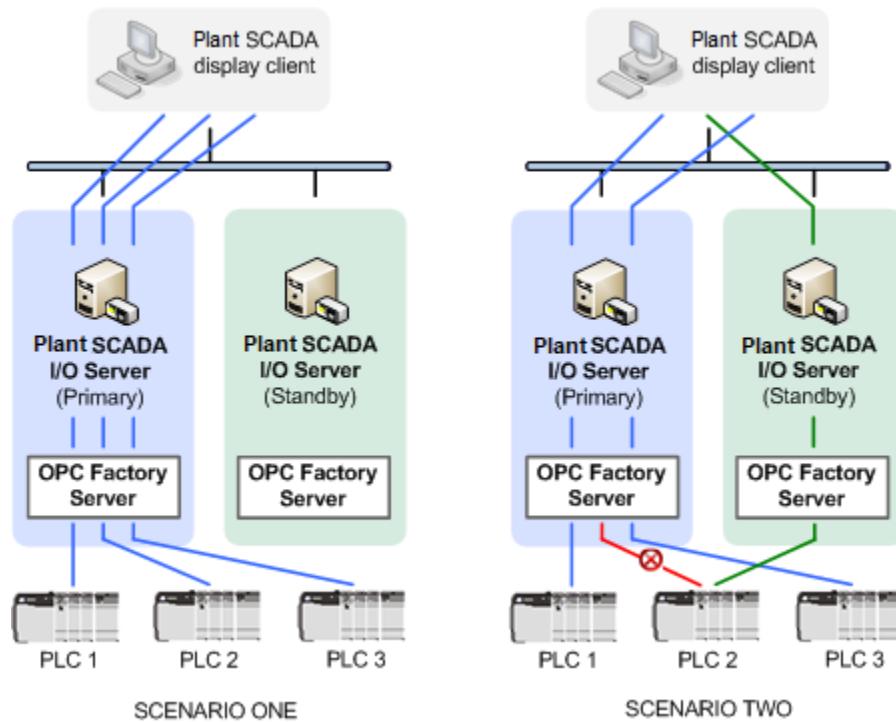

- Configuring Redundancy
- Using the Batch-write Mechanism
- Push Data Support
- OFS Group Management
- Source Timestamped Events Support
- Diagnostic Buffer Support
- Customizing a Project using Citect.ini Parameters

## Configuring Redundancy

The OFSOPC driver supports fully transparent redundancy across the following architectures:

- Multiple I/O server redundancy, including support for load balancing across one or more computers
- Device redundancy, where a PLC is managed by more than one I/O server
- Communication redundancy, where each PLC is on a redundant network.

To facilitate a complex redundant architecture, the OFSOPC driver represents each PLC as a separate I/O device. This allows a switchover to occur on a per-PLC basis, as demonstrated by the diagram below.

Scenario one demonstrates the system in normal operating state, with the client connected to the three PLCs via the primary server. In scenario two, the link from the primary server to PLC2 is broken. Under these circumstances, the client is able to re-establish communication with PLC2 via the standby server.

The OFSOPC driver subscribes to **#PLCQualStatus** and system bit %S0 on each PLC to determine the current operational status of a device. If these tags report bad quality, the I/O device will be declared offline and a switchover to the standby will occur.

---

**Note:** It is also possible to specify a custom item value that the driver will check in addition to #PLCQualStatus. See [Dynamic Status Item Parameters](#).

---

## Using the Batch-write Mechanism

The OFSOPC driver supports a batch-write mechanism that allows a defined set of tags to be updated at the same time.

A batch-write is implemented by creating a special tag with the address "BatchWrite". This functionality will be implemented on a per-PLC basis (you need to create one special tag per device).

Once BatchWrite has been written to with a value of 1, subsequent writes to the I/O device will be deferred until a write operation to BatchWrite with value 0 (zero) is received. At that time, the deferred writes will be performed together to the OFS server.

If a 0 value is not received within a pre-defined timeout period, the batch write operation will be performed on the deferred writes currently held by the driver. The BatchWrite tag will be reset with to a value of 0 (zero) to

help prevent infinite waiting. This timeout period (set to 30 seconds by default), can be adjusted using the **BatchWriteTimeout** parameter.

---

**Note:** The OFSOPC driver does not support a batch write operation during any kind of redundancy switchover. Under these circumstances, the batch-write operation will not work.

---

## Push Data Support

OPC Factory Server (OFS) supports "push data", which allows a remote device to connect as a Modbus/TCP server and write data in a format that includes a timestamp.

The OFSOPC driver supports this functionality by implementing push-data items as time-stamped digital alarms, time stamped analog alarms and event trends.

## Subscribing to a push-data item

The OFSOPC driver initially gathers push-data configuration information from the OFS configuration file **DeviceConfig.xml**. For each item, the address is checked to determine if it is located within a push-data area. If this is the case, the item is added to the OFS group that has the fastest subscription rate to help ensure that changes will be transmitted from OFS to Plant SCADA as efficiently as possible.

## OFS Group Management

The OFSOPC driver uses OFS groups to prioritize and manage device communication.

For each device instance, the driver creates three groups in OFS, each with a different update rate. Items are then allocated to a group according to a detected polling rate. For example, status tags and heavily sampled items fall into the fastest group, rarely accessed items are added to the slowest group.

The subscription rate used for each Plant SCADA tag is then adjusted to match the polling rate set for the group to which the related OFS item is allocated. Tags will be dynamically moved between the groups in response to changes in demand for an item.

It is possible to manually adjust the update rate for each group either globally or per I/O device. This requires adjustments to the `citect.ini` file, and is only recommended for advanced users.

See [Group Management Parameters](#).

## Source Timestamped Events Support

### Source Timestamped (TS) Event Group Support

Time stamped functionality is currently implemented and supported only for digital events. For configuration details refer to [TS Quality Support](#).

The driver creates a new OPC group to manage all OPC items with TS Event support. There is only one TS Event OPC group created per driver instance.

The driver creates and activates an OPC group called `##TSEventsGroup##` at start up and deactivates and removes that group at shutdown.

After the TS Event OPC group has been created, the driver periodically (every 500ms) signals that it is active by writing to the `<<system>>! #ClientAlive` OPC item.

As start up the driver reads the TS Event Support item property (Id: 5012) and adds those items which support TS Events to the TS Event Group.

After TS Event items have been added and activated the driver writes to the #TSEventSynchro item to get the current values of all TS Event items.

## Plant SCADA Configuration for Source TS Support - Ports and I/O Devices

There must be only one logical device and one port configured to communicate with all available TS Sources. This is to ensure the following

- Single client connection to OFS
- Driver issues only a single request to OFS for initial data from all available TS sources.

Accordingly, only one primary IO Device/Port and one Standby IO Device/Port can exist in the project in the case of redundancy.

## Compatibility

The driver initializes TS Event support only if the following conditions are true:

- Plant SCADA v7.20 or higher version is used.
- OFS Server v3.40 or higher version is used.
- EventServiceSupport setting in DeviceConfig.xml is set to True for a specific device alias.

**Note:** When the source event buffer in the PLC is full, any new events will not be stored. In this case the value of SOE\_Uncertain variable becomes TRUE. When the buffer becomes available again, the PLC will provide the values of all time-stamped event variables. As these values are timestamped with a current time, the time quality of these values will be set to Invalid. The SOE\_Uncertain is a variable in a time stamped event source whose value becomes TRUE when there is no space in the event buffer.

### **WARNING**

#### **LOSS OF ALARMS**

- To be able to detect that the event buffer is full, configure a tag and an alarm tag associated with the SOE\_Uncertain parameter in UnityPro.
- Respond quickly to a buffer full alarm if it appears, as this will avoid a situation where the buffer becomes inoperable.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

## TS Quality Support

TS Event OPC item have not only the value quality, but also the time quality associated with it. The time quality is provided in the high 8 bits of the OPC Quality Word which are available for vendor specific use:

- bits 7 to 0 - OPC quality flags,
- bits 15 to 8 - Timestamp quality.

The time quality is available in SCADA v7.20 only via a separate tag and it will be stored and displayed by the alarm system in SCADA v7.30.

Time quality is defined as follows:

- bits 4 to 0 – Time Accuracy

These bits represent a time accuracy (values 2-24) or one of the error codes:

- 27 Clock In Sync
- 28 TSInit
- 29 IO Channel error
- 30 Invalid
- 31 Unspecified
- bit 5 - Clock Not Synchronized
- bit 6 - Clock Failure
- bit 7 - Leaps Seconds Known

## Support for Version 7.20

Active Alarm page can be used to display time stamped event data received from the event source. However, to display the time quality of a time stamped event on the Active Alarm page, a separate variable tag needs to be configured in addition to the time stamped digital variable tag. This new variable tag should be created with the address <item\_ID>!Q and it represents the overall quality of the original digital variable tag, where:

<item\_ID> refers to the original digital variable tag address.

The value of this tag will include time quality information: the low 8 bits represent the Quality, Substatus and Limit status according to the OPC specification; the high 8 bits represent time quality. Details of the time quality values can be found in the section on Time Quality.

In addition, a custom Cicode function will need to be written to return a string representation of time quality. To display time quality in the runtime environment this Cicode function can be placed in the "Alarm Desc" field when configuring the time stamped digital alarm in configuration time. This time quality will be displayed at runtime under the "Desc" column on the Active Alarm page.

The Cicode function should utilize the high 8 bits and translate this to a string representing the description of the time quality.

For example:

```
STRING
FUNCTION GetTimeQuality(INT iQuality)
INT iHighByte = HighByte(iQuality);
SELECT CASE iHighByte
CASE 2 TO 24
RETURN "Time Accuracy ("+IntToStr(iHighByte)+")";
CASE 27
RETURN "Clock In Sync ("+IntToStr(iHighByte)+")";
CASE 28
```

```
RETURN "TSInit ("+IntToStr(iHighByte)+"")";  
CASE 29  
RETURN "IO Channel Error ("+IntToStr(iHighByte)+"")";  
CASE 30  
RETURN "Invalid ("+IntToStr(iHighByte)+"")";  
CASE 31  
RETURN "Unspecified ("+IntToStr(iHighByte)+"")";  
CASE 32 TO 63  
RETURN "Clock Not Synchronized ("+IntToStr(iHighByte)+"")";  
CASE 64 TO 127  
RETURN "Clock Failure ("+IntToStr(iHighByte)+"")";  
CASE 128 TO 255  
RETURN "Leaps Seconds Known ("+IntToStr(iHighByte)+"")";  
CASE ELSE  
RETURN "Unknown ("+IntToStr(iHighByte)+"")";  
END SELECT  
END
```

For the alarm configuration, enter the following in the alarm's "Desc" field:

GetTimeQuality(*Tag1\_TSQuality*),

where:

*Tag1\_TSQuality* is the associated time quality tag.

## Support for Version 7.30

Citect SCADA 7.30 introduced a Sequence of Events (SOE) page which displays historical events in a sequence of events (SOE) format. Each record represents a single change of an event. This page can be utilized to display time stamped event data including time quality.

There are two columns which can be used to display time quality on the Active Alarm and SOE pages:

1. "TSQuality" column. This column displays a string representation of a synthesis of the time quality  
The column value can be one of the following:
  - Time Good,
  - Time Uncertain,
  - Clock Not Synchronized.
2. "Quality" column. This column displays a numeric value of OPC quality flags: the low 8 bits represent the Quality, Substatus and Limit status according to the OPC specification; the high 8 bits represent time quality.  
Note that time quality is not displayed on the Active Alarm or SOE pages by default, the user will need to use one of the following options:
  - Modify [Format]Alarm and [Format]SOE ini parameters in order to display it.
  - Add these columns from "Add Columns" list on the page at run time and save the changes.

The user will have to include "TSQuality" and "Quality" column names in the list of columns in [Format]Alarm and [Format]SOE ini parameters.

For example:

[Format]Alarm = {Time, 101}{OnTime,101}{Tag,100}{Name,181}{TSQuality,100}{Quality, 50},

[Format]SOE = {Time, 101}{Message,250}{Source,100}{Name,181}{TSQuality,100}{Quality, 50}.

## Timestamp Event Replication

The driver implements the replication of event data between redundant driver instances in order to be certain that all TS events are pushed to the Alarm and Tran systems.

Event replication helps in a case when there is a lack of communication between the I/O server which receives events from the OFS and the Alarm Server.

For example in a system which has primary I/O server, standby I/O server and alarm server, the primary I/O server receives events from the OFS server. It pushes them to the alarm server and also replicates them to the standby I/O server. The standby I/O server stores these events in the event buffer.

In the case of a lack of communication between the primary I/O server and the alarm server, the primary I/O server will not be able to push events to the alarm server.

If during that time switchover happens (for example the primary I/O server was shut down), the standby I/O server will push its event buffer to the alarm server. The standby I/O server will store events data for 10 minutes. Also the size of the event buffer is limited to 300,000 events.

In a normal scenario when there is no lack of communication, the primary I/O server sends a confirmation message to the standby server after an event has been successfully propagated through the alarm system. On receiving that message, the standby I/O server deletes the corresponding event from the event buffer.

Also, if there is a lack of communication between the primary and standby I/O servers and the replication of events is not possible, the primary I/O server stores events received from the OFS for a limited time (10 min) and sends them to the standby I/O server after connection has been restored.

## Diagnostic Buffer Support

A diagnostic buffer is a list of alarm records that is stored internally on a number of PLCs that support a diagnostic buffer. This is configured and managed by the software application Unity Pro™.

For diagnostic buffer management, two sets of functions have been defined:

- [Record Browsing Interface](#)  
Functions designed to read diagnostic records from a PLC.
- [Device Resynchronization Interface](#)  
Functions designed to force the driver to resend the whole content of the diagnostic buffer.

## See Also

[Diagnostic Buffer Parameters](#)

### Record Browsing Interface

The following functions are designed to read diagnostic records from a PLC that supports diagnostic buffer.

- [GetNextEvent](#) - gets the next diagnostic buffer record and sets it as the current record.
- [GetEventField](#) - retrieves the value of the field identified by the key in the current record

# GetNextEvent

Gets the next diagnostic buffer record and sets it as the current record. The first call will retrieve the first record.

## Syntax

*GetNextEvent*

(This function has no parameters.)

## Return value

0 - if there are no more records

1 - if a new record has been read

# GetEventField

Retrieves the value of the field identified by the key in the current record.

This function assumes a previous call to GetNextEvent (to set the current record), otherwise it will return an empty string.

## Syntax

**GetEventField**(*Alarm key, Error ID, Network Num, ON Time, OFF Time, Ack Time, Status, Area, Fbcomment, FBInstanceName + FBPinName*)

- *Alarm key*

The key used to identify the alarm this event belongs to. This key is generated internally using instance name, pin name, and comment

- *Error ID*

Error ID generated by the PLC, used for acknowledgement

- *Network Num*

Allow to retrieve the PLC (DEVICE) that emits this record

- *ON Time*

Time of the occurrence of the event in the PLC (UTC seconds timestamp)

- *OFF Time*

Time of disappearance of event in the PLC (UTC seconds timestamp)

- *Ack Time*

Time of acknowledgement of the event in the PLC (UTC seconds timestamp)

- *Status*

Current status of the event. The status value can be interpreted as:

Bit	Title	0	1
0	Status	Disappeared	Active
1	Acknowledgment	Not acknowledged or acknowledgment not requested	Acknowledged
2	Need Acknowledge	Acknowledgment is not required	Acknowledgment is required
3	Deleted	Not removed	Removed
4	New	Existing alarm	New alarm
5	Auto dereg	no	Detected error has been simultaneously activated and deactivated

- *Area*

Area as defined in the PLC diagnostic buffer. This may or may not match the definition of area in Plant SCADA.

- *Fbcomment*

Comment associated with the instance of the FB for this anomaly

- *FBInstanceName + FBPinName*

Name of the instance of the FB that caused this anomaly + the pin name

## Return value

String value of the field.

## Device Resynchronization Interface

These methods force the driver to read every entry for a given device.

- [GetResendState](#) - indicates if a "ResendAll" operation for a particular device has been successful.
- [ResendAll](#) - triggers an explicit resend of any existing records in the current diagnostic buffer.

## GetResendState

Returns a value that indicates when a "ResendAll" operation for a particular device is complete and if it has been successful.

## Syntax

GetResendState(*in*)

- *in*  
Network number (short)

## Return value

Return value	Field key value	Description
Successful	0	Last ResendAll call was successful for the device.
Unsuccessful	1	Last ResendAll call was unsuccessful for the device.
In progress	2	A ResendAll operation is currently running on the specified device.
Invalid parameter	-1	Device not found.

# ResendAll

Triggers an explicit resend of existing diagnostic buffer records for the specified device.

## Syntax

ResendAll(*in*)

- *in*  
Network number (short)

## Return value

None

## Customizing a Project using Citect.ini Parameters

You can customize the way Plant SCADA communicates with the OFS system by creating or editing the [OFSOPC] section of the Citect.ini file for your project. However, the default values for these parameters have been determined by driver development and testing to be optimal for the OFSOPC driver.

- Driver-specific Parameters
- Group Management Parameters
- Logging Parameters
- BatchWrite Parameters
- Diagnostic Buffer Parameters
- Dynamic Status Item Parameters

## **WARNING**

### **UNINTENDED EQUIPMENT OPERATION**

- Do not under any circumstances change or remove any of the undocumented citect.ini parameters.
- Before deleting sections of the citect.ini file, confirm that no undocumented parameters will be deleted.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

When Plant SCADA starts at runtime, it reads configuration values from the Citect.ini file stored locally. Therefore, any OFS configuration settings needs to be included in the Citect.ini file located on the computer acting as the I/O server to the OFS system.

By default, Plant SCADA looks for the ini file in the Plant SCADA project \bin directory. If it can't find it there, it searches the default Windows directory.

### **Driver-specific Parameters**

## **WARNING**

### **UNINTENDED EQUIPMENT OPERATION**

- Do not under any circumstances change or remove any of the undocumented citect.ini parameters.
- Before deleting sections of the citect.ini file, confirm that no undocumented parameters will be deleted.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

[OFSOPC] Parameter	Allowable Values	Default Value	Description
ReadAfterWrite	0 - No read, rely on the normal polling/ OnDataChange mechanism.  1 - Force sync read of item	0	Determines if a force read should be made from the server cache or from the device.

	written from the server cache after write.  2 - Force sync read of item written from device after write.		
--	--	--	--

**Group Management Parameters****UNINTENDED EQUIPMENT OPERATION**

- Do not under any circumstances change or remove any of the undocumented citect.ini parameters.
- Before deleting sections of the citect.ini file, confirm that no undocumented parameters will be deleted.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

[OFSOPC] Parameter	Allowable Values	Default Value	Description
Group1UpdateRate	Any positive value less than Group2UpdateRate	400	Group 1 polling rate in milliseconds
Group2UpdateRate	Any positive value less than Group3UpdateRate	1000	Group 2 polling rate in milliseconds
Group3UpdateRate	Any positive value less than 2147483647	3000	Group 3 polling rate in milliseconds

**Note:** The default value will apply if a specified value does not fall within the range of allowable values.

The following example demonstrates how to override the group management parameter setting for a specific I/O device.

[OFSOPC]

<Cluster>.<IOServerName>.<IODeviceName>.<Parameter>=<Value>

where:

- <Cluster> = the name of the cluster configured in Plant SCADA
- <IOServerName> = the name of the I/O server to which the device is connected
- <IODeviceName> = the name given to the device in your project
- <Parameter> = the group management parameter you would like to overwrite
- <Value> = the update rate for the specified device in milliseconds

## Logging Parameters

### WARNING

#### UNINTENDED EQUIPMENT OPERATION

- Do not under any circumstances change or remove any of the undocumented citect.ini parameters.
- Before deleting sections of the citect.ini file, confirm that no undocumented parameters will be deleted.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

[OFSOPC] Parameter	Description	Allowable Values	Default Value
DebugLevel	The trace level used for the log file.	Any combination of the following, separated by a pipe character ( ):  ERROR WARN TRACE DEBUG ALL  See <a href="#">Logging</a> for examples.	-
DebugCategory	The categories used for the log file.	Any combination of the following, separated by a pipe character ( ):  TAG = tag debug NET = network level debug PROT = protocol level debug DCB = front end debug (i.e. I/O server) BUFF = buffer level debug THRD = thread level debug MISC = any other debugging ALL = all of the above  See <a href="#">Logging</a> for examples.	-

**Note:** These parameters do not have a value specified by default. To enable logging for this driver, you need to manually configure these parameters in your INI file.

## BatchWrite Parameters

### WARNING

#### UNINTENDED EQUIPMENT OPERATION

- Do not under any circumstances change or remove any of the undocumented citect.ini parameters.
- Before deleting sections of the citect.ini file, confirm that no undocumented parameters will be deleted.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

The BatchWriteTimeout parameter specifies the maximum period of time that the OFSOPC driver will wait to receive an 'End Batch-Write' command (i.e. a setting of BatchWrite = 0) following the commencement of a batch-write (BatchWrite = 1). This is required to avoid an infinite wait period.

[OFSOPC]Parameter	Allowable Values	Default Value	Description
BatchWriteTimeout	10 - 3600 (seconds)  (The default value will apply if the specified value exceeds these limits.)	30 (seconds)	Number of seconds to wait for BatchWrite = 0 to be written following the commencement of a batch-write (BatchWrite=1).  If BatchWrite remains set at 1 for this period of time, the system will send the write and set BatchWrite back to 0.

The following example demonstrates how to override the global setting for the BatchWriteTimeout parameter for a specific I/O device.

[OFSOPC]  
*<Cluster>.<IOServerName>.<IODeviceName>.BatchWriteTimeout=<Value>*

Where:

- *<cluster>* = the name of the cluster the I/O server belongs to
- *<IOServerName>* = the name of the I/O server to which the device is connected
- *<IODeviceName>* = the name given to the device in your project
- *<Value>* = the timeout value for the specified device in milliseconds

## Diagnostic Buffer Parameters

### WARNING

#### UNINTENDED EQUIPMENT OPERATION

- Do not under any circumstances change or remove any of the undocumented citect.ini parameters.
- Before deleting sections of the citect.ini file, confirm that no undocumented parameters will be deleted.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

[OFSOPC]Parameter	Allowable Values	Default Value	Description
EnableDiagBuffer	0 = disabled 1 = enabled	0	Enables or disables diagnostic buffer support
DiagnosticArea	Short (0-65535). The value needs to be added in decimal format. The value 0 means all areas are selected (same as 65535).	0	Allows you to filter the diagnostic buffer records according to their areas value.  There are 16 possible areas, and each bit of the word is used to manage one area.  Bit 0 corresponds to Area 0 ...  Bit 15 corresponds to Area 15.

## Dynamic Status Item Parameters

### WARNING

#### UNINTENDED EQUIPMENT OPERATION

- Do not under any circumstances change or remove any of the undocumented citect.ini parameters.
- Before deleting sections of the citect.ini file, confirm that no undocumented parameters will be deleted.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

By default, the driver subscribes to #PLCQualStatus to determine the current operational status of a device. It is also possible to specify a custom item value that the driver will check in addition to #PLCQualStatus. This can be

useful to confirm that the driver will put the I/O device offline if OFS becomes unresponsive.

The item value must be periodically changing in the PLC. If it stops, the driver will put the I/O device offline. This behavior is controlled by the following parameters.

[OFSOPC]Parameter	Allowable Values	Default Value	Description
DynamicStatusItemName	PLC item name	-	<p>This parameter specifies the item name that gets updated in PLC at a certain interval.</p> <p>Some system items are already programmed in the PLC and can be used to avoid changes to the PLC program.</p> <p>For example, %S4, %S5, %S6 have value updates every 5ms, 50ms, or 500ms correspondingly.</p>
DynamicStatusItemInterval	1 - 2147483647 (seconds)	0	<p>This parameter specifies the period which the driver will use to check the status of the item specified by the DynamicStatusItemName parameter.</p> <p>If the item value has not changed during the period specified, the driver will put the I/O device offline.</p> <p>For the system items %S4, %S5, %S6, the parameter can be set to 1 second.</p>

These parameters can only be specified for a specific I/O device using the syntax below.

[OFSOPC]  
*<Cluster>.<IOServerName>.<IODeviceName>.<Parameter>=<Value>*

Where:

- *<Cluster>* = the name of the cluster configured in Plant SCADA.
- *<IOServerName>* = the name of the I/O server to which the device is connected.
- *<IODeviceName>* = the name given to the device in your project.
- *<Parameter>* = the parameter name.
- *<Value>* = the parameter value.

## Performance Tuning

OPC is a standard protocol that is widely used in industrial automation systems. OPC is chosen for use to simplify and standardize PLC communication.

The OPC communications solution is based on an OPC DA server called OFS. OFSOPC is a dedicated driver implemented for Plant SCADA that connects the SCADA system to OFS.

### Communicating with PLCs through OFS

The performance of the communications between a Plant SCADA system and a PLC through OFS involves many factors other than just the driver, because of the number of components involved.

These components, each of which could be a bottleneck, are:

- PLC: depending on the firmware/hardware, the limitations may vary. The cycle time of the application may also have a large impact on the communications performance, because the PLC will process a predefined maximum number of requests per cycle.
- Network (PLC/OFS)
- OFS server: depending on its configuration and the application, OFS can be very demanding of CPU usage.
- OFSOPC Driver: depending on its configuration, it can affect the speed of communications.

These tuning suggestions only deals with the OFS/OFSOPC driver communications. For tuning other components, please refer to other relevant documents or specifications.

### See Also

[Tuning Parameters](#)

### Tuning Parameters

The implementation of the OFSOPC driver is based on the OPC standards but also takes into account specific enhancements in the current implementation of OFS that optimizes communications with Schneider Electric PLCs.

This section explains how to optimize the communications between PLCs and a Plant SCADA system through OFS. It presents generic principles to be adapted for each project depending on its specific needs.

It is written to optimize a configuration with OFSOPC driver 1.02.12.001 or greater, and OFS Server 3.35 or greater.

Tuning for performance consists of adjusting several configurations in both the [OFS Server](#) and the [OFSOPC Driver](#).

### OFS Server Configuration

The values provided in this section are recommended default values for SCADA usage. They can be adapted depending on project needs.

## OFS version

Use the latest version of OFS that is available. This information targets OFS V3.35, or greater.

## Processor affinity

In multi-processor machines, set the processor affinity of the OFS server so that it does not run on the same processor as the Plant SCADA I/O Server.

## Device Settings

These settings can be adjusted on a device-by-device basis (see [Device Settings](#)).

## Communications settings

- Sampling rate on reception
- Minimum group update rate
- QuickSetActive
- Communication Overrun behavior

See [Communications Settings](#).

## Summary of recommended OFS Configuration parameters

In summary, the recommended OFS parameter settings for optimal performance are as follows:

Parameter	Recommended Setting
Communication Overrun behavior	Rate adapt
MaxChannels	Equipment dependent, set to the same as the MaxPending value calculated by OFS.
MaxPending	0 (Equipment dependent. OFS to calculate a value).
Minimum group update rate	Rate <= Fastest Group rate / 2, and Rate is the greatest common divisor of the group rates (provided this doesn't violate the previous rule).
OFS version	3.35 or later
Processor affinity	Different to Plant SCADA I/O server
QuickSetActive	True
Sampling rate on reception	20ms

# Device Settings

## MaxPending

By default, in the OFS configuration, "MaxChannels" is set to 1, and "MaxPending" is set to 0.

A setting of MaxPending=0 means the OFS server automatically detects the PLC's target communications port and decides how many parallel requests may be sent at the same time. OFS will choose the appropriate MaxPending value using a predefined table of communications modules (NOE/COPRO/TSY...).

The runtime value being used by OFS can be seen in the OFS server, network window.

It is preferable to let OFS choose the value of the MaxPending parameter, unless a new release of firmware (after the last OFS server release) changes the capability of the device.

In case of multiple OFS connections to the same PLC (redundant IO Server), it is recommended to set MaxPending to "Used" value / Number of connection. The automatic calculation done by OFS is based on one single OFS-PLC connection.

## Max Channels

For Ethernet communications, it is advisable to set "MaxChannels" to the same value as the "MaxPending" value currently in operation in the OFS server.

Setting the MaxChannels parameter should be done after MaxPending has been optimized according to the recommendations above.

# Communications Settings

## Sampling rate on reception

The lower the value of this parameter, the better the response times for synchronous access will be. However, this parameter only affects CPU load on the PC on which OFS is installed and has no impact on the network bandwidth usage.

Typically, the sampling rate on reception should be set to 20ms.

## Minimum group update rate

OFS manages communications with devices based on the group update rate. This rate is the limit below which OFS will not accept OPC client requests.

To maximize performance, it is recommended to set this rate according to the following rules:

Rate  $\leq$  Fastest Group rate / 2, and

Rate is the greatest common divisor of the group rates (provided this doesn't violate the previous rule)

For example:

Group1UpdateRate = 400 ms

Group2UpdateRate = 800 ms

Group3UpdateRate = 2000 ms

Therefore, the recommended group update rate is 200 ms, (the greatest common divisor of the three group rates, which is also <= 400 /2).

**Note:** If your group rate is too high compared to your system capabilities then OFS will display a message "Polling rate overrun for ..." in OFS diagnostic window when "verbose" mode is set (Menu Misc/verbose).

The Quality of some of the items will then become uncertain (depending on Communication Overrun behavior). This quality will be propagated up to the Plant SCADA system, and therefore should be avoided.

Therefore a general rule is to set the OPC client's refresh rate to twice the calculated "OFS group scan time".

---

The OFS group scan time can be calculated with the formula:

TS=group average time (2) \* group number request (3) / max pending request used (1).

The different parameters of the equation are provided by the OFS server in "Varman" and "Network" windows.

## QuickSetActive

This parameter is new in OFS v3.35. It causes the value of an item to be read immediately after activation instead of waiting for the next cycle. This is useful, for example, in reducing the delay for first display of variables in a popup. Therefore, it should be set active.

## Communication Overrun behavior

This parameter allows deciding whether the overrun in OFS should be notified to Plant SCADA as a "Bad quality" or if the server should instead try to auto-adapt its own polling rate. Set this parameter to "rate adapt" to avoid some false "bad quality" when the load on the OFS server is high.

## OFSOPC Driver Parameters

### OFSOPC Driver Version

Use the latest version of OFSOPC that is available. This document targets OFSOPC 1.2.x, or greater.

## Group Management

The OFSOPC driver defines 3 groups per PLC. These groups are polled at a rate defined by the Group<i>UpdateRate parameter in citect.ini. Set these poll rates such that:

- Group1UpdateRate < Group2UpdateRate < Group3UpdateRate
- Group1UpdateRate < Alarm scan Time
- Group2UpdateRate < Trend sampling Time

The "Group Minimum Update rate" is different for each of these groups and can be set using OFS parameters.

The default values are:

Group1UpdateRate = 400 ms

Group2UpdateRate = 1000 ms

Group3UpdateRate = 3000 ms

Each requested tag will be activated in the group which provides the lowest (e.g. fastest) update rate that is faster than the requested rate. For example, a tag with a requested rate of 2s will be activated in Group 2 if the default values are being used.

If no group provides such a rate then the fastest one is used. For example tags requested at 200 ms with default configuration will be put in 400 ms group.

Usually Group 1 (the fastest group) is associated with tags in the active page and alarms. The Group 2 should be targeted for trends and the group 3 is mostly there for slow trends if they are configured.

With the default Plant SCADA configuration, the Group1 (400 ms) will contain alarms ([Alarm] ScanTime =500ms) and page items ([Page] ScanTime =250ms).

See [Group Management Parameters](#).

## Logging

The OFSOPC driver can log combinations of trace levels across different categories. This is achieved by setting the following Citect.ini parameters:

[OFSOPC]DebugLevel

[OFSOPC]DebugCategory

These settings have an impact on the performance of the driver and therefore it is recommended to switch them off by removing these parameters from the citect.ini file to get optimal performance.

See [Logging Parameters](#).

## MaxPending

This parameter defines the maximum number of pending commands that the OFSOPC driver holds for immediate execution. The default value is now 1200. If this value exists in Citect.ini, it should be updated (or removed to take into account this new default value).

This parameter is common to other drivers it is defined under [OPC] and not [OFSOPC] section in the Citect.ini file.

## Summary of recommended OFSOPC Configuration parameters

In summary, the recommended driver parameters settings for optimal performance are as follows:

Parameter	Recommended Setting
Group management [OFSOPC]Group1UpdateRate=G1 [OFSOPC]Group2UpdateRate=G2 [OFSOPC]Group3UpdateRate=G3	G1< G2< G3 G1 < Alarm scan time G2 < Trend sampling time G3 < slow trend sampling time The above are multiple number of the "Group Minimum Update Rate" in OFS parameters.
Logging [OFSOPC]DebugLevel	Remove/disable

Parameter	Recommended Setting
[OFSOPC]DebugCategory	
Commands	Remove/disable
[OPC]MaxPending	

## Troubleshooting

The following topics provide information about the Plant SCADA tools available to diagnose and resolve any unexpected behavior within the runtime system.

[Driver Errors](#)

[Driver Statistics](#)

[Logging](#)

### Driver Errors

Plant SCADA has two kinds of protocol driver errors: generic and specific.

- **Generic errors** are hardware errors 0-31, which are common to many protocols.
- **Specific errors** are unique to a particular driver.

When a driver specific error occurs, the hardware alarm system will not recognize it. The driver converts the specific error into a generic error that can be identified by the I/O server.

This means a driver error may be represented by a specific error, and a corresponding generic error.

When a hardware error occurs, Plant SCADA generates an alarm and displays it on the hardware alarm page. To see the error number, you need to have Alarm Category 255 defined with a display format that includes {ErrDesc,15} {ErrPage,10}.

Refer to the Plant SCADA Help for more information on generic hardware errors.

See the topic [OFSOPC Driver Specific Errors](#) for information on the errors specific to the OFSOPC driver.

If you need more information to resolve an error, refer to the documentation that accompanied the I/O device (or network). If, after reviewing the documentation, you still cannot solve your problem, contact Technical Support for this product.

### OFSOPC Driver Specific Errors

The following errors, listed in (hexadecimal) order, are specific to the Plant SCADA OFSOPC driver.

Error Value (Hex)	Error Definition	Error Description
0XC0040001	GENERIC_SOFTWARE_ERROR	Invalid handle was passed.
0XC0040002	GENERIC_SOFTWARE_ERROR	A duplicate parameter was passed where one is not allowed.

0xC0040004	GENERIC_INVALID_DATA_FORMAT	Server cannot convert between the passed or requested data type and the canonical type.
0xC0040006	GENERIC_ACCESS_VIOLATION	Item's access rights do not allow the operation.
0xC0040007	GENERIC_SOFTWARE_ERROR	Item definition does not exist within the server's address space.
0xC0040008	GENERIC_SOFTWARE_ERROR	Item definition does not conform to the server's syntax.
0xC004000B	GENERIC_INVALID_DATA_FORMAT	Value passed to WRITE was out of range.
0x80020008	GENERIC_SOFTWARE_ERROR	Bad variable type.
0x8002000A	GENERIC_SOFTWARE_ERROR	Out of present range.
0x80020005	GENERIC_SOFTWARE_ERROR	Type mismatch.
0x100	GENERIC_SOFTWARE_ERROR	Could not access variable dbf.
0x101	DRIVER_BAD_DATA	Read of data value bad.
0x102	GENERIC_GENERAL_ERROR	Write of one or more items not completed.
0x103	DRIVER_UNIT_OFFLINE	Could not resolve the server CLASSID.
0x104	GENERIC_SOFTWARE_ERROR	Could not add one or more items to the Server
0x80010006	GENERIC_CHANNEL_OFFLINE	Connection terminated
0x80010007	GENERIC_CHANNEL_OFFLINE	Server not available.
0x8001000F	GENERIC_INVALID_RESPONSE	Received data is invalid.
0x80010012	GENERIC_SOFTWARE_ERROR	Call did not execute.
0x80010100	GENERIC_SOFTWARE_ERROR	System call aborted.
0x80010101	GENERIC_SOFTWARE_ERROR	Could not allocate some required resource.
0x80010103	GENERIC_BAD_PARAMETER	Requested interface not registered on server object.
0x80010104	GENERIC_SOFTWARE_ERROR	Could not call server.

0x80010105	GENERIC_CHANNEL_OFFLINE	Server threw an exception.
0x80010108	GENERIC_CHANNEL_OFFLINE	Server has disconnected from its clients.
0x8001011B	GENERIC_CHANNEL_OFFLINE	Access denied.
0x8001011C	GENERIC_CHANNEL_OFFLINE	Remote calls not allowed for this process.

## Driver Statistics

You can use the following driver statistic counters to help you debug the OFSOPC driver. These statistics can be viewed within the Plant SCADA Kernel using the Page Driver command and then by pressing the 'v' key to select verbose mode.

See the topic *Runtime > Debug Runtime > The Kernel > Kernel Commands > Page Driver* in the main Plant SCADA help for more information.

Statistic	Description
Total Tags	Number of tags added to the OFSOPC driver, this might include the virtual tags.
# Uncertain Reads	The number of reads that cannot be completed immediately due to a stale cache value. When a tag is read that has uncertain quality, it will trigger item activation on the OFS server, allowing diagnosis of the tag status.
# OPC Item Updates	Number of items updated from OFS server via OnDataChange event.
# Read Unsuccessful	Number of unsuccessful ReadDCBs.
# Writes Unsuccessful	Number of unsuccessful WriteDCBs.
Pending DCB Size	Number of DCB not replied.
Pending Tasks	Number of tasks requested by the front-end and not served by the back-end driver.
Pending Write Tasks	Number of WriteDCBs not replied.
Completed Tasks	Number of tasks completed in the back-end.
Configured OPC Items	Number of OPC items added to the OFS server.
Bad OPC Items	Number of OPC items add to the OFS server unsuccessful.

Statistic	Description
Inactive Items	Number of deactivated OPC items (representing a total of the inactive items in groups 1, 2 and 3).
Temp Group Items	Number of items assigned to OPC temporary group. (This is the internal group used by the OFSOPC driver to hold temporary subscriptions.)
Group1 Items	Number of items assigned to OPC group 1.
Group2 Items	Number of items assigned to OPC group 2.
Group3 Items	Number of items assigned to OPC group 3.
Push Data Items	Number of items assigned to OPC push-data group. An item is considered a push-data item if its address is defined within the configured push-data address range.
Batch Write Units	Number of units that are currently have BatchWrite on mode.
Batch Write Items	Numbers of WriteDCBs in batch-write mode.

## Logging

The OFSOPC driver can log combinations of trace levels across different categories. This is achieved by setting the following INI parameters.

### [OFSOPC]DebugLevel

This parameter allows you to define the trace level. The options include:

Option	Description
WARN	Output warning messages.
ERROR	Output error messages.
TRACE	Output trace messages.
DEBUG	Output debug messages.
ALL	All of the above.

### [OFSOPC]DebugCategory

This parameter allows you to enable logging for a particular category of trace. The options include:

Option	Description
TAG	Tag debug.
NET	Network level debug.
PROT	Protocol level debug.
DCB	Front end driver trace.
BUFF	Buffer level debug.
THRD	Thread level debug.
MISC	Any other debugging.
ALL	All of the above.

In both cases, you can use any combination of the available options separated by a pipe character ( | ).

### Example

```
[OFSOPC]
DebugLevel=WARNING|ERROR|TRACE
DebugCategory=ALL
```

In most cases, you can set the DebugLevel and DebugCategory parameters to ALL. If this results in a large, cumbersome log file that causes older data to be overwritten, you can consider refining the debug options.

---

**Note:** These parameters do not have a value specified by default. To enable logging for this driver, you need to manually configure these parameters in your INI file.

The events generated by the OFSOPC driver are logged in the following Plant SCADA syslog file:

`syslog.IOServer.<Cluster name>.<IO Server name>.dat`

This file is located in the directory specified by the Citect.ini parameter **[CtEdit]Logs**. By default, this location will be:

`%PROGRAMDATA%\AVEVA Plant SCADA <VersionNumber>\Logs`

The size of the syslog file and its rollover process is configured via the **[Debug]SysLogSize** and **[Debug]SysLogArchive** INI parameters. For more information, see the topic *Debug Parameters* in the Plant SCADA documentation.

---

**Note:** If the number of messages being processed for a driver exceeds the value specified by the Plant SCADA parameter **[Kernel]ErrorBuffers**, the pending messages will not be logged. If this occurs, you can increase the value of this parameter so that all the messages generated by the driver are reported. The number of messages that are not logged can be monitored via the Kernel's General window under the item "Lost Errors". If you adjust **[Kernel]ErrorBuffers** and Lost Errors are still occurring, you may need to adjust the level of system logging.

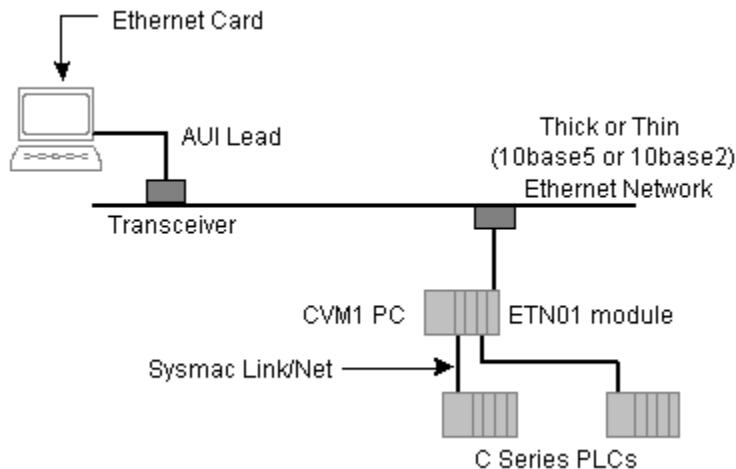

### See Also

[Logging Parameters](#)

## OMFINS Driver

The OMFINS driver allows Plant SCADA to communicate with Omron PLCs via UDP/IP. To enable this type of communication, a PLC needs to be supported by an Ethernet unit, such as a CV500-ETN01 or CV500-ETN21.

Using this method, you can connect to single PLCs or to multiple PLCs as in the following diagram:

**Note:** You can communicate with Omron PLCs using a variety of communication methods and/or protocols. To help decide which method to use for your system, see the topic [Communicating With Omron PLCs](#).

## Safety Information

### Hazard categories and special symbols

The following symbols and special messages may appear in this manual or on the product to warn of potential hazards or to call attention to information that clarifies or simplifies a procedure.

Symbol	Description
 or 	The addition of either symbol to a "Danger" or "Warning" safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.
	This is the safety alert symbol. It is used to alert you to personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.

### DANGER

**DANGER** indicates an imminently hazardous situation, which, if not avoided, will result in death or serious injury.

**⚠ WARNING**

**WARNING** indicates a potentially hazardous situation, which, if not avoided, can result in death or serious injury.

**⚠ CAUTION**

**CAUTION** indicates a potentially hazardous situation which, if not avoided, can result in minor or moderate injury.

**NOTICE**

**NOTICE** used without a safety alert symbol, indicates a potentially hazardous situation which, if not avoided, can result in property or equipment damage.

**Please Note**

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by AVEVA for any consequences arising out of the use of this material.

**Before You Begin**

Plant SCADA is a Supervisory Control and Data Acquisition (SCADA) solution. It facilitates the creation of software to manage and monitor industrial systems and processes. Due to Plant SCADA's central role in controlling systems and processes, you must appropriately design, commission, and test your Plant SCADA project before implementing it in an operational setting. Observe the following:

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not use Plant SCADA or other SCADA software as a replacement for PLC-based control programs. SCADA software is not designed for direct, high-speed system control.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**⚠ WARNING****LOSS OF CONTROL**

- The designer of any control scheme must consider the potential failure modes of control paths and, for certain critical control functions, provide a means to achieve a safe state during and after a path failure. Examples of critical control functions are emergency stop and overtravel stop, power outage and restart.
- Separate or redundant control paths must be provided for critical control functions.
- System control paths may include communication links. Consideration must be given to the implications of unanticipated transmission delays or failures of the link.
- Observe all accident prevention regulations and local safety guidelines.<sup>1</sup>
- Each implementation of a control system created using Plant SCADA must be individually and thoroughly tested for proper operation before being placed into service.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

1. For additional information, refer to NEMA ICS 1.1 (latest edition) "Safety Guidelines for the Application, Installation, and Maintenance of Solid State Control", and to NEMA ICS 7.1 (latest edition) "Safety Standards for Construction and Guide for Selection, Installation and Operation of Adjustable-Speed Drive Systems" or their equivalent governing your particular location.

## Communicating with Omron PLCs

Omron PLCs support a variety of communications methods and protocols including standards such as DeviceNet and Profibus. They also support some native protocols, including:

- Sysmac Way (also called HostLink) - a simple serial protocol supported by every Omron PLC.
- FINS (Factory Intelligent Network Service) - a network protocol using UDP/IP that supports networked PLCs.

Plant SCADA provides the following drivers to support these communication methods:

- **OMRON Driver** - which implements the Sysmac Way serial protocol
- **OMFINS Driver** - which natively implements the FINS protocol
- **FINS Driver** - which uses FINS Gateway middle ware to communicate using the FINS protocol.

To support communication with the FINS gateway middleware, Plant SCADA also includes a low level FINS transport driver.

Complicating the issue further is the fact the range of Omron PLCs is logically split into three distinct series:

Omron PLC Series	PLC Model
Series 1	<b>C Series</b> - including C20, C**P, C**K, C120, C500, C1000H, C2000, C2000H, C**H, CPM1*, CPM2*, CQM1, CQM1H, C200H, C200HS, C200HE, C200HG, C200HX, IDSC and SRM1 PLCs
Series 2	<b>CV, CVM1 Series</b> - including all CV*** and CVM1 CPUs
Series 3	<b>CP, CJ/CS, NSJ Series</b> - including all CP1, CJ1, CS1 and NSJ controllers

The differences between each series is most noted when using Serial communication. Plant SCADA's **OMRON** driver is designed for serial communication with only Series 1 devices. It is based on Omron's native C-Mode HostLink protocol, which is too simplified to support all the tag types required by the Series 2 and 3 devices. Therefore, serial communication with these devices is based on the FINS encapsulation protocol, which requires Plant SCADA's **OMFINS** driver.

Each series also requires Plant SCADA to provide a separate variant of the FINS and OMFINS drivers. Each variant is indicated within a project configuration by a numeric suffix on the driver name, i.e. OMFINS1, OMFINS2, OMFINS3.

The following table should help you decide which Plant SCADA driver you will need to use to communicate with a specific Omron device.

Omron PLC Series	Communication method	Transport Driver	Plant SCADA Driver
Series 1 (C devices)	Serial	COMx	OMRON
	Ethernet	TCP/IP	OMFINS1
	FINS Gateway	FINS	FINS1
Series 2 (CV, CVM1)	Serial	COMx	OMFINS2
	Ethernet	TCP/IP	OMFINS2
	FINS Gateway	FINS	FINS2
Series 3 (CP, CJ/CS, NSJ)	Serial	COMx	OMFINS3
	Ethernet	TCP/IP	OMFINS3
	FINS Gateway	FINS	FINS3

## Omron PLCs via Ethernet

The OMFINS protocol supports UDP/IP communication with the Omron PLCs via the Omron CV500-ETN01/21 Ethernet modules.

Communication is via UDP/IP over Ethernet. The commands within the UDP packets use OMRON Factory Interface Network Service (FINS). The CV-series Ethernet interface uses binary code in its packets - these will be

automatically translated to/from ASCII if passed through a gateway to another SYSMAC network which requires ASCII.

This protocol requires only Winsock TCP/IP software to be installed in your computer. No Omron hardware or software is required on your Plant SCADA workstation. The maximum request length for the OMFINs protocol is 996 words for Ethernet. 512 bytes if also going via other OMRON networks.

The CV500-ETN01/21 has a DIX connector that requires an AUI cable to attach via a transceiver to the thin or thick Ethernet backbone network cable. By installing other network units such as SYSMAC NET Link (SNT) or SYSMAC LINK (SLK) in the Programmable Controller CPU Bus which also contains an ETN unit, Plant SCADA can communicate with any unit on these other networks using FINS commands with the appropriate node/unit addresses.

The same Ethernet card that is being used for Plant SCADA communication can be used for PLC communication.

## Device Address

The information you enter here will be placed in the Special Options field in the Ports settings, with the following format:

**-Ia -Pn -U**

where:

- **a** = the destination IP address in standard Internet dot format. (For example, 192.9.2.60)
- **n** = the destination port (UDP socket) number. Often one physical port has several virtual ports, used for different purposes. The acceptable range is 1024 to 65535, with the default being 9600.
- **-U** = forces the driver to use UDP rather than TCP.

---

**Note:** Declare a separate port for each CV PC on the network.

---

## Unit Address

The I/O Device Address for a Omron CV Series PC is specified as follows:

**w/n/u** (there are no defaults)

Where

- **w** is the FINS network address (1-127)
- **n** is the FINS node number (1-126)
- **u** is the FINS PC Bus unit number (0-15)

Specify the FINS network address, node number, unit number. The FINS node number must be the same as the IP address node number. The FINS network number must be the same for all ETN's on the Ethernet segment.

Note also there is no relationship between FINS network numbers and IP network numbers.

Some examples:

IO Server IP address	IO Server net mask	PC node number	Resultant PC IP address
a.b.c.d	255.255.255.0	10	a.b.c.10
a.b.c.d	255.255.0.0	10	a.b.0.10

## Hardware Setup

Addressing and communication information must be loaded into the system setup area using CVSS or other programming device. Consult the SYSMAC CV-series Ethernet manual for details of installation of the Ethernet unit (ETN) and options available.

## OMRON CV500-ETN01 Settings

Set the front panel switches to the following:

- UNIT (01-15) note that 00 appears to be used for the CPU (e.g.01)
- NODE(1-126) must be unique for each ETN module(s) sharing a FINS network (e.g 06)

Be certain that the OMFINS Source parameter is correctly set (see [OMFINS Parameters](#)).

## Discussion

In the simplest scenario, the last 8 bits of the IP address are the same as the ETN node number - i.e. in the IP address a.b.c.d, 'd' is the same as the node number. The UDP port number must also be set at installation. The same UDP port must be used for all ETN units on a network, and the default port value is 9600.

Communications is done using the FINS protocol inside UDP/IP packets. The addresses used with FINS are the network number, the node number and unit number. The network number is in the range 1-127 (or 0 for local), the node number in the range 1-126 is unique for each Programmable Controller on the network (which may include interconnections to other OMRON networks as well as Ethernet ones). The unit number in the range 0-15 is unique for each CPU bus unit (including the ETN unit) installed in a particular Programmable Controller.

The node number and unit number are set by front panel switches, while the network number is configured with CVSS. As well as supporting FINS over UDP, the ETN unit supports standard TCP, FTP and ICMP (ping).

## Plant SCADA Computer Setup

Set up your specific Ethernet card as required and confirm basic network communications before proceeding with the communications configuration for the OMFINS driver. Refer to the documentation accompanying your hardware for instruction.

---

**Note:** Setup the UDP/IP protocol on your Plant SCADA computer.

---

## Communication Settings

To establish communication with a device, configure the associated Board, Port and I/O Devices in Plant SCADA Studio's **Topology** activity. If you use the Express Communications Wizard to connect to a device, these settings will be automatically configured for you. However, if you need to manually configure or verify these settings, use the values outlined below.

## Board Settings

Field	Value
Board Type	Enter TCPIP.
Address	Enter 0.
I/O Port	Leave this field blank.
Interrupt	Leave this field blank.
Special Options	Leave this field blank.

## Port Settings

Field	Value
Port Number	Leave this field blank.
Baud Rate	Leave this field blank.
Data Bits	Leave this field blank.
Stop Bits	Leave this field blank.
Parity	Leave this field blank.
Special Options	<p>Enter the destination IP address of Ethernet module. Use the following format:</p> <p><b>-la -Pn -U</b></p> <p>where:</p> <p><b>a</b> = the destination IP address in standard Internet dot format. (For example 192.9.2.60)</p> <p><b>n</b> = the destination port (UDP socket) number. Often one physical port has several virtual ports, used for different purposes. Use this option only if you want to override the default of 9600. The acceptable range is 1024 to 65535.</p> <p><b>-U</b> = forces the driver to use UDP , rather than TCP. Only use this if required.</p> <p>A separate Port should be declared for each CV PC on the network.</p>

## I/O Device Settings

Field	Value
I/O Device Address	<p>The station address for an Omron CV Series PC is specified as follows:</p> <p><b>w/n/u/V</b> for CV mode</p> <p>or</p> <p><b>w/n/u/S</b> for CS1 mode</p> <p>where</p> <p><b>w</b> is the FINS network address (1-127)</p> <p><b>n</b> is the FINS node number (1-126)</p> <p><b>u</b> is the FINS unit address (0)</p> <p>There are no defaults for w, n, or u, but if you do not specify a mode (with a V or S), it will default to CV mode.</p> <p>The FINS node number should be the same as the IP address node number. The FINS network number should be the same for all ETNs on the Ethernet segment.</p> <p>There is no relationship between FINS network numbers and IP network numbers.</p>
I/O Device Protocol	Enter OMFINS

## Examples:

IO Server IP address	IO Server net mask	PC node number	Resultant PC IP address
a.b.c.d	255.255.255.0	10	a.b.c.10
a.b.c.d	255.255.0.0	10	a.b.0.10

## Data Types

Omron's range of PLCs is logically split into three distinct series:

Omron PLC Series	PLC Model
Series 1	<b>C Series</b> - including C20, C**P, C**K, C120, C500, C1000H, C2000, C2000H, C**H, CPM1*, CPM2*, CQM1, CQM1H, C200H, C200HS, C200HE, C200HG, C200HX, IDSC and SRM1 PLCs
Series 2	<b>CV, CVM1 Series</b> - including all CV*** and CVM1 CPUs
Series 3	<b>CP, CJ/CS, NSJ Series</b> - including all CP1, CJ1, CS1 and

Omron PLC Series	PLC Model
	NSJ controllers

Each series has the same memory areas, but different ranges. For this reason, the supported data types for each series are tabled separately.

- Omron 'Series 1' Devices
- Omron 'Series 2' Devices
- Omron 'Series 3' Devices

The following notation is used within the tables:

Enclosing square brackets ([ ]) mean the content is optional and may be omitted.

In some cases, however (where the native tag type can be either DIGITAL or INT), the inclusion of optional content may define the tag type. For example:

- CIO123 is INTEGER
- CIO123.9 becomes DIGITAL (i.e. [.9] changes the tag's type)

**Native type** means default type for a given tag address.

**No Write Command** means that the tag is read-only.

**S.MODE** tag can be written to (unlike other status tags). The allowable write values are "Go to RUN mode" and "Go to MONITOR mode". For the OMFINS driver, RUN=2 and MONITOR=4.

### Omron 'Series 1' Devices

Data Type	Address Format	Native Type	Range
Status (word 1 byte 1) Status (word 1 byte 2) Status (words 3 - 5)	S.STATUS S.MODE S.FATAL S.NFATAL S.ERRCODE	INT (anything else will give #COM)	
Status (error message)	S.ERRMSG	STRING	
CIO Area	[CIO]x[.y]	INT / DIGITAL	x = 0-511 y = 0-15
LR Area	L[R]x[.y]	INT / DIGITAL	x = 0-63 y = 0-15

Data Type	Address Format	Native Type	Range
HR Area	H[R]x[y]	INT / DIGITAL	x = 0-99 y = 0-15
AR Area	A[R]x[y]	INT / DIGITAL	x = 0-27 y = 0-15
Timer Area Completion Flag	TFx	DIGITAL	x = 0-511
Counter Area Completion Flag	CFx	DIGITAL	x = 0-511
Timer Area PV	Tx	INT	x = 0-511
Counter Area PV	Cx	INT	x = 0-511
DM Area	D[M]x[y]	INT / DIGITAL	x = 0-9999 y = 0-15
Expansion DM Area Current Bank	E[M]x[y]	INT / DIGITAL	x = 0-6143 y = 0-15
Expansion DM Area Any Bank	E[M]b:x[y]	INT / DIGITAL	b = 0-15 x = 0-6143 y = 0-15
EM Area Current Bank Number	EMN	INT / DIGITAL	

**Omron 'Series 2' Devices**

Data Type	Address Format	Native Type	Range
Status (word 1 byte 1) Status (word 1 byte 2) Status (words 3 – 6)	S.STATUS S.MODE S.FATAL	INT (anything else will give #COM)	

Data Type	Address Format	Native Type	Range
	S.NFATAL S.MSG S.ERRCODE		
Status (error message)	S.ERRMSG	STRING	
CIO Area	[CIO]x[.y]	INT / DIGITAL	x = 0-2555 y = 0-15
LR Area	L[R]x[.y]	INT / DIGITAL	x = 0-199 y = 0-15
AR Area	A[R]x[.y]	INT / DIGITAL	x = 0-511 y = 0-15
Timer Area Completion Flag	TFx	DIGITAL	x = 0-1023
Counter Area Completion Flag	CFx	DIGITAL	x = 0-1023
Timer Area PV	Tx	INT	x = 0-1023
Counter Area PV	Cx	INT	x = 0-1023
DM Area	D[M]x[.y]	INT / DIGITAL	x = 0-24575 y = 0-15

Data Type	Address Format	Native Type	Range
CPU Bus Link Area	Gx[.y]	INT / DIGITAL	x = 0-255 y = 0-15
TR Area	TR[.y]	INT / DIGITAL	y = 0-15
Step Area	STx	INT	x = 0-1023
Step Area Flag	STFx	DIGITAL	x = 0-1023
Transition Area Flag	TNx	DIGITAL	x = 0-1023
Action Area Flag	ACx	DIGITAL	x = 0-2047
Data Register	DRx	INT	x = 0-2
Index Register	IRx	INT	x = 0-2
Expansion DM Area Current Bank	E[M]x[.y]	INT / DIGITAL	x = 0-32765 y = 0-15
Expansion DM Area Any Bank	E[M]b:x[.y]	INT / DIGITAL	b = 0-7 x = 0-32765 y = 0-15

Data Type	Address Format	Native Type	Range
Expansion DM Area Current Bank Number	EMN	INT	

**Omron 'Series 3' Devices**

Data Type	Address Format	Native Type	Range
Status (word 1 byte 1) Status (word 1 byte 2) Status (words 3 – 6)	S.STATUS S.MODES.FATAL S.NFATAL S.MSG S.ERRCODE	INT (anything else will give #COM)	
Status (error message)	S.ERRMSG	STRING	
CIO Area	[CIO]x[.y]	INT / DIGITAL	x = 0-6143 y = 0-15

## OMFINS Parameters

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

## [OMFINS]Block

A value (bytes) used by the I/O Server to determine if two or more packets can be blocked into one data request before being sent to the I/O Device. For example, if you set the value to 10, and the I/O Server receives two simultaneous data requests - one for byte 3, and another for byte 8 - the two requests will be blocked into a single physical data request packet. This single request packet is then sent to the I/O Device, saving on bandwidth and processing.

**Allowable Values** 5 to 256

**Default Value** 64

## [OMFINS]Delay

The period (in milliseconds) to wait between receiving a response and sending the next command.

**Allowable Values** 0 to 300 (milliseconds)

**Default Value** 0

## [OMFINS]IgnoreNonFatalError

Determines whether Plant SCADA will stay online if the remote rack is powered off.

**Allowable Values** 0 (recoverable errors not ignored) or 1 (recoverable errors ignored)

**Default Value** 0

## [OMFINS]MaxPending

The maximum number of pending commands that the driver holds ready for immediate execution.

**Allowable Values** 1 to 32

**Default Value** 2

## [OMFINS]PollTime

The interrupt or polling service time (in milliseconds). Setting the polling time to 0 puts the driver in interrupt mode.

**Allowable Values** 0 to 300 (milliseconds)

**Default Value** 0

## [OMFINS]Retry

The number of times to retry a command after a timeout.

**Allowable Values** 0 to 8

**Default Value** 1

## [OMFINS]Source

Specify the FINS network address, node number and unit number for the Plant SCADA I/O server. This will be the source address of messages from Plant SCADA, and the destination address of responses from the PCs.

**Format** w/n/u where:

w is s the FINS network address (1-127)

n is the FINS node number (1-126)

u is the FINS unit number (0-15)

**Default Value** 1/1/0

## [OMFINS]Timeout

Specifies how many milliseconds to wait for a response before displaying an error message.

**Allowable Values** 0 to 32000 (milliseconds)

**Default Value** 1000

## [OMFINS]WatchTime

The frequency (in seconds) that the driver uses to check the communications link to the I/O Device.

**Allowable Values** 0 to 128 (seconds)

**Default Value** 30

## Port/IO Device-specific Parameters

To apply a parameter globally to every device, place it under the [OMFINS] section of the Citect.ini file.

To apply a parameter to a specific device, or every device connected to a specific port, use one of the following sections in the Citect.ini file:

- [OMFINS.<PortName>]
  - <PortName> is the name specified for the port in your Plant SCADA project.  
For example, parameters set within the section [OMFINS.PrimaryPort1] impact every device connected to the port defined as "PrimaryPort1".
- [OMFINS.<PortName>.<DeviceName>]
  - <PortName> defines the name specified for the port in your Plant SCADA project.
  - <DeviceName> defines the name of the I/O device.  
For example, parameters set within the section [OMFINS.PrimaryPort1.PrimaryIODev128] only impact

the device connected to the port defined as "PrimaryPort1" and named "PrimaryIODev128."

You can set the following parameters for a specific I/O device:

- Source
- Block
- Delay
- IgnoreNonFatalError

You can set the following parameters for a specific port:

- Source
- Block
- Delay
- IgnoreNonFatalError
- Retry
- Timeout

## Example

The following **Citect.ini** file format is an example of specifying the source parameter differently for different I/O devices communicating with the OMFINS PLC.

Assume that there are two ports in use: PORT1 and PORT2.

- PORT1 has two I/O devices attached: DEV1A and DEV1B.
- PORT2 has two I/O devices attached: DEV2A and DEV2B.

The **Citect.ini** file contains the following entries:

```
[OMFINS]
Source = 1/0/0
[OMFINS.PORT1]
Source =1/0/1
[OMFINS.PORT2]
Source =1/1/0
[OMFINS.PORT1.DEV1A]
Source =0/1/0
[OMFINS.PORT2.DEV2B]
Source =1/1/1
```

The resultant sources for the I/O devices are as follows:

I/O Device	Source	A result of
DEV1A	0/1/0	[OMFINS.PORT1.DEV1A]
DEV1B	1/0/1	[OMFINS.PORT1]
DEV2A	1/1/0	[OMFINS.PORT2]
DEV2B	1/1/1	[OMFINS.PORT2.DEV2B]

## Protocol-specific Parameters

Plant SCADA uses three variations of the OMFINS driver to support the three Omron PLC Series (see [Communicating with Omron PLCs](#)).

To apply a parameter to a specific protocol version, place it under the following section of the Citect.ini file:

[OMFINSx]

Where:

- x = 1 (Series 1)
- x = 2 (Series 2)
- x = 3 (Series 3)

For example, parameters set within the section [OMFINS2] will only impact the device defined to use the OMFINS2 protocol variant.

You can set the following parameters for a specific protocol:

- MaxPending
- PollTime
- WatchTime

See [OMFINS Parameters](#).

## OMFINS Driver Errors

In addition to standard driver errors, the OMFINS driver may use the following driver errors:

Driver Error	Explanation
<b>0x10001</b> (Bad response)	this error means the amount of data received back does not match what was requested (e.g. requested was for two LONGs, but received 7 bytes back instead of 8 bytes).
<b>0x10002</b> (Bad request)	this error indicates that you are trying to write the wrong amount of data for a given type

Driver Error	Explanation
<b>0x10003</b> (Bad tag type)	this error indicates a request cannot be serviced because the tag is not of the native type (e.g. S.MODE must be an INT, but it was configured as a LONG)

## OMFINS Specific Errors

When a hardware error occurs, Plant SCADA generates an alarm, and displays the alarm on the hardware alarm page (in the alarm description of the hardware alarm). To see the error number, you need to have Alarm Category 255 defined with a display format that includes {ErrDesc,15} {ErrPage,10}.

There are a number of generic errors that are common to many protocols. In some cases, only the generic error is available, though often both the generic error and a specific error are given.

The following errors, listed in (hexadecimal) sequence, are specific to this protocol. Plant SCADA displays the error number and description for common protocol-specific errors. Uncommon errors are not contained in the Plant SCADA error database, in which case Plant SCADA will only display the error number.

You may require additional information to enable you to rectify an error. This information should be detailed in the documentation that accompanied the I/O Device (or network). If, after reviewing the documentation, you cannot rectify an error, contact Technical Support for this product.

Messages return a FINS response code. This is two bytes, the main response code and the sub-response code. Response codes are shown in the second table presented. If bit 6 or 7 of the sub-response code is on, the error has occurred in the PC returning the response. If the main response code has bit 7 set, a network relay error has occurred - in this case a further two words will be returned to the driver indicating the location of the error. In the following table response codes are listed in hexadecimal, with xx indicating any value here will return the same generic errors. The two-byte response code will be returned as the Plant SCADA driver error (except for 0001, which will be returned as -1).

Response codes (hex)	Plant SCADA generic error
0000	NOERROR
0001 (returned as -1)	INVALID_RESPONSE
0101, 0102, 0105, 0106, 0201, 0202, 0203, 0304, 0402, 05xx, 20xx	GENERAL_ERROR
0103, 0104, 0204, 0205, 25xx	UNIT_TIMEOUT
0301, 0303, 0302, 22xx, 2301, 2303, 24xx	HARDWARE_ERROR
0401, 10xx, 11xx, 2302	INVALID_COMMAND
21xx	WRITE_PROTECT

Main Code	Sub-Code	Probable Cause	Remedy
00: Normal Completion	00	---	---
01:Local node error	03	Send error in local node was caused by lack of available space in internal buffers	Reduce the load (traffic) on the Ethernet Unit. Check your user applications.
02: Remote node error	01	IP address of remote node not set correctly in IP address table or IP router table	Set IP address of remote node into IP address table and, if inter network transmission is required, into the IP router table.
	02	No node with the specified unit address	Check the remote node's unit address and make sure the correct one is being used in the control data.
	05	Message packet was corrupted by transmission error.	Check the protocol and controller status by reading them with FINS commands. Increase the number of transmit retry attempts.
		Response time-out, response watchdog timer interval too short.	Increase the value for the response monitor time in the control data.
		The transmission frame may be corrupted or the internal reception buffer full.	Read out the error log and correct as required.
03: Communications controller error	01	Error occurred in the communications controller, ERC indicator is lit.	Take corrective action, referring to troubleshooting procedures in this section

	02	CPU error occurred in the PC at the remote node.	Check CPU indicators at the remote node and clear the error in the CPU (refer to the PC's operation manuals)
	04	Unit number setting error	Check that the unit number is specified within range and that the same unit number is not used twice in the same network.
04: Not executable (service not supported)	01	An undefined command has been used.	Check the command code is supported by the Unit to which you are sending it
		A short frame (4 bytes) is being used for the FINS header frame.	Check the FINS header frame length. The Ethernet Unit does not support short headers.
05: Routing error	01	Remote node is not set in the routing tables	Set the remote node in the routing tables
	02	Routing tables aren't registered completely	Set routing tables at the local node, remote node, and any relay nodes.
	03	Routing table error	Set the routing tables correctly
	04	The maximum number of relay nodes (2) was exceeded in the command.	Redesign the network or reconsider the routing table to reduce the number of relay nodes in the command. Communications are possible on three network levels, including the local network.
10: Command format	01	The command is longer	Check the command

error		than the max. permissible length.	format of the command and set it correctly. Verify that broadcast transmissions don't exceed 1,473 bytes.
	02	The command is shorter than minimum permissible length	Check the command format of the command and set it correctly
	03	The designated number of data items differs from the actual number in the command data.	Check the number of items and the data agree
	05	Data for another node on the same network was received from the network	Check the header parameters in the command data, and that the correct command format is being used.
		An attempt was made to send response data for a broadcast address.	
11: Parameter error	00	The parameters in the command data were incorrect or the UDP/TCP socket number was not within the proper range.	Check the parameters, and that the socket number is between 1 and 8.
	01	A correct memory area code has not been used or Expansion Data Memory is not available	Check the command's memory area code and set the appropriate code.
	03	The first word is in an inaccessible area or the bit number is no 00.	Set a first word that is in an accessible area. The bit number needs to be 00 for Ethernet Units.
22: Status error	0F	The same socket service is already in progress at	Use the socket status flag in PC memory to

		the specified socket number.	check that socket service has finished before starting services again.
	10	The specified socket is not open	Open the socket. For TCP sockets, wait until connection is made.
23: Environment error	05	IP address conversion incomplete	Check the IP address and subnet mask in the System Setup are correct.
	07	IP address conversion is set for automatic conversion only.	Check the mode settings in the System Setup. This error will be generated for the READ IP ADDRESS command only.
25: Unit error	03	I/O setting error (The I/O table differs from the actual Unit configuration.)	Either change the actual configuration to match the registered one, or generate the I/O table again.
	05	CPU bus error (An error occurred during data transfer between the CPU and a CPU Bus Unit.)	Check the Units and cable connections and send the ERROR CLEAR command.
	0A	An error occurred during CPI Bus Unit data transfer.	Check the Units and cable connections and send the ERROR CLEAR command.

See 9-3 Troubleshooting via response codes of SYSMAC CV-series Ethernet System Manual pages 109-114 of FINS commands reference (section 8-3)

### Example:

Plant SCADA Error 18501 response code = 0501, (main response = 5, sub response = 1)

Driver Err: 18501 for an incorrect routing table, with relay error flag set

Refers to the error bit preceding the main response code which should be masked, as per the two bits preceding

the sub response code.

Thus if main = 5, sub = 1 then error 10501

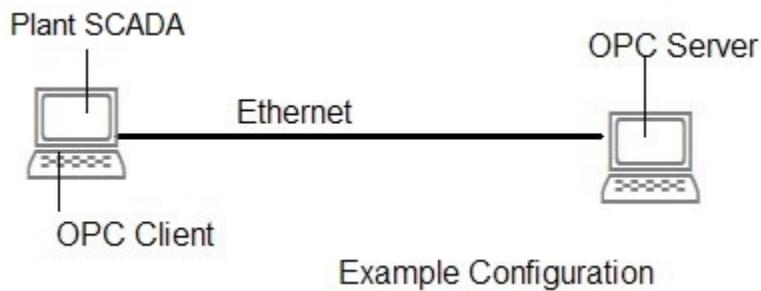

Returned code: [0001][1000][0101][0000][0001] -> 18501

Mask red bits: [1111][0111][1111][0011][1111]

Presented code: [0001][0000][0101][0000][0001] -> 10501

## OPC Driver

The OPC method of communication to OPC devices uses the OPC driver. OPC specifications v1.0a and v2.0 are supported. Using this method you can connect to single or multiple OPC devices, as shown in this example configuration:

The OPC server can also exist on the same computer as the OPC client. Be reminded that the maximum request length (that is, the maximum of data bits that can be read from the I/O device at any one time) for the OPC protocol is 2040.

**Note:** With the release of version 7.20, Plant SCADA supports the retrieval of time-stamped data directly from field devices. This capability is enabled by the Driver Runtime Interface (DRI), a component of Plant SCADA that is used by the OPC driver to directly update time-stamped digital alarms, time-stamped analog alarms and event-based trends. For more information, see the topic *Retrieving Time-stamped Data from Field Devices* in the main Plant SCADA help.

## Safety Information

### Hazard categories and special symbols

The following symbols and special messages may appear in this manual or on the product to warn of potential hazards or to call attention to information that clarifies or simplifies a procedure.

Symbol	Description
 or 	The addition of either symbol to a "Danger" or "Warning" safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.
	This is the safety alert symbol. It is used to alert you to personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.
<b>⚠ DANGER</b>	<b>DANGER</b> indicates an imminently hazardous situation, which, if not avoided, will result in death or serious injury.
<b>⚠ WARNING</b>	<b>WARNING</b> indicates a potentially hazardous situation, which, if not avoided, can result in death or serious injury.
<b>⚠ CAUTION</b>	<b>CAUTION</b> indicates a potentially hazardous situation which, if not avoided, can result in minor or moderate injury.
<b>NOTICE</b>	NOTICE used without a safety alert symbol, indicates a potentially hazardous situation which, if not avoided, can result in property or equipment damage.

## Please Note

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by AVEVA for any consequences arising out of the use of this material.

## Before You Begin

Plant SCADA is a Supervisory Control and Data Acquisition (SCADA) solution. It facilitates the creation of software to manage and monitor industrial systems and processes. Due to Plant SCADA's central role in controlling systems and processes, you must appropriately design, commission, and test your Plant SCADA project before implementing it in an operational setting. Observe the following:

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not use Plant SCADA or other SCADA software as a replacement for PLC-based control programs. SCADA software is not designed for direct, high-speed system control.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**⚠ WARNING****LOSS OF CONTROL**

- The designer of any control scheme must consider the potential failure modes of control paths and, for certain critical control functions, provide a means to achieve a safe state during and after a path failure. Examples of critical control functions are emergency stop and overtravel stop, power outage and restart.
- Separate or redundant control paths must be provided for critical control functions.
- System control paths may include communication links. Consideration must be given to the implications of unanticipated transmission delays or failures of the link.
- Observe all accident prevention regulations and local safety guidelines.<sup>1</sup>
- Each implementation of a control system created using Plant SCADA must be individually and thoroughly tested for proper operation before being placed into service.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

1. For additional information, refer to NEMA ICS 1.1 (latest edition) "Safety Guidelines for the Application, Installation, and Maintenance of Solid State Control", and to NEMA ICS 7.1 (latest edition) "Safety Standards for Construction and Guide for Selection, Installation and Operation of Adjustable-Speed Drive Systems" or their equivalent governing your particular location.

## Preparing the OPC System

This section explains how to prepare your OPC devices for communication with Plant SCADA.

- [Hardware Requirements](#)
- [Software Requirements](#)

### Hardware Requirements

In the OPC architecture, each variety of server is allocated a unique identifier, known as a Class ID. OPC clients use these 128-bit numbers, frequently displayed in the form 6B29FC40-CA47-1067-B31D-00DD010662DA, to access the particular vendor's OPC server. To make it easier for users, these numbers are often referred to by a more manageable string identifier called a ProgID (Program Identifier). These identifiers usually take the form **Vendor.Application** with an optional version number appended; for example, the Plant SCADA OPC Server ProgID is **Plant SCADA.OPC**.

Before the OPC client driver can access a particular OPC server, the server's ProgID needs to be entered into the

Plant SCADA I/O server registry. Where an in-process server or a local server is being used, this should have been done automatically when the server was installed. To access a remote server, refer to the documentation accompanying the server. Frequently, this step is achieved using a registry script (a .REG file) or a small executable.

**Note:**

- Familiarize yourself with the target OPC server(s) before using this driver. This will help you enter the item identifiers for the tag addresses using the correct syntax.
- Using remote servers requires configuring DCOM security. Since configuring security can be complex, you should plan your system settings in advance, and establish a protocol so that the Windows accounts to be used by operators have sufficient privilege. If sufficient privileges are not established, communications errors may result. See [Software Requirements](#) for more information.

## Software Requirements

OPC operates using the Microsoft Distributed COM (DCOM) architecture, which is part of the Windows operating system.

If a distributed OPC system is being accessed (i.e., remote servers), you need to configure DCOM security settings on the remote machines to allow operators access to the servers. To configure these settings, use the program DcomCnfg.exe.

If sufficient privileges are not established, communications errors may result, so take care when configuring your system.

**Note:** You need to confirm with the supplier of the OPC Server you are connecting to that their product is DCOM compliant.

## OPC Devices and Clients

This section provides information required to configure OPC devices and clients within your Plant SCADA project.

- [Device Address Information](#)
- [Communication Settings](#)
- [Data Types](#)
- [Include Project Support](#)
- [Arrays Support](#)
- [Quality Values](#)
- [Timestamp and Quality Support](#)

### Device Address Information

The address to use is the ProgID for the desired server.

This usually takes the form "<Vendor>.<Application>" (e.g. Plant SCADA.OPC) and should be found in the documents accompanying the OPC Server.

## See Also

[Communication Settings](#)

### Communication Settings

To establish communication with a device, configure the associated Boards, Ports and I/O Devices in Plant SCADA Studio's **Topology** activity. The following tables show the recommended settings for communication with an OPC device.

If you use the Express Communications Wizard to connect to a device, these settings will be automatically configured for you. However, if you need to manually configure these settings use the information outlined below.

### Boards

The Boards view in Plant SCADA Studio's **Topology** activity lists all boards used in the Plant SCADA project. Each board record defines a separate board within the project.

Field	Value
Board Name	A unique name (up to 16 alphanumeric character) per server for the computer board being used to connect with the device. This is used by Plant SCADA in the Ports view.
Board Type	The type of board. Enter <b>OPC</b> .
Address	Plant SCADA doesn't need an address for the OPC client. Instead you use the <b>Address</b> box to set the device scan rate on the OPC Server in milliseconds. The value read from the OPC server is typically taken from the OPC server cache. The scan rate value is often used to indicate how often the OPC server polls the device and updates its cache.  Enter <b>0</b> (zero) to use the default of 250ms. Enter any other value to use that value. Valid values range from eight character decimal 0 to 99999999. Up to six character hex values can be used; however, these must be preceded with 0x.  <b>Note:</b> As Plant SCADA supports unsolicited OPC requests, if you set the OPC server to notify Plant SCADA of changes to the value or quality of an OPC device item, make sure the OPC server scan rate is short enough to provide Plant SCADA within an adequate timeframe.
I/O Port	Leave this field blank.

Interrupt	Leave this field blank.
Special Options	<p>OPC server machine name. (Do not enter this name using the traditional dash delimited style. Enter the machine name, for example <b>Cit_Primary</b>.)</p> <p><b>Note:</b> The name entered here is the Windows machine name. For Windows NT and Windows 95 or 98 based OPC servers, you can obtain this from the <b>Identification</b> tab of the OPC server machine's network properties. For other OPC server configurations, refer to the server's documentation.</p> <p>If this field is left blank, the server name is sought in the following manner: a) The in-process (DLL) server on the IO Server machine; b) The local (EXE) server on the I/O server machine; c) The remote server as entered in the I/O server machine's DCOM settings.</p>
Comment	Any useful comment.

## Ports

The Ports view in Plant SCADA Studio's **Topology** activity lists all ports used in the Plant SCADA project. Each port record defines a separate port within the project.

Field	Value
Port Name	A unique name (up to 16 alphanumeric character) for the computer port being used to connect with the device. This is used by Plant SCADA in the Devices dialog box.
Port Number	An integer value, unique to the board as defined in the Board Name field. The Ethernet port needs no identification; however, the Plant SCADA communication database requires a value in this field.
Board Name	The name of the board this port is attached to as defined on the Boards view.
Baud Rate	Leave this field blank.
Data Bits	Leave this field blank.
Stop Bits	Leave this field blank.
Parity	Leave this field blank.
Special Options	Leave this field blank.

Comment	Any useful comment.
---------	---------------------

## I/O Devices

The I/O Devices view in Plant SCADA Studio's **Topology** activity lists all I/O devices used in the Plant SCADA project. Each record defines a separate I/O device within the project.

Field	Value
Name	A unique name (up to 16 alphanumeric characters) for the I/O device being identified. Each I/O device must have a unique name in the Plant SCADA system.
Number	A unique number for the I/O device (0–16383). Each I/O device must have a unique number in the Plant SCADA system (unless I/O device redundancy is being used).
Address	ProgID for the desired server. These usually take the form Vendor.Application (for example, Plant SCADA.OPC) and should be found in the documents accompanying the OPC Server.
Protocol	Enter "OPC" or "OPC1". See <a href="#">Arrays Support</a> .
Port Name	This field must contain one of the names previously defined in the <b>Port Names</b> field of the Ports view. There must be only one I/O device per port.
Comment	Any useful comment.

## Data Types

OPC servers can provide data in different data formats. An OPC client can request data in a specific format or use the server's type (that is, the type in which the data is stored within the server).

When specifying a data type, consider whether the server will be able to convert data to the requested type.

Use the table below to help you specify a type for a variable tag. It shows mappings from the types used by OPC (VARTYPE) to Plant SCADA data types. If followed, these data types coerce the OPC data Plant SCADA data types.

OPC Type (VARTYPE)	Description	Plant SCADA Data Type
VT_BOOL	Boolean	DIGITAL
VT_UI1	Byte	BYTE
VT_I2	2 byte integer	INT
VT_UI2	2 byte unsigned integer	UINT

VT_I4	4 byte integer	LONG
VT_U14	4 byte unsigned integer	ULONG (requires v7.0)
VT_CY	Currency	STRING
VT_R4	4 byte real	REAL
VT_R8	8 byte real	STRING
VT_DATE	Date	STRING
VT_BSTR	String	STRING
VT_ERROR	Error value	LONG
VT_QUALITY	2 byte integer	INT
VT_TIMESTAMP	4 byte integer	LONG
VT_MILLISECOND	4 byte integer	LONG

## Include Project Support

By default, the OPC driver does not support the definition of variable tags in projects that are included below the main project.

Variable tags defined in a project compiled on a Plant SCADA client needs to match exactly the tags defined in the project compiled on the I/O server. If a tag is added on the client, it needs to also be added on the I/O server. Otherwise client requests may become mismatched and show incorrect data.

## Arrays Support

To associate a Plant SCADA variable tag with an OPC array, follow the OPC array address string with a delimiter like "!", the capital letter "A" (which when combined like this instructs the Plant SCADA OPC driver that the address is for an array), and follow both with the array size as an integer enclosed within square brackets, like this:

<OPCArrayName>!A[<OPCArrayLength>]

---

**Note:** Replace the placeholders <OPCArrayName> and <OPCArrayLength> in the **Address** box with the actual valid values of the OPC Array **Name** and **Length** you want to use, as defined in the OPC server.

---

In the following example with an OPC tag defined on a BACnet OPC server, five register addresses are associated with the Plant SCADA variable tag named Status\_Flags:

- **Variable Tag Name:** Status\_Flags
- **Address:** device(7196).analog-output(1).status!A[5]

You can access individual elements of an OPC array in Plant SCADA by specifying the Plant SCADA tag name and an index number representing the individual element of the array. For example, to refer to the third variable of the array in the above example (Status\_Flags), use this syntax in Plant SCADA:

Variable Tag: Status\_Flags[2]

**Note:** OPC arrays use zero-based indexing. For example, a five register array would contain individual elements indexed as 0, 1, 2, 3, and 4.

The OPC address checking in Plant SCADA always ensures that the !A[<n>] suffix is used, otherwise the tag is not recognized as an OPC array, regardless of whether OPC or OPC1 variant is used. Therefore the format '!A[<n>]' must be followed in a tag address if the tag is defined as an array tag.

For example:

With access path: DB1,DINT0,10!A[10]

Without access path: S7:[OPCFLR]DB1,DINT0,10!A[10]

The OPC1 protocol is used to support Cicode functions TagRead() and TagWrite() for tags with a left square bracket "[" in their address.

However, if there is no left square bracket "[" in the OPC address string, you can use the array length specifier at the end of the address string, and so you should declare OPC as the I/O device protocol used in the I/O device setup procedure.

## **WARNING**

### **UNINTENDED EQUIPMENT OPERATION**

Ensure that the OPC address format used is compliant for the OPC Server with which you are communicating.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

## **Array offset support**

The array tag address can include an optional array offset.

The maximum size of an array tag is limited to 256 bytes due to the underlying infrastructure of Plant SCADA. For example, if the tag data type is integer (2 bytes), Plant SCADA only allows the array tag to be configured with 128 elements. However, special array offset syntax can be used to address a sub-array with the particular offset and range within a large array. For example:

<OPCArrayName>\<OFFSET>!A[<OPCArrayLength>]

When Plant SCADA writes to an OPC array, the whole array is read from the driver cache, modified, then written back to the OPC server. However, the driver cache is not updated with the newer data until the server performs its housekeeping tasks and notifies the driver that the array value has been changed. During this time, it is possible for another write request to have been issued with a now out-of-date copy of the original array data from the not-yet-updated driver cache. If subsequently written back to the server, any changes made in the first request of this scenario might be lost inadvertently if they are overwritten by the original duplicated data in the second write back.

To try and minimize this, the OPC driver in Plant SCADA is forced to do a synchronized read before data is modified. However it still has the possibility of losing data if that data is changed by other OPC clients between the time the data is read out and written back. For this reason, it is not recommended that OPC arrays be used in Plant SCADA while other OPC clients might be accessing the same data.

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not use OPC arrays in Plant SCADA while other OPC clients have access to the same data.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Quality Values**

The following masks are general bitmasks:

OPC_QUALITY_MASK	0xC0
OPC_STATUS_MASK	0xFC
OPC_LIMIT_MASK	0x03

These are specific quality values:

OPC_QUALITY_BAD	0x00
OPC_QUALITY_UNCERTAIN	0x40
OPC_QUALITY_GOOD	0xC0
OPC_QUALITY_CONFIG_ERROR	0x04
OPC_QUALITY_NOT_CONNECTED	0x08
OPC_QUALITY_DEVICE_FAILURE	0x0C
OPC_QUALITY_SENSOR_FAILURE	0x10
OPC_QUALITY_LAST_KNOWN	0x14
OPC_QUALITY_COMM_FAILURE	0x18
OPC_QUALITY_OUT_OF_SERVICE	0x1C
OPC_QUALITY_LAST_USABLE	0x44
OPC_QUALITY_SENSOR_CAL	0x50
OPC_QUALITY_EGU_EXCEEDED	0x54
OPC_QUALITY_SUB_NORMAL	0x58
OPC_QUALITY_LOCAL_OVERRIDE	0xD8

These can modify any of the above:

OPC_LIMIT_OK	0x00
OPC_LIMIT_LOW	0x01
OPC_LIMIT_HIGH	0x02
OPC_LIMIT_CONST	0x03

## See Also

[Timestamp and Quality Support](#)

### Timestamp and Quality Support

The Plant SCADA OPC driver can use additional variable tags for quality and timestamp values. Quality or timestamp tags are duplicates of a variable tag, with an appended "!Q" or "!T" or "!M" in the address field to define their purpose. Quality tags need to be configured as either INT or DIGITAL data types, whereas Timestamp tags need to be configured as LONG data types.

If you just need to know if an OPC item is good or bad quality (i.e. not uncertain), you should consider using DIGITAL data types for quality tags in combination with [OPC]DigitalQualityUncertainIsBad, rather than using Cicode to compare the value of an INT quality tag against 0xC0.

---

**Note:** The quickest way to create a quality or timestamp tag in Plant SCADA is to locate the relevant variable tag using the Variable Tags dialog box, edit it as required to create a quality or timestamp tag, and save it. This creates a copy of the original variable tag with the required changes saved.

---

#### To create a quality tag:

1. Open the Plant SCADA Studio.
2. In the **Topology** activity, go to **Equipment** tab.
3. In the editor, create a new variable tag, or locate the tag that you want to associate the quality tag with.
4. In the **Name** field, enter an appropriate and unique name for the quality tag, such as "<Tagname>\_Quality".
5. In the **Type** field, choose INT or DIGITAL from the menu.
6. In the **I/O Device** field, select the appropriate I/O device for the tag (if not already displayed).
7. In the **Display Name** box, enter the name of the tag you want to associate with the quality value (if not already displayed), and append "**!Q**" directly to the end of the address (without the quotes and without any spaces).
8. Click **Save**.

---

**Note:** If the exclamation mark character (!) is already defined in the Display Name field (for example, you have already used it to declare an array size "!A[n]"), you either need to include another exclamation mark (e.g. append "!Q" to the display name) after the closing square bracket of the array size declaration, or you can specify quality for arrayTag!A[5] with just arrayTag!Q".

---

#### To create a timestamp tag:

1. Open the Plant SCADA Studio.

2. In the **Topology** activity, go to **Equipment** tab.
3. In the editor, create a new variable tag, or locate the tag that you want to associate the quality tag with.
4. In the **Name** field, enter an appropriate and unique name for the timestamp tag, such as <Tagname>\_sTimestamp (for seconds) or <Tagname>\_msTimestamp (for milliseconds).
5. In the **Type** field, choose **Long** from the menu (if not already selected).
6. In the **I/O Device** field, select the appropriate I/O device for the tag (if not already displayed).
7. In the **Display Name box**, enter the name of the tag you want to associate with a timestamp value (if not already displayed), and append "**!T**" or "**!M**" (as appropriate).

**Note:** If there is already an exclamation mark with other declarations included in the display name, you don't need to include them for timestamping. For example, a timestamp tag monitoring TagName!A[64] can be addressed as TagName!T.

8. Click **Add**.

---

**Note:** Timestamps store the number of seconds since 01/01/1970 when using the "**!T**" element, or the number of milliseconds since midnight using the "**!M**" element. If you want to store a complete time in millisecond accuracy, you need to create two separate timestamp tags, one for seconds and one for milliseconds, each addressed appropriately.

---

## Examples

In the following examples, an OPC device tag defined on a BACnet OPC server is associated with the base Plant SCADA variable tag named **Present\_Value**:

<b>Variable Tag Name</b>	Present_Value
<b>Address</b>	device(7196).analog-output(1).present-value
<b>Plant SCADA Data Type</b>	Data type required by project (for a list of data types, see <a href="#">Data Types</a> ).

### Example 1

Use the following settings to associate a Plant SCADA variable tag with the quality stamp of the OPC register value:

<b>Variable Tag Name</b>	Present_Value_Quality
<b>Address</b>	device(7196).analog-output(1).present-value!Q
<b>OPC Type</b>	VT_QUALITY
<b>Plant SCADA Data Type</b>	INT or DIGITAL

### Example 2

The following tag definition will read the Timestamp value measured in seconds from 1/Jan/1970:

<b>Variable Tag Name</b>	Present_Value_Timestamp
<b>Address</b>	device(7196).analog-output(1).present-value!T

<b>OPC Type</b>	VT_TIMESTAMP
<b>Plant SCADA Data Type</b>	LONG

**Example 3**

The tag definition below will read the Millisecond Timestamp value measured in UTC FileTime from beginning (midnight) of the current day:

<b>Variable Tag Name</b>	Present_Value_Millisecond
<b>Address</b>	device(7196).analog-output(1).present-value!M
<b>OPC Type</b>	VT_MILLISECOND
<b>Plant SCADA Data Type</b>	LONG

The base Plant SCADA tag needs to be defined in Plant SCADA before the timestamp and quality values of the associated OPC Server tag value can be read.

## Advanced Configuration and Maintenance

This section provides advanced configuration instructions.

- [Status Tags](#)
- [Customizing a Project using Citect.ini Parameters](#)
- [Configuring Redundancy](#)
- [Scan Rates](#)

### Status Tags

You can define status tags in your Citect.ini file to allow the OPC driver to determine the current state of an OPC device. For example, a status tag could be configured to monitor an OPC item that indicates the current operational state of a connected device. If the condition of the status tag is true, the OPC driver can allow the device to come online; otherwise the device may be set to offline.

By default, no status tags are created for the OPC driver. They need to be defined in the project Citect.ini file using the OPC status tag parameters. These parameters determine which OPC items are monitored, the condition values, and how often polling occurs.

A status tag can be defined in the [OPCStatusTags] section of the Citect.INI file to determine the online status of OPC devices. You can also create status tag set for each individual I/O device using the following format:

```
[OPCStatusTags]
<IOServerName>.<IODeviceName>.<parameter>=<value>
```

For example:

```
[OPCStatusTags]
io1.iodev1.tag=ARB3183800_S_2.REQNUM
io1.iodev1.condition= <=10
```

Where "ARB3183800\_S\_2.REQNUM" refers to an OPC item configured in the device.

If you are not regularly reading from a particular device, it is recommended that you enable status units checks. To do this, you need to enable the parameter [IOServer]WatchDogPrimary.Standby units are enabled by default.

## See Also

[OPC Status Tag Parameters](#)

## Customizing a Project using Citect.ini Parameters

You use Citect.ini parameters to fine tune the performance of the Plant SCADA OPC driver and to perform runtime maintenance diagnostics.

- [Common Driver Parameters](#)
- [Driver-specific Parameters](#)
- [Logging Parameters](#)
- [OPC Device-specific Parameters](#)
- [OPC Access Path Parameters](#)
- [OPC Status Tag Parameters](#)

### UNINTENDED EQUIPMENT OPERATION

- Do not under any circumstances change or remove any of the undocumented citect.ini parameters.
- Before deleting sections of the citect.ini file, confirm that no undocumented parameters will be deleted.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

You can customize the way Plant SCADA communicates with the OPC system, and even individual PLCs, by creating or editing the [OPC] section of the Citect.ini file for your project.

There are some common Plant SCADA driver settings, and custom Plant SCADA OPC driver settings.

When Plant SCADA starts at runtime, it reads configuration values from the Citect.ini file stored locally. Therefore, any OPC configuration settings need to be included in the Citect.ini file located on the computer acting as the I/O server to the OPC system.

**Note:** By default, Plant SCADA looks for the ini file in the Plant SCADA project \bin directory. If it can't find it there, it searches the default Windows directory.

The default values for these parameters have been determined by driver development and testing to be optimal for the Plant SCADA OPC driver. Parameters default to a value tested to work in common configurations. Do not

adjust these default values except on the direct advice of AVEVA Global Customer Support.

## Common Driver Parameters

The following table describes the common `citect.ini` driver parameters.

[OPC] Parameter	Allowable Values	Default Value	Description
Block	5 to 256	255	A value (bytes) used by the Plant SCADA I/O server to determine if two or more packets can be blocked into one data request before being sent to the OPC driver. For example, if you set the value to 10, and the I/O Server receives two simultaneous data requests (one for byte 3, and another for byte 8) the two requests are blocked into a single physical data request packet. This single request packet is then sent to the I/O device, saving on bandwidth and processing.
Delay	0 to 300	0	Period (in ms.) to wait between receiving a response and sending the next command to the I/O server.
MaxPending	1 to 1024	250	Maximum number of pending commands that the Plant SCADA OPC driver holds ready for immediate execution.
Polltime	0 to 300	1000	Polling service time (in milliseconds) at which cached data is updated. Recommended to be at least twice that of the value used in the Citect.INI [ALARM]

			ScanTime parameter.
Retry	0 to 8	0	Number of times to retry a command after a timeout.
Timeout	0 to 32000	3000	Milliseconds to wait for a response before considering a write or polling request to be invalid and displaying an error message in Plant SCADA .
Watchtime	0 to 128 (seconds)	15	Frequency that the Plant SCADA OPC driver uses to check the communications link to the OPC system and attempts to bring offline units back online. Also determines the frequency of STATUS_UNIT commands to the driver. See <a href="#">Configuring Redundancy</a> .

## Driver-specific Parameters

The following table describes the driver-specific Citect.ini parameters.

[OPC] Parameter	Allowable Values	Default Value	Description
AddItemAsVtEmpty	0 - Specify data types 1 - Use native data type	1	Determines whether the OPC driver specifies a data type when adding an item, or whether it uses the native data type when adding items.  This parameter is used to select whether the OPC client will specify a type to force the OPC Server to coerce the data, or for the OPC server to provide the type as configured on the server.

ArrayRecordBase	-	-	This parameter has been deprecated.
CacheRead	0 – Value is refreshed and the latest value returned. 1 – Last known value returned.	1	Determines the value returned when an inactive item is read.  See <a href="#">Overriding [OPC]CacheRead</a> for information on how to override the value of this parameter for a particular tag.
DigitalQualityUncertainIsBad	0 or 1	1	Determines how an uncertain quality result is treated when a Digital quality reading is taken.  0 - An uncertain quality will be treated as GOOD when a digital quality reading is taken (normal INT version is unaffected) 1 - an uncertain quality will be treated as BAD when a digital quality reading is taken (normal INT version is unaffected)
FailOnBadData	-	-	The parameter has been deprecated since Citect SCADA v7.30
FailOnUncertain	-	-	The parameter has been deprecated since Citect SCADA v7.30
FillCacheOnStartup	0 - Subscriptions are created in the inactive state and are only activated as read request are received.  1 - Subscriptions are created in the active state.	1	Determines whether subscriptions are created in the active or inactive state initially.
GoOfflineForBadTag	0 – disabled. Do not go offline.  1 - enabled. Go offline.	0	Sets all tags on an OPC device to an OPC_QUALITY status of

			<p>GOOD before Plant SCADA declares the I/O device online.</p> <p>This parameter would only be set on the I/O server where the device is defined as primary, so it can only take over from a standby device definition when all tags and the status tag are valid. This minimizes the chances that com-breaks occur during switchover from standby to primary. It is strongly recommended not to set it on a standby, as it might only be one tag that is invalid.</p>
InhibitActivationOnStandby	0 – A standby server will follow the same rules for subscription activation as the primary server. 1 – A standby server will only active a subscription if it believes the primary server is not active.	1	<p>This parameter allows a standby server to deliberately leave subscriptions in an inactive state when the primary server is online. This is usually used when the primary and standby server are talking to independent OPC servers to reduce the load the standby OPC server would place on field devices.</p> <p>On startup of a standby server, if this parameter is set to 1, items will not be activated immediately. They will only be activated when the unit itself becomes the active unit.</p>
ItemLifeTime	Time (seconds)	5	<p>Determines the time in before a tag is deemed inactive.</p> <p>The global LeaveTagsActive parameter overrides the</p>

			<p>ItemLifeTime parameter to force OPC tags to remain active even though Plant SCADA is no longer requesting them from the driver.</p> <p>The ItemLifeTime parameter can be individually overridden for any OPC device by the Active parameter.</p>
LeaveTagsActive	<p>0 - Do not leave tags active.</p> <p>1 - Leave tags active.</p>	1	<p>Determines whether OPC tags remain active even though Plant SCADA is no longer requesting them from the driver. Normally tags are made inactive 5 seconds after the last time they are requested.</p> <p>Some OPC servers take a long time to return a call to activate/inactivate tags, or doing so slows them down, therefore leaving tags active can sometimes improve performance.</p> <p>The global LeaveTagsActive parameter can be individually overridden by an Active parameter.</p> <p>See ItemLifeTime parameter (above).</p> <p>Note: This parameter minimizes the likelihood of deactivation of tags on the currently active unit only. Tags on units that have become inactive (standby) will still deactivate</p>
NumConcurrentServerInitS	-1 – Unlimited 32767	-1	Represents the maximum number of concurrent initialization and

			shutdown operations that are performed on each configured OPC Server. Higher values, or -1 (unlimited), will incur greater load on the server, while 0 and 1 determine that initialization is serialized into effectively a single thread.
OPCGroupName	Any string (maximum 32 characters)	CitectGroup_<n>	By default, each OPC server is allocated a sequential group name by the OPC driver, i.e. CitectGroup_1, CitectGroup_2, etc. This parameter allows you to replace the default group name with a customized name. You can set this parameter at a device level using <a href="#">OPC Device-specific Parameters</a> .
ReadAfterWrite	0 - No read, rely on the normal polling/OnDataChange mechanism.  1 - Force sync read of item written from OPC server cache after write.  2 - Force sync read of item written from device after write.	0	Determines if a force read should be made, and if it should be from the OPC server cache or from the device.  <b>Note:</b> RefreshAfterWrite causes a refresh of all active items, whereas ReadAfterWrite reads back only the item being written to. You should use one or the other. Where both RefreshAfterWrite and ReadAfterWrite are set to 1, RefreshAfterWrite will take precedence, and ReadAfterWrite will be set to 0.
RefreshAfterAdd	0 - No REFRESH.	1	Determines whether an

	1 - Request a REFRESH from the OPC server cache.  2 - Request a REFRESH from the device.		OPC REFRESH is requested from the OPC server after activating the group.  This parameter can be disabled if slow start up times are experienced.  The server could be automatically sending a REFRESH, in which case another request may be unnecessary.
RefreshAfterWrite	0 – Disable forced REFRESH.  1 - Enable forced REFRESH from OPC server cache.  2 - Enable forced REFRESH from device.	0	Determines whether to force an OPC REFRESH from the OPC Server of ALL active items after Plant SCADA writes to an item.
RefreshBeforeArrayWrite	0 – No refresh command sent  1 – Read command sent to refresh the OPC server cache  2 – Read command sent to refresh the OPC device	0	Enables the driver to send a read command to the OPC server before a write command is sent to the OPC server for an array variant.
ServerOnlineStates	"RUNNING" "FAILED" "NOCONFIG" "SUSPENDED" "TEST"	"RUNNING"	Defines the list of OPC Server states that the driver considers online. The format is a " " separated string, without spaces.  If you experience the OPC Server shutting down on startup, it is recommended that the following states are used: "RUNNING   NOCONFIG   SUSPENDED"
ShutdownWait	Time (milliseconds).	30000	Determines the time the OPC driver waits before shutting down. On shutdown, the driver attempts to close the connection to the OPC

			server. If this takes longer than the time specified by this parameter, the driver shuts down anyway (sometimes with unexpected results). This parameter might be needed if the OPC server does not respond within the default wait time.
StatusWaitPeriod	Time (milliseconds)	5000	Determines the time the OPC driver waits before requesting tag status for an OPC I/O device. On startup, the OPC driver waits for a Unit status from the OPC server before adding tags to the server. If the value of this parameter is exceeded, the tags are added anyway.  The OPC server should respond within a few seconds. The default wait time of 5 seconds should usually be adequate.
SuppressDataNotYetValidError	0 or 1	0	Determines whether "Data Not Yet Valid" error messages are suppressed, or whether they are displayed in the Kernel window and written to the Syslog.dat file. For Plant SCADA to display the message "Error Suppressed", you need V5.50 or above.  0 – Displays "Data Not Yet Valid" errors in the Kernel window and logs them to the Syslog.dat file.  1 - Suppresses "Data Not Yet Valid" errors, which are not displayed in the Kernel window or logged.

			In the Runtime kernel, under View -> I/O Devices, Plant SCADA will display "Error Suppressed" in the Error Message field for the particular device.
UseArrays	-	-	This parameter has been deprecated.
UseAsyncWrites	0 - use synchronous writes. 1 - use asynchronous writes.	0	Determines whether writes are synchronous or asynchronous.  Note: UseAsyncWrites=1 is only valid when [OPC]UseOPC2=1, since OPC1 does not support asynchronous writes.
UseOPC2	0 – OPC2 support disabled (Use OPC 1.0a interface). 1 – OPC2 support enabled (Use OPC DA2 interface).	0	Globally determines whether to use OPC 1.0a or OPC 2.0 interface. Individual overrides can be set using the UseOPC2 parameter to force the use of a particular version OPC interface with a particular I/O device.
UseStatusTags	0 – disabled. 1 – enabled.	0	Determines whether parameters in the [OPCStatusTags] section are active. Individual overrides can be set using the OPC Device-specific Parameters to force the use of a particular status tag parameter with a particular I/O device.
ValidDataWaitPeriod	Time (milliseconds)	10 seconds	Determines the maximum time that the OPC driver will wait for OPC_QUALITY to be GOOD for all tags before declaring that Device online. This minimizes the likelihood of a client

			<p>swapping from a standby to a primary prematurely and suppresses alarm flooding at startup.</p> <p>Set this parameter to 0 to allow units to come online regardless of whether all items for the unit have been verified as good quality.</p> <p><b>Note:</b> FillCacheOnStartup=1 needs to be set when ValidDataWaitPeriod&gt;0</p>
WriteTrueAs1	<p>0 - write true as VARIANT_TRUE(-1).</p> <p>1 - write true as 1.</p>	0	<p>Determines whether a digital value of TRUE is written as "VARIANT_TRUE(-1)" or "1". This parameter should only be required for incorrectly designed OPC servers. When the Plant SCADA data type is digital, VARIANT_TRUE (-1) is used with VT_BOOL variant type to write a value of true. This happens even if [OPC]AddItemAsVtEmpty is set, as OPC servers should be designed to convert the value when they receive it.</p>

## Logging Parameters

The following table describes the OPC logging parameters.

[OPC] Parameter	Description	Allowable Values	Default Value
DebugLevel	<p>The trace level used for log file.</p> <p>See <a href="#">Logging</a> for examples.</p>	<p>ALL or any combination of the following, separated by a pipe character ( ):</p> <p>WARN</p> <p>ERROR</p> <p>TRACE</p>	-

DebugCategory	The categories used for the log file. See <a href="#">Logging</a> for examples.	ALL or any combination of the following, separated by a pipe character ( ): TAG: Tag configuration trace. PROT: Operations related to the OPC protocol interface. CACHE: Operations related to the driver cache. DCB: Front end driver trace. THRD: Thread trace. MISC: Miscellaneous operations. BEND Operations related to the back-end thread of the driver. FEND: Operations related to the front-end thread of the driver.	-
DebugUnits	Controls which units logging is performed for. Multiple units can be specified. Debug messages that are unrelated to a specific unit are logged against the (GLOBAL) unit.	ALL, (GLOBAL) [include the round brackets] or any combination of I/O device names and (GLOBAL) separated by ' ' characters.	All

### OPC Device-specific Parameters

For each OPC I/O device you can specify parameter conditions that override the default global settings. To do this, use the following format in the [OPC] section of the Citect.ini file.

**[OPC]<IOServerName>.<IODeviceName>.<Parameter>=<Value>**

where:

- <IOServerName> = Name of I/O server configured in Plant SCADA .
- <IODeviceName> = Name of I/O device configured for OPC communications.
- <Parameter> = Parameter of the I/O device being overridden.
- <Value> = Value of the overriding parameter being set.

---

**Note:** There are also a number of status tag parameters that you can override global settings for in the

[OPCStatusTags] section of the Citect.ini file. For more information see [OPC Status Tag Parameters](#).

The following device-specific parameters are supported.

[OPC] Parameter	Allowable Values	Default Value	Description
Active	<b>0</b> - deactivate tag. <b>1</b> - leave tag active.	Value of the LeaveTagsActive parameter.	Allows user to individually override the global default LeaveTagsActive parameter to specify whether tags should be left active or inactive for a particular OPC I/O device. Replace the placeholders <IOServerName> and <IODeviceName> in the parameter with the names of the OPC 'I/O Server' and 'I/O Device' you want to override and have remain active. Determines whether individual OPC tags are left active even though Plant SCADA is no longer requesting them from the driver. Normally tags are made inactive 5 seconds from the last time they are requested. See the LeaveTagsActive parameter in <a href="#">Driver-specific Citect.ini Parameters</a> .
Update	0 to 32000 (milliseconds)	Scan rate specified in the <b>Address</b> field of the Boards settings.	Allows the user to individually override the.Default.Update parameter to specify the tag update rate for a particular I/O device. The update rate is the frequency with which the OPC server polls the device for values and updates its own cache. Replace the placeholders <IOServerName> and <IODeviceName> in the

			parameter with the actual names of the OPC I/O server and I/O device you want to override with a specific update rate.  This parameter controls polling performed by the OPC server, not by Plant SCADA. The scope of the parameter is communication between the OPC server and a device, not between the OPC server and Plant SCADA.
UseAsyncWrites	0 - use synchronous writes. 1 - use asynchronous writes.	0	Determines whether writes are synchronous or asynchronous.  <b>Note:</b> UseAsyncWrites=1 is only valid when [OPC]UseOPC2=1, since OPC1 does not support asynchronous writes.
UseOPC2	0 – Individual OPC2 support disabled (Use OPC 1.0a interface). 1 – Individual OPC2 support enabled (Use OPC DA2 interface).	Value of global UseOPC2 parameter	Allows users to individually override the global default UseOPC2 parameter and to specify whether to use OPC 1.0a or OPC 2.0 for a particular I/O device.  Replace the placeholders <IOServerName> and <IODeviceName> in the parameter with the actual names of the OPC I/O server and I/O device you want to override and have with a particular version OPC interface.

## OPC Access Path Parameters

In some instances, an OPC server might have several ways to access a particular item. For instance, a particular server, which communicates by means of modem, might have multiple modems at its disposal. It might be desired that certain items in the OPC server are always accessed using a particular modem, the fastest of the

group, for example. OPC allows you to specify this preference by using the Access Path <OPCAccessPath> value. An access path is optional, provided in addition to the Item ID (the tag address), which is provided as a recommendation to the server, regarding how to access the data.

**Note:** The availability, format, and use of access paths is server-specific. Refer to your OPC server documentation for details relevant to your server.

[OPCAccessPaths]<IOServerName>.<IODeviceName>=<OPCAccessPath>

where:

- <IOServerName> = Name of I/O server configured in Plant SCADA .
- <IODeviceName> = Name of I/O device configured for OPC communications.
- <OPCAccessPath> = Access path to set up communications to the OPC server.

This parameter is not normally required with most OPC servers.

The Plant SCADA OPC client driver supports specification of a single access path for each configured I/O device using the [OPCAccessPaths] section of the Citect.ini file.

To specify the access path for a particular device, add an entry to the ini file in the format <IOServerName>.<IODeviceName>. For example, to specify that the access path COM1: should be used for the I/O device OPC1 on I/O server IOServer1, add the following entry to the Citect.ini file:

[OPCAccessPaths]  
IOServer1.OPC1=COM1:

Multiple entries are also acceptable:

[OPCAccessPaths]  
IOServer1.PLC1=PLC4  
IOServer1.PLC2=TestPLC

## OPC Status Tag Parameters

The OPC status tag parameters determine the online or offline state of an OPC I/O device using the condition of a specified OPC item in the device. For more information, see [Status Tags](#).

When configuring these parameters, be careful not to confuse the OPC item required for status monitoring with a normal Plant SCADA tag.

You should also use a full path to identify an OPC item, as a configured access path in your Citect.ini file will not be known to a device.

**Note:** Use the UseStatusTags parameter to enable or disable support for OPC status tags.

[OPCStatusTags] Parameter	Allowable Values	Default Value	Description
StartWait	time in milliseconds - or - -1 (infinite)	30000 (milliseconds)	On driver startup, this parameter determines the time the OPC driver will wait before requesting status tag data for an OPC I/O device.  The OPC server should

			respond within a few seconds. The default wait time of 30 seconds is usually adequate.
Default.Tag	An OPC item name	STATUS	This parameter specifies the default OPC item to be monitored at runtime to determine the operational status of an associated device.  <b>Note:</b> This parameter implements a global setting for all OPC I/O devices, unless it is specifically overridden using the equivalent <a href="#">OPC Device-specific Parameters</a> .
Default.Update	0 -32000 (milliseconds)	The scan rate from Address field in the Plant SCADABards configuration.	This parameter specifies the default update rate for OPC status tags at runtime. This is the frequency with which the OPC server polls the device for status tag values and then updates its own cache.  This parameter controls polling performed by the OPC server, not by Plant SCADA. The scope of the parameter is communication between the OPC server and a device, not between the OPC server and Plant SCADA.  <b>Note:</b> This parameter implements a global setting for all OPC I/O devices, unless it is specifically overridden using the equivalent <a href="#">OPC Device-specific Parameters</a> .

Default.Condition	<condition> (see table below)	ISGOOD	<p>This parameter is used to determine if the OPC device is online at runtime, by comparing the &lt;Condition&gt; with the value of the default OPC item named in the .Default.Tag parameter.</p> <p>If the specified condition is determined to be true, the device will be considered online.</p> <p>This parameter represents the default condition for all OPC status tags, unless it is individually overridden using the <a href="#">OPC Device-specific Parameters</a>.</p>
-------------------	----------------------------------	--------	--

Allowable values for <condition>	Description
=<Value>	is equal to <Value>
!<Value>	is NOT <Value>
!<Value>	is NOT equal to <Value>
><Value>	is greater than <Value>
>=<Value>	is greater than or equal to <Value>
<<Value>	is less than <Value>
<=<Value>	is less than or equal to <Value>
ISGOOD	the tag Quality is GOOD
ISBAD	the tag Quality is BAD
ISUNCERTAIN	the tag Quality is UNKNOWN

Where:

- <Value> is a placeholder for any valid LONG data type value.

If the specified condition is determined to be true, the device will be considered online.

## Overriding [OPC]CacheRead

You can override the value in [OPC]CacheRead for a particular tag by suffixing the tag name with:

The delimiter "!"

The letter C or D, as follows:

- <Tag Name>!C - The tag value returned will be the cache value at the time of the read.
- <Tag Name>!D - A refresh of the tag value is forced before it is returned.

### Examples:

- Tag1!D - Forces a refresh of Tag1 before the value is returned.
- Tag!C - The last known cache value of Tag2 is returned.

When the tag qualifiers C and D are used with other OPC qualifiers (see [Timestamp and Quality Support](#)), they must appear last.

### Example:

- Tag3QC - Tag3 is associated with a quality tag and the last known value of Tag3 will be returned.

## Configuring Redundancy

Redundancy is handled in Plant SCADA by the Plant SCADA clients. They determine which I/O server to request I/O device data from by allowing the scan rate to be specified per I/O device, and then configuring multiple I/O devices to the same PLC.

A status tag can be defined in the Citect.ini file to determine whether or not to set a unit offline or online depending on the condition of the status tag. If the condition is true the unit is allowed to come online, otherwise the unit is set to offline.

The status tag is polled at the same rate configured for the groups of the corresponding unit. The driver supports STATUS\_UNIT commands on the inactive server, so even though a particular unit is not currently servicing Plant SCADA requests, the state of the status condition will be checked periodically allowing the unit to be taken either offline or online (assuming that [IOServer]WatchDog has not changed from its default of 1).

Both the primary and standby devices will be offline if both have the same status condition and the condition is an error condition. All points in the system for that unit would therefore be #COM.

Status tags can be defined on a per-device or global basis. For more information, see [OPC Status Tag Parameters](#) and [OPC Device-specific Parameters](#).

## Scan Rates

The Plant SCADA OPC driver can define I/O devices with different scan rates. This provides you with the ability to better tune your system, by ordering the tag database into logical groups and defining different scan rates for each group. For example, tags that are being read frequently can be placed in a group that is scanned frequently, and tags that are read infrequently can be placed in a group that is scanned infrequently.

By default, tags are scanned at the default scan rate defined by the ScanRate parameter in the project Citect.INI file. See Citect.INI specific parameters for details.

## Examples

- Set the project scan rate to 1 second (1000 milliseconds):  
[OPC]  
ScanRate=1000
- Set the project scan rate to 1 second (1000 milliseconds), and the inactive server scan adjust rate to a factor of 5:  
[OPC]  
ScanRate=1000
- Set a faster (half second) scan rate for a specific port named "Port1" on the I/O server named "CLServer":  
[CLServer.Port1]  
ScanRate=500
- Set a slower (5 second) scan rate for a specific port named "Port123" on the I/O port named "CLServer":  
[CLServer.Port123]  
ScanRate=5000

## Troubleshooting

Many problems have simple solutions and require only perseverance to solve them. The following topics provide information about the Plant SCADA tools provided to help resolve problems with communication and configuration.

- [Driver Errors](#)
- [Driver Statistics](#)
- [Logging](#)
- [Maintaining the Project Database](#)

### Driver Errors

Plant SCADA OPC driver errors can occur when an OPC device does not respond, is disconnected or offline, or returns an error itself.

- [Common Protocol Errors](#)
- [OPC Protocol Errors](#)

### Common Protocol Errors

Plant SCADA has two kinds of protocol driver errors - generic and specific. Generic errors are hardware errors 0-31, and are common to many protocols. Sometimes only the generic error is available, though often both the generic error and a specific error are given.

Protocol drivers also have their own specific errors, which can be unique and therefore cannot be recognized by the hardware alarm system. The drivers convert specific errors into generic errors that can be identified by the I/O server. For example, when a driver experiences an error, there is often both a protocol-specific error and a corresponding generic error.

When a hardware error occurs, Plant SCADA generates an alarm, and displays the alarm on the hardware alarm page (in the alarm description of the hardware alarm). To see the error number, you need to have Alarm Category 255 defined with a display format that includes {ErrDesc,15} {ErrPage,10}.

If you need more information to resolve an error, refer to the documentation that accompanied the I/O device (or network). If, after reviewing the documentation, you still cannot solve your problem, contact support via the AVEVA Knowledge & Support Center (<https://softwaresupport.aveva.com/>).

## OPC Protocol Errors

The following errors, listed in (hexadecimal) order, are specific to the Plant SCADA OPC protocol:

Error Value (Hex)	Error Definition	Error Description
0XC0040001	GENERIC_SOFTWARE_ERROR	Invalid handle was passed.
0XC0040002	GENERIC_SOFTWARE_ERROR	A duplicate parameter was passed where one is not allowed.
0XC0040004	GENERIC_INVALID_DATA_FORMAT	Server cannot convert between the passed or requested data type and the canonical type.
0xC0040006	GENERIC_ACCESS_VIOLATION	Item's access rights do not allow the operation.
0xC0040007	GENERIC_SOFTWARE_ERROR	Item definition does not exist within the server's address space.
0xC0040008	GENERIC_SOFTWARE_ERROR	Item definition does not conform to the server's syntax.
0xC004000B	GENERIC_INVALID_DATA_FORMAT	Value passed to WRITE was out of range.
0x80020008	GENERIC_SOFTWARE_ERROR	Bad variable type.
0x8002000A	GENERIC_SOFTWARE_ERROR	Out of present range.
0x80020005	GENERIC_SOFTWARE_ERROR	Type mismatch.
0x100	GENERIC_SOFTWARE_ERROR	Could not access variable dbf.
0x101	DRIVER_BAD_DATA	Read of data value bad.
0x102	GENERIC_GENERAL_ERROR	Write of one or more items not completed.
0x103	DRIVER_UNIT_OFFLINE	Could not resolve the server CLASSID.
0x104	GENERIC_SOFTWARE_ERROR	Could not add one or more items to

		the Server
0x80010006	GENERIC_CHANNEL_OFFLINE	Connection terminated
0x80010007	GENERIC_CHANNEL_OFFLINE	Server not available.
0x8001000F	GENERIC_INVALID_RESPONSE	Received data is invalid.
0x80010012	GENERIC_SOFTWARE_ERROR	Call did not execute.
0x80010100	GENERIC_SOFTWARE_ERROR	System call aborted.
0x80010101	GENERIC_SOFTWARE_ERROR	Could not allocate some required resource.
0x80010103	GENERIC_BAD_PARAMETER	Requested interface not registered on server object.
0x80010104	GENERIC_SOFTWARE_ERROR	Could not call server.
0x80010105	GENERIC_CHANNEL_OFFLINE	Server threw an exception.
0x80010108	GENERIC_CHANNEL_OFFLINE	Server has disconnected from its clients.
0x8001011B	GENERIC_CHANNEL_OFFLINE	Access denied.
0x8001011C	GENERIC_CHANNEL_OFFLINE	Remote calls not allowed for this process.

## Driver Statistics

You can use the following driver statistics to help you debug the OPC driver operation.

Statistic	Description
Cached Reads	Number of reads that have been serviced directly from the internal cache of current values.
Cache Misses	Number of reads that were not in the internal cache of current values which resulted in a direct request from the server.
Active Items	Number of items with valid server subscriptions which have been activated to receive data change notification. This may be a subset of the total number of items currently subscribed to.
Total Items	Total number of items with valid server subscriptions. These items might or might not be currently activated to receive data change notifications.

Bad Items	Number of items that were not successfully subscribed to. These items might not exist on the server.
Start ms	Internal driver statistic used for driver debugging by AVEVA Global Customer Support.
Last ms	Internal driver statistic used for driver debugging by AVEVA Global Customer Support.
Difference	Internal driver statistic used for driver debugging by AVEVA Global Customer Support.
ReadItemsReQueued	Internal driver statistic used for driver debugging by AVEVA Global Customer Support.
DCBsInHandlingQ	Internal driver statistic used for driver debugging by AVEVA Global Customer Support.
DataNotYetValid	Internal driver statistic used for driver debugging by AVEVA Global Customer Support.

## Logging

The OPC driver can log combinations of trace levels across different categories. This is achieved by setting the following INI parameters.

### [OPC]DebugLevel

This parameter allows you to define the trace level. The options include:

WARN	Output warning messages.
ERROR	Output error messages.
TRACE	Output trace messages.
DEBUG	Output debug messages.
ALL	All of the above.

### [OPC]DebugCategory

This parameter allows you to enable logging for a particular category of trace. The options include:

TAG	Tag configuration trace
PROT	Operations related to the OPC protocol interface

CACHE	Operations related to the driver cache
DCB	Front end driver trace
MISC	Miscellaneous operations
THRD	Thread trace
BEND	Operations related to the back-end thread of the driver
FEND	Operations related to the front-end thread of the driver
ALL	All of the above

In both cases, you can use ALL or any combination of the available options separated by a pipe character ( | ).

### Example

```
[OPC]
DebugLevel=WARN|ERROR|TRACE
DebugCategory=ALL
```

In most cases, you can set the DebugLevel and DebugCategory parameters to ALL. If this results in a large, cumbersome log file that causes older data to be overwritten, you can consider refining the debug options.

---

**Note:** These parameters do not have a value specified by default. To enable logging for this driver, you need to manually configure these parameters in your INI file.

The events generated by the OPC driver are logged in the following Plant SCADA syslog file:

```
syslog.IOServer.<Cluster name>.<IO Server name>.dat
```

This file is located in the directory specified by the Citect.ini parameter **[CtEdit]Logs**. By default, this location will be:

```
%PROGRAMDATA%\AVEVA Plant SCADA <VersionNumber>\Logs
```

---

**Note:** In Citect SCADA v7.0 and earlier, this file was delivered to the Windows system directory (for example, C:\Windows) and its location was not configurable. With the release of Citect SCADA v7.10, the file is delivered to the location specified in the **[CtEdit]Logs** parameter, which is configurable.

---

The size of the syslog file and its rollover process is configured via the **[Debug]SysLogSize** and **[Debug]SysLogArchive** INI parameters. For more information, see the topic *Debug Parameters* in the Plant SCADA documentation.

---

**Note:** If the number of messages being processed for a driver exceeds the value specified by the Plant SCADA parameter **[Kernel]ErrorBuffers**, the pending messages will not be logged. If this occurs, you can increase the value of this parameter so that all the messages generated by the driver are reported. The number of messages that are not logged can be monitored via the Kernel's General window under the item "Lost Errors". If you adjust **[Kernel]ErrorBuffers** and Lost Errors are still occurring, you may need to adjust the level of system logging.

[Logging Parameters](#)

## Maintaining the Project Database

Over time with editing, the project database underlying a project can become fragmented and performance can be reduced. During project development you should periodically clear out all duplicated records and any orphaned ones.

Improperly maintained databases can result in communication errors at runtime. A large number of communications errors come from having duplicated or orphaned records in the communications database.

Sometimes orphaned records from a previous I/O server are left behind in the database files. As the forms are indexed on the I/O server name, you can use the scroll bar to quickly navigate to the end of the current range of records for a particular I/O server and examine the last few and next few records to validate that they should be there. If you find extra (unwanted) records, delete them.

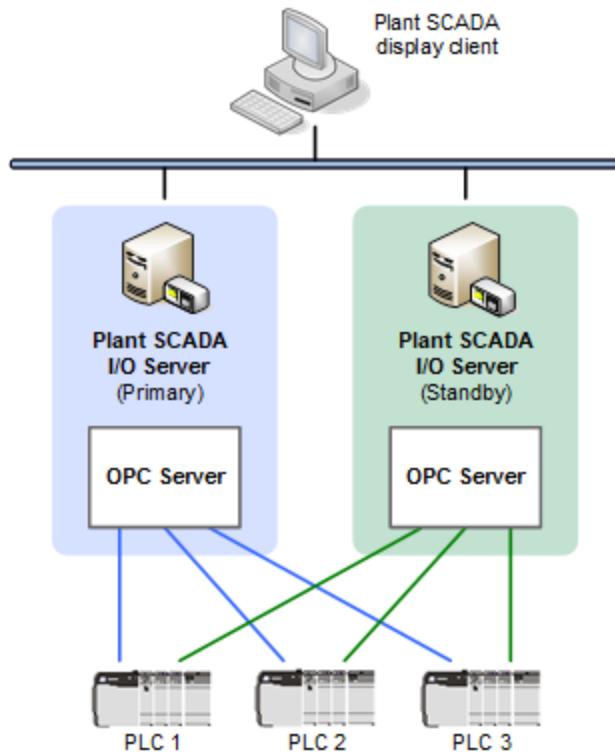

You should also check that there are no duplicated records. Use the record search facility to search for duplicate entries of devices that are causing unexplained communication errors. If you find extra (unwanted) records, delete them.

Once you have deleted orphaned and duplicated records, pack the project. Packing the database removes deleted records, and re-indexes the database. To pack the project databases, use the **Pack** button on the command bar of the **Project** activity in Plant SCADA Studio.

## OPCLX Driver

The OPCLX driver enables Plant SCADA to communicate to ControlLogix system PLCs via the OPC DA protocol and Rockwell software OPC servers.

The OPCLX driver leverages the Ethernet/IP protocol included in the Rockwell software OPC servers, and connects using an industry standard protocol OPC. The OPC specifications v1.0a and v2.0 are supported. Using this method, you can connect to single or multiple [OPC Devices and Clients](#), as shown in this example configuration.

The Rockwell software OPC servers can also exist on the same computer as the Plant SCADA I/O server and OPCLX driver. Remember that the maximum request length (that is, the maximum of data bits that can be read from the I/O device at any one time) for the OPCLX driver is 2040.

**Note:** With the release of version 7.20, Plant SCADA supports the retrieval of time-stamped data directly from field devices. This capability is enabled by the driver runtime interface (DRI), a component of Plant SCADA that is used by the OPCLX driver to update time-stamped digital alarms, time-stamped analog alarms, and event-based trends directly. For more information, see the topic [Retrieving time-stamped data from field devices](#) in the main Plant SCADA help.

## Safety Information

### Hazard categories and special symbols

The following symbols and special messages may appear in this manual or on the product to warn of potential hazards or to call attention to information that clarifies or simplifies a procedure.

Symbol	Description
 or 	The addition of either symbol to a "Danger" or "Warning" safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.
	This is the safety alert symbol. It is used to alert you to personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.
<b>⚠ DANGER</b>	<b>DANGER</b> indicates an imminently hazardous situation, which, if not avoided, will result in death or serious injury.
<b>⚠ WARNING</b>	<b>WARNING</b> indicates a potentially hazardous situation, which, if not avoided, can result in death or serious injury.
<b>⚠ CAUTION</b>	<b>CAUTION</b> indicates a potentially hazardous situation which, if not avoided, can result in minor or moderate injury.
<b>NOTICE</b>	NOTICE used without a safety alert symbol, indicates a potentially hazardous situation which, if not avoided, can result in property or equipment damage.

## Please Note

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by AVEVA for any consequences arising out of the use of this material.

## Before You Begin

Plant SCADA is a Supervisory Control and Data Acquisition (SCADA) solution. It facilitates the creation of software to manage and monitor industrial systems and processes. Due to Plant SCADA's central role in controlling systems and processes, you must appropriately design, commission, and test your Plant SCADA project before implementing it in an operational setting. Observe the following:

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not use Plant SCADA or other SCADA software as a replacement for PLC-based control programs. SCADA software is not designed for direct, high-speed system control.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**⚠ WARNING****LOSS OF CONTROL**

- The designer of any control scheme must consider the potential failure modes of control paths and, for certain critical control functions, provide a means to achieve a safe state during and after a path failure. Examples of critical control functions are emergency stop and overtravel stop, power outage and restart.
- Separate or redundant control paths must be provided for critical control functions.
- System control paths may include communication links. Consideration must be given to the implications of unanticipated transmission delays or failures of the link.
- Observe all accident prevention regulations and local safety guidelines.<sup>1</sup>
- Each implementation of a control system created using Plant SCADA must be individually and thoroughly tested for proper operation before being placed into service.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

1. For additional information, refer to NEMA ICS 1.1 (latest edition) "Safety Guidelines for the Application, Installation, and Maintenance of Solid State Control", and to NEMA ICS 7.1 (latest edition) "Safety Standards for Construction and Guide for Selection, Installation and Operation of Adjustable-Speed Drive Systems" or their equivalent governing your particular location.

## Prepare the OPC System

This section of the help explains how to prepare your Allen Bradley devices to communicate with Plant SCADA through OPC.

## Software Requirements

In the OPC architecture, each server is allocated a unique identifier, known as a class ID. OPC clients use these 128-bit numbers, frequently displayed in the form 6B29FC40-CA47-1067-B31D-00DD010662DA, to access the OPC server of a particular vendor. These numbers are often referred by a manageable string identifier called a Program Identifier (ProgID). These identifiers usually take the format Vendor.Application with an optional version number appended. For example, the Allen Bradley FactoryTalk OPC server ProgID is RSOPC Gateway.

Before the OPCLX client driver can access a particular OPC server, the ProgID of the server needs to be entered into the Plant SCADA I/O server registry. If an in-process server or a local server is used, this is done automatically during the installation of the server. To access a remote server, refer to the documentation accompanying the server. Frequently, this step is achieved using a registry script (a .REG file) or a small

executable.

#### NOTICE

#### LOSS OF DATA

- Appropriately configure DCOM settings to browse the remote OPC servers.
- Assign appropriate privileges to the accounts being used by the operators.

**Failure to follow these instructions can result in equipment damage.**

#### Note:

- Familiarize yourself with the target OPC server before using this driver. This will help you enter the item identifiers for the tag addresses using the correct syntax.
- Using remote servers requires configuring DCOM security. Since configuring security is complex, you can plan your system settings in advance, and establish a protocol so that the Windows accounts to be used by operators have sufficient privilege. If sufficient privileges are not established, there may be communication interruptions found.

## OPC Devices and Clients

This section provides information required to configure Allen Bradley OPC devices and clients within your Plant SCADA project.

- [Device Address](#)
- [Communication Settings](#)
- [Data Types](#)
- [Include Project Support](#)

### Device Address

The address to use is the ProgID for the desired server.

This usually takes the form "<Vendor>.<Application>" and can be found in the documents accompanying the OPC server.

### See Also

[Communication Settings](#)

### Communication Settings

To establish communication with a device, configure the Boards, Ports and I/O Devices in the Plant SCADA Studio's **Topology** activity correctly. If you use the Express Communications Wizard to connect to a device, these will be automatically configured for you. However, if you need to configure them manually, use the settings outlined below.

## Boards

Field	Value
Board Name	A unique name (up to 16 alphanumeric characters) per server for the computer board being used to connect with the device. This is used by Plant SCADA in the Ports dialog box.
Board Type	The type of board. Select OPCLX.
Address	<p>Plant SCADA does not need an address for the OPC client. Instead you use the <b>Address</b> box to set the device scan rate on the OPC server in milliseconds. The value read from the OPC server is typically taken from the OPC server cache. The scan rate value is often used to indicate how often the OPC server polls the device and updates its cache.</p> <p>Enter 0 (zero) to use the default of 250 ms. Enter any other value to use that value. Valid values range from eight character decimal 0 to 99999999. Up to six character hex values can be used; however, these must be preceded with 0x.</p> <p><b>Note:</b> Plant SCADA supports unsolicited OPC requests. So if you set the OPC server to notify Plant SCADA of changes to the value or quality of an OPC device item, make sure that the OPC server scan rate is short enough to provide Plant SCADA within an adequate timeframe.</p>
I/O Port	Leave this field blank.
Interrupt	Leave this field blank.
Special Options	<p>OPC server machine name. (Do not enter this name using the traditional dash delimited style. Enter the machine name, for example Cit_Primary.)</p> <p><b>Note:</b> The name entered here is the Windows machine name. For Windows NT and Windows 95 or 98 based OPC servers, you can obtain this from the Identification tab of the network properties of OPC server machine. For other OPC server configurations, refer to the documentation of the server. If this field is left blank, the server name is sought in the following manner:</p> <ul style="list-style-type: none"> <li>a) The in-process (DLL) server on the I/O server machine;</li> <li>b) The local (EXE) server on the I/O server machine;</li> </ul>

Field	Value
	c) The remote server as entered in the DCOM settings of the I/O server machine.
Comment	Any useful comment.

## Ports

Field	Value
Port Name	A unique name (up to 16 alphanumeric characters) for the computer port being used to connect with the device. This is used by Plant SCADA in the Devices dialog box.
Port Number	An integer value, unique to the board as defined in the Board name field. The Ethernet port needs no identification; however the Plant SCADA communication database requires a value in this field.
Board Name	The name of the board this port is attached to as defined on the Boards dialog box.
Baud Rate	Leave this field blank.
Data Bits	Leave this field blank.
Stop Bits	Leave this field blank.
Parity	Leave this field blank.
Special Options	Leave this field blank.
Comment	Any useful comment.

## I/O Devices

Field	Value
Name	A unique name (up to 16 alphanumeric characters) for the I/O Device being identified. Each I/O Device must have a unique name in the Plant SCADA system.
Number	A unique number for the I/O Device (0–16383). Each I/O Device must have a unique number in the Plant SCADA system (unless redundancy of the I/O Device is being used).

Field	Value
Address	ProgID for the desired server. These usually take the form Vendor.Application (for example, Allen Bradley FactoryTalk OPC server ProgID is RSOPC.Gateway) and should be found in the documents accompanying the OPC server.
Protocol	Enter OPCLX. See <a href="#">Arrays Support</a> .
Port Name	This field must contain one of the names previously defined in the Port Names field of the Ports dialog box. There must be only one I/O device per port.
Comment	Any useful comment.

## Data Types

OPC servers can provide data in different data formats. An OPC client can request data in a specific format or use the type of the server (that is, the type, in which the data is stored within the server).

When specifying a data type, consider whether the server is able to convert data to the requested type.

Use the table below to help you specify a type for a variable tag. It shows mappings from the types used by OPCLX (VARTYPE) to Plant SCADA data types.

OPCLX type (VARTYPE)	Description	Plant SCADA data type
VT_BOOL	Boolean	DIGITAL
VT_UI1	Byte	BYTE
VT_I2	2 byte integer	INT
VT_UI2	2 byte unsigned integer	UINT
VT_I4	4 byte integer	LONG
VT_U14	4 byte unsigned integer	ULONG (requires v7.0)
VT_CY	Currency	STRING
VT_R4	4 byte real	REAL
VT_R8	8 byte real	STRING
VT_DATE	Date	STRING
VT_BSTR	String	STRING
VT_ERROR	Error Value	LONG

OPCLX type (VARTYPE)	Description	Plant SCADA data type
VT_QUALITY	2 byte integer	INT
VT_TIMESTAMP	4 byte integer	LONG
VT_MILLISECOND	4 byte integer	LONG

## Include Project Support

Variable tags defined in a project compiled on a Plant SCADA client need to match exactly to the tags defined in the project compiled on the I/O server. If a tag is added on the client, it also needs to be added on the I/O server. Otherwise client requests may become mismatched and result in inaccessible tag data.

## Configure Variable Tags

This section provides information that describes how to configure variable tags for OPCLX devices within your Plant SCADA project.

- [Tag Address Configuration](#)
- [Arrays Support](#)
- [Quality Values](#)
- [Time Stamp and Quality Tags Configuration](#)

### Tag Address Configuration

The tags supported by OPCLX are:

- Controller tags
- Program tags.

### Controller Tags

Controller tags contain data which is accessible to the programs within the RSLogix project. When controller tag is configured in OPC gateway, the same can be configured in the Plant SCADA in the following formats depending on the OPC server:

[OPCTopic]TagName

Syntax with the FactoryTalk and RSLinx Classic is the same in case of controller tags.

The table below describes the syntax and example for configuring controller tags:

Address	Plant SCADA type	OPCLX type	Example
[OPCTopic]<item_id>	DIGITAL	VT_BOOL	[OPCLX_test]bool_symbol
[OPCTopic]<item_id>	BYTE	VT_UI1	[OPCLX_test]byte_symbol

Address	Plant SCADA type	OPCLX type	Example
[OPCTopic]<item_id>	INT	VT_I2	[OPCLX_test]int_symbol
[OPCTopic]<item_id>	LONG	VT_I4	[OPCLX_test]long_symbol
[OPCTopic]<item_id>	REAL	VT_R4	[OPCLX_test]real_symbol
[OPCTopic]<item_id>	STRING	VT_ARRAY of VT_UI1	[OPCLX_test]bool_symbol

## Program Tags

Program tags contain data that is used exclusively within a program in RSLogix project. When a program tag is configured in OPC gateway, the same can be configured in Plant SCADA in the following formats depending on the OPC server:

Syntax with the FactoryTalk OPC server is:

::[OPCTopic]Program:MainProgram.<TagName>

Syntax with the RSLinx Classic OPC server is:

[OPCTopic]Program:MainProgram.<TagName>

The table below describes the syntax and example for configuring program tags RSLinx Classic:

Address	Plant SCADA type	OPCLX type	Example
[OPCTopic]<Program:MainProgram>.<item_id>	DIGITAL	VT_BOOL	[OPCLX_test] Program:MainProgram.bool_symbol
[OPCTopic]<Program:MainProgram>.<item_id>	BYTE	VT_UI1	[OPCLX_test] Program:MainProgram.byte_symbol
[OPCTopic]<Program:MainProgram>.<item_id>	INT	VT_I2	[OPCLX_test] Program:MainProgram.int_symbol
[OPCTopic]<Program:MainProgram>.<item_id>	LONG	VT_I4	[OPCLX_test] Program:MainProgram.long_symbol
[OPCTopic]<Program:MainProgram>.<item_id>	REAL	VT_R4	[OPCLX_test] Program:MainProgram.real_symbol
[OPCTopic]<Program:MainProgram>.<item_id>	STRING	VT_ARRAY of VT_UI1	[OPCLX_test] Program:MainProgram.bool_symbol

The table below describes the syntax and examples for configuring program tags FactoryTalk:

Address	Plant SCADA type	OPCLX type	Example
::[OPCTopic]<Program:Ma inProgram>. <item_id>	DIGITAL	VT_BOOL	::[OPCLX_test] Program:MainProgram. bool_symbol
::[OPCTopic]<Program:Ma inProgram>. <item_id>	BYTE	VT_UI1	::[OPCLX_test] Program:MainProgram. byte_symbol
::[OPCTopic]<Program:Ma inProgram>. <item_id>	INT	VT_I2	::[OPCLX_test] Program:MainProgram. int_symbol
::[OPCTopic]<Program:Ma inProgram>. <item_id>	LONG	VT_I4	::[OPCLX_test] Program:MainProgram. long_symbol
::[OPCTopic]<Program:Ma inProgram>. <item_id>	REAL	VT_R4	::[OPCLX_test] Program:MainProgram. real_symbol
::[OPCTopic]<Program:Ma inProgram>. <item_id>	STRING	VT_ARRAY of VT_UI1	::[OPCLX_test] Program:MainProgram. bool_symbol

## Arrays Support

To associate a Plant SCADA variable tag with an OPC array, you can place a delimiter like "!" after OPC array address string. The capital letter "A" which when combined as below, instructs the Plant SCADA OPCLX driver that the address is for an array. Follow both with the array size as an integer enclosed within square brackets, as below:

<OPCTOPIC><OPCArrayName>,L<OPCArrayLength>!A[<OPCArrayLength>]

---

**Note:** Replace the placeholders <OPCTOPIC>, <OPCArrayName>, and <OPCArrayLength> in the Address box with the actual valid values of the OPC Topic, OPC array name, and length you want to use, as defined in the OPC server.

In the following example with an OPCLX tag defined on a OPC server, five register addresses are associated with the Plant SCADA variable tag named Status\_Flags:

- **Variable Tag Name:** Status\_Flags
- **Address:** [OPCLX\_test]status\_flags,L10!A[10]

You can access individual elements of an OPC array in Plant SCADA by specifying the Plant SCADA tag name and an index number representing the individual element of the array. For example, to refer to the third variable of the array in the above example (Status\_Flags), use this syntax in Plant SCADA:

Variable tag: Status\_Flags[2]

---

**Note:** OPC arrays use zero-based indexing. For example, a five register array would contain individual elements

---

indexed as 0, 1, 2, 3, and 4.

The OPCLX address checking in Plant SCADA always checks if the '!A[<n>]' suffix is used; otherwise the tag is not recognized as an OPC array. Therefore the format '!A[<n>]' must be followed in a tag address if the tag is defined as an array tag.

## **WARNING**

### **UNINTENDED EQUIPMENT OPERATION**

Ensure that the OPCLX address format used is compliant for the OPC server with which you are communicating.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

## **Example**

When Plant SCADA writes to an OPC array, the whole array is read from the driver cache, modified, then written back to the OPC server. However, the driver cache is not updated with the newer data until the server performs its housekeeping tasks and notifies the driver that the array value has been changed. During this time, it is possible for another write request to have been issued with a now out-of-date copy of the original array data from the not-yet-updated driver cache. Later if you write back to the server, any changes made in the first request of this scenario may be lost inadvertently if they are overwritten by the original duplicated data in the second write-back.

To minimize this, the OPCLX driver in Plant SCADA is forced to do a synchronized read before data is modified. However it still has the possibility of losing data if that data is changed by other OPC clients between the time the data is read out and written back. For this reason, it is not recommended that OPC arrays be used in Plant SCADA while other OPC clients may be accessing the same data.

## **WARNING**

### **UNINTENDED EQUIPMENT OPERATION**

Do not use OPC arrays in Plant SCADA while other OPC clients have access to the same data.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

The table below describes the syntax and examples for configuring a full array accessing tags:

Address	Plant SCADA type	OPCLX type	Example
[OPCTopic]<item_id>, L<size>!A[size]	DIGITAL	array of VT_BOOL	[OPCLX_test]bool_symbol, , L10!A[10]
[OPCTopic]<item_id>, L<size>!A[size]	BYTE	array of VT_UI1	[OPCLX_test]byte_symbol, , L10!A[10]
[OPCTopic]<item_id>, L<size>!A[size]	INT	array of VT_I2	[OPCLX_test]int_symbol, , L10!A[10]

Address	Plant SCADA type	OPCLX type	Example
[OPCTopic]<item_id>, L<size>!A[size]	LONG	array of VT_I4	[OPCLX_test]long_symbol, L10!A[10]
[OPCTopic]<item_id>, L<size>!A[size]	REAL	array of VT_R4	[OPCLX_test]real_symbol, L10!A[10]

The table below describes the syntax and examples for configuring index-based array tags:

Address	Plant SCADA type	OPCLX type	Example
[OPCTopic]<item_id>[index]	DIGITAL	VT_BOOL	[OPCLX_test]bool_symbol[9]
[OPCTopic]<item_id>[index]	BYTE	VT_UI1	[OPCLX_test]bytee_symbol[9]
[OPCTopic]<item_id>[index]	INT	VT_I2	[OPCLX_test]int_symbol[9]
[OPCTopic]<item_id>,[index]	LONG	VT_I4	[OPCLX_test]long_symbol[9]
[OPCTopic]<item_id>[index]	REAL	VT_R4	[OPCLX_test]real_symbol[9]

The table below describes the syntax and examples for configuring full array accessing tags from the specified start index:

Address	Plant SCADA type	OPCLX type	Example
[OPCTopic]<item_id>[index],L<size>!A[size]	DIGITAL	array of VT_BOOL	[OPCLX_test]bool_symbol[1], L10!A[10]
[OPCTopic]<item_id>[index],L<size>!A[size]	BYTE	array of VT_UI1	[OPCLX_test]bytee_symbol[1], L10!A[10]
[OPCTopic]<item_id>[index],L<size>!A[size]	INT	array of VT_I2	[OPCLX_test]int_symbol[1], L10!A[10]
[OPCTopic]<item_id>[index],L<size>!A[size]	LONG	array of VT_I4	[OPCLX_test]long_symbol[1], L10!A[10]
[OPCTopic]<item_id>[index],L<size>!A[size]	REAL	array of VT_R4	[OPCLX_test]symbol[1], L10!A[10]

The table below describes the syntax and examples for configuring structured array tags:

Address	Plant SCADA type	OPCLX type	Example
[OPCTopic]<item_id> [index1].<subindex> [index2],L<size>!A[size]	DIGITAL	array of VT_BOOL	[OPCLX_test]bool_symbol [1].tag[2], L10!A[10]
[OPCTopic]<item_id> [index1].<subindex> [index2],L<size>!A[size]	BYTE	array of VT_UI1	[OPCLX_test]byte_symbol [1].tag[2], L10!A[10]
[OPCTopic]<item_id> [index1].<subindex> [index2],L<size>!A[size]	INT	array of VT_I2	[OPCLX_test]int_symbol[1] .tag[2], L10!A[10]
[OPCTopic]<item_id> [index1].<subindex> [index2],L<size>!A[size]	LONG	array of VT_I4	[OPCLX_test]long_symbol [1].tag[2], L10!A[10]
[OPCTopic]<item_id> [index1].<subindex> [index2],L<size>!A[size]	REAL	array of VT_R4	[OPCLX_test]symbol[1].ta g[2], L10!A[10]

## Quality Values

The following masks are general bitmasks:

OPC_QUALITY_MASK	0xC0
OPC_STATUS_MASK	0xFC
OPC_LIMIT_MASK	0x03

These are specific quality values:

OPC_QUALITY_BAD	0x00
QUALITY_UNCERTAIN	0x40
OPC_QUALITY_GOOD	0xC0
OPC_QUALITY_CONFIG_ERROR	0x04
OPC_QUALITY_NOT_CONNECTED	0x08
OPC_QUALITY_DEVICE_FAILURE	0x0C

OPC_QUALITY_SENSOR_FAILURE	0x10
OPC_QUALITY_LAST_KNOWN	0x14
OPC_QUALITY_COMM_FAILURE	0x18
OPC_QUALITY_OUT_OF_SERVICE	0x1C
OPC_QUALITY_LAST_USABLE	0x44
OPC_QUALITY_SENSOR_CAL	0x50
OPC_QUALITY_EGU_EXCEEDED	0x54
OPC_QUALITY_SUB_NORMAL	0x58
OPC_QUALITY_LOCAL_OVERRIDE	0xD8

These can modify any of the above:

OPC_LIMIT_OK	0x00
OPC_LIMIT_LOW	0x01
OPC_LIMIT_HIGH	0x02
OPC_LIMIT_CONST	0x03

[Time Stamp and Quality Tags Configuration](#)

### Time Stamp and Quality Tags Configuration

The Plant SCADA OPCLX driver can use additional variable tags for quality and time stamp values. Quality or time stamp tags are duplicates of a variable tag, with an appended "!Q" or "!T" or "!M" in the address field to define their purpose. Quality tags need to be configured as either INT or DIGITAL data types, whereas time stamp tags need to be configured as LONG data types.

Below table shows the example of quality or timestamp tags:

Address	Plant SCADA type	Description
[OPCTopic]<item_id>!Q	INT	The quality reported for the item.
[OPCTopic]<item_id>!T	LONG	The second's component of the timestamp reported for the item (in UTC seconds).
[OPCTopic]<item_id>!M	LONG	The milliseconds component of the timestamp reported for the item.

If you need to know if an OPC item is good or bad quality (that is, not uncertain), you should consider using DIGITAL data types for quality tags in combination with [OPCLX]DigitalQualityUncertainIsBad, rather than using Cicode to compare the value of an INT quality tag against 0xCO

---

**Note:** The quickest way to create a quality or time stamp tag in Plant SCADA is to locate the relevant variable tag using the Variable Tags dialog box. Edit it as required to create a quality or time stamp tag, and save it. This creates a copy of the original variable tag with the required changes saved.

#### To create a quality tag:

1. Go to the **System Model** activity of the Plant SCADA **Studio**.
2. On the menu below the Command Bar, select **Variables**.
3. Add a row to the Grid Editor, or locate and display the equipment to which you want to associate the quality tag.
4. Type the required information in each column, or in the fields in the **Property Grid**.
5. In the **Tag Name** box, enter an appropriate and unique name for the quality tag, such as "<Tagname>\_Quality".
6. In the **Data Type** box, choose INT or DIGITAL from the menu.
7. In the **I/O Device** box, select the appropriate I/O device for the tag (if not already displayed).
8. In the **Address** box, enter the name of the tag you want to associate with the quality value (if not already displayed), and append "!Q" directly to the end of the address (without the quotes and without any spaces).
9. Click **Save**.

---

**Note:** If the exclamation mark character (!) is already defined in the tag address field (for example, you have already used it to declare an array size "!A[n]"), you either need to include another exclamation mark (for example, append "!Q" to the tag address) after the closing square bracket of the array size declaration, or you can specify quality for arrayTag!A[5] with arrayTag!Q".

#### To create a time stamp tag:

1. Go to the **System Model** activity of the Plant SCADA **Studio**.
2. On the menu below the Command Bar, select **Variables**.
3. Add a row to the Grid Editor, or locate and display the equipment to which you want to associate the quality tag.
4. Type the required information in each column, or in the fields in the **Property Grid**.
5. In the **Tag Name** box, enter an appropriate and unique name for the quality tag, such as "<Tagname>\_sTimestamp" (for seconds) or "<Tagname>\_msTimestamp" (for milliseconds).
6. In the **Data Type** box, choose LONG from the menu.
7. In the **I/O Device** box, select the appropriate I/O device for the tag (if not already displayed).
8. In the **Address** box, enter the name of the tag you want to associate with a time stamp value (if not already displayed), and append "!T" or "!M" (as appropriate).

---

**Note:** If there is already an exclamation mark with other declarations included in the tag address, you do not need to include them for timestamping. For example, a time stamp tag monitoring TagName!A[64] can be addressed as TagName!T.

1. Click **Save**.

**Note:** Time stamps store the number of seconds since 01/01/1970 when using the "!T" element, or the number of milliseconds since midnight using the "!M" element. If you want to store a complete time in millisecond accuracy, you need to create two separate time stamp tags, one for seconds and one for milliseconds, each addressed appropriately.

## Examples

In the following examples, an OPC device tag defined on a OPC server is associated with the base Plant SCADA variable tag named Present\_Value:

<b>Variable Tag Name</b>	Present_Value
<b>Address</b>	[OPCLX_test]present_value
<b>Plant SCADA Data Type</b>	Data type required by project (for a list of data types, see <a href="#">Data Types</a> )

### Example 1

Use the following settings to associate a Plant SCADA variable tag with the quality stamp of the OPC register value:

<b>Variable Tag Name</b>	Present_Value
<b>Address</b>	[OPCLX_test]present_value!Q
<b>OPCLX Type</b>	VT_QUALITY
<b>Plant SCADA Data Type</b>	INT or DIGITAL

### Example 2

The following tag definition reads the timestamp value measured in seconds from 1/Jan/1970:

<b>Variable Tag Name</b>	Present_Value
<b>Address</b>	[OPCLX_test]present_value!T
<b>OPCLX Type</b>	VT_TIMESTAMP
<b>Plant SCADA Data Type</b>	LONG

### Example 3

The tag definition below reads the Millisecond time stamp value measured in UTC FileTime from beginning (midnight) of the current day:

<b>Variable Tag Name</b>	Present_Value
<b>Address</b>	[OPCLX_test]present_value!M
<b>OPCLX Type</b>	VT_MILLISECOND
<b>Plant SCADA Data Type</b>	LONG

The base Plant SCADA tag needs to be defined in Plant SCADA before the time stamp and quality values of the associated OPC server tag value can be read.

See also [Data Types](#) and [Quality Values](#).

## Advanced Configuration and Maintenance

This section provides advanced configuration instructions.

- [Status Tags](#)
- [Customize a Project Using Citect.ini Parameters](#)
- [Configure Redundancy](#)
- [Scan Rates](#)
- [Diagnostics](#)

### Status Tags

You can define status tags in your Citect.ini file to allow the OPCLX driver to determine the current state of an OPCLX device. For example, a status tag could be configured to monitor an OPC item that indicates the current operational state of a connected device. If the condition of the status tag is true, the OPCLX driver can allow the device to be online; otherwise the device may be set to offline.

By default, no status tags are created for the OPCLX driver. They need to be defined in the project Citect.ini file using the OPCLX status tag parameters. These parameters determine which OPC items are monitored, the condition values, and how often polling occurs.

A status tag can be defined in the [OPCLXStatusTags] section of the Citect.ini file to determine the online status of OPCLX devices. You can also create status tag set for each individual I/O device using the following format:

```
[OPCLXStatusTags]
<IOServerName>.<IODeviceName>.<parameter>=<value>
```

For example:

```
[OPCLXStatusTags]
io1.iodev1.tag=ARB3183800_S_2.REQNUM
io1.iodev1.condition=<=10
```

Where:

"ARB3183800\_S\_2.REQNUM" refers to an OPC item configured in the device.

If you are not regularly reading from a particular device, it is recommended that you enable status unit checks. To do this, you need to enable the parameter [IOServer]WatchDogPrimary. Standby units are enabled by default.

See also [Time Stamp and Quality Tags Configuration](#).

## Customize a Project Using Citect.ini Parameters

You use Citect.ini parameters to fine-tune the performance of the Plant SCADA OPCLX driver and to perform runtime maintenance diagnostics.

- Common Driver Parameters
- Driver-specific Parameters
- OPCLX Device-specific Parameters
- OPCLX Access Path Parameters
- Status Tag Parameters
- Logging Parameters

**Note:** Support for array parameters in the OPCLX driver has been deprecated in Plant SCADA version 7. To use similar functionality, you should use the procedures described in [Arrays Support](#).

### **WARNING**

#### UNINTENDED EQUIPMENT OPERATION

- Under any circumstances do not change or remove any of the undocumented citect.ini parameters.
- Before deleting sections of the citect.ini file, confirm that no undocumented parameters are deleted.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of technical support personnel for this product regarding undocumented features.

You can customize the way Plant SCADA communicates with the OPC system, and even individual PLCs, by creating or editing the [OPCLX] section of the Citect.ini file for your project.

There are some common Plant SCADA OPCLX driver settings, and custom Plant SCADA OPCLX driver settings. When Plant SCADA starts at runtime, it reads configuration values from the Citect.ini file stored locally. Therefore, any OPCLX configuration settings need to be included in the Citect.ini file located on the computer acting as the I/O server to the OPC system.

**Note:** By default, Plant SCADA looks for the ini file in the Plant SCADA project \bin directory. If it cannot find it there, it searches the default Windows directory.

The default values for these parameters have been determined by driver development and testing to be optimal for the Plant SCADA OPCLX driver. Parameters with a default value are tested to work in common configurations. Do not adjust these default values except on the direct advice of customer support.

### Common Driver Parameters

The following table describes the common citect.ini driver parameters.

[OPCLX] Parameters	Allowable values	Default value	Description
Block	5 to 256	255	A value (bytes) used by

[OPCLX] Parameters	Allowable values	Default value	Description
			the Plant SCADA I/O server to determine if two or more packets can be blocked into one data request before being sent to the OPCLX driver. For example, if you set the value to 10, and the I/O server receives two simultaneous data requests (one for byte 3, and another for byte 8) the two requests are blocked into a single physical data request packet. This single request packet is then sent to the I/O device, saving on bandwidth and processing.
Delay	0 to 300	0	Period (in Milliseconds) to wait between receiving a response and sending the next command to the I/O server.
MaxPending	1 to 1024	250	Maximum number of pending commands that the Plant SCADA OPCLX driver holds ready for immediate execution.
Poltime	0 to 300	1000	Polling service time (in milliseconds) at which cached data is updated. Recommended to be at least twice that of the value used in the Citect.INI [ALARM] ScanTime parameter.
Retry	0 to 8	0	Number of times to retry a command after a timeout.

[OPCLX] Parameters	Allowable values	Default value	Description
Timeout	0 to 32000	3000	Waiting period (in Milliseconds) between a response before considering a write or polling request to be invalid and displaying a detected error message in Plant SCADA.
Watchtime	0 to 128 (seconds)	15	Frequency that the Plant SCADA OPCLX driver uses to check the communications link to the OPC system and attempts to bring offline units back online. Also determines the frequency of STATUS_UNIT commands to the driver. See Configuring Redundancy.

### Driver-specific Parameters

The following table describes the citect.ini parameters that are specific to the OPCLX driver.

[OPCLX] Parameters	Allowable values	Default value	Description
AddItemAsVtEmpty	0 - Specify data types 1 - Use native data type	1	Determines whether the OPCLX driver specifies a data type when adding an item, or whether it uses the native data type when adding items. This parameter is used to select whether the OPC client specifies a type to force the OPC server to coerce the data, or for the OPC server to provide the type as configured on the server.
ArrayRecordBase	Greater than total	30000	Specifies the base of the

[OPCLX] Parameters	Allowable values	Default value	Description
	number of tags and less than (65000 – number of arrays)		array record numbers. Plant SCADA communicates with the OPCLX client driver by the record number of the tag in variable.dbf, so this parameter needs to be greater than the total number of tags in the project.
CacheRead	0 – Value is refreshed and the latest value returned. 1 – Last known value returned.	1	Determines the value returned when an inactive item is read. See <a href="#">Overriding [OPCLX]CacheRead</a> for information on how to override the value of this parameter for a particular tag.
DigitalQualityUncertainIsBad	0 - An uncertain quality is treated as GOOD when a digital quality reading is taken (normal INT version is unaffected)  1 - an uncertain quality is treated as BAD when a digital quality reading is taken (normal INT version is unaffected)	1	Determines how an uncertain quality result is treated when a digital quality reading is taken.
FailOnBadData	0 - If the OPC_QUALITY status for data from a tag is BAD, the driver returns the last known value, and reports no error detected.  1 - If the OPC_QUALITY status for data from a tag is BAD, the driver reports a severity error detected and displays #BAD on all tags of the read block.  2 - If the OPC_QUALITY status for data from a tag	1	Determines whether read requests sent to the OPC client driver return a detected error if one or more of the requested tags are of bad quality data. Bad quality is still a valid value for a tag, and indicated by the OPC_QUALITY status of BAD.

[OPCLX] Parameters	Allowable values	Default value	Description
	is BAD, the driver reports a severity error detected and displays #BAD on all tags of the read block. The start UnitAddress of the read block appears in the kernel window.		
FailOnUncertain	0 - Driver returns the last known tag value and the read succeeds. 1 - Driver returns ERROR_BAD_DATA_VALUE .	0	Determines the value returned when reading data from tags for which the OPC_QUALITY status is UNCERTAIN.
FillCacheOnStartup	0 - Subscriptions are created in the inactive state and are only activated as read request are received. 1 - Subscriptions are created in the active state.	0	Determines whether subscriptions are created in the active or inactive state initially.
GoOfflineForBadTag	0 - disabled. Do not go offline. 1 - enabled. Go offline.	0	Sets all tags on an OPC device to a OPC_QUALITY status of GOOD before Plant SCADA declares the I/O device online.  This parameter would only be set on the I/O server where the device is defined as primary. So it can only take over from a standby device definition when all tags and the status tag are valid. This minimizes the chances that com-breaks occur during switchover from standby to primary. It is recommended not to set it on a standby, as it may only be one tag that is invalid.

[OPCLX] Parameters	Allowable values	Default value	Description
InhibitActivationOnStandby	0 - A standby server follows the same rules for subscription activation as the primary server.  1 - A standby server only activates a subscription if it believes that the primary server is not active.	0	This parameter allows a standby server to leave subscriptions in an inactive state deliberately, when the primary server is online. This is used when the primary and standby servers are talking to independent OPC servers to reduce the load that the standby OPC server would place on field devices.  On startup of a standby server, if this parameter is set to 1, items are not activated immediately. They are only activated when the unit itself becomes the active unit.
ItemLifeTime	Time (seconds)	5	Determines the time in before a tag is deemed inactive.  The global LeaveTagsActive parameter overrides the ItemLifeTime parameter to force OPCLX tags to remain active even though Plant SCADA is no longer requesting them from the driver.  The ItemLifeTime parameter can be individually overridden for any Allen Bradley OPC device by the active parameter.

[OPCLX] Parameters	Allowable values	Default value	Description
LeaveTagsActive	0 - Do not leave tags active. 1 - Leave tags active.	0	<p>Determines whether OPCLX tags remain active even though Plant SCADA is no longer requesting them from the driver. Normally tags are made inactive 5 seconds from the last time they are requested.</p> <p>Some OPC servers take a long time to return a call to activate/inactivate tags, or doing so slows them down. Therefore leaving tags active can improve performance.</p> <p>The global LeaveTagsActive parameter can be individually overridden by an Active parameter. See ItemLifeTime parameter (above).</p> <p><b>Note:</b> This parameter minimizes the likelihood of deactivation of tags on the currently active unit only. Tags on units that have become inactive (standby) still deactivates.</p>
NumConcurrentServerInits	-1 - Unlimited 32767	-1	Represents the maximum number of concurrent initialization and shutdown operations that are performed on each configured OPC server. Higher values, or -1 (unlimited), incur greater load on the server. While 0 and 1 determine that initialization is serialized into effectively a single thread.

[OPCLX] Parameters	Allowable values	Default value	Description
OPCGroupName	Any string (maximum 32 characters)	CitectGroup_<n>	<p>By default, each OPC server is allocated a sequential group name by the OPCLX driver, that is, CitectGroup_1, CitectGroup_2, and so on.</p> <p>This parameter allows you to replace the default group name with a customized name.</p> <p>You can set this parameter at a device level using <a href="#">OPCLX Device-specific Parameters</a>.</p>
ReadAfterWrite	<p>0 - No read, rely on the normal polling/ OnDataChange mechanism.</p> <p>1 - Force sync read of item written from OPC server cache after write.</p> <p>2 - Force sync read of item written from device after write.</p>	0	<p>Determines if a force read should be made, and if it should be from the OPC server cache or from the device.</p> <p><b>Note:</b> RefreshAfterWrite causes a refresh of all active items, whereas ReadAfterWrite reads only the item being written. You should use one or the other. Where both RefreshAfterWrite and ReadAfterWrite are set to 1, RefreshAfterWrite takes precedence, and ReadAfterWrite is set to 0.</p>
RefreshAfterAdd	<p>0 - No REFRESH.</p> <p>1 - Request a REFRESH from the OPC server cache.</p> <p>2 - Request a REFRESH from the device.</p>	1	<p>Determines whether an OPC REFRESH is requested from the OPC server after activating the group.</p> <p>This parameter can be disabled if slow start-up time is experienced. The server could be automatically sending a REFRESH, in which case another request may be</p>

[OPCLX] Parameters	Allowable values	Default value	Description
			unnecessary.
RefreshAfterWrite	0 – Disable forced REFRESH.  1 - Enable forced REFRESH from OPC server cache.  2 - Enable forced REFRESH from device.	0	Determines whether to force an OPC REFRESH from the OPC server of ALL active items after Plant SCADA writes to an item.
RefreshBeforeArrayWrite	0 – No refresh command sent  1 – Read command sent to refresh the OPC server cache  2 – Read command sent to refresh the OPC device	0	Enables the driver to send a read command to the OPC server before a write command is sent to the OPC server for an array variant.
ServerOnlineStates	"RUNNING"  "FAILED"  "NOCONFIG"  "SUSPENDED"  "TEST"	"RUNNING"	Defines the list of OPC server states that the driver considers online. The format is a "   " separated string, without spaces. If you experience the OPC server shutting down on startup, it is recommended that the following states are used: "RUNNING   NOCONFIG   SUSPENDED"
ShutdownWait	Time (milliseconds)	30000	Determines the time the OPCLX driver waits before shutting down. On shutdown, the driver attempts to close the connection to the OPC server. If this takes longer than the time specified by this parameter, the driver shuts down anyway

[OPCLX] Parameters	Allowable values	Default value	Description
			(sometimes with unexpected results). This parameter may be needed if the OPC server does not respond within the default wait time.
StatusWaitPeriod	Time (milliseconds)	50000	Determines the time the OPCLX driver waits before requesting tag status for an OPC I/O device. On startup, the OPCLX driver waits for a unit status from the OPC server before adding tags to the server. If the value of this parameter is exceeded, the tags are added anyway. The OPC server should respond within a few seconds. The default wait time of 5 seconds should usually be adequate.
SuppressData NotYetValidError	0 – Displays "Data Not Yet Valid" errors in the Kernel window and logs them to the Syslog.dat file.  1 - Suppresses "Data Not Yet Valid" errors, which are not displayed in the Kernel window or logged. In the kernel, under View -> I/O Devices, Plant SCADA will display "Error Suppressed" in the Error Message field for the particular device.	0	Determines whether "Data Not Yet Valid" error messages are suppressed, or whether they are displayed in the Kernel window and written to the Syslog.dat file. For Plant SCADA to display the message "Error Suppressed", you need v5.50 or above.

[OPCLX] Parameters	Allowable values	Default value	Description
UseArrays	0 - OPC array support disabled. 1 - OPC array support enabled.	1	Determines whether array support parameters in the [OPCArrays] section are active. See OPC Array Parameters.
UseAsyncWrites	0 - use synchronous writes. 1 - use asynchronous writes.	0	Determines whether writes are synchronous or asynchronous.
UseStatusTags	0 - disabled. 1 - enabled.	0	Determines whether parameters in the [OPCLXStatusTags] section are active. Individual overrides can be set using the <a href="#">OPCLX Device-specific Parameters</a> to force the use of a particular status tag parameter with a particular I/O device.
ValidDataWaitPeriod	Time (milliseconds)	10 seconds	<p>Determines the maximum time that the OPCLX driver waits for OPC_QUALITY to be GOOD for all tags before declaring the device online. This minimizes the likelihood of a client swapping from a standby to a primary prematurely and suppresses alarm flooding at startup. Set this parameter to 0 to allow units to be online regardless of whether all items for the unit have been verified as good quality.</p> <p><b>Note:</b> FillCacheOnStartup=1</p>

[OPCLX] Parameters	Allowable values	Default value	Description
			needs to be set when ValidDataWaitPeriod>0.
WriteTrueAs1	0 - write true as VARIANT_TRUE(-1). 1 - write true as 1.	0	Determines whether a digital value of TRUE is written as "VARIANT_TRUE(-1)" or "1". This parameter should only be required for incorrectly designed OPC servers. When the Plant SCADA data type is digital, VARIANT_TRUE (-1) is used with VT_BOOL variant type to write a value of true. This happens even if [OPCLX]AddItemAsVtEmpty is set, as OPC servers should be designed to convert the value when they receive it.

### OPCLX Device-specific Parameters

The following table describes the citect.ini parameters that are specific to the OPCLX driver.

[OPCLX] Parameters	Allowable values	Default value	Description
Active	0 - deactivate tag. 1 - leave tag active.	Value of LeaveTagsActive parameter.  See <a href="#">Driver-specific Parameters</a> .	Allows you to override the global default value of LeaveTagsActive parameter individually to specify whether tags should be left active or inactive for a particular OPCLX I/O device.  Replace the placeholders <IOServerName> and <IODeviceName> in the

[OPCLX] Parameters	Allowable values	Default value	Description
			<p>parameter with the names of the OPC I/O server and I/O device you want to override and be active.</p> <p>Determines whether individual OPCLX tags are left active even though Plant SCADA is no longer requesting them from the driver. Normally tags are made inactive 5 seconds from the last time they are requested.</p> <p>See the ItemLifeTime parameter in <a href="#">Driver-specific Parameters</a>.</p>
Update	Time (seconds)	5	<p>Determines the time in before a tag is deemed inactive.</p> <p>The global LeaveTagsActive parameter overrides the ItemLifeTime parameter to force OPCLX tags to remain active even though Plant SCADA is no longer requesting them from the driver.</p> <p>The ItemLifeTime parameter can be individually overridden for any Allen Bradley OPC device by the active parameter.</p>
UseAsyncWrites	0 - use synchronous writes. 1 - use asynchronous writes.	0	Determines whether writes are synchronous or asynchronous.

## OPCLX Access Path Parameters

OPCLX does not include access path parameters since OPC topic is addressed as a part of variable tag address.

### Status Tag Parameters

The OPCLX status tag parameters determine the online or offline state of an OPCLX I/O device using the condition of a specified OPC item in the device. For more information, see [Status Tags](#).

When configuring these parameters, be careful not to confuse the OPC item required for status monitoring with a normal Plant SCADA tag.

You should also use a full path to identify an OPC item, as a device does not know a configured access path in your Citect.ini file.

**Note:** Use the UseStatusTags parameter to enable or disable support for OPCLX status tags (see See "Driver-specific Citect.ini Parameters").

[OPCLXStatusTags] Parameters	Allowable values	Default value	Description
StartWait	Time in milliseconds - or - -1 (infinite)	30000 (milliseconds)	On driver startup, this parameter determines the time the OPCLX driver waits before requesting status tag data for an OPC I/O device.  The OPC server should respond within a few seconds. The default wait time of 30 seconds is adequate.
Default.Tag	An OPC item name	STATUS	This parameter specifies the default OPC item to be monitored at runtime to determine the operational status of an associated device.  <b>Note:</b> This parameter implements a global setting for all OPC I/O devices, unless it is overridden using the equivalent <a href="#">OPCLX Device-specific Parameters</a> .
Default.Update	0 -32000 (milliseconds)	The scan rate from <b>Address</b> field in the Plant SCADA Boards settings	This parameter specifies the default update rate for OPCLX status tags at

[OPCLXStatusTags] Parameters	Allowable values	Default value	Description
			<p>runtime. This is the frequency with which the OPC server polls the device for status tag values and then updates its own cache.</p> <p>This parameter controls polling performed by the OPC server, not by Plant SCADA. The scope of the parameter is to communicate between the OPC server and a device, not between the OPC server and Plant SCADA.</p> <p><b>Note:</b> This parameter implements a global setting for all OPC I/O devices, unless it is overridden using the equivalent <a href="#">OPCLX Device-specific Parameters</a>.</p>
Default.Condition	<condition> (see table below)	ISGOOD	<p>This parameter is used to determine if the OPC device is online at runtime, by comparing the &lt;Condition&gt; with the value of the default OPC item named in the.Default.Tag parameter.</p> <p>If the specified condition is determined to be true, the device is considered online.</p> <p>This parameter represents the default condition for all OPCLX status tags, unless it is individually overridden using the <a href="#">OPCLX Device-specific Parameters</a>.</p>

Allowable values for <condition>	Description
=<Value>	Is equal to <Value>
!<Value>	Is NOT <Value>
!=<Value>	Is NOT equal to <Value>
><Value>	Is greater than <Value>
>=<Value>	Is greater than or equal to <Value>
<<Value>	Is less than <Value>
<=<Value>	Is less than or equal to <Value>
ISGOOD	The tag quality is GOOD
ISBAD	The tag quality is BAD
ISUNCERTAIN	The tag quality is UNKNOWN

Where <Value> is a placeholder for any valid LONG data type value.

If the specified condition is determined to be true, the device is considered online.

See also [Status Tags](#).

## Logging Parameters

The following table describes the OPCLX logging parameters.

[OPCLX] Parameter	Description	Allowable Values	Default Value
DebugLevel	The trace level used for log file. See <a href="#">Logging</a> for examples.	ALL or any combination of the following, separated by a pipe character ( ): WARN ERROR TRACE	-
DebugCategory	The categories used for the log file. See <a href="#">Logging</a> for examples.	ALL or any combination of the following, separated by a pipe character ( ): TAG: Tag configuration trace. PROT: Operations related to the OPC protocol interface. CACHE: Operations	-

		<p>related to the driver cache.</p> <p>DCB: Front end driver trace.</p> <p>THRD: Thread trace.</p> <p>MISC: Miscellaneous operations.</p> <p>BEND Operations related to the back-end thread of the driver.</p> <p>FEND: Operations related to the front-end thread of the driver.</p>	
DebugUnits	Controls which units logging is performed for. Multiple units can be specified. Debug messages that are unrelated to a specific unit are logged against the (GLOBAL) unit.	ALL, (GLOBAL) [include the round brackets] or any combination of I/O device names and (GLOBAL) separated by ' ' characters.	All

### Overriding [OPCLX]CacheRead

You can override the value in [OPCLX]CacheRead for a particular tag by suffixing the tag address with:

- The delimiter "!"
- The letter C or D, as follows:

<Tag Name>!C - The tag value returned is the cache value at the time of the read.

<Tag Name>!D - A refresh of the tag value is forced before it is returned.

### Examples:

- Tag1!**D** - Forces a refresh of Tag1 before the value is returned.
- Tag2!**C** - The last known cache value of Tag2 is returned.

When the tag qualifiers C and D are used with other OPCLX qualifiers (see [Time Stamp and Quality Tags Configuration](#)), they must appear last.

For example, with "Tag3!Q!C", Tag3 is associated with a quality tag and the last known value of Tag3 is returned

### Configure Redundancy

Redundancy is handled in Plant SCADA by the Plant SCADA clients. They determine which I/O server to request I/O device data by allowing the scan rate to be specified per I/O device, and then configuring multiple I/O

devices to the same PLC.

A status tag can be defined in the Citect.ini file to determine whether to set a unit offline or online depending on the condition of the status tag. If the condition is true the unit is allowed to come online, otherwise the unit is set to offline.

The status tag is polled at the same rate configured for the groups of the corresponding unit. The driver supports STATUS\_UNIT commands on the inactive server. So even though a particular unit is not currently servicing Plant SCADA requests, the state of the status condition is checked periodically. This allows the unit to be taken either offline or online (assuming that [IOServer]WatchDog has not changed from its default of 1).

Both the primary and standby devices are offline if both have the same status condition and the condition is a detected error condition. All points in the system for that unit would therefore be #COM.

Status Tags can be defined on a per-device or global basis. For more information, see [OPCLX Status Tag Parameters](#) and [OPCLX Device-specific Parameters](#).

## Scan Rates

The Plant SCADA OPCLX driver can define I/O devices with different scan rates. This provides you with the ability to tune your system better, by ordering the tag database into logical groups and defining different scan rates for each group. For example, tags that are read frequently can be placed in a group that is scanned frequently. Tags that are read infrequently can be placed in a group that is scanned infrequently.

By default, tags are scanned at the default scan rate defined by the ScanRate parameter in the project Citect.ini file.

## Examples

- Set the project scan rate to 1 second (1000 milliseconds):  
[OPCLX]  
ScanRate=1000
- Set the project scan rate to 1 second (1000 milliseconds), and the inactive server scan adjust rate to a factor of 5:  
[OPCLX]  
ScanRate=1000
- Set a faster (half second) scan rate for a specific port named "Port1" on the I/O server named "CLServer":  
[CLServer.Port1]  
ScanRate=500
- Set a slower (5 second) scan rate for a specific port named "Port123" on the I/O port named "CLServer":  
[CLServer.Port123]  
ScanRate=5000

## Diagnostics

This feature is supported only by the FactoryTalk OPC server and not by the RSLinx Classic OPC server. FactoryTalk diagnostics collects and provides access to activity, status, warning, and detected error messages generated throughout a FactoryTalk system.

The syntax for configuring the diagnostic tag in Plant SCADA is:

[OPCTOPIC]@<DiagnosticItemName>

For further details of the diagnostic items, refer to the FactoryTalk documentation.

## Migrate from ABCLX to OPCLX

A migration tool can be used to migrate the Plant SCADA projects from ABCLX to the standard OPC formats supported by the OPCLX driver.

This eases upgrading the projects and automating the configuration of the old ABCLX projects to the new format.

- [Migrate a Project from ABCLX to OPCLX](#)
- [Migration of I/O Devices](#)
- [Tag Address Formats](#)

### Migrate a Project from ABCLX to OPCLX

This chapter provides details on how to migrate from a Plant SCADA project configured with the ABCLX driver to the OPCLX driver.

---

**Note:**

- The migration feature is available in all versions of Plant SCADA from v7.20. The migration tool may require a Service Pack and/or Hotfix on versions prior to v7.50.
  - Virtual Port (VP) is obsolete in OPCLX compare to ABCLX.
- 

**To migrate a project from ABCLX to OPCLX:**

1. Open the **Projects** activity in Plant SCADA Studio.
  2. Select the project that you want to migrate.
  3. On the command bar, select **Migration Tool**.  
The **Project Migration** dialog box appears.
  4. In the **Select a project to migrate** drop-down box, select the project that you want to migrate.
  5. Initially the **Migrate ABCLX to OPCLX** check box is disabled. Click **Configure**. The <Project>:<Project Name> dialog box appears.  
For more information on the fields on this dialog box, see the *Field Description and Layout of <Project>:<Project Name> Dialog Box* section below.
  6. In the **OPCServer Type** group box, select the OPC server name (**FactoryTalk** or **RSLinx Classic**).
  7. If you want to migrate all the listed devices to OPCLX, then choose **Select All** check box. Else, select the required I/O devices.
  8. You can change the corresponding **OPC Topic** and **OPC Server**.
- 

**Note:**

- By default the **OPC Server** drop-down list is empty with an edit option to enter the OPC server name manually.
  - To select an OPC server under **OPC Server** drop-down list, in the **OPCServerBrowse** field, click **Browse**. The available OPC servers on the local machine are listed under OPC Server drop-down list. Select the required OPC server from the drop-down list. If no servers are found, then click **edit** and enter OPC server details manually.
-

9. If you want to browse the OPC servers on a remote machine, in the **Machine Name** field, enter the IP address or machine name of the remote server..

---

**Note:**

- The Browse button is disabled until you enter the remote machine name or IP address.
  - If the machine name or IP address is invalid, a pop-up with the message invalid machine name is displayed.
  - If the local machine is unable to establish connection with the specified remote machine, a pop-up with the message **Failed to retrieve OPC servers** is displayed.
  - If the connection is not successful, click edit and provide OPC server details manually.
- 

On successful connection with the remote server, the OPC servers of the remote machine are displayed in the **OPC Server** drop-down list. The first OPC server is selected by default.

10. After updating the required fields, click **OK**.

If you do not want to proceed with the migration process, then click the close button at the top-right corner of the <Project>:<Project Name> dialog box.

---

**Note:** If migration does not happen or some of the items are not migrated properly, then the log file will be updated with the items that are not migrated.

---

## Field Description and Layout of <Project>:<Project Name> Dialog Box

Different fields and their descriptions are given below:

- **OPCServer Type:** FactoryTalk and RSLinx Classic are the supported OPCSERVER/GATEWAY. Based on the selected gateway/OPC server, tags are migrated.
- **OPC Topic:** This is the alias name configured for the device in the Allen Bradley OPC server.
- **OPC SERVER:** This is the Prog IDs of the OPC servers installed on the given machine.

The layout of <Project>:<Project Name> dialog box is as below:

- It lists the devices in the project that you can migrate from ABCLX to OPCLX.
- Different clusters are displayed in separate tabs. Related primary and standby I/O devices are listed under each cluster.
- Each of the primary and standby device names is displayed as <Devicename>\_<Mode>\_<Priority>.
- You can enter OPC topic only for the primary devices. You cannot modify the OPC topic for the standby devices. By default, the I/O device name is displayed as **Topic Name** which can be changed by editing **OPC Topic** field.
- For the standby devices, OPC topic is set to the OPC topic of its corresponding primary device. If you modify the OPC topic in the primary device, the OPC topic for its standby devices is automatically updated.

---

**Note:** Once migration is completed it is recommended to pack the main project and all included projects individually. Packing the database removes deleted records, and re-indexes the database. To pack the project databases, from the **Projects** activity in Plant SCADA Studio, click **Pack**.

---

[Migration of I/O Devices](#)

## Migration of I/O Devices

After migrating the project successfully, the following changes can be observed in Boards, Ports, and I/O Devices grid for the migrated SCADA project.

**Note:** You can modify or delete all the configurations manually.

### Boards

The existing ABCLX boards are not modified. For each server, an OPCLX board is created. The board name for the first server is OPCLX\_BOARD1 and that for the second server it is OPCLX\_BOARD2 and so on.

Below table describes different field names for a Board and corresponding changes observed.

Field	Value
Board Type	A new board with type set to OPCLX is created. The earlier boards also exist and you can delete if required.
Address	The value of this field is set to 0 by default. You can manually enter it.
I/O Port	The value of this field is deleted.
Interrupt	The value of this field is deleted.
Special Options	The value of this field is deleted.

### Ports

New ports are created. Number of ports is equal to the number of devices selected in the migration form. By default the port name for the devices is OPCLX1\_PORT1 and that for the second device is OPCLX1\_Port2 and so on. If OPCLX1\_Port1 is created, then Port1 is created for OPCLX1 board. Based on the number of I/O devices selected for that board, equal number of ports are created. Similarly if multiple I/O devices are selected across multiple boards, then multiple ports are created for each board.

Below table describes different field names of the Ports and corresponding changes observed.

Field	Value
Board Name	The board name is the same as the new board of type OPCLX that is created.
Server Name	The server name of the selected device.
Baud Rate	The value of this field is deleted.
Data Bits	The value of this field is deleted.
Stop Bits	The value of this field is deleted.

Field	Value
Parity	The value of this field is deleted.
Special Options	The value of this field is deleted.

## Devices

The table below describes different field names for I/O devices and corresponding changes observed.

Field	Value
Protocol	The protocol name gets changed from ABCLX to OPCLX.
Address	Address field in the I/O devices form gets updated to the corresponding Prog ID of Allen Bradley OPC server that you have entered in the migration tool form for that I/O device.
Port	The port name is the same as the new port that is created.

[Tag Address Formats](#)

### Tag Address Formats

After migrating the project successfully, the following changes can be observed in tag addresses.

## Controller Tags

- **Controller Tags**

For the Tag address [OPCTOPIC] will be added to the tag address format.

Example:

ABCLX Tag address => TagAddress\_00

OPCLX Tag address => [OPCTOPIC]TagAddress\_00

- **Controller Array Tags**

If the Tag address contains "{}" braces it will be changed to the [] braces.

Example

ABCLX Tag address => TagAddress\_00{100}

OPCLX Tag address => [OPCTOPIC]TagAddress\_00[100]

- **Controller Array Tags referring to a particular bit in the array**

If the Tag address contains "/" character it will be changed to "." character.

Example

ABCLX Tag address => TagAddress\_00{100}/5

OPCLX Tag address => [OPCTOPIC]TagAddress\_00[100].5

- **Controller sub array tags**

If the Tag address contains "!A[<count>]" then it will be changed to ",L<Count>!A[<count>].

Example

ABCLX Tag address => TagAddress\_00!A[5]

OPCLX Tag address => [OPCTOPIC] TagAddress\_00,L5!A[5]

- **Controller sub array tags**

If the Tag address contains "/<startIndex>!A[<count>]" then it will be changed to "[startIndex],L<Count>!A[<count>].

Example

ABCLX Tag address => TagAddress\_00/10!A[5]

OPCLX Tag address => [OPCTOPIC] TagAddress\_00[10],L5!A[5]

## Program Tags

For FactoryTalk Tag address formats are:

- **Program Tags**

::[OPCTOPIC]PROGRAM:MainProgram.TagName

Example:

ABCLX Tag address => PROGRAM:MainProgram.TagAddress\_00

OPCLX Tag address => ::[OPCTOPIC]PROGRAM:MainProgram.TagAddress\_00

- **Program Array Tags**

::[OPCTOPIC]PROGRAM:MainProgram.TagName

For RSLinx Classic Tagaddress formats are:

- **Program Tags**

[OPCTOPIC]PROGRAM:MainProgram.TagAddress\_00

Example:

ABCLX Tag address => PROGRAM:MainProgram.TagAddress\_00

OPCLX Tag address => [OPCTOPIC]PROGRAM:MainProgram.TagAddress\_00

- **Program Array Tags**

[OPCTOPIC]PROGRAM:MainProgramTagName[ArraySize]

Example:

ABCLX Tag address => PROGRAM:MainProgramTagName{10}

OPCLX Tag address => [OPCTOPIC]PROGRAM:MainProgramTagName[10]

## Troubleshooting

This chapter provides information about the Plant SCADA tools provided to help resolve problems with communication and configuration.

- [Detected Driver Errors](#)
- [Driver Statistics](#)
- [Logging](#)
- [Maintaining the Project Database](#)

### **Detected Driver Errors**

Plant SCADA OPCLX detected driver errors can occur when an OPC device does not respond, is disconnected or offline, or returns an error itself.

This section includes:

- [Detected Common Protocol Errors](#)
- [Detected OPCLX Protocol Errors](#)

The OPCLX driver can log combinations of trace levels across different categories. For more information, see [Logging](#).

### **Detected Common Protocol Errors**

Plant SCADA has two kinds of protocol driver errors - generic and specific. Generic errors are hardware errors 0-31, and are common to many protocols. Sometimes only the generic error is available, though often both the generic error and a specific error are given.

Protocol drivers also have their own specific errors, which can be unique and therefore cannot be recognized by the hardware alarm system. The drivers convert specific errors into generic errors that can be identified by the I/O server. For example, when a driver detects an error, there is often both a protocol-specific error and a corresponding generic error.

When a hardware error occurs, Plant SCADA generates an alarm, and displays the alarm on the hardware alarm page (in the alarm description of the hardware alarm). To see the detected error number, you need to have Alarm Category 255 defined with a display format that includes {ErrDesc,15} {ErrPage,10}.

If you need more information to resolve a detected error, refer to the documentation that accompanied the I/O device (or network). After viewing the documentation, if you still cannot solve your problem, contact technical support for this product.

See also [Detected OPCLX Protocol Errors](#).

### **Detected OPCLX Protocol Errors**

The following detected errors, listed in (hexadecimal) order, are specific to the Plant SCADA OPCLX protocol:

Error value (Hex)	Error definition	Error description
0XC0040001	GENERIC_SOFTWARE_ERROR	Invalid handle was passed.
0XC0040002	GENERIC_SOFTWARE_ERROR	A duplicate parameter was passed where one is not allowed.
0XC0040004	GENERIC_INVALID_DATA_FORMAT	Server cannot convert between the passed or requested data type and the canonical type.
0xC0040006	GENERIC_ACCESS_VIOLATION	Item's access rights do not allow the operation.
0xC0040007	GENERIC_SOFTWARE_ERROR	Item definition does not exist within the server's address space.
0xC0040008	GENERIC_SOFTWARE_ERROR	Item definition does not conform to the server's syntax.
0xC004000B	GENERIC_INVALID_DATA_FORMAT	Value passed to WRITE was out of range.
0x80020008	GENERIC_SOFTWARE_ERROR	Bad variable type.
0x8002000A	GENERIC_SOFTWARE_ERROR	Out of present range.
0x80020005	GENERIC_SOFTWARE_ERROR	Type mismatch.
0x100	GENERIC_SOFTWARE_ERROR	Could not access variable dbf.
0x101	DRIVER_BAD_DATA	Read of data value bad.
0x102	GENERIC_GENERAL_ERROR	Write of one or more items not completed.
0x103	DRIVER_UNIT_OFFLINE	Could not resolve the server CLASSID.
0x104	GENERIC_SOFTWARE_ERROR	Could not add one or more items to the server
0x80010006	GENERIC_CHANNEL_OFFLINE	Connection terminated
0x80010007	GENERIC_CHANNEL_OFFLINE	Server not available.
0x8001000F	GENERIC_INVALID_RESPONSE	Received data is invalid.
0x80010012	GENERIC_SOFTWARE_ERROR	Call did not execute.
0x80010100	GENERIC_SOFTWARE_ERROR	System call aborted.

Error value (Hex)	Error definition	Error description
0x80010101	GENERIC_SOFTWARE_ERROR	Could not allocate some required resource.
0x80010103	GENERIC_BAD_PARAMETER	Requested interface not registered on server object.
0x80010104	GENERIC_SOFTWARE_ERROR	Could not call server.
0x80010105	GENERIC_CHANNEL_OFFLINE	Server threw an exception.
0x80010108	GENERIC_CHANNEL_OFFLINE	Server has disconnected from its clients.
0x8001011B	GENERIC_CHANNEL_OFFLINE	Access denied.
0x8001011C	GENERIC_CHANNEL_OFFLINE	Remote calls not allowed for this process.

See also [Detected Common Protocol Errors](#).

## Driver Statistics

You can use the following driver statistics to help you debug the OPCX driver operation:

Statistics	Description
Cached Reads	Number of reads that have been serviced directly from the internal cache of current values.
Cache Misses	Number of reads that were not in the internal cache of current values which resulted in a direct request from the server.
Active Items	Number of items with valid server subscriptions which have been activated to receive data change notification. This may be a subset of the total number of items that are currently subscribed.
Total Items	Total number of items with valid server subscriptions. These items may or may not be currently activated to receive data change notifications.
Bad Items	Number of items that were not successfully subscribed to. These items may not exist on the server.
Start ms	Internal driver statistic used for driver debugging by Citect support engineers.

Statistics	Description
Last ms	Internal driver statistic used for driver debugging by Citect support engineers.
Difference	Internal driver statistic used for driver debugging by Citect support engineers.
ReadItemsReQueued	Internal driver statistic used for driver debugging by Citect support engineers.
DCBsInHandlingQ	Internal driver statistic used for driver debugging by Citect support engineers.
DataNotYetValid	Internal driver statistic used for driver debugging by Citect support engineers.

## Logging

The OPCLX driver can log combinations of trace levels across different categories. This is achieved by setting the following INI parameters.

### [OPCLX]DebugLevel

This parameter allows you to define the trace level. The options include:

WARN	Output warning messages.
ERROR	Output error messages.
TRACE	Output trace messages.
DEBUG	Output debug messages.
ALL	All of the above.

### [OPCLX]DebugCategory

This parameter allows you to enable logging for a particular category of trace. The options include:

TAG	Tag configuration trace
PROT	Operations related to the OPC protocol interface
CACHE	Operations related to the driver cache
DCB	Front end driver trace
MISC	Miscellaneous operations

THRD	Thread trace
BEND	Operations related to the back-end thread of the driver
FEND	Operations related to the front-end thread of the driver
ALL	All of the above

In both cases, you can use ALL or any combination of the available options separated by a pipe character ( | ).

### Example

```
[OPCLX]
DebugLevel=WARN|ERROR|TRACE
DebugCategory=ALL
```

In most cases, you can set the DebugLevel and DebugCategory parameters to ALL. If this results in a large, cumbersome log file that causes older data to be overwritten, you can consider refining the debug options.

---

**Note:** These parameters do not have a value specified by default. To enable logging for this driver, you need to manually configure these parameters in your INI file.

The events generated by the OPCLX driver are logged in the following Plant SCADA syslog file:

syslog.IOServer.<Cluster name>.<IO Server name>.dat

This file is located in the directory specified by the Citect.ini parameter **[CtEdit]Logs**. By default, this location will be:

%PROGRAMDATA%\AVEVA Plant SCADA <VersionNumber>\Logs

If you are running the driver on a version of Plant SCADA prior to v7.20, a file called OPCLX.log will be delivered to the "Logs\Drivers" directory instead.

The size of the syslog file and its rollover process is configured via the **[Debug]SysLogSize** and **[Debug]SysLogArchive** INI parameters. For more information, see the topic *Debug Parameters* in the Plant SCADA documentation.

---

**Note:** If the number of messages being processed for a driver exceeds the value specified by the Plant SCADA parameter **[Kernel]ErrorBuffers**, the pending messages will not be logged. If this occurs, you can increase the value of this parameter so that all the messages generated by the driver are reported. The number of messages that are not logged can be monitored via the Kernel's General window under the item "Lost Errors". If you adjust **[Kernel]ErrorBuffers** and Lost Errors are still occurring, you may need to adjust the level of system logging.

## See Also

[Logging Parameters](#)

## Maintaining the Project Database

Over time with editing, the project database underlying a project can become fragmented and performance can be reduced. During project development, you should periodically clear out all duplicated records and any orphaned ones.

Improperly maintained databases can result in communication errors detected at runtime. Many

communications errors detected come from having duplicated or orphaned records in the communications database.

Sometimes orphaned records from a previous I/O server are left behind in the database files. As the forms are indexed on the I/O server name, you can use the scroll bar to navigate quickly to the end of the current range of records for a particular I/O server. You can examine the last few and next few records to validate that they should be there. If you find extra (unwanted) records, delete them.

You should also check that there are no duplicated records. Use the record search facility to search for duplicate entries of devices that are causing unexplained communication errors detected. If you find extra (unwanted) records, delete them.

Once you have deleted orphaned and duplicated records, pack the project. Packing the database removes deleted records, and re-indexes the database. To pack the project databases, from the **Projects** activity in Plant SCADA Studio, click **Pack**.

## OPCUA Driver

The OPCUA driver enables Plant SCADA to communicate with a system that implements the OPC UA server standard for data access. The server endpoint needs to support OPC.TCP binary protocol.

Citect SCADA 2016 (or later) is required to use the OPCUA Driver.

The driver uses the Unified Automation OPC UA Client SDK v1.7.7.

---

**Note:** If you are installing the OPCUA driver on a legacy version of Plant SCADA (2020 R2 or earlier), you will need to manually install PCS Framework 7.0.0. See [Manually Install PCS Framework](#).

## Safety Information

### Hazard categories and special symbols

The following symbols and special messages may appear in this manual or on the product to warn of potential hazards or to call attention to information that clarifies or simplifies a procedure.

Symbol	Description
 or 	The addition of either symbol to a "Danger" or "Warning" safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.
	This is the safety alert symbol. It is used to alert you to personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.
<b> DANGER</b>	
<b>DANGER</b> indicates an imminently hazardous situation, which, if not avoided, will result in death or serious injury.	
<b> WARNING</b>	
<b>WARNING</b> indicates a potentially hazardous situation, which, if not avoided, can result in death or serious injury.	
<b> CAUTION</b>	
<b>CAUTION</b> indicates a potentially hazardous situation which, if not avoided, can result in minor or moderate injury.	
<b>NOTICE</b>	
<b>NOTICE</b> used without a safety alert symbol, indicates a potentially hazardous situation which, if not avoided, can result in property or equipment damage.	

## Please Note

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by AVEVA for any consequences arising out of the use of this material.

## Before You Begin

Plant SCADA is a Supervisory Control and Data Acquisition (SCADA) solution. It facilitates the creation of software to manage and monitor industrial systems and processes. Due to Plant SCADA's central role in controlling systems and processes, you must appropriately design, commission, and test your Plant SCADA project before implementing it in an operational setting. Observe the following:

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not use Plant SCADA or other SCADA software as a replacement for PLC-based control programs. SCADA software is not designed for direct, high-speed system control.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**⚠ WARNING****LOSS OF CONTROL**

- The designer of any control scheme must consider the potential failure modes of control paths and, for certain critical control functions, provide a means to achieve a safe state during and after a path failure. Examples of critical control functions are emergency stop and overtravel stop, power outage and restart.
- Separate or redundant control paths must be provided for critical control functions.
- System control paths may include communication links. Consideration must be given to the implications of unanticipated transmission delays or failures of the link.
- Observe all accident prevention regulations and local safety guidelines.<sup>1</sup>
- Each implementation of a control system created using Plant SCADA must be individually and thoroughly tested for proper operation before being placed into service.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

1. For additional information, refer to NEMA ICS 1.1 (latest edition) "Safety Guidelines for the Application, Installation, and Maintenance of Solid State Control", and to NEMA ICS 7.1 (latest edition) "Safety Standards for Construction and Guide for Selection, Installation and Operation of Adjustable-Speed Drive Systems" or their equivalent governing your particular location.

## Third Party Software

You acknowledge that the Software may contain copyrighted software of third parties which are obtained under a license from such parties. All third party licensors retain all right, title and interest in and to such Third Party Software and all copies thereof, including all copyright and other intellectual property rights. Your use of any

Third Party Software shall be subject to, and You shall comply with, the terms and conditions of this Agreement, and the applicable restrictions and other terms and conditions set forth in any Third Party Software documentation or printed materials, including without limitation an end user license agreement.

Below is a list of third party libraries requiring a special note:

1. MIT License (<https://opensource.org/licenses/MIT>):

THE SOFTWARE IS PROVIDED "AS IS", WITHOUT WARRANTY OF ANY KIND, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NONINFRINGEMENT. IN NO EVENT SHALL THE AUTHORS OR COPYRIGHT HOLDERS BE LIABLE FOR ANY CLAIM, DAMAGES OR OTHER LIABILITY, WHETHER IN AN ACTION OF CONTRACT, TORT OR OTHERWISE, ARISING FROM, OUT OF OR IN CONNECTION WITH THE SOFTWARE OR THE USE OR OTHER DEALINGS IN THE SOFTWARE.

Libraries:

- GalaSoft MVVM Light Toolkit
- libexpatw
- Newtonsoft.Json
- BouncyCastle
- Autofac
- Irony

2. Apache License (<https://opensource.org/licenses/Apache-2.0>).

Libraries:

3. The OPC UA Driver is based on C++ Based OPC UA Client SDK from Unified Automation.

© Unified Automation GmbH - All rights reserved.

The UA Driver contains the following additional third party software:

Third Party Licenses and Open Source License Acknowledgment

- OPC UA ANSI C Stack (Unified Automation Edition)
- OpenSSL
- LibXML2
- WCELIBCEX (used in AnsiC-Stack Platform Layer for WindowsCEonly)

- WCECOMPAT (used in OpenSSL for WindowsCEonly, requires dynamic linking)
- Bouncy Castle Crypto API
- C-ARES async address resolver
- ICU4C Unicode Library (minimum Windows 7)
- JSMN a lightweight JSON parser in C
- MQTT-C a light weight MQTT client library in C
- Eclipse Mosquitto a MQTT C-Client Library

Overview on used third party components:

	AnsiC Stack	OpenSSL	LibXML 2	WCE LIBCEX	WCE COMPAT	Bouncy Castle	C-ARES	ICU4C	JSMN	MQTT-C	Mosquitto
<b>HP C SDK</b>	-	o	-	-	-	-	o	-	o	o	-
<b>ANSI C SDK</b>	m	o (1)	-	o (3)	o (4)	-	-	-	o	o	-
<b>C++ SDK</b>	m	o (1)	o	o (3)	o (4)	-	-	-	o	-	o
<b>.NET SDK</b>	-	o (2)	-	-	-	o (5)	-	-	-	-	-
<b>UaModeler</b>	-	-	-	-	-	-	-	-	-	-	-

<b>UaExpert</b>	m	m	m	-	-	-	-	-	m	-	m
<b>UaGDS</b>	-	m		-	-	-	m	m	-	-	-

m=mandatory;

o=optional;

-=not used;

(1) recommended on Windows;

(2) used by certificategenerator.exe;

(3) used to compile SDK for WindowsCE only;

(4) used to compile OpenSSL for WindowsCE only, requires dynamic linking of OpenSSL;

## 1. OPC UA ANSI C Stack

This component includes software that was initially developed by the OPC Foundation. Unified Automation acquired a Commercial Source Code License (Buyout Agreement) with the OPC Foundation. Unified Automation has made custom modifications to the original code and its APIs which are kept proprietary. The derivative works as delivered with the SDKs, toolkits and runtime products of Unified Automation now completely falls under the respective license grant as in Section 1 and 2 of this SLA.

### 1.1 Copyright

This software is based in part on the OPC Foundation. Initial version was founded and copyrighted by OPC Foundation, Inc. Copyright (C) 2008, 2014 OPC Foundation, Inc., All Rights Reserved.

### 1.2 License Issues

The OPC UA ANSI C Stack including any custom modifications and enhancements as shipped/delivered by Unified Automation stays under respective license grant as of Section 1 and 2 of this Software License Agreement (SLA) and its source code is confidential. The recipient of this component is NOT bound to any other license the original code may be distributed under i.e. not bound to RCL/RBCL nor any other license.

## 2. OpenSSL crypto and pki

This product includes software developed by the OpenSSL Project for use in the OpenSSL Toolkit (<http://www.openssl.org/>).

### 2.1 Copyright

Copyright (C) 1995-1998 Eric Young (eay@cryptsoft.com) All rights reserved.

This product includes cryptographic software written by Eric Young (eay@cryptsoft.com)

This Windows version of this product includes software written by Tim Hudson (tjh@cryptsoft.com)

### 2.2 License Issues

The OpenSSL toolkit stays under a dual license, i.e. both the conditions of the OpenSSL License and the original SSLeaylicense apply to the toolkit. See below for the actual license texts. Actually both licenses are BSD-style Open Source licenses. In case of any license issues related to OpenSSL please contact openssl-core@openssl.org.

#### Original OpenSSL License:

Copyright (C) 1998-2007 The OpenSSL Project. All rights reserved.

Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met:

- a. Redistributions of source code must retain the copyright notice, this list of conditions and the following disclaimer.
- b. Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution.
- c. All advertising materials mentioning features or use of this software must display the following acknowledgement:  
"This product includes cryptographic software written by Eric Young (eay@cryptsoft.com)".
- d. The word 'cryptographic' can be left out if the routines from the library being used are not cryptography-related.
- e. If you include any Windows specific code (or a derivative thereof) from the apps directory (application

code) you must include an acknowledgement:

"This product includes software written by Tim Hudson (tjh@cryptsoft.com)".

THIS SOFTWARE IS PROVIDED BY THE OpenSSL PROJECT "AS IS" AND ANY EXPRESSED OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE OpenSSL PROJECT OR ITS CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

This product includes cryptographic software written by Eric Young (eay@cryptsoft.com). This product includes software written by Tim Hudson (tjh@cryptsoft.com).

#### **Original SSLeayLicense:**

Copyright (C) 1995-1998 Eric Young (eay@cryptsoft.com). All rights reserved.

This package is an SSL implementation written by Eric Young (eay@cryptsoft.com).

The implementation was written so as to conform with Netscape's SSL. This library is free for commercial and non-commercial use as long as the following conditions are adhered to. The following conditions apply to all code found in this distribution, be it the RC4, RSA, SHA, DES, etc., code; not just the SSL code. The SSL documentation included with this distribution is covered by the same copyright terms except that the holder is Tim Hudson (tjh@cryptsoft.com).

Copyright remains Eric Young's, and as such any Copyright notices in the code are not to be removed. If this package is used in a product, Eric Young should be given attribution as the author of the parts of the library used. This can be in the form of a textual message at program startup or in documentation (online or textual) provided with the package.

THIS SOFTWARE IS PROVIDED BY ERIC YOUNG "AS IS" AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE AUTHOR OR CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

The license and distribution terms for any publicly available version or derivative of this code cannot be changed. i.e. this code cannot simply be copied and put under another distribution license [including the GNU Public License].

## **3. LibXML2 -- XML Parser**

This product includes code that was developed for the XML toolkit from the GNOME project (<http://xmlsoft.org/>).

### **3.1 Copyright**

Copyright (C) 1998-2003 Daniel Veillard. All Rights Reserved.

### **3.2 License Issues**

The libxml2 library is released under the MIT License and includes following copyright notice:

Except where otherwise noted in the source code (e.g. the files hash.c, list.c and the trio files, which are covered by a similar license but with different Copyright notices) all the files are:

Copyright (C) 1998-2003 Daniel Veillard. All Rights Reserved.

Permission is hereby granted, free of charge, to any person obtaining a copy of this software and associated documentation files (the "Software"), to deal in the Software without restriction, including without limitation the rights to use, copy, modify, merge, publish, distribute, sublicense, and/or sell copies of the Software, and to permit persons to whom the Software is furnished to do so, subject to the following conditions:

The above copyright notice and this permission notice shall be included in all copies or substantial portions of the Software.

THE SOFTWARE IS PROVIDED "AS IS", WITHOUT WARRANTY OF ANY KIND, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NONINFRINGEMENT. IN NO EVENT SHALL THE DANIEL VEILLARD BE LIABLE FOR ANY CLAIM, DAMAGES OR OTHER LIABILITY, WHETHER IN AN ACTION OF CONTRACT, TORT OR OTHERWISE, ARISING FROM, OUT OF OR IN CONNECTION WITH THE SOFTWARE OR THE USE OR OTHER DEALINGS IN THE SOFTWARE.

Except as contained in this notice, the name of Daniel Veillard shall not be used in advertising or otherwise to promote the sale, use or other dealings in this Software without prior written authorization from him.

## 4. WCELIBCEX (Windows CE only)

The Windows platform layer of the AnsiC Stack can be configured to run on Windows CE, but than requires WCELIBCEX: The WCELIBCEX is a package of C library extensions for Windows CE operating system. It is a supplement to standard C library available on Windows CE system. This extensions library is needed to fully support OPC UA SDK functionality.

### 4.1 Copyright

Initial version of WCELIBCEX was founded and copyrighted by Taxus SI Ltd., (<http://www.taxussi.com.pl>)

Copyright (c) 2006 Taxus SI Ltd.

Created by Mateusz Loskot(mateusz@loskot.net)

### 4.2 License Issues

The source code of the WCELIBCEX library is licensed under MIT License:

Permission is hereby granted, free of charge, to any person obtaining a copy of this software and associated documentation files (the "Software"), to deal in the Software without restriction, including without limitation the rights to use, copy, modify, merge, publish, distribute, sublicense, and/or sell copies of the Software, and to permit persons to whom the Software is furnished to do so, subject to the following conditions: The above copyright notice and this permission notice shall be included in all copies or substantial portions of the Software.

THE SOFTWARE IS PROVIDED "AS IS", WITHOUT WARRANTY OF ANY KIND, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NONINFRINGEMENT. IN NO EVENT SHALL THE AUTHORS OR COPYRIGHT HOLDERS BE LIABLE FOR ANY CLAIM, DAMAGES OR OTHER LIABILITY, WHETHER IN AN ACTION OF CONTRACT, TORT OR OTHERWISE, ARISING FROM, OUT OF OR IN CONNECTION WITH THE SOFTWARE OR THE USE OR OTHER DEALINGS IN THE SOFTWARE.

The complete license agreement can be found here:

( <http://opensource.org/licenses/mit-license.php> )

## 5. WCECOMPAT (Windows CE only)

The OpenSSL Library can be compiled to run on Windows CE, but therefore requires wcecompat: Windows CE C Runtime Library, a "compatibility" library to fully support OpenSSL functionality. The files of wcecompat are released under the GNU LGPL (Lesser General Public License). By this the OpenSSL Library becomes LGPL and can only be used by linking this library dynamically (do not link static).

### 5.1 Copyright

Copyright (C) 2001-2002 EssemerPty Ltd. All rights reserved.

( <http://www.essemer.com.au/> )

### 5.2 License Issues

This library is free software; you can redistribute it and/or modify it under the terms of the GNU Lesser General Public License as published by the Free Software Foundation; either version 2.1 of the License, or (at your option) any later version.

This library is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the GNU Lesser General Public License for more details.

You should have received a copy of the GNU Lesser General Public License along with this library; if not, write to the Free Software Foundation, Inc., 59 Temple Place, Suite 330, Boston, MA 02111-1307 USA

## 6. Bouncy Castle Crypto API (.NET SDK only)

The Bouncy Castle Crypto APIs for Java consist mainly of the following: A lightweight cryptography API for Java and C# and a provider for the Java Cryptography Extension and the Java Cryptography Architecture. The Bouncy Castle Crypto API license is an adaptation of the MIT X11 License and should be read as such.

### 6.1 Copyright

Copyright (c) 2000 - 2009 The Legion Of The Bouncy Castle (<http://www.bouncycastle.org>)

### 6.2 License Issues

Permission is hereby granted, free of charge, to any person obtaining a copy of this software and associated documentation files (the "Software"), to deal in the Software without restriction, including without limitation the rights to use, copy, modify, merge, publish, distribute, sublicense, and/or sell copies of the Software, and to permit persons to whom the Software is furnished to do so, subject to the following conditions: The above copyright notice and this permission notice shall be included in all copies or substantial portions of the Software.

THE SOFTWARE IS PROVIDED "AS IS", WITHOUT WARRANTY OF ANY KIND, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NONINFRINGEMENT. IN NO EVENT SHALL THE AUTHORS OR COPYRIGHT HOLDERS BE LIABLE FOR ANY CLAIM, DAMAGES OR OTHER LIABILITY, WHETHER IN AN ACTION OF CONTRACT, TORT OR OTHERWISE, ARISING FROM, OUT OF OR IN CONNECTION WITH THE SOFTWARE OR THE USE OR OTHER DEALINGS IN THE SOFTWARE.

The complete license agreement can be found here:

<http://www.bouncycastle.org/licence.html>

## 7. C-ARES - Async Address Resolution

c-ares is a C library for asynchronous DNS requests (including name resolves), C89 compatibility, MIT licensed, builds for and runs on POSIX, Windows, Netware, Android and many more operating systems.

### 7.1 Copyright

Copyright 1998 by the Massachusetts Institute of Technology.

### 7.2 License Issues

Permission to use, copy, modify, and distribute this software and its documentation for any purpose and without fee is hereby granted, provided that the above copyright notice appear in all copies and that both that copyright notice and this permission notice appear in supporting documentation, and that the name of M.I.T. not be used in advertising or publicity pertaining to distribution of the software without specific, written prior permission. M.I.T. makes no representations about the suitability of this software for any purpose. It is provided "as is" without express or implied warranty.

## 8. ICU4C – Unicode Library

The C and C++ languages and many operating system environments do not provide full support for Unicode and standards-compliant text handling services. Even though some platforms do provide good Unicode text handling services, portable application code can not make use of them. The ICU4C libraries fills in this gap. ICU4C provides an open, flexible, portable foundation for applications to use for their software globalization requirements. ICU4C closely tracks industry standards, including Unicode and CLDR (Common Locale Data Repository). The ICU license is intended to allow ICU to be included both in free software projects and in proprietary or commercial products. Since ICU 58, ICU is covered by the Unicode license which is very similar to the previous ICU license.

### 8.1 Copyright

Copyright © 1991-2022 Unicode, Inc. All rights reserved.

### 8.2 License Issues

#### UNICODE, INC. LICENSE AGREEMENT - DATA FILES AND SOFTWARE

See Terms of Use (<https://www.unicode.org/copyright.html>) for definitions of Unicode Inc.'s Data Files and Software.

Except as contained in this notice, the name of a copyright holder shall not be used in advertising or otherwise to promote the sale, use or other dealings in these Data Files or Software without prior written authorization of the copyright holder.

## 9 JSMN – JSON parser in C

jsmn (pronounced like 'jasmine') is a minimalistic JSON parser in C. It can be easily integrated into resource-limited or embedded projects. Most JSON parsers offer you a bunch of functions to load JSON data, parse it and extract any value by its name. jsmn proves that checking the correctness of every JSON packet or allocating temporary objects to store parsed JSON fields often is an overkill.

### 9.1 Copyright

Copyright (c) 2010 Serge A. Zaitsev

### 9.2 License Issues

This software is distributed under MIT license, so feel free to integrate it in your commercial products.

## 10. MQTT-C – JSON parser in C

MQTT-C is an MQTT v3.1.1 client written in C. MQTT is a lightweight publisher-subscriber-based messaging protocol that is commonly used in IoT and networking applications where high-latency and low data-rate links are expected. The purpose of MQTT-C is to provide a portable MQTT client, written in C, for embedded systems and PC's alike.

### 10.1 Copyright

## 11. MQTT – Eclipse Mosquitto

Eclipse Mosquitto is an open source (EPL/EDL licensed) message broker that implements the MQTT protocol versions 5.0, 3.1.1 and 3.1. Mosquitto is lightweight and is suitable for use on all devices from low power single board computers to full servers. The MQTT protocol provides a lightweight method of carrying out messaging using a publish/subscribe model. This makes it suitable for Internet of Things messaging such as with low power sensors or mobile devices such as phones, embedded computers or microcontrollers. The Mosquitto project also provides a C library for implementing MQTT clients, and the very popular mosquitto\_pub and mosquitto\_sub command line MQTT clients.

Mosquitto is part of the Eclipse Foundation, is an iot.eclipse.org project and is sponsored by cedalo.com.

### 11.1 Copyright

Mosquitto was written by Roger Light (roger@atchoo.org)

### 11.2 License Issues

This project is dual licensed under the Eclipse Public License 2.0 and the Eclipse Distribution License 1.0 as described in the epl-v20 and edl-v10 files (<https://www.eclipse.org/org/documents/edl-v10.php>)

Eclipse Public License - v 2.0 see here for details: (<https://www.eclipse.org/legal/epl-2.0/>)

Eclipse Distribution License - v 1.0

## Appendix B

### 1. Parts of the Licensed Software that are permitted for distribution ("Redistributables"):

- The licensed Software's main and plug-in libraries of the SDK in object code form
- The licensed Software's communication stack in object code form ("C-Stack", "JAVA-Stack", ".NET Stack")
- The licensed Software's administration and configuration tool ("UaAdminDialog, UaConfigTool")
- The licensed Software certificate generation tool ("Opc.Ua.CertificateGenerator.exe")

### 2. Parts of the Licensed Software that are NOT permitted for distribution include, but are not limited to:

- The licensed Software's source code and/or header files of any of the SDK modules
- The licensed Software's binary files together with header files of any of the SDK modules
- The licensed Software's source code and header files of the communication stacks ("C-Stack", "JAVA-Stack", ".NET Stack")
- The licensed Software's source code and header files of the UA Stack's platform layer
- The licensed Software's tool for modelling Addressspace and code generation ("UaModeler")
- The licensed Software's documentation

## Manually Install PCS Framework

You will need to manually install PCS Framework 7.0.0 if you use one of the following versions of Citect SCADA or Plant SCADA:

- Citect SCADA 2016
- Citect SCADA 2018
- Citect SCADA 2018 R2 Update 22 (November 2021)
- Plant SCADA 2020 R2 (RTM).

You need to download, unzip and install "PCS Framework 7.0.0 (x64).exe".

The PCS 7.0.0 installer can be downloaded from **AVEVA Knowledge and Support Center** (located at <https://softwaresupport.aveva.com>). Go to the **Product Hub** and locate the download page for this version of the OPCUA driver.

You will also need to download and install **Operations Control Logger** from this page.

## PCS Framework Prerequisites

You also need to download and install these prerequisites from the Microsoft website. They are required for PCS 7.0.0.

- .NET Framework 4.8 Full

- Microsoft .NET 6 ASP.NET Core Runtime (x64)
- Microsoft .NET 6 Desktop Runtime (x64)
- Visual C++ 2015 - 2022 Redistributable (x86 and x64). Use Universal C Runtime.

## Setting up Device Communications

The information included in the following topics describes how to establish communication with Plant SCADA and OPC UA server using the OPCUA driver.

- [Communication Settings](#)

### Communication Settings

To establish communication with a device, the associated Board, Port and I/O Device need to be correctly configured in Plant SCADA Studio's Topology activity.

If you use the Express Communications Wizard to connect to a device, these settings will be automatically configured for you. However, if you need to manually configure them, use the settings outlined below.

**Note:** The OPCUA driver only one requires one Board and one Port to be configured.

## Boards

The Boards view in Plant SCADA Studio lists the boards used in the Plant SCADA project. Each board record defines a separate board within the project.

Field	Value
Board Name	This field is user defined (e.g. 'Board1').
Board Type	Enter OPCUA.
Address	Enter zero (0).
I/O Port	Leave this field blank.
Interrupt	Leave this field blank.
Special Options	Leave this field blank.

## Ports

The Ports view in Plant SCADA Studio lists the ports used in the Plant SCADA project. Each port record defines a separate port within the project.

Field	Value
Port Name	This field is user defined.
Port Number	Leave this field blank.
Board Name	Refers to the board previously defined in Boards (e.g. 'Board1').
Baud Rate	Leave this field blank.
Data Bits	Leave this field blank.
Stop Bits	Leave this field blank.
Parity	Leave this field blank.
Special Options	Leave this field blank.
Comment	Any useful comment. This field is user defined and not required by the driver.

## I/O Devices

The I/O Devices view in Plant SCADA Studio lists the I/O Devices used in the Plant SCADA project. Each device record defines a device within the project.

Field	Value
Name	This field is user defined.
Number	I/O device number which needs to be unique for each logical device, but identical for redundant devices.
Address	<p>The OPC UA server endpoint URL. The URL can include the host name, IPv4, or IPv6 address. For example:</p> <ul style="list-style-type: none"> <li>• <code>opc.tcp://MyComputer:48010</code> For this URL, the driver will use the dual TCP IPv4/IPv6 protocol stack if it is available, otherwise the IPv4 protocol stack.</li> <li>• <code>opc.tcp://192.168.0.15:48010</code> For this URL, the driver will use IPv4 protocol stack.</li> <li>• <code>opc.tcp://[fe80::20ec:3acb:55d9:a3da]:48010</code> For this URL, the driver will use IPv6 protocol stack.</li> </ul>

Field	Value
Protocol	Enter OPCUA.
Port Name	Refers to the port previously defined in Ports.
Comment	Any useful comment. This field is user defined and not required by the driver.

## Configuring Variable Tags

Variable tags are addressed using the OPC UA NodeId configured in the OPC UA server.

NodeId consists of a namespace index and a unique identifier which can be a numeric value(i=), a string(s=), a globally unique identifier (g=), or an opaque value(b=).

Examples of NodeIds: "ns=2; i=12345" or "ns=3; s=SoftwareRevision"

---

**Note:** .The <Node ID> in a tag address cannot contain the following characters: "\", "!A" and ";!E=".

"\\" and "!A" characters are used for array tag addresses, and ";!E=" characters are used for extension object tag addresses.

The following table demonstrates the variable tag address formats you can use to read and write values.

Address format	OPC UA data type	Plant SCADA data type	Example
<Node ID>	BOOLEAN	DIGITAL	FALSE or TRUE
<Node ID>	SBYTE	INT, LONG	-128 to 127
<Node ID>	BYTE	INT, UINT, LONG, ULONG	0 to 255
<Node ID>	INT16	INT, LONG	-32768 to 32767
<Node ID>	UINT16	UINT, LONG, ULONG	0 to 65535
<Node ID>	INT32	LONG	-2147483648 to +2147483647
<Node ID>	UINT32	ULONG	0 to 4294967295
<Node ID>	INT64	<NOT SUPPORTED>	
<Node ID>	UINT64	<NOT SUPPORTED>	
<Node ID>	FLOAT	REAL	-3.4E38 to 3.4E38
<Node ID>	DOUBLE	REAL	-3.4E38 to 3.4E38
<Node ID>	STRING	STRING	ASCII string (0 to 254 characters)
<Node ID>	DATETIME	STRING	1990-01-01-00:00:00.000

Address format	OPC UA data type	Plant SCADA data type	Example
			to 2089-12-31-23:59:59.999
<Node ID>	GUID	<NOT SUPPORTED>	
<Node ID>	XMLElement	<NOT SUPPORTED>	
<Node ID>	NodeId	<NOT SUPPORTED>	
<Node ID>	Expanded NodeId	<NOT SUPPORTED>	
<Node ID>	Qualified Name	STRING	Update the Qualified Name as string in the tag value
<Node ID>	Localized Text	STRING	Update the text in English Locale in the tag value
<Node ID>	Status Code	LONG	Update the Integer code in the tag value
<Node ID>	ByteString	STRING	Array of Bytes
<Node ID>	Enumeration	LONG	
<Node ID>	Variant	<NOT SUPPORTED>	
<Node ID>	Extension Object	Plant SCADA data type corresponding to the Extension Object element data type.	See the topic <a href="#">Extension Object Support</a> .
<Node ID>	Number  This is a Variant data type which can be FLOAT or DOUBLE.	REAL  Note: Only FLOAT OPC UA data type is supported, and the data type must not change on the server.	
<Node ID>	Integer  This is a Variant data type which can be SBYTE, INT16, INT32 or INT64.	SBYTE: INT, LONG INT16: INT, LONG INT32: LONG  Note: Only SBYTE, INT16 and INT32 OPC UA data types are supported, and the data type must not change on the server.	
<Node ID>	UInteger	BYTE: INT, UINT, LONG,	

Address format	OPC UA data type	Plant SCADA data type	Example
	This is a Variant data type which can be BYTE, UINT16, UINT32 or UINT64.	ULONG UINT16: UINT, LONG, ULONG UINT32: ULONG  Note: Only BYTE, UINT16 and UINT32 OPC UA data types are supported, and the data type must not change on the server.	
<Node ID>	DiagnosticInfo	<NOT SUPPORTED>	

The driver supports conversions between OPC UA data types and Plant SCADA data types. When a configured tag data type cannot be converted into OPC UA data type, the driver marks that tag with quality Bad, Configuration Error.

The following table shows supported conversions between Plant SCADA and OPC UA data types.

Plant SCADA data type	OPC UA data type
DIGITAL	BOOLEAN
INT, UINT	SBYTE, BYTE, INT16, UINT16
LONG, UINT	SBYTE, BYTE, INT16, UINT16, INT32,UINT32
REAL	REAL
STRING	All OPCUA data types supported by the driver, except for BYTE, UINT16, UINT32, UINT64

## See Also

[Array Support](#)

## Array Support

The driver maps the OPCUA arrays to Plant SCADA arrays. The following table demonstrates the variable tag address formats you can use to read array values for supported OPCUA array data types.

Address	OPC UA array data type	Plant SCADA data type
<Node ID>\<OFFSET>!A[SIZE]	BOOLEAN	DIGITAL
<Node ID>\<OFFSET>!A[SIZE]	SBYTE	INT, LONG
<Node ID>\<OFFSET>!A[SIZE]	BYTE	INT, UINT, LONG, ULONG

Address	OPC UA array data type	Plant SCADA data type
<Node ID>\<OFFSET>!A[SIZE]	INT16	INT, LONG
<Node ID>\<OFFSET>!A[SIZE]	UINT16	UINT, LONG, ULONG
<Node ID>\<OFFSET>!A[SIZE]	INT32	LONG
<Node ID>\<OFFSET>!A[SIZE]	UINT32	ULONG
<Node ID>\<OFFSET>!A[SIZE]	FLOAT	REAL

The array tag address should include the array size and an optional array offset.

The maximum size of an array tag is limited to 256 bytes due to the underlying infrastructure of Plant SCADA. For example, if the tag data type is integer (2 bytes), Plant SCADA only allows the array tag to be configured with 128 elements. However, special array offset syntax can be used to address a sub-array with the particular offset and range within a large array.

## Extension Object Support

The OPCUA driver supports OPC UA extension objects which contain a structure (or an array of structures) encoded in a binary format. Each structure member is represented as a separate tag in Plant SCADA.

The Plant SCADA tags are created during tag import. The OPC UA tag import component allows you to browse the supported extension objects and displays the Plant SCADA tags corresponding to the extension object elements.

It is only possible to browse and create tags for the simple OPC UA data types supported by the driver. The simple data type arrays inside the extension objects (BOOLEAN, INT32, and so on) are currently not supported.

When writing to a tag which corresponds to an extension object member, the driver has to update the entire extension object value as the OPC UA protocol does not allow to update the specific extension object element.

Before performing the write request, the driver reads the whole extension object value, updates the specified element and writes the extension object value to the server.

### **WARNING**

#### **LOSS OF CONTROL**

When configuring your system, you need to make sure the extension object value cannot be updated when it is being updated by the driver. Although the driver uses the most up-to-date extension object value when performing a write, if the extension object value is changed by the server at that time (for example by a PLC program), there is a chance the extension object value will be incorrect after the write.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

## Advanced Configuration and Maintenance

This section provides instructions for advanced configuration and maintenance tasks. It includes the following topics:

- Configuring Redundancy
- Subscription Management
- Security Configuration
- Customizing a Project using Citect.ini Parameters
- Tag Import.

## Configuring Redundancy

The Plant SCADA driver supports multiple I/O server / device redundancy.

The driver represents each OPC UA server as a separate I/O device. In a normal operating state, the driver will communicate to the server via the primary I/O device. If the connection to the server via the primary I/O device is lost, the server will be communicated via a standby I/O device which is connected to the server and has the next highest priority if multiple redundant I/O devices are configured.

## Subscription Management

Plant SCADA's OPCUA driver uses the subscription model described in 5.13.1 of the OPC UA standard to receive value updates from an OPC UA server.

The driver can create up to three OPC UA subscriptions per I/O device with different publishing intervals to provide granular handling of Plant SCADA subscription update rates.

The publishing interval of OPC UA subscriptions can be set by using the ini parameters `Subscription1PublishingInterval`, `Subscription2PublishingInterval`, `Subscription3PublishingInterval` (see [Subscription Parameters](#)).

The default value of `Subscription1PublishingInterval` parameter is set to 400 msec. The default values of `Subscription2PublishingInterval` and `Subscription3PublishingInterval` are set to 0, which means that by default the driver will only create one OPC UA subscription with a publishing interval specified by `Subscription1PublishingInterval` parameter.

The user can change `Subscription2PublishingInterval` and `Subscription3PublishingInterval` parameters to enable OPC UA subscriptions with these publishing intervals.

By default, the driver sets the OPC UA subscription sampling interval to half the length of the associated publishing interval. You can also set the sampling interval to a specific value using the INI parameters `Subscription1SampleRate`, `Subscription2SampleRate` and `Subscription3SampleRate`.

The driver adds monitored items for all I/O Device tags to each of the enabled OPC UA subscriptions. The monitoring mode for all items is set to DISABLED. When the driver gets a subscribe request, it will define the OPC UA subscription in which the item should be enabled based on the Plant SCADA subscription update rate and then it will change the item monitoring mode in that subscription to REPORTING.

If the Plant SCADA subscription update rate changes, the driver will re-evaluate the corresponding OPC UA subscription for the item and change it if required.

## Security Configuration

### NOTICE

When establishing secure connection either via user authentication or message encryption with client and

server certificates, the anonymous connection and non-secure endpoint should be disabled to make sure that unauthorized user cannot connect and perform actions on the OPC UA server.

Also, make sure that the [OPCUA]SecuritySettingsName ini parameter is set to the correct value. The driver log messages will specify the security mode/policy and the authentication mode which the driver will use for a specific I/O device. The driver logs can be found in syslog.IOServer.<Cluster name>.<IO Server name>.dat file.

The OPCUA driver provides the ability to use user credentials when connecting to the device and also to establish secure connection between the driver and the OPC UA server using the client and server X509 certificates. In order to establish a secure connection, the driver needs access to the server certificate and the server needs access to the driver client certificate.

For more information about OPC UA security model, refer to the OPC Unified Architecture Specification, Part 2: Security Model. You can download the document from the OPC Foundation website ([www.opcfoundation.org](http://www.opcfoundation.org)).

The configuration of the secure connection is done via Configurator. After the driver is installed, the Configurator will have a plugin "OPC UA Client Driver".

This plugin allows you to:

- Create security settings.
- Select the client certificate from the Windows certificate store.
- Import the client certificate from a file into the Windows certificate store.
- Issue Plant SCADA OPC UA client certificate, store it in the Windows certificate store and export it to a file.
- Import the server certificate from the file into the Windows certificate store.
- Test connection to the OPC UA Server.

#### To configure the security settings (on a local computer):

1. In the panel on the left side of the Configurator, select OPC UA Client Driver. The SETTINGS page will display. Select the existing settings or enter the settings name to create a new one. If there are no existing settings "Select existing settings" option is disabled.
2. Click the **Next** button. The USER page will display.

On that page, you can enable user authentication and specify the user name and the password which the driver will use to connect to the OPC UA server.

The Configurator stores the user name and the password to the ArchestraA™ Data Store (ADS) service. For the driver to be able to read the user name and the password from ADS, the I/O Server process user account needs to exist in the Citect.User.Drivers Windows group.

The Configurator will add 'Citect.Driver.Users' Windows group if it does not exist and it will also add the currently logged in user to that group. Note that after the user has been added, you need either to restart the computer or to log in / log out so that the driver can read the user name and the password from ADS.

In case when the Plant SCADA I/O process will be configured to run as a service, you will need to select the option 'The driver process will run as a service'. In that case the Configurator will add the Runtime Manager service account to 'Citect.Driver.Users' group.

When user authentication is used, it is recommended that you configure the secure communication with the client and server certificates as well. Otherwise the user name and password will be sent to the server as a plain text.

If you do not do this, it will not be possible to proceed with the configuration after the SECURITY page and an

error message will be displayed.

There are two options to fix this:

- a. Configure a valid security mode on the SECURITY page.
- b. Set the Disable encrypted password check option on the USER page to allow the user name and password to be sent to the server as a plain text.
3. Click the **Next** button. The SECURITY page will display.

Select the message security mode and the security policy.

The security mode specifies the mode of encryption that will be used when messages between the driver and server are sent. There are three options: None, Sign and SignAndEncrypt.

The security policy parameter specifies the endpoint security policy. The supported options are:

- None
- Basic256 and Basic128Rsa15
- Basic256Sha256
- Aes128Sha256RsaOaep
- Aes256Sha256RsaPss.

In the case where the security mode is set to None, the driver will establish a non-secure connection.

4. Click the **Next** button. The CLIENT page will display.

On that page you will need to select the client certificate from the list of available client certificates in the Windows Certificate Store.

If there are no client certificates available, there are two options to add a new one:

- a. Create a new Plant SCADA client certificate.

When this option is selected and you click the "Create" button, the Configurator creates a new OPC UA Client self-signed certificate and adds it to the Windows certificate store.

The newly created client certificate is automatically selected in the list of available certificates.

- b. Import the client certificate from a file.

When this option is selected, you should select the file in which the client certificate is stored. Use the password box if the file is password protected.

The imported client certificate must have a private key and its "Subject Alternative Name" field should be in the format "urn:HostMachineName:Citect.OPCUA.Client.Driver", where the HostMachineName is the host name of the computer running the driver.

In order to install the client certificate on the OPC UA server machine, there is an option on the page to export the client certificate to a file.

The page also provides an option to view the currently selected certificate and to export the client certificate to a file, so it can be installed on the OPC UA server machine.

When you select the Export option, the Configurator will export the client certificate into a file with a public key. If the certificate was issued by a Certificate Authority, then the Certificate Authority certificate will be exported.

5. Click the **Next** button. The SERVER page will display.

On that page you can add the OPC UA server certificate to the Windows certificate store.

If the server certificate with a public key is already in the Windows certificate store, the driver will load it automatically.

There are two options to import the server certificate:

- a. Import a server certificate from a file. When this option is selected, the Configurator will import the server certificate to the Windows Certificate Store.
- b. Import a server certificate directly from the OPC UA server. This option allows to select one of the available server certificates and add it to the Windows Certificate store. You will need to specify the OPC UA server URL and then click the Browse button. After that the Configurator will connect to the server and get certificates for all endpoints exposed by the server. If the operation was successful, the server certificates will be added to the drop-down list of available certificates.

---

**Note:** Importing a server certificate directly from OPC UA server only works for self-signed server certificates.

---

6. Click the **Next** button. The FINISH page will display.

This page informs you that the Configurator is ready to store the configured settings. After you click the Configure button, the settings will be stored in OPCUASettings file in the Plant SCADA Config folder. The Configuration Messages panel will indicate if the configuration was successful. If required, you can use the Previous button to make any changes to your settings before you complete the configuration process or create and configure new settings.

There is also an option to check the connection to the server after the settings have been configured. You will need to specify the OPC UA server URL and then click the Test connection button. If the connection was successful, a message about that will appear in the Configuration Messages panel. Otherwise a message will indicate a specific error.

7. Use device specific SecuritySettingsName ini parameter to apply the settings to a specific I/O device. For example, you can enter:

```
[OPCUA.PORT1_BOARD1.IODev1]  
SecuritySettingsName=MySettings
```

---

**Note:** The security settings are stored in the OPCUASetting.xml file in the Citect SCADA config folder. When upgrading Citect SCADA to a new version, that file has to be manually copied to the new Plant SCADA/Citect SCADA config folder.

---

## Customizing a Project using Citect.ini Parameters

### **WARNING**

#### **UNINTENDED EQUIPMENT OPERATION**

- Do not under any circumstances change or remove any of the undocumented citect.ini parameters.
- Before deleting sections of the citect.ini file, confirm that no undocumented parameters will be deleted.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

Citect.ini parameters are used to tune the performance of the Plant SCADA OPC UA driver, and to perform runtime maintenance diagnostics.

You can customize the way Plant SCADA communicates with the OPC UA system (and even individual PLCs) by creating or editing the [OPCUA] section of the Citect.ini file for your project.

When Plant SCADA starts at runtime, it reads configuration values from the Citect.ini file that is stored locally.

Therefore, any OPC UA configuration settings must be included in the Citect.ini file located on the computer acting as the I/O server to the OPCUA system.

- [Connection Parameters](#)
- [Subscription Parameters](#)
- [Security Parameters](#)
- [Logging Parameters](#)

**Note:** Any parameters placed under the [OPCUA] section of the Citect.ini file will apply globally to every device using the OPCUA driver. However, you can also set parameters for a specific device, or for every device connected to a specified port. For more information, see [Device-specific Parameters](#).

## Connection Parameters

### **WARNING**

#### **UNINTENDED EQUIPMENT OPERATION**

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

[OPCUA] Parameter	Description	Allowable Values	Default Value
BrowseTimeout	The browse timeout (in milliseconds).  This parameter specifies the amount of time that an OPC UA server browsing window will wait for a browse call to succeed on an OPC UA server. If browsing is not successful in this period of time, it will stop.	1- 1800000	60000 (ms)
ConnectionDelay	The connection delay between reconnection attempts.  If the connection to the server is unsuccessful, by default the driver will immediately try to reconnect. This parameter allows you to specify a delay before the next	0-30000	0 ms

	connection attempt occurs.		
ConnectionTimeout	The connection timeout (in milliseconds). This parameter specifies the time in milliseconds that the driver will wait for a connection with the OPC UA server to be made.	1-1000000	10000 ms
CallTimeout	The timeout in milliseconds for individual service calls. This parameter defines how long the driver will wait for a server response after sending a service call.	1-1000000	10000 ms
ItemsMaximumBlockSize	Maximum number of monitored items the driver can add or read in one request to the OPC UA server.	1-10000	100
SessionTimeout	The session timeout (in milliseconds) for the server connection. If the driver is unable to issue a request within this interval, the server will automatically stop the connection.	1 - 10000000	3600000 ms
StatusItemNodeId	<p>The status item Node ID. If this parameter is specified, the driver will only put the I/O device online if the value of this item is equal or greater than the value specified for the StatusItemValue parameter (see below).</p> <p>For example, if the standard OPC UA ServiceLevel item is used as the status item, these parameters can be set as follows:</p>	-	Not specified.

	StatusItemNodId=i=2267 StatusItemValue=200		
StatusItemValue	The comparison value for the status item specified by the StatusItemNodId parameter (see above).	0 – 1000000	0
UseSamplingMonitoringMode	When a tag is not subscribed in Plant SCADA, the driver sets the OPC UA item monitoring mode to Disabled. This parameter allows you to set it to Sampling mode instead.  This can be useful in case where the OPC UA server does not publish the current item value after the tag is subscribed and the driver changed the item monitoring mode from Disabled to Reporting.	0 – monitoring mode is set to Disabled for unsubscribed tags  1 - monitoring mode is set to Sampling for unsubscribed tags	0
WatchdogTime	The time (in milliseconds) between watchdog checks. This parameter defines how often the driver will perform watchdog read to check the connection to the server.	1- 100000	10000 ms
WatchdogTimeout	The timeout (in milliseconds) for a specific watchdog check.	1- 100000	10000 ms

**Subscription Parameters****UNINTENDED EQUIPMENT OPERATION**

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

[OPCUA ] Parameter	Description	Allowable Values	Default Value
ItemDeactivationDelay	Item deactivation time in seconds.	1 - 600	30 (seconds)
QueueSizePerItem	Maximum number of updates per item queued in the server before publishing.	1 - 10000	10
ReadAfterWrite	<p>Determines if, after writing to an item, the driver performs a synchronous read of the same item.</p> <p>This parameter can be useful in cases where the OPC UA server reports that a write was successful, when in reality the value of the item had not changed. In this case, the tag value on the graphics screen is updated to the written value if [Code]WriteLocal is set to 1 (default behavior). This is not correct.</p> <p>Setting this parameter to 1 will make sure the driver will read the item value after the write is completed, and that the value on the graphics page will be updated to the correct one.</p>	<p>0 - the driver does not perform an item read after write</p> <p>1 - the driver performs a synchronous read of the item after write</p>	0
Subscription1PublishingInterval	Subscription 1 publishing interval in milliseconds.	Any positive value less than Subscription2 PublishingInterval if Subscription2 PublishingInterval is greater than 0.	400 ms
Subscription2PublishingInterval	Subscription 2 publishing	Any positive value less	0 ms

terval	interval in milliseconds.	than Subscription3 PublishingInterval if Subscription3 PublishingInterval is greater than 0.	
Subscription3PublishingIn terval	Subscription 3 publishing interval in milliseconds.	Any positive value less than 86400000.	0 ms
Subscription1SampleRate	Subscription 1 sampling interval in milliseconds.	Any positive value less than 86400000.	0 - this parameter is not used. The sample rate will automatically adjust to half of the associated publishing interval.  You only need to set this parameter if a specific sampling rate is required.
Subscription2SampleRate	Subscription 2 sampling interval in milliseconds.	Any positive value less than 86400000.	0 - this parameter is not used. The sample rate will automatically adjust to half of the associated publishing interval.  You only need to set this parameter if a specific sampling rate is required.
Subscription3SampleRate	Subscription 3 sampling interval in milliseconds.	Any positive value less than 86400000.	0 - this parameter is not used. The sample rate will automatically adjust to half of the associated publishing interval.  You only need to set this parameter if a specific sampling rate is required.

## Security Parameters

### UNINTENDED EQUIPMENT OPERATION

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

[OPCUA] Parameter	Description	Allowable Values	Default Value
SecuritySettingsName	I/O Device security settings name		Not Specified
SecureChannelLifetime	The time (in milliseconds) after which the SecureChannel between the client and server is automatically renewed. For more information about the SecureChannel Services, please consult the OPC UA specification.	1 - 10000000	3600000 ms

## See Also

[Security Configuration](#)

## Logging Parameters

### **WARNING**

#### **UNINTENDED EQUIPMENT OPERATION**

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

[OPCUA ] Parameter	Description	Allowable Values	Default Value
DebugLevel	The trace level used for the log file.	ALL or any combination of the following, separated by a pipe character ( ):  ERROR WARN TRACE DEBUG See <a href="#">Logging</a> for examples.	-
DebugCategory	The categories used for the log file.	ALL or any combination of the following, separated	-

		<p>by a pipe character ( ):</p> <p>PROT = protocol level debug</p> <p>DCB = front end debug (i.e. I/O server)</p> <p>BEND = back end debug</p> <p>MISC = any other debugging</p> <p>See <a href="#">Logging</a> for examples.</p>	
DebugUnits	Specifies the I/O devices that will have log messages written to a log file.	The names of one or more units separated by a pipe character ( ).	Empty string (log messages sent for every device).

## Device-specific Parameters

### **WARNING**

#### UNINTENDED EQUIPMENT OPERATION

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

Any parameters placed under the [OPCUA] section of the Citect.ini file will apply globally to every device using the OPCUA driver. However, you can also set parameters for a specific device, or for every device connected to a specified port.

To do this, use one of the following section names within the Citect.ini file.

- [<Protocol>.<PortName>]  
where: <Protocol> is OPCUA and <PortName> is the 'Port Name' defined for a specified port on the Ports form.  
For example, any parameters set within the section [OPCUA.PrimaryPort1] will impact every device connected to the port defined as "PrimaryPort1" on the Ports Form.
- [<Protocol>.<PortName>.<DeviceName>]  
where: <Protocol> is OPCUA, <PortName> is the 'Port Name' defined for a specified port on the Ports form and <DeviceName>. For example, any parameters set within the section [OPCUA.PrimaryPort1.PrimaryIODev128] will only impact the device named "PrimaryIODev128".

## Tag Import

You can use Plant SCADA's Import Variables Tags tool to automatically create variable tags that correspond to

OPC UA server items.

### To create variable tags based on OPC UA variables/properties:

1. Open Plant SCADA Studio.
2. In the **Topology** activity, select **I/O Devices** then **Import Variable Tags**.
3. In the Destination panel, select the required I/O Device. The drop-down menu includes a list of all the I/O devices currently configured in your Plant SCADA project. The device you select needs to be configured to use the OPCUA protocol, otherwise an error message will be displayed when you attempt to configure the device connection.
4. In the Source panel, set the **Database Type** to "OPCUA". You can ignore the value of the External Database field.
5. Click on the **Browse...** button to display the OPC UA Browse dialog box.

If the OPC UA server does not allow unsecured or anonymous connections, you will need to configure the security settings via the OPC UA Configurator plugin before browsing or importing tags. You then need to select the security settings name from the drop-down list at the top of the page.

---

**Note:** Select the "Import Item Description" check box to import the OPCUA item description.

6. Click on the expand button (+) to display all the namespaces on the OPC UA Server. Plant SCADA will connect to the OPC UA server to read the names of the namespaces and the folders under each.

There are two options you can use to import the tags:

- a. Create tags for all items under the selected folder node or select the specific items. When using this option, you need to select the namespace or folder in the tree.
  - b. For the second option, you need to click on one of the folder nodes which will display all items under this node. Select which items you want to import. The selected items will be added to the list at the bottom of the page.
7. When you have made your selections, click OK.
  8. On the Import Variable Tags dialog box, click the **Import** button.

If the first tag import option is used, Plant SCADA will connect to the OPC UA server to read the tag name, data type and address (Node ID). If the second import option is used, Plant SCADA will create tags for all selected items.

---

**Note:** The number of items which can be browsed for a particular folder node and the number of tags you can import is limited to 100,000.

The value of the property **Browse Name** will be used as the tag name. If it has a parent folder, it will be pre-fixed with the folder name (separated by '\').

---

**Note:** If the name of the tag is greater than 78 characters then it will be truncated to 78 characters. A warning message will be logged in the tag import log file.

9. On Tag Import Results dialog box, click **Yes** to display the log file.

## Troubleshooting

The following topics provide information about the Plant SCADA tools available to diagnose and resolve any unexpected behavior within the runtime system.

- [OPC UA Server Connection](#)

- [Driver Errors](#)
- [Driver Statistics](#)
- [Logging](#)

## OPC UA Server Connection

If secure connection is not required, only the OPC UA server URL needs to be specified in the I/O Device address form to establish the connection. But if the user authentication or message encryption is required, the security settings will need to be configured by using the "OPC UA Client Driver" Configurator plugin.

The plugin provides an option to check if the connection can be established after the settings have been configured.

If the connection cannot be established, the specific error will help to identify the cause of the problem.

Points to consider include:

- The user credentials are stored in ArchestraA™ Data Store and the ArchestraA™ Data Store service must be running on the machine for the plug-in to store the data and for the driver to read it. The ArchestraA™ Data Store service should be installed and running after the driver installation.
- When the user credentials are configured for the first time, the plug-in adds the currently logged-in user to the Citect.User.Drivers Windows group so that the I/O Server running under the same user account can read the data. When a user is added to that group for the first time, you will need either to restart the computer or to log in / log out.
- The client and server certificates must be present in the Windows certificate store. The client certificate must have a private key and its "Subject Alternative Name" field should be in the format "urn:HostMachineName:Citect.OPCUA.Client.Driver", where the HostMachineName is the host name of the computer running the driver.

The driver logs can also help to find out why the driver cannot connect to the server.

When full driver logging is enabled by setting the ini parameters ([OPCUA]DebugLevel=ALL and [OPCUA]DebugCategory=ALL), the driver log will contain a number of messages or errors describing the connection attempt for each I/O Device.

## Driver Errors

Plant SCADA has two kinds of protocol driver errors: generic and specific.

- Generic errors are hardware errors 0-31, which are common to many protocols.
- Specific errors are unique to a particular driver.

When a driver specific error occurs, the hardware alarm system will not recognize it. The driver converts the specific error into a generic error that can be identified by the I/O server.

This means a driver error may be represented by a specific error, and a corresponding generic error.

When a hardware error occurs, Plant SCADA generates an alarm and displays it on the hardware alarm page. To see the error number, you need to have Alarm Category 255 defined with a display format that includes {ErrDesc,15} {ErrPage,10}.

Refer to the Plant SCADA Help for more information on generic hardware errors.

If you need more information to resolve an error, refer to the documentation that accompanied the I/O device (or network). If, after reviewing the documentation, you still cannot solve your problem, contact Technical Support for this product.

## Driver Statistics

You can use the following driver statistic counters to help you debug the OPCUA driver. These statistics can be viewed within the Plant SCADA Kernel using the Page Driver command and then by pressing the 'v' key to select verbose mode.

See the topic Runtime > Debug Runtime > The Kernel > Kernel Commands > Page Driver in the main Plant SCADA help for more information.

Statistic	Description
# tags subscribed	Total number of subscribed tags for all I/O Devices.
# total updates	Total number of tag value updates received from the OPC UA server for all I/O Devices.
# updates per second	Total number of tag value updates per second received from the OPC UA server for all I/O Devices.
# writes	Total number of write requests processed by the driver for all I/O Devices.
# writes failed	Total number of failed write requests for all I/O Devices.
# configured units	Number of configured I/O Devices.
# units online	Number of I/O Devices which are online.

## Logging

The OPCUA driver can log combinations of trace levels across different categories. This is achieved by setting the following INI parameters.

### [OPCUA]DebugLevel

This parameter allows you to define the trace level. The options include:

WARN	Output warning messages.
ERROR	Output error messages.
TRACE	Output trace messages.
DEBUG	Output debug messages.

ALL	All of the above.
-----	-------------------

## [OPCUA]DebugCategory

This parameter allows you to enable logging for a particular category of trace. The options include:

PROT	Operations related to the OPC protocol interface
DCB	Front end driver trace
BEND	Operations related to the back-end thread of the driver
MIISC	Miscellaneous operations
ALL	All of the above

In both cases, you can use ALL or any combination of the available options separated by a pipe character ( | ).

### Example

```
[OPCUA]
DebugLevel=WARNING|ERROR|TRACE
DebugCategory=ALL
```

In most cases, you can set the DebugLevel and DebugCategory parameters to ALL. If this results in a large, cumbersome log file that causes older data to be overwritten, you can consider refining the debug options.

---

**Note:** These parameters do not have a value specified by default. To enable logging for this driver, you need to manually configure these parameters in your INI file.

The events generated by the OPCUA driver are logged in the following Plant SCADA syslog file:

```
syslog.IOServer.<Cluster name>.<IO Server name>.dat
```

This file is located in the directory specified by the Citect.ini parameter **[CtEdit]Logs**. By default, this location will be:

```
%PROGRAMDATA%\AVEVA Plant SCADA <VersionNumber>\Logs
```

The size of the syslog file and its rollover process is configured via the **[Debug]SysLogSize** and **[Debug]SysLogArchive** INI parameters. For more information, see the topic *Debug Parameters* in the Plant SCADA documentation.

## S7TCP Driver

The S7TCP Driver enables Plant SCADA to communicate with Siemens S7-PLC series via an Ethernet connection. The driver provides access to a Siemens S7-PLC through standard Ethernet network interface card in the computer.

The driver supports symbolic tag names of PLC items.

The following diagram demonstrates a simple system configuration, with Plant SCADA connected Siemens S7-PLC via the S7TCP driver hosted on a single pair of redundant I/O servers.

**Note:** The S7TCP driver requires Citect SCADA version 7.50 Service Pack 1 (Patch 9) or a later release to operate successfully.

## Safety Information

### Hazard categories and special symbols

The following symbols and special messages may appear in this manual or on the product to warn of potential hazards or to call attention to information that clarifies or simplifies a procedure.

Symbol	Description
 or 	The addition of either symbol to a "Danger" or "Warning" safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.
	This is the safety alert symbol. It is used to alert you to personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.
<b>⚠ DANGER</b>	<b>DANGER</b> indicates an imminently hazardous situation, which, if not avoided, will result in death or serious injury.
<b>⚠ WARNING</b>	<b>WARNING</b> indicates a potentially hazardous situation, which, if not avoided, can result in death or serious injury.
<b>⚠ CAUTION</b>	<b>CAUTION</b> indicates a potentially hazardous situation which, if not avoided, can result in minor or moderate injury.
<b>NOTICE</b>	NOTICE used without a safety alert symbol, indicates a potentially hazardous situation which, if not avoided, can result in property or equipment damage.

## Please Note

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by AVEVA for any consequences arising out of the use of this material.

## Before You Begin

Plant SCADA is a Supervisory Control and Data Acquisition (SCADA) solution. It facilitates the creation of software to manage and monitor industrial systems and processes. Due to Plant SCADA's central role in controlling systems and processes, you must appropriately design, commission, and test your Plant SCADA project before implementing it in an operational setting. Observe the following:

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not use Plant SCADA or other SCADA software as a replacement for PLC-based control programs. SCADA software is not designed for direct, high-speed system control.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**⚠ WARNING****LOSS OF CONTROL**

- The designer of any control scheme must consider the potential failure modes of control paths and, for certain critical control functions, provide a means to achieve a safe state during and after a path failure. Examples of critical control functions are emergency stop and overtravel stop, power outage and restart.
- Separate or redundant control paths must be provided for critical control functions.
- System control paths may include communication links. Consideration must be given to the implications of unanticipated transmission delays or failures of the link.
- Observe all accident prevention regulations and local safety guidelines.<sup>1</sup>
- Each implementation of a control system created using Plant SCADA must be individually and thoroughly tested for proper operation before being placed into service.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

1. For additional information, refer to NEMA ICS 1.1 (latest edition) "Safety Guidelines for the Application, Installation, and Maintenance of Solid State Control", and to NEMA ICS 7.1 (latest edition) "Safety Standards for Construction and Guide for Selection, Installation and Operation of Adjustable-Speed Drive Systems" or their equivalent governing your particular location.

## Supported Devices

The S7TCP driver allows Plant SCADA to communicate with the Siemens S7-PLC family of controllers.

- The driver supports S7-1500 firmware up to v3.1.0.
- The driver supports S7-1200 firmware between v4.0 and v4.5.

---

**Note:** The driver does not support secure communication to a PLC.

---

## See Also

[Setting up Device Communications](#)

## Setting up Device Communications

The information included in the following topics describes how to establish communication with Plant SCADA and S7-PLC devices using the S7TCP driver.

### See Also

[Device Address](#)

[Communication Settings](#)

### Device Address

The address to use for an I/O device using the S7TCP driver is the IP address of the Ethernet interface on the S7-PLC.

### See Also

[Communication Settings](#)

### Communication Settings

To establish communication with a device, the associated **Board**, **Port** and **I/O Device** need to be correctly configured in Plant SCADA Studio's **Topology** activity.

If you use the Express Communications Wizard to connect to a device, these settings will be automatically configured for you. However, if you need to manually configure them, use the settings outlined below.

### Boards

The Boards view in Plant SCADA Studio's Topology activity lists all boards used in the Plant SCADA project.

Field	Value
Board Name	This field is user defined (e.g. 'Board1').
Board Type	Enter S7TCP
Address	Enter zero (0)
I/O Port	Leave this field blank
Interrupt	Leave this field blank
Special Options	Leave this field blank
Comment	Any useful comment. This field is user defined and not required by the driver.

## Ports

The Ports view in Plant SCADA Studio's Topology activity lists the ports used in the Plant SCADA project.

Field	Value
Port Number	This field is user defined
Baud Rate	Leave this field blank
Board Name	Refers to the board previously defined in the Board settings
Data Bits	Leave this field blank
Stop Bits	Leave this field blank
Parity	Leave this field blank
Special Options	Leave this field blank
Comment	Any useful comment. This field is user defined and not required by the driver.

## I/O Devices

The I/O Devices view in Plant SCADA Studio's Topology activity lists I/O devices used in the Plant SCADA project.

Field	Value
Name	This field is user defined
Number	I/O device number which needs to be unique for each logical device, but identical for redundant devices.
Address	The IP address of the remote S7-PLC
Protocol	Enter S7TCP.
Port Name	Refers to the port previously defined in the Port settings.
Comment	Any useful comment. This field is user defined and not required by the driver.
Min Update Rate	Defines the period in seconds at which the driver polls the PLC for tag value updates. You may select any predefined value from the drop-down list, or enter your own in the format of HH:MM:SS. If you do not enter a value, the default value of 0 seconds will be used in which case the polling period will be equal to

Field	Value
	1 second.

## Configuring Variable Tags

Variable tags are addressed using the symbolic tag names configured for Siemens S7-PLC device. The following table demonstrates the variable tag address formats you can use to read and write values

Address Format	S7-1500 Data Type	S7-1200 Data Type	Plant SCADA Type	Value Range
<Symbolic Tag Name>	BOOL	BOOL	DIGITAL	FALSE or TRUE
<Symbolic Tag Name>	BYTE	BYTE	INT, UINT, LONG, ULONG	0 to 255
<Symbolic Tag Name>	WORD	WORD	UINT, LONG, ULONG	0 to 65535
<Symbolic Tag Name>	DWORD	DWORD	ULONG	0 to 4294967295
<Symbolic Tag Name>	SINT	SINT	INT, LONG	128 to 127
<Symbolic Tag Name>	USINT	USINT	INT, UINT, LONG, ULONG	0 to 255
<Symbolic Tag Name>	INT	INT	INT, LONG	-32768 to 32767
<Symbolic Tag Name>	UINT	UINT	UINT, LONG, ULONG	0 to 65535
<Symbolic Tag Name>	DINT	DINT	LONG	-2147483648 to +2147483647
<Symbolic Tag Name>	UDINT	UDINT	ULONG	0 to 4294967295
<Symbolic Tag Name>	REAL	REAL	REAL	-3.4E38 to 3.4E38
<Symbolic Tag Name>	CHAR	CHAR, STRING	CHAR, STRING	ASCII character
<Symbolic Tag Name>	WCHAR	WCHAR	STRING	Unicode character represented as ASCII character in Plant

Address Format	S7-1500 Data Type	S7-1200 Data Type	Plant SCADA Type	Value Range
				SCADA <b>Note:</b> Driver supports multi-byte strings only when it is possible to convert a multi-byte character to the ASCII.
<Symbolic Tag Name>	WSTRING	WSTRING	STRING	Unicode string (0-254 characters) represented as ASCII string in Plant SCADA <b>Note:</b> Driver supports multi-byte strings only when it is possible to convert a multi-byte character to the ASCII.
<Symbolic Tag Name>	S5TIME	N/A	LONG	0 to 9990000 (milliseconds)
<Symbolic Tag Name> -	TIME	TIME	LONG	-2147483648 to +2147483647 (milliseconds)
<Symbolic Tag Name>	DATE	DATE	LONG	0 to 65378 (days)
<Symbolic Tag Name>	TIME_OF_DAY (TOD)	TIME_OF_DAY (TOD)	ULONG	0 to 86399999 (milliseconds)
<Symbolic Tag Name>	DATE_AND_TIME	N/A	STRING	1990-01-01-00:00:00.000 to 2089-12-31-23:59:59.999
<Symbolic Tag Name>	LTIME	N/A	STRING	-9223372036854775808 to +9223372036854775807 (nanoseconds)
<Symbolic Tag Name>	LTOD (LTIME_OF_DAY)	N/A	STRING	0 to 8639999999999 (nanoseconds)

Address Format	S7-1500 Data Type	S7-1200 Data Type	Plant SCADA Type	Value Range
<Symbolic Tag Name>	LDT (DATE_AND_LTIME)	N/A	STRING	0 to 9254908036854775 808 (nanoseconds)

When configuring tags to access PLC arrays and structures, a separate tag needs to be created for each array or structure element.

The driver supports conversions between S7-PLC data types and Plant SCADA data types. When a configured tag data type cannot be converted into PLC data type, the driver marks that tag with quality Bad, Configuration Error. The following table shows supported conversions between Plant SCADA and S7-PLC data types.

Plant SCADA Data Type	S7-PLC Data Type
DIGITAL	BOOL
INT, UINT	BYTE, WORD, SINT, USINT, INT,UINT
LONG, UINT	BYTE, WORD, DWORD, SINT, USINT, INT,UINT, DINT, UDINT
REAL	REAL
STRING	All S7-PLC data types supported by the driver, except for BYTE, USINT, WORD, UINT, DATE

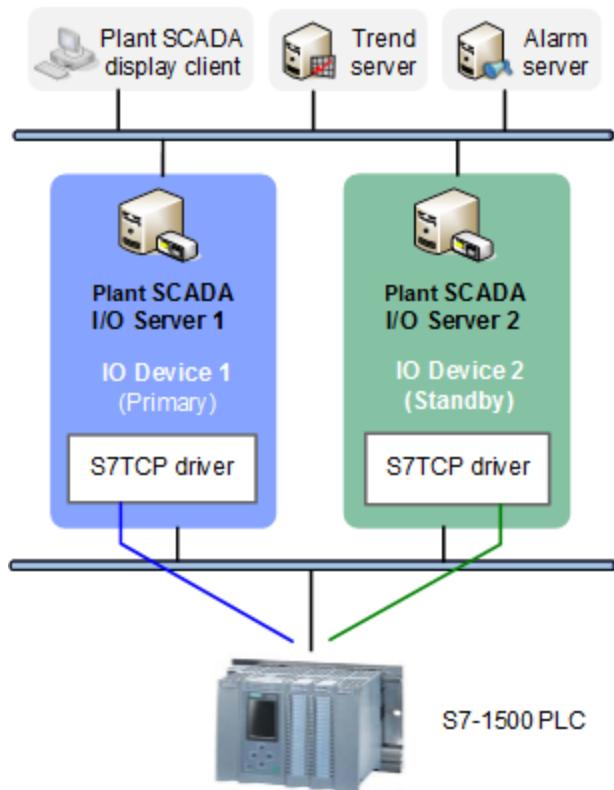

## Advanced Configuration and Maintenance

This section provides instructions for advanced configuration and maintenance tasks.

- [Configuring Redundancy](#)
- [Customizing a Project Using Citect.ini Parameters](#)
- [Tag Import](#)

### Configuring Redundancy

The S7TCP driver supports multiple I/O server / device redundancy. The driver represents each S7-PLC as a separate I/O device. In normal operating state, the driver will poll the PLC via the primary I/O device. If the connection to the PLC via the primary I/O device is lost, the PLC will be polled via a standby I/O device which is connected to the PLC and has the highest priority in case when multiple redundant I/O devices are configured.

**Note:** The redundancy switchover will only work properly if Plant SCADA periodically checks the communication connection to the primary and standby I/O devices. Plant SCADA automatically checks the primary I/O device, but this process can be disabled for the standby I/O device if the I/O server parameter [IOServer]WatchDog is set to 0 (disabled). By default, this parameter enables Watch Dog functionality for a standby I/O device. It should not be changed.

### Customizing a Project using Citect.ini Parameters

#### **WARNING**

##### UNINTENDED EQUIPMENT OPERATION

- Do not under any circumstances change or remove any of the undocumented citect.ini parameters.
- Before deleting sections of the citect.ini file, confirm that no undocumented parameters will be deleted.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

Citect.ini parameters are used to tune the performance of the Plant SCADA S7TCP driver, and to perform runtime maintenance diagnostics.

You can customize the way Plant SCADA communicates with the S7TCP system (and even individual PLCs) by creating or editing the [S7TCP] section of the Citect.ini file for your project.

When Plant SCADA starts at runtime, it reads configuration values from the Citect.ini file that is stored locally.

Therefore, any S7TCP configuration settings must be included in the Citect.ini file located on the computer acting as the I/O server to the S7TCP system.

## S7TCP Driver Parameters

### **WARNING**

#### **UNINTENDED EQUIPMENT OPERATION**

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

[S7TCP] Parameter	Description	Allowable Values	Default Value
ConnectionTimeout	This parameter specifies the time in milliseconds that the driver will wait for a connection with a PLC to be made.	0-100000	20000
HeartBeatTag	This parameter specifies the name of the item that gets updated in the PLC at a rate determined by the HeartBeatInterval parameter.  Some system items are already programmed in the PLC and can be used to avoid changes to the PLC program.  For example, "db_test.Test_Uint32" has value updates every 5ms.	PLC item name	-
HeartBeatInterval	This parameter defines the period the driver will use to check the status of the item specified by the	1 - 2147483647 (seconds)	60

[S7TCP] Parameter	Description	Allowable Values	Default Value
	<p>HeartBeatTag parameter. If the item value has not changed during the period specified, the driver will put the I/O device offline.</p> <p><b>Note:</b> The driver checks the HeartBeatTag value every Minimum Update rate specified by either the "Min Update Rate" field in the I/O Device configuration settings (which equals 1 sec by default), or by the MinUpdateRate parameter.</p>		
MinUpdateRate	<p>This parameter defines the period in milliseconds at which the driver polls the PLC for tag value updates. Note that by default the polling period is specified by the "Min Update Rate" field in the I/O Device configuration settings which equals to 1 sec by default. The ini parameter allows to specify the minimum update rate in milliseconds.</p> <p>If this parameter is specified and is not equal to 0, the driver will use it to define the polling rate. Otherwise the "Min Update Rate" field in the I/O Device settings will be used.</p>	0-100000	0
ReplyTimeout	This parameter specifies the time in milliseconds that the driver will wait for a response from the	0-100000	5000

[S7TCP] Parameter	Description	Allowable Values	Default Value
	PLC		
StandbyDbCheckInterval	<p>This parameter defines the period in seconds at which the driver polls the PLC to check for database changes in the PLC.</p> <p>If this parameter is specified, the driver will use it to define the database check interval only for standby devices to reduce the network traffic. In this case the primary device will be polled every 3 seconds.</p> <p>If the primary device is down and the secondary device is active, the secondary device will be polled every 3 seconds.</p>	1-120 (seconds)	3

## Logging Parameters

### **WARNING**

#### **UNINTENDED EQUIPMENT OPERATION**

- Do not under any circumstances change or remove any of the undocumented citect.ini parameters.
- Before deleting sections of the citect.ini file, confirm that no undocumented parameters will be deleted.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

[S7TCP] Parameter	Description	Allowable Values
DebugLevel	The trace level used for the log file.	ALL or any combination of the following, separated by a pipe character ( ) : ERROR WARN TRACE

		DEBUG See note below. See <a href="#">Logging</a> for examples.
DebugCategory	The categories used for the log file.	ALL or any combination of the following, separated by a pipe character ( ): PROT = protocol level debug DCB = front end debug (i.e. I/O server) MISC = any other debugging ALL = all of the above See <a href="#">Logging</a> for examples.

**Note:** Setting DebugLevel to DEBUG or ALL will cause the driver to log a large amount of debugging information (for example, sent and received protocol messages in binary format). This information is typically unnecessary for driver diagnostics. This may impact performance and result in multiple wraparounds that write over data.

It is recommended that you use the following DebugLevel and DebugCategory settings:

- [S7TCP]DebugLevel=ERROR|WARN|TRACE
- [S7TCP]DebugCategory=ALL

### Using Device or Port-specific Parameters

#### **WARNING**

##### **UNINTENDED EQUIPMENT OPERATION**

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

Any parameters placed under the [S7TCP] section of the Citect.ini file will apply globally to every device using the S7TCP driver. However, you can also set parameters for a specific device, or for every device connected to a specified port.

To do this, use one of the following section names within the Citect.ini file.

- [<Protocol>.<PortName>]

where:

<Protocol> is S7TCP

<PortName> is the 'Port Name' defined for a specified port in the Ports grid.

For example, any parameters set within the section [S7TCP.PrimaryPort1] will impact every device connected to the port defined as "PrimaryPort1" in the Ports grid.

- [<Protocol>.<PortName>.<DeviceName>]

where:

<Protocol> is S7TCP

<PortName> is the name defined for the specified port in the Ports grid.

<DeviceName> is the name defined for the specified device on the I/O Devices grid.

For example, any parameters set within the section [S7TCP.PrimaryPort1.PrimaryIODev128] will only impact the device named "PrimaryIODev128".

The following list includes the parameters you can set at a device or port-specific level.

- ConnectionTimeout
- ReplyTimeout

## Tag Import

You can use Plant SCADA's Import Variables Tags tool to automatically create variable tags that correspond to S7 1200/1500 PLC items.

### To create variable tags based on S7 tag properties:

1. Open Plant SCADA Studio.
2. In the **Topology** activity select **I/O Devices**, then **Import Tags**.
3. In the Destination panel, select the required I/O Device. The drop-down menu includes a list of all the I/O devices currently configured in your Plant SCADA project. The device you select needs to be configured to use the S7TCP protocol, otherwise an error message will appear when you attempt to configure the device connection.
4. In the Source panel, set the **Database type** to "S7TCP". You can ignore the value of the **External database** field.
5. Click **Browse...** to display the S7TCP Browse dialog box. To select the tags for import:
  - a. Click **Browse...** to display all the tags corresponding to S7 PLC. Plant SCADA will connect to the S7 PLC to read the tag database.
  - b. Select the items you want to import. The selected items will be added to the list at the bottom of the page.
  - c. If you want to prefix the I/O device name to the tag names, select the check box **I/O Device name as a prefix to tag name**.
  - d. When you have made your selections, click **OK**.
6. Click **Import**. Plant SCADA will create tags for all selected items.

---

#### Note:

- The number of items which can be browsed for a PLC, and the number of tags you can import, is limited to 100,000.
  - If the name of the tag is greater than 78 characters, then it will be truncated to 78 characters. A warning message will be logged in the tag import log file.
-

7. On **Tag Import Results** dialog box, click **Yes** to display the log file.

## Troubleshooting

The following topics provide information about the Plant SCADA tools available to diagnose and resolve any unexpected behavior within the runtime system.

- [Driver Errors](#)
- [Driver Statistics](#)
- [Logging](#)

### Driver Errors

Plant SCADA has two kinds of protocol driver errors: generic and specific.

- **Generic errors** are hardware errors 0-31, which are common to many protocols.
- **Specific errors** are unique to a particular driver.

When a driver specific error occurs, the hardware alarm system will not recognize it. The driver converts the specific error into a generic error that can be identified by the I/O server.

This means a driver error may be represented by a specific error, and a corresponding generic error.

When a hardware error occurs, Plant SCADA generates an alarm and displays it on the hardware alarm page. To see the error number, you need to have Alarm Category 255 defined with a display format that includes {ErrDesc,15} {ErrPage,10}.

Refer to the Plant SCADA Help for more information on generic hardware errors.

If you need more information to resolve an error, refer to the documentation that accompanied the I/O device (or network). If, after reviewing the documentation, you still cannot solve your problem, contact Technical Support for this product.

### Driver Statistics

You can use the following driver statistic counters to help you debug the S7TCPdriver. These statistics can be viewed within the Plant SCADA Kernel using the Page Driver command and then by pressing the 'v' key to select verbose mode.

See the topic *Using Plant SCADA > Monitoring and Debugging Runtime > Using the Kernel > Kernel Commands > Page Driver* in the main Plant SCADA help for more information.

Statistic	Description
# tags subscribed	Total number of subscribed tags for all I/O Devices
# plc tags resolved	Total number of resolved PLC tags for all I/O Devices
# plc tags polled	Total number of polled PLC tags for all I/O Devices
# plc reads	Total number of PLC read requests sent by the driver

Statistic	Description
	for all I/O Devices
# writes	Total number of write requests processed by the driver for all I/O Devices
# writes failed	Total number of failed write requests for all I/O Devices
# configured units	Number of configured I/O Devices
# units online	Number of I/O Devices which are online

## Logging

The S7TCP driver can log combinations of trace levels across different categories. This is achieved by setting the following INI parameters.

### [S7TCP]DebugLevel

This parameter allows you to define the trace level. The options include:

WARN	Output warning messages.
ERROR	Output error messages.
TRACE	Output trace messages.
DEBUG	Output debug messages.
ALL	All of the above.

You can use a combination of these options separated by a pipe character ( | ).

#### CAUTION

Setting [S7TCP]DebugLevel to DEBUG or ALL will cause the driver to log a large amount of debugging information (for example, sent and received protocol messages in binary format). This information is typically unnecessary for driver diagnostics and may result in multiple wraparounds that write over data.

#### Example

```
[S7TCP]
DebugLevel=WARNING|ERROR|TRACE
```

### [S7TCP]DebugCategory

This parameter allows you to enable logging for a particular category of trace. The options include:

PROT	Operations related to the OPC protocol interface
DCB	Front end driver trace
MIsc	Miscellaneous operations
ALL	All of the above

You can use ALL or a combination of these options separated by a pipe character ( | ).

#### Example

```
[S7TCP]
DebugLevel=WARNING|ERROR|TRACE
DebugCategory=ALL
```

---

**Note:** These parameters do not have a value specified by default. To enable logging for this driver, you need to manually configure these parameters in your INI file.

The events generated by the S7TCP driver are logged in the following Plant SCADA syslog file:

```
syslog.IOServer.<Cluster name>.<IO Server name>.dat
```

This file is located in the directory specified by the Citect.ini parameter **[CtEdit]Logs**. By default, this location will be:

```
%PROGRAMDATA%\AVEVA Plant SCADA <VersionNumber>\Logs
```

The size of the syslog file and its rollover process is configured via the **[Debug]SysLogSize** and **[Debug]SysLogArchive** INI parameters. For more information, see the topic *Debug Parameters* in the Plant SCADA documentation.

---

**Note:** If the number of messages being processed for a driver exceeds the value specified by the Plant SCADA parameter **[Kernel]ErrorBuffers**, the pending messages will not be logged. If this occurs, you can increase the value of this parameter so that all the messages generated by the driver are reported. The number of messages that are not logged can be monitored via the Kernel's General window under the item "Lost Errors". If you adjust **[Kernel]ErrorBuffers** and Lost Errors are still occurring, you may need to adjust the level of system logging.

[Logging Parameters](#)

## SBUS Driver

The SBUS driver supports SERIAL communication with the [SAIA PCD PLCs](#). The protocol can use three different transmission methods:

- 1) Parity changing method
- 2) Break mode transmission
- 3) Data mode transmission

The transmission method is determined by the **[SBUS]SendBreak** parameter. Refer to [SBUS Protocol Parameters](#) for information on how to set the transmission method.

The maximum request length for the SBUS protocol is 16 bits.

## Hints and Tips

To setup the proper communication modes for SBUS with PCDs, you may need to use the utilities provided by SAIA to alter the firmware settings of the PCD devices. Refer to the topic titled [Software Setup](#) for software and firmware version required for SBUS Data Mode.

## Safety Information

### Hazard categories and special symbols

The following symbols and special messages may appear in this manual or on the product to warn of potential hazards or to call attention to information that clarifies or simplifies a procedure.

Symbol	Description
 or 	The addition of either symbol to a "Danger" or "Warning" safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.
	This is the safety alert symbol. It is used to alert you to personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.

#### DANGER

**DANGER** indicates an imminently hazardous situation, which, if not avoided, will result in death or serious injury.

#### WARNING

**WARNING** indicates a potentially hazardous situation, which, if not avoided, can result in death or serious injury.

#### CAUTION

**CAUTION** indicates a potentially hazardous situation which, if not avoided, can result in minor or moderate injury.

#### NOTICE

NOTICE used without a safety alert symbol, indicates a potentially hazardous situation which, if not avoided, can result in property or equipment damage.

## Please Note

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by AVEVA for any consequences arising out of the use of this material.

## Before You Begin

Plant SCADA is a Supervisory Control and Data Acquisition (SCADA) solution. It facilitates the creation of software to manage and monitor industrial systems and processes. Due to Plant SCADA's central role in controlling systems and processes, you must appropriately design, commission, and test your Plant SCADA project before implementing it in an operational setting. Observe the following:

### **WARNING**

#### **UNINTENDED EQUIPMENT OPERATION**

Do not use Plant SCADA or other SCADA software as a replacement for PLC-based control programs. SCADA software is not designed for direct, high-speed system control.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

### **WARNING**

#### **LOSS OF CONTROL**

- The designer of any control scheme must consider the potential failure modes of control paths and, for certain critical control functions, provide a means to achieve a safe state during and after a path failure. Examples of critical control functions are emergency stop and overtravel stop, power outage and restart.
- Separate or redundant control paths must be provided for critical control functions.
- System control paths may include communication links. Consideration must be given to the implications of unanticipated transmission delays or failures of the link.
- Observe all accident prevention regulations and local safety guidelines.<sup>1</sup>
- Each implementation of a control system created using Plant SCADA must be individually and thoroughly tested for proper operation before being placed into service.

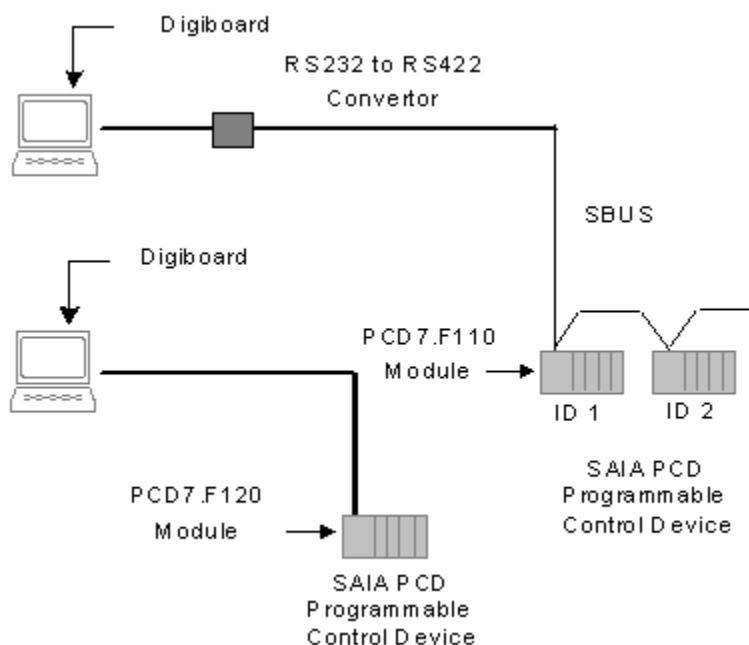

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

1. For additional information, refer to NEMA ICS 1.1 (latest edition) "Safety Guidelines for the Application, Installation, and Maintenance of Solid State Control", and to NEMA ICS 7.1 (latest edition) "Safety Standards for Construction and Guide for Selection, Installation and Operation of Adjustable-Speed Drive Systems" or their equivalent governing your particular location.

## SAIA PCD PLCs

The SBUS Driver supports SERIAL communication to the Programmable Control Device (PCD) family of PLCs, manufactured by SAIA. Using this method, you can connect to single PCDs or to multiple PCDs as in the following

diagram:

**Note:** To setup the proper communication modes for SBUS with PCDs, you may need to use the utilities provided by SAIA to alter the firmware settings of the PCD devices. For details, see [Software Setup](#).

## Device Address

The I/O Device Address for a PCD is the station address (1-90) configured on the PCD, for example:

- **1** specifies PCD address **1**.
- **49** specifies PCD address **49**.

See [Communications Settings](#) for more information about this setup.

## Hardware Setup

### PCD Family of PLCs

The Saia PCD (Programmable Control Device) is a family of PLCs which are programmed with the same instruction set. All PLCs in the family have 8192 flags, 1520 timer counters and 4096 registers.

- PCD2 - This is the economy PLC which allows up to 128 I/O points, has up to 160kb of memory and up to 4 serial interfaces.
- PCD4 - This is the midrange PLC which allows up to 512 I/O points, has up to 428kb of memory and up to 4 serial interfaces.
- PCD6 - This is the deluxe PLC which allows up to 5120 I/O points, has up to 1MB of memory and up to 28 serial interfaces. This PLC also allows multi processors.

## PCDs Setup

Set your PCD to the communication setting you want. The default hardware settings for the PCD are as follows:

Setting	Value
Baud Rate	9600
Data Bits	8
Stop Bits	1
Parity	0 (See note below.)

These settings are recommendations only. If you use the Communications Express Wizard, these default settings are configured in your project automatically, though your hardware may support other values. If you do set the baud rate, data bits, stop bits or parity to another value, you must manually set the new value(s) in your project.

**Note:** This protocol can use two different transmission methods:

- 1) Parity changing method
- 2) Break method of transmission.

The Plant SCADA SBUS driver uses as default the parity changing method. Run the SAIA PCD Programming Utilities to set the the transmission method.

## PCD6 Hardware Configuration Example

A basic configuration of the PCD6 is as follows:

PCD6-M540Single processor module with 4 serial interfaces.  
PGU, RS232 connection for the programming unit.  
Port 1, RS422 or RS485 for point to point or SAIA bus connection.  
Port 2, RS232 connection for a modem.  
Port 3, 20mA current loop.

PCD7-R210Memory module with 64k RAM and real time clock, or ...

PCD7-R220Memory module with 256k RAM and real time clock.

PCD6-N100D4Power supply unit.

PCD6-C100Rack unit (card cage).

SAIA bus cableRS422 cable for connection to the PC.

PGU cableRS232 cable for the programming interface.

## Software Setup

Each PCD will need to be set up with the right communication configuration. SAIA provides configuration programs (such as PG3 or PG4) to configure the desired protocol, baud rate, timeout, and so on.

The **Run** indicator displayed on the front panel of the PCD indicates whether there is a program loaded into the CPU of the unit. A running program is not required for the unit to function, however, any specific register (such as the LCD display register) may not be accessible without the use of a proper configuration program.

To select SBUS - Data Mode, you need to have the following firmware and software that supports it:

SAIA Program	Firmware Version
PCD1 Firmware	From V 002
PCD2 Firmware	From V 005
PCD4.xx5 Firmware	From V 00D
PCD6.M3 Firmware	From V 001
PG3	From V 2.1
PG4	From V 1.4
SCCOMM-DLL 32 bit	From V \$114
S-Bus Analyser	From V \$ 007

## Wiring Diagram

The PCD Family of PLCs support the following serial communications:

- RS422 or RS485 with PCD7.F110 plug in module.
- RS232 with PCD7.F120 plug in module.
- 20mA current loop with PCD7.F130 plug in module

The serial cable is connected to Interface number 1 on the PLC (pins 10-19). The actual connections depend on the type of serial link. Refer to the PCD2 Series Hardware Manual.

## Communication Settings

To establish communication with a device, the associated Board, Port and I/O Device need to be correctly configured in Plant SCADA Studio's **Topology** activity.

If you use the Express Communications Wizard to connect to a device, these settings will be automatically configured for you. However, if you need to manually configure them, use the settings outlined below.

## Boards

Typically, you would use a serial board or COM port for this communication.

### Board Type

Enter COMx.

### Address

Enter 0.

### I/O Port

Leave this field blank.

### Interrupt

Leave this field blank.

#### Special Options

Leave this field blank.

## Ports

#### Port Number

This value should match the COM port number. This number is defined in the Ports section of the Control Panel.

#### Baud Rate

This value must match the setting of the PCD - 9600 is the default.

#### Data Bits

Enter 8.

#### Stop Bits

Enter 1.

#### Parity

This protocol can use two different transmission methods: 1) a Parity changing method or 2) a Break method of transmission. The Plant SCADA SBUS driver uses as default the parity changing method. Run the SAIA PCD Programming Utilities to set the PLC the transmission method.

#### Special Options

You may want to use the Special Options for the COMx Driver if you are using a Modem (or similar) and want the driver to perform differently.

## I/O Devices

#### I/O Device Address

The station address (1-90) configured on the PCD, for example:

- **1** specifies PCD address **1**.
- **49** specifies PCD address **49**.

#### I/O Device Protocol

Enter SBUS.

## Data Types

Data Types	Address Format	Range ( <i>n</i> )	Plant SCADA Data Type
Flag	F <i>n</i>	0 to 8191	DIGITAL
Output	O <i>n</i>	0 to 5120	DIGITAL
Inputs	I <i>n</i>	0 to 5120	DIGITAL

Data Types	Address Format	Range (n)	Plant SCADA Data Type
Status	S $n$	0 to 7	INTEGER
Version	Version	-	STRING
Display	D[.n ]	-	LONG
Display	D	-	REAL
Register	R $n$ [.n ]	0 to 4095	LONG
Register	R $n$	0 to 4095	FLOAT
Counter	C $n$ [.n ]	0 to 1599	LONG
Timer	T $n$ [.n ]	0 to 1599	LONG
RealTime Clock	K[.n ]	-	LONG

**EXAMPLES:**

Data Type	INTEGER
Address	S6
Comment	Status 6
Data Type	DIGITAL
Address	I107
Comment	Running feedback indicator

## SBUS Driver Parameters

The SBUS driver supports the capability to apply different initialisation parameter values to specific I/O Devices. For further information, see [SBUS Port Specific Parameters](#).

**UNINTENDED EQUIPMENT OPERATION**

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

---

**Note:** Always seek the advice of Technical Support for this product regarding undocumented features.

## [SBUS]Block

A value (bytes) used by the I/O Server to determine if two or more packets can be blocked into one data request before being sent to the I/O Device. For example, if you set the value to 10, and the I/O Server receives two simultaneous data requests - one for byte 3, and another for byte 8 - the two requests will be blocked into a single physical data request packet. This single request packet is then sent to the I/O Device, saving on bandwidth and processing.

**Allowable Values** 5 to 256

**Default Value** 8

## [SBUS]Delay

The period (in milliseconds) to wait between receiving a response and sending the next command.

**Allowable Values** 0 to 300 (milliseconds)

**Default Value** 0

## [SBUS]DisableGmtOffset

Forces the driver to use UTC time for reads and writes to the "K" time register.

**Allowable Values** 0 or 1 (disables the GmtOffset)

**Default Value** 0

## [SBUS]FailOnBadData

Determine whether or not to force the display of good data within a block read which contains bad tags.

**Allowable Values** 0 or 1

0 = Ignore any bad tags in the block reads and just show 0 for those tags.

1 = Display reads that include a bad tag in the block with #BAD.

**Default Value** 1

## [SBUS]GmtOffset

Specifies an offset from GMT in hours to use for reads and writes to the "K" time register.

**Allowable Values**

Local time zone difference on the computer:

-12 to +14 (hours)

**Default Value** 0

## [SBUS]MaxPending

The maximum number of pending commands that the driver holds ready for immediate execution.

**Allowable Values** 1 to 32

**Default Value** 2

## [SBUS]PollTime

The interrupt or polling service time (in milliseconds). Setting the polling time to 0 puts the driver in interrupt mode.

**Allowable Values** 0 to 300 (milliseconds)

**Default Value** 0

## [SBUS]Retry

The number of times to retry a command after a timeout.

**Allowable Values** 0 to 8

**Default Value** 4

## [SBUS]Timeout

Specifies how many milliseconds to wait for a response before displaying an error message.

---

**Note:** Only set this value if the time taken for the return of a data request is greater than the default of 1second. In this situation, set the value to a time period greater than the time taken for the return of a data request.

**Allowable Values** 0 to 32000 (milliseconds)

**Default Value** 1000

## [SBUS]WatchTime

The frequency (in seconds) that the driver uses to check the communications link to the I/O Device.

**Allowable Values** 0 to 128 (seconds)

**Default Value** 30

## [SBUS]SendBreak

This protocol can use three different transmission methods:

- Parity changing method
- Break mode transmission
- Data mode transmission.

Omission of a setting for this parameter will result in Parity changing method being implemented by default.

**Allowable Values**

0 = Parity changing method

1 = break mode

2 = data mode

**Default Value** 0

---

**Note:** This driver level parameter can be over-ridden on an individual port basis with the use of the SBUS.<PortName> parameter. See [SBUS Port Specific Parameters](#).

## Port-specific Parameters

To set parameters for a particular port, you have to create a new section in the Citect.INI file. Label it with the driver name followed by the full stop character (.) and the name of the particular port you want to specify the parameter setting for.

### [SBUS.<PortName>]SendBreak

This applies the SendBreak parameter setting to the specified port.

**Allowable Values** 0 = Parity changing method

1 = break mode

2 = data mode

**Default Value** 0

---

**Note:** This port level parameter will over-ride the driver wide setting made with the use of the parameter.

---

**Example:**

If two ports named PORT1 and PORT2 are being used, and we want to set the SendBreak parameter for PORT2 only, the Citect.INI would contain the following parameters:

[SBUS.PORT2] SendBreak = 1

See also [SBUS Protocol Parameters](#).

## SBUS Driver Specific Errors

When a hardware error occurs, Plant SCADA generates an alarm, and displays the alarm on the hardware alarm page (in the alarm description of the hardware alarm). To see the error number, make sure you have Alarm Category 255 defined with a display format that includes {ErrDesc,15} {ErrPage,10}.

There are a number of generic errors that are common to all protocols. In some cases, only the generic error is available, though often both the generic error and a specific error are given.

The following errors are specific to this protocol. Plant SCADA displays the error number and description for common protocol-specific errors. Uncommon errors are not contained in the Plant SCADA error database, in which case Plant SCADA will only display the error number.

The error below is common to all three modes of transmission used by the SBUS protocol (parity, break, data).

- **28h GENERIC\_GENERAL\_ERROR**

Negative acknowledgement

The following errors only apply when the protocol is set to data mode of transmission.

- **29h GENERIC\_GENERAL\_ERROR**

Negative acknowledgement because of password

- **30h GENERIC\_GENERAL\_ERROR**

Negative acknowledgement because the port is configured with the reduced protocol

- **31h GENERIC\_GENERAL\_ERROR**

Negative acknowledgement because PGU is active (involve from full to reduced protocol)

You may require additional information to enable you to rectify an error. This information should be detailed in the documentation that accompanied the I/O Device (or network). If, after reviewing all documentation, you cannot rectify an error, contact Technical Support.

## SNMP II Driver

The SNMP II driver enables Ethernet-based communication between Plant SCADA and a Simple Network Management Protocol (SNMP II) system.

The maximum request length for the SNMP II protocol is 255 bytes (2040 bits) for a string. Strings use one SNMP request per string tag, while numeric data can be grouped into one SNMP request.

### About SNMP II

SNMP II is a request-and-response protocol. An SNMP manager sends a request to an agent. The agent replies with a response that indicates if the operation was performed successfully or if an error is detected.

Each SNMP operation has its own type of message. Each of these messages is used by a management system to request that an operation be performed on managed variables maintained by an SNMP agent. There are three request and response operations: **Get**, **GetNext**, and **Set**.

A fourth operation, **Trap**, is an unsolicited message sent by an agent; it therefore does not have a corresponding request message. Trap messages can be generated for changes such as host system startup, shutdown, or password violation. Trap destinations can be configured by a user, but the occurrences which generate a trap message are internally defined by the SNMP agent.

The SNMP II protocol specifies the behavior of the Get, GetNext, Set, and Trap operations, and defines the format of the SNMP messages exchanged by managers and agents.

---

**Note:**

- The Plant SCADA driver does not support the GetNext request.
  - SNMP II driver supports SNMP GETS and PUTS (read and write), trap receiving, forwarding and trap generation. Each device runs in a separate NT thread for maximum speed.
  - If an SNMP device only supports a fixed IP reply address, then Plant SCADA I/O Server redundancy will not be supported for that device.
  - SNMP II driver has partial support for SNMP protocol version V2C and currently it supports only the SNMP GETS and PUTS (read and write) operation. The other operations will be supported in the future release version of this driver.
- 

## Safety Information

### Hazard categories and special symbols

The following symbols and special messages may appear in this manual or on the product to warn of potential hazards or to call attention to information that clarifies or simplifies a procedure.

Symbol	Description
 or 	The addition of either symbol to a "Danger" or "Warning" safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.
	This is the safety alert symbol. It is used to alert you to personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.
<b> DANGER</b>	
<b>DANGER</b> indicates an imminently hazardous situation, which, if not avoided, will result in death or serious injury.	
<b> WARNING</b>	
<b>WARNING</b> indicates a potentially hazardous situation, which, if not avoided, can result in death or serious injury.	
<b> CAUTION</b>	
<b>CAUTION</b> indicates a potentially hazardous situation which, if not avoided, can result in minor or moderate injury.	
<b>NOTICE</b>	
<b>NOTICE</b> used without a safety alert symbol, indicates a potentially hazardous situation which, if not avoided, can result in property or equipment damage.	

## Please Note

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by AVEVA for any consequences arising out of the use of this material.

## Before You Begin

Plant SCADA is a Supervisory Control and Data Acquisition (SCADA) solution. It facilitates the creation of software to manage and monitor industrial systems and processes. Due to Plant SCADA's central role in controlling systems and processes, you must appropriately design, commission, and test your Plant SCADA project before implementing it in an operational setting. Observe the following:

**⚠ WARNING****UNINTENDED EQUIPMENT OPERATION**

Do not use Plant SCADA or other SCADA software as a replacement for PLC-based control programs. SCADA software is not designed for direct, high-speed system control.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

**⚠ WARNING****LOSS OF CONTROL**

- The designer of any control scheme must consider the potential failure modes of control paths and, for certain critical control functions, provide a means to achieve a safe state during and after a path failure. Examples of critical control functions are emergency stop and overtravel stop, power outage and restart.
- Separate or redundant control paths must be provided for critical control functions.
- System control paths may include communication links. Consideration must be given to the implications of unanticipated transmission delays or failures of the link.
- Observe all accident prevention regulations and local safety guidelines.<sup>1</sup>
- Each implementation of a control system created using Plant SCADA must be individually and thoroughly tested for proper operation before being placed into service.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

1. For additional information, refer to NEMA ICS 1.1 (latest edition) "Safety Guidelines for the Application, Installation, and Maintenance of Solid State Control", and to NEMA ICS 7.1 (latest edition) "Safety Standards for Construction and Guide for Selection, Installation and Operation of Adjustable-Speed Drive Systems" or their equivalent governing your particular location.

## Preparing the SNMP II System

This section explains how to prepare your SNMP II-based devices for communication with Plant SCADA.

This section includes the following topics:

- [Hardware Requirements](#)
- [Installing the SNMP Service](#).

Before installing or configuring your SNMP II driver, you might want to read the [Setup Tips and Techniques](#) section for information on how to avoid problems arising from incorrect setup or installation.

### Hardware Requirements

This section describes how to set up the device that Plant SCADA will query via SNMP.

**To set up the device:**

1. Connect the device to the TCP/IP network for a PC, a network card needs to be installed.
2. If the device is a PC running Windows 2000/7/8/XP, or Windows Server 2003/2008/2012, the TCP/IP protocol needs to be installed and configured, as well as the SNMP service. For details, see [Installing the SNMP Service](#). Refer to the help in the Windows Control Panel for more information.
3. Reinstall any installed Service Pack after installing the TCP/IP protocol or SNMP service.
4. Configure the device with an IP address. Refer to the device's hardware documentation for details; or if the device is a PC, refer to the online help in Control Panel.

**Installing the SNMP Service****To install the SNMP service on Windows:**

1. Go to Control Panel and select **Programs**, then **Turn Windows features on or off**.
2. In the Windows Features dialog box, select **Simple Network Management Protocol (SNMP)** and click **OK**. Installation will commence. You will be notified when it is complete.

**To check that the SNMP service is running:**

1. Go to Control Panel, and select **System and Security**, then **Administrative Tools**.
2. Double-click on **Services**.
3. Scroll down the list of services and locate **SNMP Service** and **SNMP Trap**.
4. Check that the Status column for SNMP Service is "Running". If not, highlight the SNMP Service row and click **Play** on the toolbar to start the service.

**Setup Tips and Techniques**

- This section describes techniques to consider when setting up your system.
- Before the first writing to a variable, at least one read has to be made so that the driver can get the SNMP data type of that variable.
- Trap data types can only be used on IP networks. Trap data is treated as global and stored in a queue in this driver; i.e., trap variables could be defined under any I/O device and any two trap variables with the same address (such as T0) will have the same value. A read will get the variable value from the first elements of the queue and a write will delete that first element from the queue. The queue length is limited by available memory.
- The default value of TF is 127.0.0.1; that is, the local PC address.
- The GET-NEXT SNMP functionality is not supported in the driver.
- The target device has to support large PDU packets if PDUGroupOK is high. Some devices might become inoperable if this value is too large.
- When an error is detected in reading one item in a group, all items are flagged as errors. To establish which item is causing the error, set PDUGroupOK = 0, so that the driver sends a separate SNMP packet for each item, and set ReturnError = 0, so that the driver does not return an error to the I/O Server. Then the item which is causing the problem will be displayed with the value "Bad" if it is a string, or the value 2989 (the

decimal equivalent of the hex 0xBAD) if it is numeric. Once the problem item has been located, always remember to set ReturnError = 1, so that further errors generate #COM.

- The fields of a Variable Tag correspond to the entries in the SNMPVARS.DBF file defined for the port the device is on. Note that the **Address** field is a combination of the INDEX and SNMPTYPE entries in the SNMPVARS.DBF. You do not have to adjust these parameters in Plant SCADA or Excel; the utility allows you to do this.

---

**Note:** From version 2.7.20.0, the SNMPII driver includes new functionality that prevents a device from going online if duplicate indexes exist. This functionality requires every index to be unique at all times. Unique indexes can be achieved by creating multiple ports and splitting the SNMPVARS.DBF into multiple databases (one for each respective port).

---

## Configuration Overview

Simple Network Management Protocol (SNMP) is a network management standard widely used in TCP/IP networks to monitor and control computers, routers, printers, and other devices connected to a network.

SNMP uses distributed architecture consisting of managers and agents. A manager is an SNMP application that generates queries to SNMP agent applications. An agent is an SNMP application that responds to queries from SNMP manager applications. The SNMP agent is responsible for retrieving and updating local management information based on the requests of the SNMP manager. The agent also notifies registered managers when a significant event or a trap occurs.

The SNMP manager is realized in Plant SCADA through the SNMPII driver. On computers running Windows 2000, the SNMP agent is implemented by the SNMP service (SNMP.exe). Run the SNMP services on the machine that the I/O server is running on.

The Plant SCADA driver uses the Microsoft SNMP services and thus supports SNMPv1 and SNMPv2C.

Every SNMP-manageable device has a set of "objects" that can be read or modified via SNMP. This set of managed objects is known as a Management Information Base (MIB).

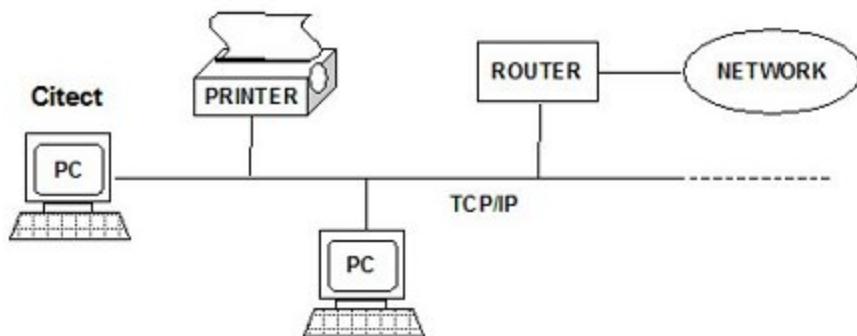

---

**Note:**

- The Plant SCADA driver does not support the GetNext request.
- SNMPII driver supports SNMP GETS and PUTS (read and write), trap receiving, forwarding, and trap generation. Each device runs in a separate NT thread for maximum speed.
- If an SNMP device only supports a fixed IP reply address, Plant SCADA I/O server redundancy will not be supported for that device.
- SNMPII driver has partial support for SNMP protocol version V2C and currently it supports only the SNMP GETS and PUTS (read and write) operation. The other operations will be supported in the future release version of this driver.

---

Each device to be monitored or controlled by Plant SCADA has to be connected to a TCP/IP network as illustrated in the following diagram:

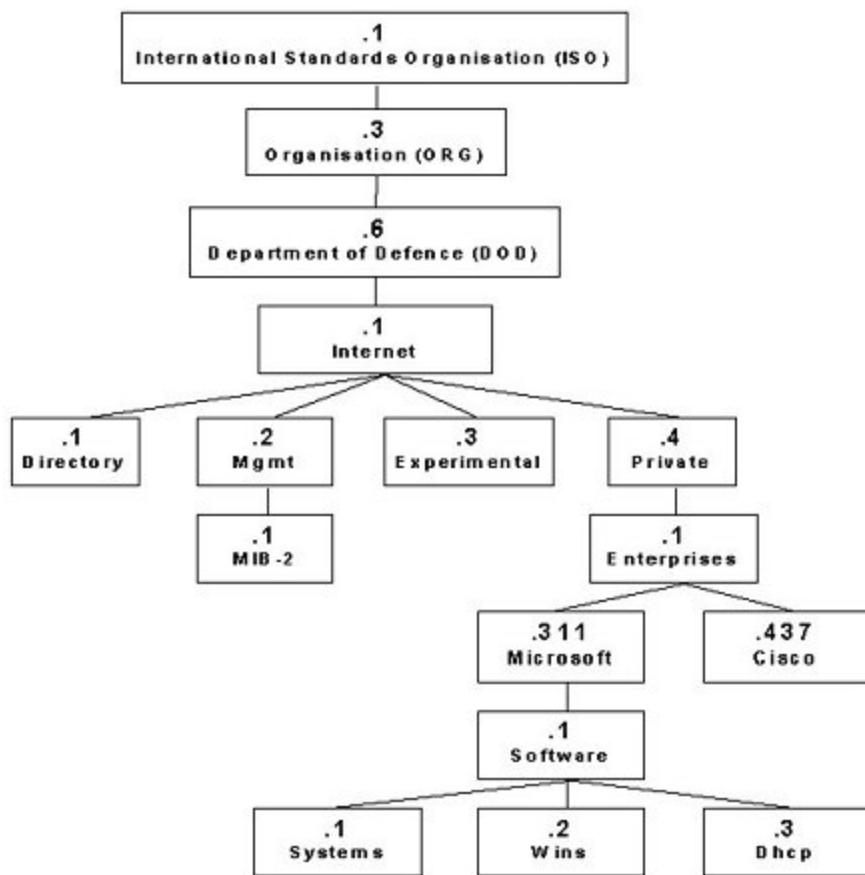

All SNMP-manageable devices that reside on a TCP/IP network are required to support a minimum standard set of managed objects, collectively known as MIB-II. Industry vendors can define additional MIBs that allow unique hardware or software services developed by the vendor to be monitored and managed by an SNMP server.

Every object in a MIB is identified by a universally unique label referred to as an object-identifier (OID). The identifier includes the object's type (such as counter, string, gauge or address), the object's access level (such as read/write), size restrictions and range information. (For more information about how OIDs work in Plant SCADA, see [Tag-based Driver Considerations](#).)

The object name space is implemented as a multi-part, hierarchical, naming scheme. A hierarchical naming scheme can be viewed as an inverted tree with the branches pointing downward. Each point where a new branch is added is referred to as a node. This OID is internationally accepted and allows developers and vendors to create new components and resources and assign a unique OID to each new component or resource.

The OID naming scheme is governed by the Internet Engineering Task Force (IETF). The IETF grants authority for parts of the name space to individual organizations such as Microsoft. For example, Microsoft has the authority to assign the OIDs that can be derived from branching downward from the node in the MIB name tree that starts at .1.3.6.1.4.1.311, as illustrated here:

SNMP programs use the OID to identify the objects on each device that can be managed by using SNMP. For example, when Plant SCADA needs information about managed objects from a computer on the network, the SNMP II driver sends a message over the network that requests information about the object as identified by the OID. The computer that receives the message can use the OID to retrieve information from the specific object on the computer and send the information back to Plant SCADA.

The OID in the hierarchy is written as a sequence of sub-identifiers beginning at the root and ending at the object. Sub-identifiers are separated with a period. For example, the OID for "sysDescr", which is a textual description of the SNMP manageable device, is **.1.3.6.1.2.1.1.1.0**.

## SNMP Redundancy

Redundancy (in the Plant SCADA context) is a function of the support provided in the SNMP device you are talking to. Some SNMP devices have a fixed IP address of who can talk to them. In this case, only one Plant SCADA I/O server can talk to them and redundancy is impossible.

However, most SNMP devices allow any device to talk to them provided their SNMP community name (like a password) is valid. In this case, Plant SCADA redundancy will work.

For an SNMP device to support trap redundancy (that is, to send traps to multiple places) the device has to support allowing two or more trap IP addresses. Each trap has to be sent to the primary and standby I/O server. If the SNMP device only supports one trap IP address, the standby I/O server cannot receive traps if the primary server is down.

## SNMP Enterprise Numbers

The SNMP MIB tree has parts that are universal and reflect various RFC standards; that is, each SNMP-enabled device supports the common lot of these functions; for example, sysDescr or .1.3.6.1.2.1.1.1.0 under mib-2-system returns the name of the device.

When you want to return data specific to your device, use the iso.org.dod.internet.private.enterprises path or under .1.3.6.1.4.1.x, where x is the unique number assigned to an organization or piece of equipment.

Microsoft's number is 311; that is, anything under .1.3.6.1.4.1.311.y is a Microsoft MIB item. Plant SCADA's number is 6216.

These enterprise numbers are needed in a global WAN so that every unique piece of equipment in the world can be identified. In a private network, you can essentially use any enterprise number you want. You can obtain new numbers from <http://www.iana.org/cgi-bin/enterprise.pl>.

You can use this number when generating user-defined traps. The number .1.3.6.1.4.1.6216.1.x is reserved by Plant SCADA for internal use and testing. Users are free to use .1.3.6.1.4.1.6216.2.y , .1.3.6.1.4.1.6216.3.y, and so on.

## SNMPII Driver Recommended Settings

This section includes the required [Device Address](#) and recommended settings for communication with an SNMPII device.

These are the settings implemented by the Express Communications Wizard on the Boards, Ports, and I/O Devices dialog boxes. To manually configure these settings, see [Communication Settings](#).

See also [Data Types](#) and [SNMPII Protocol-specific Parameters](#).

### Device Address

Use a valid IP address. The format is:

**aaa.bbb.ccc.ddd** (community string).

The community string has to be correct to access the remote agent.

The IP address can also be a device name known by the IP network (the network must have name resolving services running. The 'ping' program can be used to check that names are resolved to the correct IP address). The common community string used is *public*.

### Communication Settings

To establish communication with a device, the associated Board, Port and I/O Device need to be configured in Plant SCADA Studio's **Topology** activity.

If you use the Express Communications Wizard to connect to a device, these settings will be automatically configured for you. If you need to manually configure them, you should use the values outlined below.

## Boards

Field	Value
Board Name	This field is user defined and is not used by this driver.
Board Type	The type of board. Enter <b>SNMPII</b> .
Address	Enter <b>0</b> .
I/O Port	Leave this field blank.
Interrupt	Leave this field blank.
Special Opt	Leave this field blank.
Comment	This field is user defined and is not used by this driver.

## Ports

Field	Value
Port Name	This field is user defined and is not used by the driver.
Port Number	Needs to be unique but is not used in this driver.
Board Name	Refers to the board previously defined.
Baud Rate	Leave this field blank.
Data Bits	Leave this field blank.
Stop Bits	Leave this field blank.
Parity	Leave this field blank.
Special Options	The .DBF file used to store additional tag data, for example, SNMPVARS.DBF. If there is no SNMPVARS.DBF in the project directory, the port will not initialize.
Comment	This field is user-defined and is not used by this driver.

**Note:** From version 2.7.20.0, the SNMPII driver includes new functionality that prevents a device from going online if duplicate indexes exist. This functionality requires every index to be unique at all times. Unique indexes can be achieved by creating multiple ports and splitting the SNMPVARS.DBF into multiple databases (one for each respective port).

## I/O Devices

Field	Value
I/O Device Name	This field is user defined, and is not used by this driver.
I/O Device Number	Has to be unique, but is not used by this driver.
I/O Device Address	<p>Use a valid IP address; format is: 'aaa.bbb.ccc.ddd community _string'. The community string has to be correct to enable access to the remote agent.</p> <p>The IP address can also be a device name known by the IP network (the network must have name resolving services running). The 'ping' program can be used to check that names are resolved to the correct IP address. The common community_string used is public; for example, "192.168.1.34 public"</p> <p>If you added your own community "PlantSCADA" into the SNMP service, the address would be "192.168.1.34 PlantSCADA".</p>
I/O Device Protocol	Enter <b>SNMPII</b> .
Port Name	Refers to the port previously defined.
Comment	This field is user-defined and is not used by this driver.

## Data Types

All managed objects defined under SNMP are based on the three ASN.1 UNIVERSAL types:

- **INTEGER** - A signed whole number with no specific size limit, although most SNMP implementations define INTEGERS to be signed or unsigned 32-bit numbers.
- **OCTET STRING** - A sequence of octets, where each octet is defined as an 8-bit byte. The sequence may be printable ASCII characters or arbitrary binary data.
- **OBJECT IDENTIFIER** - Stores the location of a variable (managed object) within an MIB. The location is stored as an array of 16-bit unsigned integers called sub-identifiers.

The following table describes the data types, address format, Plant SCADA data type, and applicable SNMP data type.

Data Types	Address Format	Plant SCADA Data Type	Applicable SNMP Data Type
Alphanumeric (display string) objects	DAn	STRING	ASN_OCTETSTRING, ASN_BITS, ASN_OPAQUE, ASN_IPADDRESS, ASN_OBJECTIDENTIFIER
Alphanumeric (binary	BAn	STRING	ASN_OCTETSTRING,

string) objects			ASN_BITS, ASN_OPAQUE
Numeric objects (treat as long in Plant SCADA )	Nn	LONG	ASN_INTEGER, ASN_INTEGER32, ASN_UNSIGNED32, ASN_COUNTER64, ASN_COUNTER32, ASN_GAUGE32, ASN_TIMECLIDKS
Numeric objects (treat as real in Plant SCADA )	Rn	REAL	ASN_INTEGER, ASN_INTEGER32, ASN_UNSIGNED32, ASN_COUNTER64, ASN_COUNTER32, ASN_GAUGE32, ASN_TIMECLIDKS
Trap objects (null terminated string)	Ta	STRING	Trap object
Trap objects (binary string)	BTa	STRING	Trap object (only for ASN_OCTETSTRING, ASN_BITS, ASN_OPAQUE type value in varbinding field).
Trap forwarding (write only)	TF	STRING	IP address to forward a copy of the last trap to. One IP address is required per call to TF. TF can be called multiple times.
Trap Next (read and write)	TN	LONG	TN as read is the traps in queue, 0 for nothing. A TN write removes the current entry and gets the next.
Multiple Trap Variable	TNVB	LONG	A read of TNVB returns the number of varbinds in the trap, a write to TNVB controls which varbinds data is read or written to.

Where:

n	0 to 65535
a	0 to 6 (T0 to T6 are read and write variables)

For string types, **DA** stands for null-terminated string and **BA** for binary string.

A null-terminated string is a string with 0x00 as an end flag, but in a binary string a 0x00 may be valid content.

For example, <0x41><0x42><0x43><0x00><0x61><0x62><0x63>:

- If defined as **DA**, Plant SCADA will display it as 'ABC' and the content from <0x61> will be truncated.
- If defined as **BA**, Plant SCADA will display it as '41424300616263'.

This also applies to those ASN\_OCTETSTRING type fields in a trap object, with **DA** replaced by **T**, and **BA** replaced by **BT**.

Whether a tag is readable/writable depends on how the SNMP object to which it corresponds is defined in the appropriate .MIB file.

For the type **DA**, **BA**, **N** and **R**, the n represents the value of the INDEX field for a tag's entry in the SNMPVARS.DBF file.

You should not directly modify the tag database.

For each tag, you can specify the Plant SCADA data type you require; however you have to verify that the selection you make is appropriate for the corresponding SNMP object.

Tags with a Plant SCADA data type of STRING are limited to a maximum length of 255 characters. Tags with a required numeric range outside the range 147483648 to 2147483647 can be assigned a Plant SCADA data type of REAL.

## Numeric Data Grouping Considerations

Plant SCADA allows you to group enquiries together to enable greater SNMP efficiency. The user has to decide which items need to be grouped together. It is recommended no more than 20 items are grouped together. This means that if any one item is read, the whole group will be read.

Groups should be separated in units of 100; for example, N0,N2,N3, then N100,N101, and so on.

### SNMP II Protocol-specific Parameters

#### **WARNING**

##### **UNINTENDED EQUIPMENT OPERATION**

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage..**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

This section describes the SNMP II protocol-specific parameters. The parameter values have been set to the usual value for this protocol. You cannot change these values except on the advice of Technical Support for this product.

**Note:** If you plan on using Include projects and your communications settings are not in the main project, you need to set the [driver-specific parameter ComSettingsInInclude](#) to 1.

Parameter	Description
[SNMPII]Block	This value is not used by the driver.
[SNMPII]Delay	The period (in milliseconds) to wait between receiving a response and sending the next command. <b>Allowable Values:</b> 0 to 300 (milliseconds) <b>Default Value:</b> 0
[SNMPII]MaxPending	The maximum number of pending commands that the driver holds ready for immediate execution. <b>Allowable Values:</b> 1 to 256 <b>Default Value:</b> 2 You need to adjust MaxPending so that at least 2 DCBs are available per unit on a port; for example, if you have 10 devices on a port, Maxpending should have a minimum value of 20, or else when one unit is offline it can cause significant slowing of the responses from other units.
[SNMPII]PollTime	The interrupt or polling service time (in milliseconds). Setting the polling time to 0 puts the driver in interrupt mode. <b>Allowable Values:</b> 500 to 2000 (milliseconds) <b>Default Value:</b> 1000
[SNMPII]Retry	Not used by the driver. See the <a href="#">driver-specific parameter</a> [SNMPII]SnmpRetry.
[SNMPII]Timeout	Not used by the driver. See the <a href="#">driver-specific parameter</a> [SNMPII]SnmpTimeout.
[SNMPII]WatchTime	The period (in seconds) that the driver uses to check the communications link to the I/O Device. <b>Allowable Values:</b> 0 to 128 (seconds) <b>Default Value:</b> 30 (seconds)

## Driver-Specific Parameters

 **WARNING**

**UNINTENDED EQUIPMENT OPERATION**

Do not change these protocol parameters, except on the advice of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage..**

**Note:** Always seek the advice of Technical Support personnel for this product regarding undocumented features.

This section describes the SNMPII driver-specific parameters.

Parameter	Description
[SNMPII]MaxTimeouts	<p>When SNMP API detected timeout errors exceed this value, DRIVER_UNIT_OFFLINE will be returned by the driver, otherwise DRIVER_TIMEOUT will be returned.</p> <p><b>Allowable Values:</b> 1 to 3 (requests to SNMP API)</p> <p><b>Default Value:</b> 1</p>
[SNMPII]SnmpTimeout	<p>Period in milliseconds to consider an SNMP timeout when using the SNMP API. Timeout is internal to the SNMP API.</p> <p><b>Allowable Values:</b> 200 to 6000 (ms)</p> <p><b>Default Value:</b> 1000</p> <p>You can override the values set for this parameter for a particular device. This would appear in the Citect.INI file as follows:</p> <pre>[SNMPII] SnmpTimeOut=1200 Port1.IODev1.SnmpTimeOut=3300</pre> <p>where:</p> <p>Port1 = the port the specified device is connected to IODev1 = the name of the device</p> <p>The above configuration means all devices use an SnmpTimeOut value of 1200mS, except for the device IODev1 on Port1, which will timeout after 3300mS.</p>
[SNMPII]SnmpRetry	<p>Retry count to apply to the SnmpTimeout period before a true timeout is indicated. This then is used by the MaxTimeouts parameter. The count is internal to the SNMP API.</p> <p><b>Allowable Values:</b> 1 to 5</p> <p><b>Default Value:</b> 1</p> <p>You can override the values set for this parameter for a particular device. This would appear in the Citect.INI file as follows:</p> <pre>[SNMPII] SnmpRetry=2 Port1.IODev2.SnmpRetry=3</pre> <p>where:</p>

	<p>Port1 = the port the specified device is connected to IODev2 = the name of the device The above configuration means all devices use an SnmpRetry value of 2, except for the device IODev2 on Port1, which will retry three times.</p>
[SNMPII]PDUGroupOK	<p><b>Allowable Values:</b> 0 to disable grouping, or &gt;1 to enable grouping. This specifies the maximum number of SNMP requests which will be grouped into the one packet to the remote SNMP agent. The recommended value is 20, and it cannot exceed 98. <b>Default Value:</b> 20 When PDUGroupOK is 0 or 1, separate SNMP packets need to be generated for each item asked by the I/O server. When non-zero, items in one request from IOServer will be requested in one packet to target device. For more information on setting the PDUGroupOK value, see <a href="#">Setup Tips and Techniques</a>.</p>
[SNMPII]ExtraDebug	<p>Extra debug statements for diagnostic purposes. Debug flags need to be enabled. <b>Allowable Values:</b> 1 or 0 <b>Default Value:</b> 0</p>
[SNMPII]ReturnError	<p>Used with PDUGroupOK to isolate the variable in a group of tags that is causing an error. When this parameter is set to 1, the driver returns an error when an SNMP packet is returned with an error. When set to 0 (and PDUGroupOK=0), the driver returns either the string "Bad" or the number 2898 (0xBAD). This allows you to see the specific bad variable on your screen. <b>Allowable Values:</b> 1 or 0 <b>Default Value:</b> 1</p>
[SNMPII]UseV2C	<p>When this parameter is set to 0, it uses SNMP v1.0 and when set to 1, it uses SNMP V2C to communicate with the device. <b>Allowable Values:</b> 1 or 0 <b>Default Value:</b> 0 <b>Note:</b> To configure the parameters at device level, see <a href="#">I/O Device-specific Parameters</a>.</p>
[SNMPII]x.y.TestOIDStr (where x is portname, and y is the unitname)	<p>The SNMPII driver tests the status of each Plant SCADA I/O device by transmitting a request to read the "sysDescr" (.1.3.6.1.2.1.1.1.0) object in the device. TestOIDStr allows alternative OID to be used for</p>

	testing the status of each Plant SCADA I/O device. An OID needs to end with ".0". If the I/O device is online, it responds by transmitting the requested data. If no response is received, the Plant SCADA I/O device is considered to be offline. <b>Default Value:</b> Test OID string (x.x.x.x.x.0)
ChangePorts2000 or EnableChangePorts	Default 0. Only change if you are on a Win2000/XP/Win2003 Server machine and you want to change the default SNMP port. <b>Default value:</b> 0 or 1
x.y.Port (where x is portname, and y is the unitname)	Allows the default SNMP port (the default is 161) to be changed. Your SNMP agent needs to be able to listen on the new port number. <b>Default value:</b> Any
ComSettingsInInclude	Default 0, this needs to be set to 1 if the SNMPVARS.DBF information is going to be in Communication Settings in Include projects. <b>Default value:</b> 0 or 1

The ReturnError parameter is likely the only parameter you'll use; the other parameters relate to specialized setups.

When PDUGroupOK is 0 or 1, separate SNMP packets are generated for each item asked by the I/O server. When non-zero, items in one request from the I/O server are requested in one packet to target device.

**Note:**

- 1) The target device needs to be able to support large PDU packets if PDUGroupOK is high. Some devices may exhibit unexpected behaviour if this value is too large.
- 2) When an error occurs in reading one item in a group, all items are flagged as errors. To establish which item is causing the error, set PDUGroupOK=1 so that the driver sends a separate SNMP packet for each item, and set ReturnError =0 so that the driver does not return an error to the I/O server. Then the item which is causing the problem will be displayed with the value "Bad" if it a string, or with the value 2989 (the decimal equivalent of the hex 0xBAD) if numeric. After locating the problem item, remember to set ReturnError back to 1 so that further errors generate #COM.

## I/O Device-specific Parameters

This section describes the I/O device-specific parameters.

Parameter	Description
[IODevice]UseV2C	When this parameter is set to 0, it uses SNMP v1.0 and when set to 1, it uses SNMP V2C to communicate with the device. <b>Allowable Values:</b> 1 or 0

	<b>Default Value:</b> 0  <b>Note:</b> The <b>IODevice</b> refers to the I/O device name configured in the project.
--	--

## SNMP II Blocking

You can configure the SNMP II driver for blocking. You can only block longs and reals (N and R data-types). For every SNMP II I/O device a snmpvar.dbf file is created. In that file an index is defined for each SNMP tag. This index is used by Plant SCADA for blocking. That index in the snmpvar.dbf is also used in the tag address in the variable.dbf, with a prefix for the different data-types (N for long, R for real, DA for string).

You can implement blocking for the SNMP II driver by manually manipulating the index numbers in **snmpvar.dbf** file. If you create consecutive numbers in a data type, Plant SCADA can block these together in one request. This index number has to be unique for each tag (per I/O device); for example: N100, N101, N102, N103 will be a block of four LONGs, and R200, R201, R203 will be a block of three REALs.

The SNMP II driver by default only blocks 20 items (for longs and reals this equals 640 bits). This value is set via the [SNMP]PDUGroupOK parameter and the BIT\_BLOCK value in protdir.dbf for the SNMP II protocol. The target device has to support large PDU packets if PDUGroupOK is high. Some devices may crash if this value is too large. The [SNMP II]Block parameter is set to 256 by default.

In the Kernel use the Probe command to view the blocking behavior. There you will see all requests from the client to the I/O server and the size of these requests. The address numbers there are derived from the index numbers in the snmpvar.dbf files.

## Debug Messages

The SNMP driver generates the following debug messages:

### Data Read

```
Mon Jun 05 11:08:50 2015 02:31:28.986 StartTransmit Length 0
Mon Jun 05 11:08:50 2015 02:31:28.986 Transmit Chk 00000000 Length 0
Mon Jun 05 11:08:50 2015 02:31:28.989 Read Request Addr:2 020E75F8 1 Length 0
Mon Jun 05 11:08:50 2015 02:31:28.990 Request Finish. Thread Will Suspend. Addr:2 Length 0
```

### Data Write

```
Mon Jun 05 14:19:49 2015 00:23:04.493 Write Request Addr:56 020E75F8 1 Length 0
Mon Jun 05 14:19:49 2015 00:23:04.495 Request Finish. Thread Will Suspend. Addr:56 Length 0
```

In these debug messages, Addr:2 or Addr:56 means the variable address (index in the SNMPVARS.DBF file) is 2 or 56. The following hexadecimal string is the pointer of the corresponding DCB and the following 1 is the returned value of the ResumeThread() function.

## Driver-generated Statistics

The SNMP driver generates the following statistics:

Number	Label	Description
0	Rd Req	Number of read requests from Plant SCADA but excludes trap requests.
1	Rd OK	Number of successful read requests.
2	Wrt Req	Number of write request from Plant SCADA but excludes trap writes.
3	Wrt OK	Number of successful write requests.
4	Sent Packets	Number of packets sent to SNMP agent.
5	PDUGroupOK	Value of PDUGroupOK.
6	Att traps	Number of received traps.
7	Traps in queue	Number of traps in the queue.
8	Traps Rd	Number of trap read requests.
9	Traps Wrt	Number of trap write requests.

When PDU grouping occurs, the packet count is less than the number of desired reads and writes. The difference indicates how well the "group" feature is working.

## SNMP Traps

SNMP traps differ from other SNMP messages in that they are unsolicited messages sent by an SNMP agent when a predefined event has occurred. For this reason, the SNMPII driver in Plant SCADA handles traps differently than other SNMP variables.

Because there is no way of knowing in advance how many traps will be received by Plant SCADA, it is impossible to set up variable tags ready for each trap. Instead, incoming traps are queued and read one at a time from the queue.

A set of seven tags, addressed as T0, T1, ...T6, is used to read each trap.

### Structure of a Trap

The table below shows the components of a trap PDU and the special tags used to manipulate them.

Component	Special tag
enterprise	T0

agent-addr	T1
generic-trap	T2
specific-trap	T3
time-stamp	T4
variable-bindings	T5, T6, TNVB and SubfieldNumber

- **variable-bindings** is a list of VarBinds, each consisting of **name** (see [T5](#)) and **value** (see [T6](#)).

**Note:** Most SNMP traps only contain one record; however, it is possible to get a trap with many records. A mechanism exists using the "subfield number" to iterate and read all these trap records.

## Special Tags for Reading and Creating Traps

The table below shows the tag address and the field of the tag object assigned to the tag.

Tag Address	Field of trap object assigned to Tag
T0	Enterprise (device sending the trap), for example .1.3.6.1.4.1.311.1.1.3.1.1
T1	IP address; for example 223.125.1.17
T2	Generic type. Available options are: <b>0</b> - cold start <b>1</b> - warm start <b>2</b> - link down <b>3</b> - link up <b>4</b> - authentication unsuccessful <b>5</b> - egpNeighbor loss <b>6</b> - enterprise-specific trap
T3	Specific type (i.e., a user-defined trap in the enterprise MIB). For example, 3.
T4	Time stamp; for example, 6336403.
T5	Accesses the OID for the SNMP VarBind which holds the selected subfield of the current trap. The variable 'SubfieldNumber' (see below) determines which subfield is accessed; e.g., .1.3.6.1.2.1.1.5.0 Note that T5 contains a value. It can be a dummy value if the SNMP variable doesn't exist. This value is only of use if your MIB contains access to the trap

	variable.
T6	Accesses the data in subfields of the current trap. The variable 'SubfieldNumber' determines which subfield is accessed. When writing, you have to provide a value and a type. The type has to be "INTEGER", "COUNTER", "GAUGE", "TIMETICK", "ADDRESS", or "STRING". Strings should be less than 80 characters long.
TF	Trap forwarding IP address and community name. When writing, the trap community name parameter is optional; for example, 196.168.1.34 trap.
TN (TrapNext)	Read - Returns the number of traps in the queue. Write - Deletes the current trap from the queue. The next trap in the queue becomes the current trap.
TNVB	Read - Returns the number of VarBinds in the VarBindList of the current trap. Write - Update SubfieldNumber.
SubfieldNumber	This is not a real tag: it is a software variable. SubfieldNumber can be updated by writing to TNVB. SubfieldNumber is set to zero whenever TN is written.

## Reading Queued Traps

You can read queued traps.

### To read queued traps:

1. Read tag TN to see if it is > 0.
2. If TN is 0, there are no traps in the queue. Exit the process.
3. Read the required data from the current trap by using tags Tx (where x is any value from 0-5).
4. Log the values of the Tx or store them in other variables.
5. Read tag TNVB to see if there are any subfields.
6. If the number returned is greater than 0, read each subfield in turn by writing the subfield number to TNVB, and then reading the subfield OID and value from T5 and T6.

---

**Note:** It is not necessary to write to TNVB (SubfieldNumber) before reading the first subfield because the default behavior of T5 and T6 reads is to return the value of the first sub-field.

---

7. Write to TN to delete the current trap and move the traps in the queue forward.
8. Return to step 1.

## Trap Forwarding

If a trap needs to be forwarded to another system, Cicode has to be written to write to the "TF" tag before deleting the trap (using "TN"); for example, TF - "203.168.34.23". Multiple TF's are allowed so that several destinations can be used. If no second argument is given, the default of "trap" is used to send the trap.

Default value of TF is **127.0.0.1**.

## Generating Traps

Traps can be created by writing suitable data to T0-T6, then forwarded using the "TF" as before. This enables non-SNMP devices to generate traps via Plant SCADA .

### To create a trap:

1. Create an empty trap by writing to one of the Tx tags (T0 - T6). From that point on, all tag reads and writes are assumed to be for the newly created trap.
2. Update any other fields, as required.
3. Write to TF to specify a forwarding address and send the trap.
4. Repeat the above one or two steps as many times as required.
5. When writing to subfields you cannot skip over uninitialized subfields. For example, the sequence 0,1,2,0,2 is OK, but 0,2 is not. This is so that there are never uninitialized VarBinds in the VarBindList.
6. Write to TN to erase the generated trap and regain access to the queue.

The empty trap has these default values:

T0 (Enterprise)	.1.2.3.6.1.311.1.1
T1 (IP address)	Local IP address
T2 (GenType)	6
T3 (SpecType)	0
T4 (TimeStamp)	Time since driver was started, in 100th of seconds.
T5 (OID)	.1.3.6.1.2.4.2.0
T6 (Value and type)	0 INTEGER

## Queue Management

You can access to only one trap at a time. This is normally the trap at the head of the queue. To move the next trap you have to delete the current trap by writing to tag TN.

If you have created a trap, the trap at the head of the queue is inaccessible until the created trap is erased by a write to TN.

## Notes

It is possible for many tags to refer to the same Address tags, as tags on different I/O device names talk to different SNMP agents. Also the **I/O Device** field could be changed to refer to any other I/O device that has been set up for SNMP communications.

If you insert a trap, you need to create valid entries in a project MIB file for third-party SNMP viewers to know more about the trap.

## Troubleshooting

This chapter provides information about the Plant SCADA tools provided to help resolve problems with communication and configuration.

### Driver Errors

When a hardware error is detected, Plant SCADA generates an alarm and displays the alarm on the hardware alarm page (in the alarm description of the hardware alarm). To see the error number, you need to have Alarm Category 255 defined with a display format that includes {ErrDesc,15} {ErrPage,10}.

Several generic errors are common to many protocols. In some cases only the generic error is available, though often both the generic error and a specific error are given.

The following errors, listed in (hexadecimal) sequence, are specific to this protocol. Plant SCADA displays the error number and description for common protocol-specific errors. Uncommon errors are not contained in the Plant SCADA error database, in which case Plant SCADA only displays the error number.

You might need more information to rectify an error. This information should be in the documentation that accompanied the I/O device (or network). If, after reviewing the documentation, you cannot rectify an error, contact Technical Support for this product.

Error	Description
0x101 SNMP_ERRORSTATUS_TOOBIG	The response too large for agent to handle.
0x102 SNMP_ERRORSTATUS_NOSUCHNAME	Requested OID (1) does not exist in supported MIB view or (2) is not accessible or (3) a write operation was attempted on a read only MIB variable.
0x103 SNMP_ERRORSTATUS_BADVALUE	Bad MIB variable data type specified in variable bindings.
0x104 SNMP_ERRORSTATUS_READONLY	Attempt made to write to read-only field.
0x105 SNMP_ERRORSTATUS_GENERR	An unknown error.
0x108 SNMP_DISCONNECT	Cables have been disconnected.
0x180 GENERIC_NO_MEMORY	No memory could be allocated.
0x181 GENERIC_GENERAL_ERROR	Could not convert an OID string into a valid OID.

0x182 ERR_SNMP_TRAP_LISTEN	Could not register to receive SNMP traps.
0x183 ERR_SNMP_TRAP_QUEUE	Could not create SNMP trap queue.
0x184 ERR_SNMP_TRAP_VARBIND_NUM	Trying to access a varbind number that does not exist.

**Note:** Other errors are either standard Plant SCADA driver errors (below 0x100) or SNMP API errors. Subtract 0x100 from the value and search [www.microsoft.com](http://www.microsoft.com) for "SNMP error codes".

## Kernel Diagnostics

The Plant SCADA Kernel window diagnostics framework (known as the Kernel) is the primary gateway into the internal workings of Plant SCADA at runtime, and is provided for diagnostics and debugging purposes only.

**Note:** Use the Kernel window carefully: once you are in the Kernel, you can execute any Cicode function with no privilege restrictions. You (or anyone using the Kernel) has total control of Plant SCADA (and subsequently your plant and equipment).

### **WARNING**

#### **UNINTENDED EQUIPMENT OPERATION**

Do not use the Kernel for normal Plant SCADA operation. The Kernel is only for diagnostics and debugging purposes.

Configure your security so that only approved personnel can view or use the Kernel.

Do not view or use the Kernel unless you are an expert user of Plant SCADA and Cicode, or are under the direct guidance of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

You need to configure your Plant SCADA project to provide run-time access to the Kernel diagnostics window. You can do one or both of the following:

- Enable the Kernel on Plant SCADA start-up.
- Add the Kernel menu item to the runtime Plant SCADA Control menu.

The Plant SCADA Kernel window is a diagnostics framework that can display several different diagnostic windows, each displaying an active view into the workings of the Plant SCADA runtime system. Each window is displayed when selected from the Plant SCADA Kernel View menu. For details, refer to the Plant SCADA User Guide.

The key diagnostic windows included with the Kernel for testing I/O device communications are the I/O Devices window and the Main window:

- The [Kernel I/O Devices window](#) displays the current status of devices defined in the I/O Device database.
- The [Kernel Main window](#) displays the diagnostic messages a line at a time indicating the current Plant SCADA startup operation and status. When running, the Main diagnostics window continues to report changes in the status of the I/O Devices.

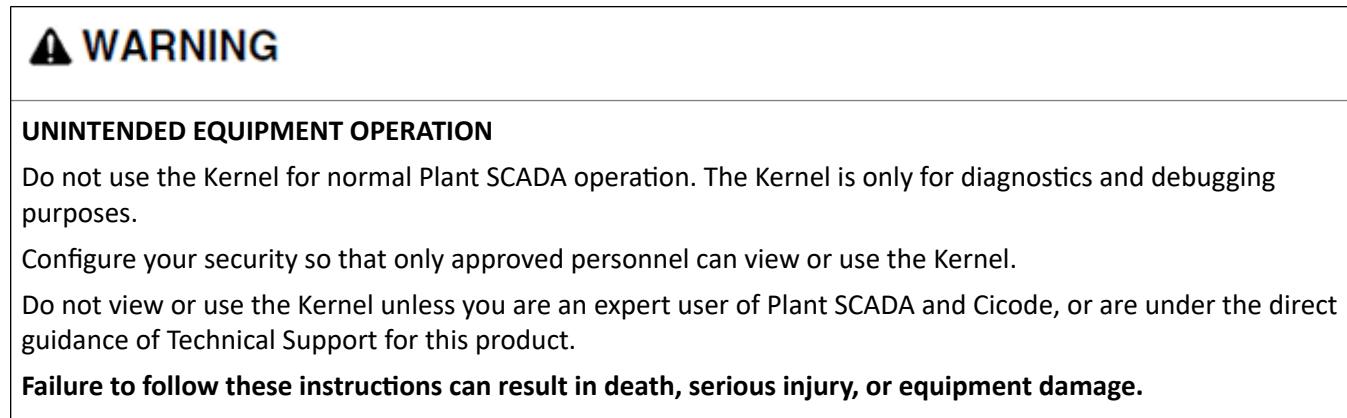

You can also use the Plant SCADA Kernel command Page Driver to call up a drivers diagnostic window that displays information about each driver in Plant SCADA . The statistics it presents include read requests, physical

reads, digital reads per second, register reads, cache reads, error count, timeouts, and so on.

This window is only displayed if the Plant SCADA computer is configured as an I/O server with physical I/O devices attached.

## Kernel I/O Devices Window

The I/O Devices diagnostics window displays the current status of all devices defined in the I/O Device database. In this window, use the **Page Up** or **Page Down** keys to browse through the available devices. Note that the below image is a generic representation of this window; your details might differ.

Check that communications with the I/O device are enabled and running by verifying the **Server Status** and **Client Status** fields. When the I/O device is online, these both display "RUNNING".

The following table contains a description of the fields displayed for each I/O device (or Unit) in the I/O Devices diagnostics window.

### Unit Statistics Fields

Field	Description
Unit	The name of the I/O device defined in the project (with the I/O Devices dialog box).
IO Server	The name of the I/O server that is servicing this I/O Device.
Comment	A description of the I/O device defined in the project (with the I/O Devices dialog box).
Unit No	The I/O device number defined in the project (with the I/O Devices dialog box).
PLC Number	Physical I/O device address defined in the project (with the I/O Devices dialog box).
Port Name	Communication port to which the I/O device is connected.
Protocol	Protocol used for communication with the I/O device.

Server Status and Client Status	<p>Status of the I/O device. The Server Status is only valid if the computer is an I/O server and it is servicing this I/O device. The Client Status field is valid for clients only, and indicates the status of the I/O device that is attached to the I/O server.</p> <p>The I/O device status can be one of the following:</p> <p><b>RUNNING</b> Indicates that the communication link with the I/O device is good.</p> <p><b>STANDBY</b> Indicates that the communication link with the I/O device is good, but communication with that I/O device is currently being performed by another port. This port is in standby mode.</p> <p><b>STARTING</b> Indicates that the server is currently establishing a communication link (with the I/O device).</p> <p><b>STOPPING</b> Indicates that the server is currently relinquishing control of the communication link (with the I/O device).</p> <p><b>OFFLINE</b> Indicates that the server cannot establish a communication channel with the I/O device. If a standby port or server is available, Plant SCADA tries to communicate to the I/O device using that port.</p> <p><b>REMOTE</b> Indicates that the status of the I/O device is OK, but it is not currently connected. Also indicates if it is a scheduled device.</p>
Primary	Indicates if the I/O device is in primary mode; Yes = Primary, No = Standby. If the I/O device is in primary mode, the server starts a communication channel with the I/O device as soon as the server is activated. If an I/O device is in standby mode, the I/O device remains inactive when the server starts (until a primary I/O device becomes inoperative).  If a unit is configured as the primary, it will be the preferred unit to service Plant SCADA requests. If the unit is configured as the standby, Plant SCADA requests will only be directed to this unit if the primary is offline.
Client Using	Name of the I/O Server that this client is using. This allows you to identify which I/O server is currently processing Plant SCADA requests.
Generic Error	Last generic error code returned by the driver. Because protocol drivers have their own special errors, they cannot be recognized by the I/O Server. The drivers convert their special errors into generic

	errors that can be identified by the server.
Error Handle	Error handle assigned by the I/O Server to each error. This handle is not used by Plant SCADA (at this time).
Driver Error	Driver-specific error code. Each driver has its own special error codes. Refer to the driver specific errors (for the particular protocol) for an explanation of each of the error codes.
Error Message	Error message associated with the generic error code.
Error Count	Total number of errors from the I/O Device.
Restarts	Number of times the server has tried to establish a connection with the I/O Device. This number is normally 1, because the server establishes a connection at startup. If this field displays a number greater than 1, this indicates there has been, or currently is, a problem with the communication channel or the device.
Response Times	<p>Time taken by the driver to process read and write requests (i.e. the time taken to process a single read or write operation to the I/O Device). This time depends only on the physical response time of the I/O Device, because no queue waiting time is included. This field reflects any tuning of the communication channel (e.g. doubling the baud rate should half the response time). The average, minimum, and maximum times are displayed.</p> <p><b>Note:</b> One I/O Device with a slow response can slow down your entire system. For example, if you have an I/O Device with a response of 2000ms, any pages in your system that use data from that device, will have a minimum update time of 2000ms.</p>
Cached	Indicates if the I/O Device data is cached.
Cache Timeout	If the I/O Device is cached, this field displays the cache timeout value. Data is held in the cache for this timeout period before being discarded and re-read from the I/O Device. Only read data is cached.
Blocking Constant	Current blocking constant value for this I/O Device, as specified in the protocol.

## Kernel Main Window

Maximize the Kernel Main window to view the diagnostic messages. This enables you to see the Plant SCADA start-up procedures.

**Note:** The Kernel Main diagnostic window has no scroll bar. New messages are added to the bottom of the message list; as the window fills, the oldest message (at the top of the window list) scrolls out of view. Maximize the Plant SCADA Kernel and the Main windows to gain the maximum view of available messages, alternatively, you can view the same information using Syslog.dat file.

### **WARNING**

#### **UNINTENDED EQUIPMENT OPERATION**

Do not use the Kernel for normal Plant SCADA operation. The Kernel is only for diagnostics and debugging purposes.

Configure your security so that only approved personnel can view or use the Kernel.

Do not view or use the Kernel unless you are an expert user of Plant SCADA and Cicode, or are under the direct guidance of Technical Support for this product.

**Failure to follow these instructions can result in death, serious injury, or equipment damage.**

After your I/O devices are properly configured, use the Main window to check that all of your I/O devices come online correctly when Plant SCADA started. First the ports will be initialized, then the I/O Device will be brought online. If there is a problem, Plant SCADA displays a message such as "PLC not responding", "I/O Device Offline", or similar.

Some I/O devices might take two attempts to come online. If so, Plant SCADA waits (usually 30 seconds) and tries again. If your I/O device does not come online after the second attempt, check your configuration (at both ends) and the network in between.

If an element repeatedly becomes inoperative at startup, you should investigate the problem. Common factors that may cause startup errors include:

- Incorrect computer setup: usually solved by running the Computer Setup Wizard.
- Networking errors or bad hardware: cables wrongly wired or unplugged, or equipment not powered up, or inoperative or improperly configured equipment .
- Communication errors: usually a configuration mistake like wrong protocol settings, wrong port, and so on.

#### **To enable the Kernel diagnostics window on Plant SCADA start-up:**

1. In the Citect Explorer menu, select **View | Configuration File**. This launches Windows Notepad and loads and displays the Citect.ini file for manual editing.
2. Scroll down to the "[Debug]" category, and edit the section to include the following parameter:  
`[DEBUG  
Kernel=1]`
3. **Save** and **Close** Notepad.

This parameter causes the Plant SCADA Kernel window diagnostics framework to appear automatically when Plant SCADA starts up. Swap to it to Plant SCADA runtime processes.

### To add the Kernel menu item to the runtime Control menu:

1. In Plant SCADA Studio's **Projects** activity, launch the Computer Setup Wizard and select Custom mode.
2. Click **Next** until you reach the **Security Setup - Control Menu** page.
3. Check the **Kernel on menu option** and click **Next** until finished.

At runtime, you can display the Kernel window by selecting Kernel from the **Control** menu (top-left corner). If a Title Bar is not displayed in your runtime project, you can access the Control menu by pressing **Alt + Spacebar** (if the Alt-Space enabled option is ticked on the Security Setup - Keyboard page).

You should clear these options before placing the system into service to minimize the likelihood of accidental or unauthorized use of the Kernel in the delivered system.

### Tag-based Driver Considerations

The Plant SCADA SNMII driver uses OIDs (object identifiers) to uniquely identify tag addresses. These OIDs are generated by Plant SCADA during compilation.

You should know how OIDs are implemented in a tag-based driver to minimize the possibility of tag mismatches, particularly if you are using network distributed systems. For example, all Plant SCADA servers and clients need to have exactly the same variable database on them, otherwise a client could make a request for a tag with an OID that does not exist on the I/O Server, or refers to a different tag. For this reason, care needs to be taken when editing a variables database.

The following information highlights activities you should pay special consideration to due to the potential impact they might have on OIDs in your system.

For details on OIDs, see Tech Note TN5868 (*How Do Object IDs (OIDs) Work?*) on the AVEVA Knowledge & Support Center (<https://softwaresupport.aveva.com/>). You will need to register to search this site.

### Project IDs

OIDs are generated using a Project ID, and the position (that is, record number) in the associated variable.dbf file. Therefore, when using control clients, standby servers and so on, check that a project restored to a PC has a consistent Project ID in each machine included in a system.

This should be checked when you restore a Plant SCADA project to a PC, because if the Project ID is in use by another project on that computer, Plant SCADA will generate a new Project ID number.

A project's ID number can be determined by selecting a project in Plant SCADA Studio's **Projects** activity and viewing its properties. The Project ID is shown on the **General** tab. It is also stored in the project backup file (.ctz).

---

**Note:** Check that each Include project has the same Project ID on each computer using the same Include project. Check this after restoring a project to a computer.

---

### Variable Databases

If you have different variable.dbf files across your plant, you might have OID mismatches.

To avoid this, check that after changing your variable.dbf on your primary server that you reset the OID (in citect.ini file set [OID]Reset=1) and do a pack and full compile (that is, ensure that incremental compile is turned off).

Then copy the variable.dbf file to the standby server and any Control Clients using the project. This sets the OID on your primary server to the same value as the OID used on your display client and/or standby server.

**Note:** If you are using Include projects, pack your variable.dbf before resetting the OIDs and doing a full compile of your project. To pack the project databases, use the **Pack** button on the command bar of the **Project** activity in Plant SCADA Studio.
